Proctolin is one of the transmitters at a dual-transmitter motor neuron innervating the longitudinal ventrolateral muscles (6A and 7A) of the larval housefly, *Musca domestica*. 6% of preparations display a muscle action potential after nerve shock or current injection into the muscle. The remaining 94% of preparations are inexcitable. In the presence of proctolin, however, these muscles display action potentials and also a change in input resistance (see also Mbungu and Adams, this meeting).

We examined the signal transduction mechanisms underlying this change in muscle excitability. Both the endogenous and the proctolin-induced action potentials were blocked by 4-bromophenacyl bromide, a broad spectrum phospholipase inhibitor, indicating that hydrolysis of membrane phospholipids is involved. The phorbol ester PMA, which mimics diacylglycerol in its activation of protein kinase C, evoked an action potential similar to the endogenous and proctolin-evoked potentials. PMA, however, did not induce a consistent change in the muscle input resistance. This response was reversible and was not reproduced by the inactive 4α analog of PMA. Intracellular injection of inositol trisphosphate, generated during hydrolysis of certain membrane phospholipids, did not evoke muscle action potentials. Two kinase inhibitors, H-7 and staurosporine, suppressed both proctolin-induced and endogenous action potentials. However, membrane permeable analogs of cAMP and cGMP did not evoke action potentials. These results are consistent with activation of PKC as a signal transduction pathway for the proctolin-mediated change in muscle excitability.

APPEARANCE OF K^+, Na^+ and Ca^{2+} CURRENTS IN RAT CEREBELLAR GRANULE NEURONS REMOVED DIRECTLY FROM THE EXTERNAL GERMINAL LAYER AND MAINTAINED IN PRIMARY CELL CULTURE. R.R. Stewart*, J.-L. Bossu, J.-L. Dupont and A. Feltz. C.N.R.S., Lab. d'Etude des Régulations Physiologiques, Strasbourg, France, F-67087

Differentiation of cerebellar granule neurons was assessed by recording voltage-dependent ionic currents using the whole-cell patch clamp method on cells maintained in medium consisting of DMEM, 10% horse serum and 10^{-7} M insulin. Single precursor cells and aggregates were removed directly from the external germinal layer (EGL). During the first 3 to 10 hours in culture (day 0), only outward currents were present: a small, rapidly activating and inactivating I_A and a large, slowly inactivat-ing sustained current that partly obscured I_A and was very sensitive to TEA. By day 5, the aggregates had spread out on the poly-ornithine substrate; I_{Ba} and I_{Na} had appeared in granule neurons; I_A had increased in amplitude to dominate the sustained K current; and a second sustained outward current had appeared that was insensitive to TEA. These experiments were undertaken to provide a baseline for assessing factors that influence the differentiation and survival of granule neurons.

ION CHANNEL EXPRESSION BY EGF-RESPONSIVE STEM CELLS ISOLATED FROM MAMMALIAN CNS. D.D. Fraser*, B.A. Reynolds, S. Weiss, and B.A. MacVicar. Neuroscience Research Group, Univ. of Calgary, AB, Canada.

Stem cells isolated from the embryonic mouse striatum were induced to proliferate *in vitro* by the mitogen EGF (Reynolds and Weiss, Science 255:1707, 1992). Under appropriate conditions, these cells differentiate into neurons or glia with phenotypes that parallel adult striatum *in vivo*.

Under whole-cell patch-clamp in the current-clamp configuration, injection of depolarizing current induced a single regenerative potential followed by small amplitude membrane oscillations (n=11). Stem cells had an input resistance of 2.02 ± 0.3 GΩ. Voltage-clamp experiments revealed whole-cell capacitance values of 6.66 ± 0.4 pF and both inward and outward current components (n=117). The activation threshold for the inward current was -40 mV with a mean peak amplitude of 320 pA at -10 mV. The current was depressed by removal of external Na^+ or 1 μM TTX and reversed at the Na^+ equilibrium potential. Steady-state inactivation was observed positive to -100 mV, half-inactivation at -76 mV, and complete inactivation at -40 mV. The time constant of inactivation ranged from 3.7 ms at -30 mV to 0.7 ms at 20 mV. Recovery from inactivation occurred within 50 msec. Inward currents carried by Ca^{2+} were never observed. Outward currents consisted of both a transient and delayed component that were depressed by 5 mM 4-AP and 10 mM TEA, respectively. Both currents reversed at the K^+ equilibrium potential. The activation threshold for the transient current was -40 mV. Steady-state inactivation was observed positive to -100 mV, half-inactivation at -64 mV, and complete inactivation at -30 mV. Recovery from inactivation occurred in 900 msec. The activation threshold for the delayed current was -30 mV. Stem cell ion channels have slow kinetics and a negative voltage dependence and therefore are more similar to immature glia channels than neuronal. Ion channel expression may contribute to stem cell function *in vivo*. Supported by the MRC(Canada) and Savoy Foundation.

EGF-RESPONSIVE PROGENITOR CELLS IN THE EMBRYONIC HUMAN CENTRAL NERVOUS SYSTEM. B.A. Reynolds*[1], C. Lundberg[2], A. Bjorklund[2], P. Brundin[3], O. Lindvall[3], P. Odin[3], R. Hasham[1], R.G. Lee[1], N.B. Rewcastle[1], O. Suchowersky[1], W.G. Tetzlaff[1], T.W.J. Watson[1] and S. Weiss[1]. [1]Neuroscience Research Group, University of Calgary, Calgary, Canada and [2]Dept. of Medical Cell Research, University of Lund, [3]Department of Neurology, University Hospital, Lund, Sweden.

The presence of EGF-responsive progenitor cells in the embryonic through to adult murine CNS (Reynolds and Weiss, *Science* 255:1707, 1992) prompted us to examine whether a similar cell exists in the human CNS. Embryonic human CNS tissue (cortex, striatum and cerebellum) was mechanically dissociated and plated onto untreated tissue culture flasks in serum-free culture medium containing 20 ng/ml of EGF. Dividing cells were observed within 7 days *in vitro*, and over the following 21 days the dividing cells formed spheres that detached from the substrate. When floating spheres were dissociated and replated at low density as single cells, proliferation was re-initiated and over a 2-4 week period new spheres were formed. When spheres were plated onto poly-L-ornithine-coated glass coverslips, cells migrated from the central core, adopting the morphology of neurons and astrocytes. The presence of neurons was confirmed with antisera directed against human neuron-specific enolase. The similarity of these findings to those we reported for the murine CNS suggest that EGF-responsive stem cells are present in the human CNS.

467.4

AN EGF-DEPENDENT STEM CELL LINE DERIVED FROM THE EMBRYONIC MOUSE CNS PRODUCES NEURONS, ASTROCYTES AND OLIGODENDROCYTES. S. Weiss*, R. Hasham and B.A. Reynolds. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

We have isolated a stem cell from the embryonic to adult mouse striatum (Reynolds and Weiss, *Science* 255:1707, 1992) which proliferates *in vitro* in response to EGF, forming a cluster of undifferentiated cells (neurospheres) which detach from the substrate and float in suspension. Neurospheres can be mechanically dissociated into single cells and a large percentage will proliferate forming new neurospheres. The spheres can be perpetuated weekly, resulting in a logarithmic growth in the number of undifferentiated cells. EGF-generated neurospheres were differentiated by mechanical dissociation and plating at high density, in the absence of EGF. After 7-14 days *in vitro* the three major cell types of the CNS were observed. Astrocytes, immunoreactive for GFAP, had a stellate morphology. Neurons were identified with antibodies recognizing MAP-2, neuron-specific enolase or neurofilament (168 kDa). Oligodendrocytes were immunoreactive for the cell surface antigens O4 and GC. All three cell types were present in differentiated EGF-generated progenitor cells that had been passaged for eight months (42 passages). A growth factor-dependent CNS stem cell line may provide a continuous source of cells for intracerebral grafting.

467.5

EGF-GENERATED MOUSE STRIATAL NEUROSPHERES EXPRESS THE *trk*B NEUROTROPHIN RECEPTOR. J.S. Williams*[1], A. Vescovi[1], B.A. Reynolds[1] J.P. Hammang[2], E.E. Baetge[2] and S. Weiss[1]. [1]Neuroscience Research Group, University of Calgary, Calgary, AB, Canada T2N 4N1 and [2]Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492.

We have identified an EGF-responsive stem cell in the embryonic and adult mouse striatum (Reynolds and Weiss, *Science* 255:1707, 1992), which will proliferate *in vitro* into a sphere of undifferentiated cells (neurospheres) that detach from the substrate after 5-7 days *in vitro*. The expression of the *trk* family of neurotrophin receptors in EGF-generated neurospheres was examined by northern blot analysis. Total mRNA was isolated from mouse and rat striatal EGF-generated neurospheres. Both rat and mouse neurospheres expressed high levels of *trk*B receptor mRNA, but did not express *trk* nor *trk*C mRNA. In preliminary experiments, single EGF-generated mouse neurospheres were plated on poly-L-ornithine coated glass coverslips and cultured in the absence or presence of 10ng/ml of BDNF. When examined after 14-28 days *in vitro*, neurospheres plated in the presence of BDNF contained NSE-immunoreactive cells with extensive and highly branched processes; well-developed NSE-IR cells were not observed in the absence of BDNF. Activation of the *trk*B receptor on EGF-generated neurospheres may enhance survival of and/or neurite outgrowth from newly generated neurons.

Supported by the Medical Research Council of Canada.

467.6

bFGF SUPPORTS THE SURVIVAL OF EGF-RESPONSIVE STRIATAL STEM CELLS. A.L. Vescovi*[1], E. Parati[1], A. Gritti[1], B.A. Reynolds[2] and S. Weiss[2]. [1]National Neurological Institute, Milan, Italy and [2]Neuroscience Research Group, University of Calgary, Calgary, AB, Canada T2N 4N1.

We have identified a stem cell, isolated from the embryonic through to adult striatum (Reynolds and Weiss, *Science* 255:1707, 1992), which in response to EGF will reproduce itself and generate cells that differentiate into neurons, astrocytes and oligodendrocytes. In previous studies, we found that when plated at low density (2500 cells/cm^2), addition of EGF up to 7 days *in vitro* (DIV) could initiate proliferation of the stem cell, but not if applied after 7 DIV. In the present study, we sought to determine if bFGF could prolong the survival of the EGF-responsive stem cell. Striatal cells (E14, 2500 cell/cm^2) were plated in the absence or presence of 20 ng/ml of bFGF. After 11 DIV, cultures were washed and media containing 20 ng/ml of EGF was added. After 4-5 DIV, in cultures that were primed with bFGF, >70% of the wells examined contained clusters of proliferating cells that developed into colonies with the morphologic and antigenic properties of the EGF-generated cells we have previously described. Cultures that had not been primed with bFGF showed no EGF-responsive proliferation. These findings suggest that the EGF-responsive striatal stem cell may possess bFGF receptors that regulate it's long term survival.

Supported by the Medical Research Council of Canada.

GAP-43 IS DEVELOPMENTALLY REGULATED IN GLIAL CELLS DERIVED FROM EGF-RESPONSIVE CNS STEM CELLS.

J.P. Hammang*[1], B.A. Reynolds[2], E.E. Baetge[1], and S. Weiss[2]. [1]Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT. 06492, and [2]Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

GAP-43 is a nervous system-specific membrane phosphoprotein which is down-regulated during development. Originally, GAP-43 was thought to be neuron-specific, however, recent reports indicate that this protein may be at least transiently expressed during development in some astrocytes, oligodendrocytes and in Schwann cells. At present, the role of GAP-43 in macroglia is not known. We have begun to investigate the transient expression of GAP-43 in glial cells generated from the EGF-responsive stem cells derived from the embryonic and adult murine striatum (Reynolds and Weiss, *Science* **255** p. 1707 1992). Astrocyte differentiation was induced by plating the stem cells in a medium containing 1% FBS with no EGF. The cells were then probed with specific antibodies for GAP-43 and GFAP using dual-label immunofluorescence. Initially, GAP-43 and GFAP expression is low in all cells, but by 3-4 days, high levels of GAP-43 and GFAP is co-expressed in a large number of cells. By one week however, the large majority of GFAP-expressing astrocytes no longer express GAP-43. The EGF-responsive stem cells may represent a useful model system for the study of the role of GAP-43 in glial and neuronal development (supported by the MRC Canada).

467.8

IGF-I STIMULATES CHICK SYMPATHETIC NEURON PROLIFERATION BOTH IN VITRO AND IN VIVO AND IS PRODUCED IN DEVELOPING SYMPATHETIC GANGLIA.

K. Zackenfels and H. Rohrer.* Abt. Neurochemie, Max-Planck-Institut für Hirnforschung, Deutschordenstr. 46 D-6000 Frankfurt/M. 71, F.R.G.

The ability of immature neurons from chick lumbosacral sympathetic ganglia to proliferate *in vitro* was used to identify factors that affect neurogenesis. We found that neuron proliferation, but not survival, is dependent on the presence of serum. Under serum-free culture conditions, IGF-I, insulin or PDGF caused an increase in both the cell number and proportion of cells that incorporated ^{3}H-thymidine. This effect was not seen when bFGF, aFGF or TGFα was used to replace serum. Application of IGF-I onto the chorioallantoic membrane of chick or quail embryos also stimulated the incorporation of 3H-thymidine in sympathetic ganglion neurons *in vivo*. IGF-I mRNA was detectable in E7 sympathetic ganglia by PCR. These results show that sympathetic neuron proliferation is subject to extrinsic control both *in vitro* and *in vivo* and suggest an autocrine/paracrine action of IGF-I in the generation of avian sympathetic ganglion neurons.

467.9

CNS GLIAL CELLS SUPPORT SURVIVAL, DIVISION AND DIFFERENTIATION OF OLFACTORY NEURONAL PRECURSOR CELLS IN VITRO.

S.K. Pixley* Dept. of Anatomy and Cell Biology, Univ. of Cincinnati, Cincinnati, OH 45367-0521.

In the adult mammal, new olfactory receptor neurons (ORNs) are produced from neuronal progenitor cells retained in the olfactory neuroepithelium. To determine whether the progenitor cells could divide and differentiate in culture, we have disaggregated nasal mucosal cells from newborn Sprague Dawley rats and plated them on either a polylysine coating or a monolayer of neonatal rat astrocytes. On polylysine, both mature and immature ORNs died within 5-6 days. On the monolayer of CNS astrocytes, mature ORNs (OMP+) again died rapidly (by 5-7 days), while immature ORNs (positive for neuron-specific tubulin, NST) appeared to multiply and formed large aggregates of neurons. OMP+ neurons re-appeared 10 days after plating and were very prominent in 15 day cutlures. Three different CNS area astrocytes were equally effective in promoting survival and differentiation. Pulse labeling with tritiated thymidine was done over 15 days in culture. Uptake of isotope in neurons was detected by combined autoradiography and immunocytochemistry. Neuronal progenitor cells both divided and differentiated in culture. Both OMP+ and NST+ neurons were generated by cell divisions that took place during restricted times after plating. Aspects of the data suggest that OMP expression is an innate property of ORNs and that expression may rely more on survival than target-specific regulatory factors. The neuronal progenitor cell appears to be negative for NST. Astrocytes (but not conditioned medium) allow survival, division and subsequent differentiation. DIFFERENTIAL EFFECTS OF CNTF, LIF AND IL-6 ON OLIGODENDROCYTE-TYPE 2-ASTROCYTE PROGENITOR CELLS.

J.C. Louis*, E. Magal, S. Takayama and S. Varon, Department of Biology 0601, University of California, San Diego, La Jolla CA 92093.

The proliferation and development of oligodendrocyte-type 2-astrocyte progenitor (O-2A) cells have been shown to be regulated by a number of peptide growth factors, including PDGF, FGF and IGFs. We report here that three members of the newly-defined family of neuropoietic cytokines (Bazan, *Neuron* 1991, 7:197-208) - ciliary neurotrophic factor (CNTF), leukemia inhibitory factor (LIF) and interleukin-6 (IL-6) - exert different influences on the CG4 cell line (Louis et al., *J. Neurosci. Res.* 1992, 30:193-204) of O-2A cells. Both LIF and IL-6 are potent mitogens for CG4 cells (cell cycle: 36-48 hr). In their presence, CG4 cells become multipolar, lose the A2B5 antigen and acquire the O4 antigen, but do not differentiate to mature oligodendrocytes or type-2 astrocytes. When given together with PDGF, LIF as well as IL-6 promote the continuous proliferation of CG4 cells as A2B5$^+$/O4$^-$ progenitors (cell cycle: 20 hr), while in PDGF alone, they would cease their proliferation and differentiate to oligodendrocytes within 5-7 days. In sharp contrast, CNTF is not mitogenic for CG4 cells. In the presence of CNTF alone, the CG4 cells express transiently the astrocyte marker GFAP (for 1-2 days), after which they differentiate to mature oligodendrocytes. CNTF, however, reduces dramatically the growth rate of CG4 cells maintained in PDGF: after 7 days in CNTF and PDGF, the length of the cell cycle is increased from 20 hr to >60 hr. This change in the growth rate is accompanied by the appearance after 7 days of a population of CG4 cells (about 40%) that displays the morphological (unipolar cells) and antigenic (O4$^+$/A2B5$^-$/galC$^-$/vimentin$^-$/GFAP$^-$) properties of *adult* O-2A progenitor cells. These results indicate that, in addition to their actions on CNS and PNS neurons, the neuropoietic cytokines, alone or in combination with other factors, are capable of regulating the proliferation and differentiation of O-2A cells. In particular, CNTF may be a major instructive factor for the generation of adult O-2A progenitors from the perinatal ones. Supported by NINDS grant NS-16349.

BETA-2 INTEGRINS ARE CONSTITUTIVELY EXPRESSED ON MICROGLIA IN THE NORMAL HUMAN FETAL BRAIN.

L.A. Mattiace*, P. Davies, W.D. Lyman, W. Rashbaum, D.W. Dickson. Depts. of Pathology and Ob-Gyn, Albert Einstein College of Medicine, Bronx, NY 10461.

To further characterize microglia in the normal fetus, serial sections from 16 wk to 23 wk abortuses of HIV seronegative mothers were examined immunocytochemically with antibodies to Beta-2 integrins. Integrins are part of a group of cell adhesion molecules that are involved in cell-cell and cell-matrix interactions. As transmembrane glycoproteins, integrins link the intracellular cytoskeleton to either extracellular matrix proteins or other cellular receptors. Beta-2 integrins are heterodimers that are characterized by a Mr 95,000 Beta-2 subunit (CD18) and alpha subunits of either Mr 180,000 (LFA-1; CD11a), 170,000 (MAC-1; CD11b) and 150,000 (P150,95; CD11c). Monoclonal antibodies to these alpha chains included LFA-1 (CD11a), Bear-1/C3bir (CD11b) and Leu-M5 (CD11c). Preliminary data suggests that these markers are constitutively expressed on microglia in normal fetal human brain at 16 wks. These antigens were expressed on both amoeboid and more ramified forms of microglia in the cortical layers and in the subcortical grey and white matter. Microglia were also found to constitutively express leucocyte common antigen, in addition to HLA-DR (LN-3, HLA-DR), a major histocompatibility complex class II antigen and FCgammaRI as previously reported (Soc Neurosci Abstr 17:734:1991). The role of Beta-2 integrins, as expressed on fetal microglia, in normal gliogenesis and brain development is not clear. On leucocytes, Beta-2 integrins are involved in mediation of phagocytosis, adhesion and migration in the immune system. The presence of adhesion molecule receptors on microglia suggest that they may participate in cell-cell interactions, in the regulation of cell migration and differentiation during brain development. Since microglia are productively infected by HIV-1 in the CNS, these receptors may also be involved in the mediation of CNS pathogenesis.

467.12

BASIC FIBROBLAST GROWTH FACTOR AND NERVE GROWTH FACTOR INCREASE NEUROBLASTS PROLIFERATION AND DIFFERENTIATION INTO NEURONS CONTAINING GLUTAMATE-LIKE IMMUNOREACTIVITY.

F.M. Vaccarino*, D. Hartigan and J. F. Leckman. Child Study Center, Yale Univ. Sch. of Med., New Haven , CT 06510.

The development of mammalian telencephalon involves a sequence of multiplication of stem cells, differentiation into neurons and glia, migration to target sites and synaptogenesis. Each phase is likely to involve the expression of cell type-specific genes in a spatially and temporally-restricted manner. In order to study transcription factors orchestrating such processes, we created an *in vitro* model simulating aspects of early telencephalic development in primary culture. The neuroepithelium of E13 rat telencephalon was grown in dissociated cell culture in serum-free medium. At the density of 80,000 cells/cm^2, the addition of growth factors (bFGF and NGF) increased the number cells immunoreactive for nestin (a marker for multipotential stem cells) and the proliferation rate (at 5 days in vitro, bromodeoxyuridine incorporation during 3 hour labelling was 9.1+/-2.2 and 14.2+/-1.6 without and with growth factors, respectively). Cells containing GABA- and glutamate-like immunoreactivity started differentiating at 2 days in vitro and their number and complexity of arborization increased with time. Growth factors increased the differentiation of cells containing glutamate-like immunoreactivity at 2 and 4 DIV, while the effect on GABA-containing neurons was modest. GFAP-positive astrocytes were entirely absent until day 6 but differentiated from nestin-positive stem cells afterwords. The sequence and timing of these developmental events closely matches the development of telencephalon *in situ*.

THE EFFECTS OF EGF AND TGF-β ON OLFACTORY NEUROGENESIS AND NEURON SURVIVAL *IN VITRO*. N. K. Mahanthappa* and G. A. Schwarting. E.K. Shriver Ctr., Waltham, MA 02254; and Prgrm. in Neurosci., Harvard Med. Sch., Boston, MA 02115.

Peptide growth factors that affect growth and differentiation of ectodermally-derived tissues were tested for neurogenic and neurotrophic activity in neonatal rat olfactory epithelium (OE) cell cultures. In dissociated OE cultures, EGF, TGF-β1, and TGF-β2 have no neurotrophic activity - few cells survive beyond 1 week. ^{3}H-thymidine (^{3}H-T) labeling, however, revealed that EGF promotes division of keratin$^+$ basal cells two-fold, while TGF-β2 inhibited this labeling completely. Though NCAM$^+$ neurons show no ^{3}H-T labeling in EGF or control conditions, TGF-β2 promotes labeling of approximately 10% of these cells. In partially dissociated OE cultures, cell survival is improved. In this condition EGF effects were as above; both TGF-β1 and TGF-β2 inhibited keratin$^+$ cell division while promoting ^{3}H-T labeling of 20-30% of NCAM$^+$ cells. Tracking identified cell clusters maintained in EGF for 4 d and then transfered to TGF-β2, suggests that EGF maintains basal cells while TGF-β2 promotes neurogenesis from this population. We are assaying the presence of endogeneous TGF-β2 production in these cultures, and are testing known neurotrophic factors for effects on OE neuron survival.

CELL LINEAGE AND DETERMINATION III

SELECTIVE ISOLATION OF NEURAL AND GLIAL PRECURSORS FROM THE DEVELOPING MURINE BOWEL WITH ANTIBODIES TO A 110 kDa CELL SURFACE LAMININ BINDING PROTEIN A. Chalazonitis,* Y.M. Tennyson, T.P. Rothman and M.D. Gershon. Dept. of Anat. & Cell Biol., Columbia Univ., College of P & S, New York, NY 10032.

A 110 kDa laminin binding protein has been shown to be expressed by enteric and other peripheral neurons. This protein is not expressed by premigratory or early migratory neural crest-derived precursor cells. Immunocytochemical observations have suggested that the 110 kDa protein might be acquired by crest-derived cells shortly after these cells colonize the developing gut of avians or mice. Experiments were carried out to test the hypothesis that the 110 kDa laminin binding protein is selectively expressed in the developing gut by the crest-derived precursors of enteric neurons and glia. The bowel of fetal mice (E16) was dissociated and the resulting single-cell suspension was exposed sequentially to rabbit antibodies to the 110 kDa protein (α-110) and magnetic beads coated with goat anti-rabbit secondary antibodies; α-110-immunoreactive cells were finally isolated with a magnet. α-110-selected and unselected (residual) cells were seeded in dishes coated with collagen and laminin at a density of 27 X 10^3 cells/dish and cultured for 8 days. Neurons were identified immunocytochemically with antibodies to neurofilament proteins or neuron specific enolase, while glia were identified with antibodies to the S-100 protein. Neurons and glia were also found to be immunostained by α-110. Significantly more neurons and glia developed in cultures of α-110-immunoselected cells than in cultures of unselected cells. The proportion of cells in the cultures of selected cells that developed as neurons was about 3-fold that found in cultures of unselected cells. Similarly, the number of S-100 immunoreactive cells in cultures of selected cells was about 4-fold that observed in the cultures of unselected cells. Immunoselection of cells from E16 fetal mice thus supports the hypothesis that neurons or glia preferentially develop in cultures of cells selected with the α-110 reagent. It has been suggested that the 110 kDa laminin binding protein is a receptor that mediates the response of enteric neural and glial precursors to laminin. The current observations support this idea. Supported by NIH grants NS26766, HD17736, HD20470, HD 21032 and NS15547.

468.2

PHENOTYPES EXPRESSED BY NEUROGENIC NEURAL CREST-DERIVED CELLS IMMUNOSELECTED FROM THE WALL OF THE DEVELOPING BOWEL OF AVIAN AND RAT EMBRYOS. T. P. Rothman,* A. Chalazonitis, H. D. Pomeranz, Y. M. Tennyson and M. D. Gershon. Dept. Anatomy & Cell Biology, Columbia University P&S, New York, NY 10032.

The enteric nervous system (ENS) is formed by cells that migrate to the bowel from vagal and sacral levels of the neural crest. Since the developmental potential of crest-derived cells that have entered the gut is less than that of premigratory or early migratory crest cells, the properties of at least some crest-derived cells change as they migrate to the gut. In order to study the characteristics of enteric crest-derived cells, it is necessary to isolate them from within the bowel. Gut from chick or quail embryos (E4-7) or fetal rats (E11-15) was dissociated with collagenase to yield a suspension of single cells, which were then subjected to immunoselection. The suspension was mixed with a murine monoclonal antibody (NC-1) that reacts with a surface epitope that is found, in the gut, only on crest-derived cells. NC-1-coated cells were then isolated with magnetic beads coated with goat anti-mouse antibodies, and selected with a magnet. NC-1$^+$ cells were cultured for up to 8 days, as were the cells remaining after the NC-1$^+$ population had been removed. Immunoselection was found to greatly enrich the population in NC-1$^+$ cells. Expression of neurofilament proteins and neurite extension were preferentially seen in cultures of immunoselected cells. Neurite outgrowth was promoted by laminin. Some neurons contained vasoactive intestinal peptide (VIP) or serotonin (5-HT); however, tyrosine hydroxylase (TH) and dopamine-β-hydroxylase (DBH) which are not expressed by avian enteric neurons, *in situ*, and are expressed only transiently in developing rat bowel were present in immunoselected cells. A glial marker, glial fibrillary acidic protein (GFAP), was apparent in a subset of immunoselected cells. Non-selected cells proliferated rapidly and relatively few expressed a neuronal or glial phenotype. These experiments demonstrate that neurogenic crest-derived cells can be isolated from within the enteric mesenchyme of both developing rats and birds. At least some of the immunoselected cells appear to be capable of expressing phenotypes appropriate for the ENS. The appearance of TH in cells immunoselected from avian bowel supports the hypothesis that the enteric microenvironment acts to suppress catecholaminergic expression *in situ*. Supported by NIH grants HD20470, NS15547, NS26766, HD17736, and a fellowship from Lilly Res. Labs.

468.3

PHENOTYPIC PLASTICITY OF EMBRYONIC CILIARY NEURONS. J. Sechrist, J. Wolf, and M. Bronner-Fraser*. Developmental Biology Center, Univ. of Calif., Irvine, CA 92717.

Ciliary neurons from 6.5 day quail embryos can change their neurotransmitter phenotype from cholinergic to adrenergic after transplantation to the trunk of chick embryos. Here, we examine if there is a critical period during which this transition can occur and if the post-mitotic neurons re-enter the cell cycle. After dissociation, individual ciliary neurons (identified by phase bright cell bodies and axonal stubs) were isolated manually, labelled with DiI and injected into the trunk somites. An average of 400 neurons per experiment (157 - 711 range) were derived from 6.5 - 10 day quail embryos and injected into 2.5 day embryonic chick trunks. To verify that these cells were neurons, some were plated on laminin and shown to be purely neuronal. Catecholamine histofluorescence in DiI-labelled cells was analyzed 4 - 5 days post-injection as described previously (Sechrist *et al.*, J.Neur.Transplant 1:113, 1989). Some embryos were treated with 2 - 3 doses of ^{3}H-thymidine after injection. For ciliary neurons derived from 6.5 to 8.5 day old embryos, as many as 14% developed catecholamine histofluorescence in the host sympathetic ganglia, aortic plexuses and adrenal medulla. In contrast, neurons from 8.5 - 10 day embryos never became catecholamine positive, indicating a limited time-frame for phenotypic conversion. Interestingly, a substantial number of DiI labelled cells took up ^{3}H-thymidine, indicating that they re-entered the cell cycle after transplantation. Our results indicate that phenotypic plasticity of ciliary neurons is age dependent and may involve re-entry into the cell cycle.

468.4

INFLUENCES OF THE NOTOCHORD ON FORMATION OF THE NEURAL CREST AND ITS DERIVATIVES. Kristin B. Artinger* and Marianne Bronner-Fraser, Developmental Biology Center, University of California, Irvine, CA 92717

Grafting experiments have shown that the notochord affects dorsoventral polarity of the neural tube by inducing formation of motor neurons and floorplate cells in the ventral neural tube. Here, we examine if the notochord inhibits formation of dorsal structures by grafting a notochord adjacent to or on the dorsal neural tube. When notochords were grafted onto the dorsum of the neural tube, a dorsal floorplate was induced; however, differentiation of dorsal structures was not inhibited. Neural crest cells formed and emigrated from the dorsal neural tube in the presence of the ectopic notochord. In addition, neurons with the appearance of commissural neurons formed adjacent to the ectopic floorplate. In fact, numerous neuronal cell bodies and axonal processes were observed traversing the induced, but not the endogenous, floorplate. When analyzed at stages after ganglion formation, the dorsal root ganglia were reduced in size and shifted in position in embryos that had received a notochord graft. Supernumerary ventral roots were observed adjacent to the implanted notochord. The effects were similar whether or not the host notochord was ablated. These results suggest that the notochord cannot prevent the formation of dorsal structures such as the neural crest, but can alter the size and position of neural crest-derived dorsal root ganglia.(Supported by USPHS HD25138)

SPECIFICATION OF THE ROSTROCAUDAL AXIS OF THE PREMIGRATORY AVIAN NEURAL CREST. Gabrielle G. Leblanc*. Dept. of Biological Structure and Function, School of Dentistry, Oregon Health Sciences University, Portland, OR 97201.

Different rostrocaudal populations of premigratory neural crest cells differ in their developmental potentials, both *in vivo* and *in vitro*. *In vivo*, cranial neural crest gives rise to large amounts of cartilage and bone, whereas trunk neural crest cells lack chondrogenic potential. *In vitro*, cranial neural crest produces large numbers of fibronectin (FN)- and procollagen I (Col I)-immunoreactive cells, whereas trunk neural crest produces relatively few of these cells. These *in vitro* differences in protein expression by cranial and trunk neural crest cells can be used to explore the mechanisms that determine the rostrocaudal axis of the premigratory neural crest.

The rostrocaudal axis of the premigratory neural crest may be specified by factors arising from the underlying mesoderm. To test this possibility, I examined whether coculture with anterior mesoderm can induce trunk neural crest cells to express cranial-specific traits *in vitro*. Trunk neural crest cells were cocultured together with explants of early (stage 3) Hensen's node, which contains prospective anterior mesodermal cells. After five days of coculture, both FN and Col I immunoreactivities were seen in the neural crest cells surrounding the Hensen's node explant. The apparent FN- and Col I-stimulating activity of early Hensen's node is mimicked by transforming growth factor (TGF)-ß1.

BASIC FIBROBLAST GROWTH FACTOR (bFGF) INFLUENCES NEURAL CREST CELL FATE VIA AN INTRACRINE MECHANISM. G. Ciment*, L. Sherman, K.M. Stocker and R.S. Morrison. Dept. Cell Biology & Anatomy, Oregon Health Sciences Univ., Portland, OR 97201.

In previous work, we found that neural crest (NC)-derived Schwann cell progenitors of early avian embryos underwent a transformation *in vivo* or in culture into another NC-derivative -- melanocytes -- following treatment with either the phorbol ester TPA or basic fibroblast growth factor (bFGF). These and other data suggest that bFGF may be involved in the commitment of bipotent intermediates in the NC cell lineage to either the melanocyte or Schwann cell fate.

In these studies, we show that TPA induces bFGF expression in these melanocyte/Schwann cell progenitors, but that bFGF need not be released in order to influence cell fate. Treatment of cultures of early embryonic peripheral nerves with TPA, for example, induced expression of bFGF mRNA and protein and caused melanogenesis in cells which would normally have given rise to Schwann cells. Addition of two different bFGF antisense oligonucleotides blocked these effects of TPA, but that sense oligonucleotides or scrambled oligonucleotides (i.e., with the same base content but with a different sequence) did not, suggesting that bFGF expression is part of signalling pathway by which TPA induces transformation into melanocytes. Addition to the culture medium of bFGF neutralizing antibodies or other agents known to inhibit bFGF-binding to its extracellular receptor had no effect on the TPA-induction of melanogenesis, indicating that bFGF does not need to be released in order to act. These data indicate that bFGF may act as an intracellular "intracrine" factor in the determination of NC cell fate.

INVESTIGATION OF THE ROLES OF TGFα/EGF AND FGF SIGNALING IN RETINAL DEVELOPMENT THROUGH ALTERATIONS IN RECEPTOR EXPRESSION. L. Lillien* and C. Cepko. Department of Genetics, Harvard Medical School, Boston MA. 02115.

In order to begin to identify the signaling systems that regulate the development of the rat retina, we used in vitro assays to screen for extracellular signaling molecules that affect proliferation and cell type choice. These functional assays showed that several peptide growth factors found in the developing retina, including TGFα and bFGF, enhanced proliferation and selectively inhibited rod photoreceptor development (Lillien and Cepko, Development 1992). The effects of TGFα and FGF on proliferation were found to be temporally regulated in vitro: cultures of younger retinal cells (< E20) were more responsive to FGF while cultures of older retinal cells (>E20) were more responsive to TGFα. To determine the roles of these signaling systems in normal retinal development, we are using retrovirus vectors to express the human EGF receptor and mouse FGF receptor-1. To analyze the function of endogenous EGF and FGF receptors, we are introducing truncated forms of the receptors to block function in a dominant-negative manner. To determine whether limiting levels of receptor expression underlie the temporal changes in responsiveness to TGFα and FGF observed in vitro, we are introducing full length forms of the receptors. In order to label cells expressing these constructs, FGF R-1 viral constructs also contain the gene encoding the histochemical marker alkaline phosphatase. Cells infected with the EGF receptor virus can be distinguished with an antibody that selectively labels the human form of the receptor. Clones of infected cells will be examined.

RETINAL LINEAGE OF THE CLEAVAGE STAGE PROGENITOR IN XENOPUS IS DEPENDENT ON POSITION. S. Huang* and S.A. Moody Dept. Anatomy & Cell Biology, Univ. Virginia, Charlottesville, VA 22908.

Our previous studies (Neurosci. Abstr., 17,924, 1991) demonstrated that the retinal lineages of cleavage stage blastomeres change after the ablation of the major retinal progenitor and the changes are different for dorsal and ventral blastomeres. To determine whether the retinal lineage changes are due to the position of the remaining blastomeres two sets of experiments were carried out. First, several different sets of blastomeres were ablated at 32-cell stage embryo to demonstrate whether the change in position of the remaining blastomeres predicts their change in retinal fate. Along the dorsal midline when a blastomere was ablated its animal neighbor took over its retinal fate and produced an amount of retinal cells typical for the ablated vegetal neighbor. When more ventral blastomeres were removed, the dorsal blastomeres did not adopt the retinal fates of their ventral/animal neighbors. These results demonstrate that the blastomeres shift fate in a dorsal/vegetal direction but not in a ventral/animal direction. In order to directly test whether blastomere position determines retinal fate, reciprocal transplantations were done between a dorsal midline blastomere, the major retinal contributor, and a ventral blastomere, which normally only gives rise to caudal trunk structures. The transplanted blastomeres adopted a new fate according to their new position. The ventral blastomere became a major retinal contributor when it was placed in the dorsal animal pole, while the clone of the major retinal progenitor was restricted to the tail region of the embryo. These results indicate that the position of a blastomere prior to gastrulation is the important determinant of whether retinal cells are among its descendants.

TEMPORAL RELATIONSHIP BETWEEN MITOSIS AND RETINAL GANGLION CELL DIFFERENTIATION. D. K. Waid*, S. C. McLoon. Dept. of Cell Biol. and Neuroanatomy, Univ. of Minnesota, Minneapolis, MN 55455.

The mature retina consists of many different cell types that develop from a seemingly homogeneous population of neuroepithelial cells. Previous studies have shown that all retinal cells arise from common precursors. It is unclear when during the life history of a retinal cell, it becomes committed to a particular phenotype. This issue was addressed in the present study. A monoclonal antibody, RA4, recognizes retinal ganglion cells in the chick retina. In embryonic chick retina, $RA4^+$ cells are found in the mitotic layer of the retina with a spatial and temporal distribution that correlates with ganglion cell birth. Dividing cells, however, were not observed to express the RA4 antigen. This early differentiation of ganglion cells shows that they are committed to this phenotype before they migrate from the mitotic cell layer. Double labeling with BrdU and RA4 antibodies allowed the temporal relationship between mitosis and ganglion cell differentiation to be established. To accomplish this, BrdU was injected into chick embryos. At various post-injection times, immunohistochemistry was used to identify $BrdU^+$ mitotic figures. The first BrdU labeled mitotic figures were seen one hour following BrdU injection. By three hours post-injection, all mitotic figures were BrdU positive. The first $BrdU^+/RA4^+$ cells appeared in the mitotic layer within minutes of mitosis. The average time between mitosis and RA4 expression for cells in E3 retina was 1.5hrs, and in E9 retina was 7hrs. This data was most consistant with there being two populations of ganglion cell differentiation: an early, fast differentiating population, and a late, slow differentiating population. The rapid differentiation of some ganglion cells is most consistent with determination taking place prior to mitosis, while the slower differentiation of other cells may indicate determination taking place after mitosis. In conclusion, these results suggest that determination of a specific phenotype may occur independent of mitosis.

AN ANALYSIS OF OLFACTORY RECEPTOR NEURON LINEAGE USING A REPLICATION INCOMPETENT RETROVIRUS ENCODING ALKALINE PHOSPHATASE. M. E. Caggiano, D. D. Hunter,* J. S. Kauer. Neuroscience Program, Tufts/New England Medical Center, Boston, MA. 02111.

Olfactory receptor neurons develop from progenitor basal cells lying in the deep region of the olfactory epithelium (OE). Two major types of basal cells (globose and horizontal) have been characterized on the basis of their response to ablation of their target, the olfactory bulb. Under these conditions, the more superficial global basal cells appear to be the major source of new cells during olfactory receptor neuron renewal. Although both types of basal cells have been partially characterized, precisely how basal cells differentiate to form receptor cells is not known. We have employed a recombinant retrovirus (DAP) that encodes the human placental alkaline phosphatase gene to infect olfactory basal cells in order to study their lineage. Ca. 5ul of concentrated DAP was injected through the skull into a region near the dorsal recess and septum of the OE in 7-10 day old rats. Following an incubation period of 5-20 days, regions of the OE that included the turbinates and septum were analyzed in whole mount preparations for incorporation of the retrovirus into cells. Under these conditions, scattered groups of small rounded cells with darkly stained cytoplasm and unstained nuclei were seen in anterior and posterior septal regions. Five days after infection, these clusters consisted of groups of 2 to 8 cells. A similar distribution was seen 15 days after infection, although some cells displayed a more oval shape and possible projections. Using specific markers we will now begin to characterize the cell types in these clusters; this should help us define the cell lineage in the OE.

CLONAL HETEROGENEITY IN THE GERMINAL ZONE OF THE DEVELOPING RAT TELENCEPHALON, S. E. Acklin* and D. van der Kooy, Dept. Anatomy, Univ. Toronto, M5S 1A8 Toronto, CANADA.

In order to characterize the proliferation characteristics of precursor cell lines in the mammalian telencephalic germinal zone, we have previously employed a simultaneous double labeling technique which combines retroviral identification of individual proliferating clones in the E17-19 developing rat forebrain and their double labeling with 3H-thymidine. After 48 hours survival we found the cortical (but no the striatal) germinal zone to be segregated into three spatially distinct horizontal bands (A, B and C), comprising clonal populations with distinctive cell cycle times, incidences of cell death and modes (symmetric vs. asymmetric) of proliferation (Acklin & van der Kooy; soc. Neurosci. Abstr. 1479, 1991). It is important to ask whether these distinct cortical germinal zone populations predict the mature phenotypic (e.g. neurons vs. glia) or spatial identity (e.g. deep vs. superficial cortical layers) of the cells they give rise to. In a first set of experiments we characterized the spatial distribution and proliferation characteristics of cortical precursor populations (using our double labeling method) after only 17 (instead of 48) hours survival. We found that although the overall thickness of the germinal zone was slightly smaller after 17 hours survival (E17-18), it was still segregated into heterogeneous clonal populations (A, B and C) with comparable proliferation characteristics to those seen at E19. We also found that with the longer survival of 48 hours (E17-19) compared to the shorter survival time of 17 hours (E17-18), the clonal population in the ventricular zone proper (A) and one (B) of two horizontal bands in the subventricular zone increased in thickness, whereas the second horizontal band (C) in the subventricular zone decreased substantially in thickness. Thus, clonal population C (perhaps giving rise to a subpopulation of neurons) may have become mostly postmitotic by E19. We are presently asking which of the different clonal populations in the germinal zone remains perinatally, when neurogenesis has largely ceased but glia still are being produced. The identification of this remaining population (presumably giving rise to glia) by its proliferation characteristics may suggest an isomorphism between it and one of the earlier germinal zone populations.

SEPARATE PROGENITOR CELLS IN THE VENTRICULAR ZONE GIVE RISE TO CORTICAL PYRAMIDAL AND NONPYRAMIDAL NEURONS THROUGHOUT THE PERIOD OF NEUROGENESIS. J.G. Parnavelas*, C. Danevic, P. Boardman, M.C. Mione and M.E. Cavanagh (SPON: European Neuroscience Association). Department of Anatomy, University College London, London WC1E 6BT, U.K.

We reported recently that early in cortical neurogenesis (E15/E16), the ventricular zone in the rat contains separate progenitor cells for the principal neuronal cell classes, the pyramidal and nonpyramidal neurons. Here we sought to investigate whether these neuronal types originate from separate progenitor cells throughout the period of neurogenesis. For this purpose, recombinant retrovirus containing the reporter gene for E. coli β-galactosidase was injected into the telencephalic ventricles of rat embryos at E14/E21. Serially cut coronal sections of adult cortex were histochemically stained for β-galactosidase and processed for electron microscopy. Camera lucida drawings were made to map the position of labelled cells. Discrete clusters of closely spaced labelled cells were considered to be derived from the same precursor cell in the ventricular zone, i.e. to belong to the same clone. Clonally-related labelled neurons were examined with the electron microscope, and their phenotypes identified using ultrastructural criteria.

Clusters of clonally-related neurons examined from animals injected with retrovirus at various times during corticogenesis contained at all times either all pyramidal or all nonpyramidal neurons. These findings suggest that the ventricular zone contains separate progenitor cells for pyramidal and nonpyramidal neurons during the entire period of neurogenesis.

NEUROTRANSMITTER EXPRESSION IN CLONALLY RELATED NEURONS IN THE RAT CEREBRAL CORTEX. M.C.Mione*, C. Danevic*, M.E. Cavanagh*, P. Boardman and J.G. Parnavelas*(SPON: Brain Research Association). Department of Anatomy, University College London, London WC1E 6BT, U.K.

We examined the neurotransmitter content of clonally related neurons in the cerebral cortex of adult rats. Such neurons were marked with a retrovirus lineage tracer, containing the reporter gene for E. coli β- galactosidase, injected into the telencephalic ventricles of rat embryos at E15–E17 and subsequently detected histochemically. Discrete clusters of β- galactosidase positive cells, considered to be clonally related, were subjected to immunohistochemical analysis for the inhibitory neurotransmitter GABA and the excitatory amino acids Glu and Asp. This analysis was performed on Araldite embedded, 0.5 μm thick sections. Three consecutive sections through every neuron of 20 discrete clusters of neurons were processed each for one of the three neurotransmitter candidates, while thin sections were used to identify the phenotype of every cell with the electron microscope. Clusters contained between 2 and 8 neurons which were either confined to one layer or distributed over 2 or more layers.

Nineteen clusters contained neurons positive for only one transmitter candidate (9 GABA; 5 Glu; 5 Asp) and one group of 3 nonpyramidal neurons was immunonegative for all 3 amino acids. However, in the clusters positive for Asp or Glu a number of neurons contained both excitatory amino acids.

These findings support the hypothesis that genetic determinants play an important role in the expression of the principal neurotransmitters in neurons of the mammalian cerebral cortex.

PARALLEL DEVELOPMENT OF RADIAL GLIA AND MYELINATION IN HUMAN FETAL SPINAL CORD. K.M. Weidenheim, I. Epshteyn, W.K. Rashbaum, C.S. Raine* and W.D. Lyman. Albert Einstein College of Medicine, Bronx, NY 10461

Radial glia and differentiated myelin-forming oligodendrocytes are present in the human fetal spinal cord (HFSC) by 10 weeks of gestation (WOG). However, neuroanatomic correlation of the development of these two cell types has not been performed. In this study, immunohistochemical methods using antibodies to vimentin and glial fibrillary acidic protein (GFAP) were used to mark radial glia and an antibody to myelin basic protein (MBP) identified oligodendrocytes and myelin in vibratome sections of 37 HFSC ranging in age from 9-20 WOG. Radial glia were more numerous in the anterior and anterolateral funiculi than the dorsal funiculus; the posterolateral funiculus had very few radial processes. In addition, radial glia were always more numerous at the cervical level. Expression of MBP followed the same pattern. The results suggest that radial glia and oligodendrocytes follow anterior-to-posterior and superior-to-inferior developmental patterns. These gradients appear to be independent of the tracts of the developing spinal cord. Interaction between these cell types may be necessary for appropriate development of each. Further work is necessary to elucidate this interaction.

THE TIMING OF MOTONEURON COMMITMENT IN THE DEVELOPING CHICK SPINAL CORD. M.P. Matise* and C. Lance-Jones, Dept.of Neurobiology, Anatomy & Cell Science, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

When 3-4 Lumbosacral (LS) spinal cord segments (+/- notochord) are reversed about the rostrocaudal (R-C) axis in stage 15-16 chick embryos, motoneuron axons which emerge from these reversed segments alter their peripheral course to project to their originally appropriate muscle targets. This finding suggests that there are differences along the R-C spinal cord axis at neural tube stages (stages 15-16) and that the motoneurons within LS segments are committed to a particular peripheral target fate when their axons grow out of the cord (stages 18+). How and when are motoneurons committed to specific target fates? We have begun to address this question by carrying out R-C cord reversals at earlier stages.

At stages 13-14, presumptive LS cord segments 1-3 were separated from the notochord and other surrounding tissues and reversed about the R-C axis. At stages 35-37, retrograde HRP labelling was used to define the R-C location of motoneurons innervating the sartorius and femorotibialis muscles. Motoneurons innervating these muscles are normally found in discrete positions within LS 1-3. In 70% of stage 13 cases (n=14) and 55% of stage 14 cases (n=9), motoneurons innervating these muscles were located in discrete positions in accord with their new R-C location. In 30% of stage 13 cases and 33% of stage 14 cases, motoneurons were dispersed throughout the reversed segments. In only one case (at stage 14) did motoneurons project in accord with their origin prior to the reversal. These findings suggest that R-C differences within the spinal cord that lead to motoneuron commitment are not present at stages 13 and 14. (Supported by NIH HD25676).

469.1

SYNAPTIC INPUT TO TRANSIENT SUBCORTICAL SYNAPTIC ZONE (TSZ) NEURONS: I. INFRAGRANULAR CORTICAL NEURONS PROVIDE DIRECT SYNAPTIC INPUT TO UNDERLYING TSZ.

A.F. Shering and P.R. Lowenstein*, Laboratory of Cellular and Developmental Neurobiology, Department of Anatomy and Physiology, University of Dundee, DD1 4HN, Scotland.

In the neonatal cat cerebral cortex antibodies raised against synapsin I and synaptophysin reveal a TSZ beneath the developing cortex. This synaptic neuropil disappears as the animal matures. We have examined the source of synaptic input to the TSZ by iontophoretically injecting the anterograde lectin Phaseolus vulgaris-leucoagglutinin (PHA-L) into the infragranular layers of the visual or somatosensory cortex. PHA-L was visualised using immunohistochemistry and sections were prepared for light and electron microscopy (EM). Terminal arborisations of labelled axons were predominantly located in the lateral geniculate nucleus. Fibres traversing the TSZ were seen to be varicose and when examined under the EM many varicosities were found to establish asymmetric synapses:

Age	Target structures: Spines	Shafts	Somata
<10 days	85%	15%	-
1 month	60%	36%	4%
Adult	-	100%	-

These results demonstrate that neurons located in the infragranular layers of the developing cortex provide direct synaptic input to subcortical TSZ neurons. The developmental transition of post-synaptic targets from spines to shafts, suggests that cortico-TSZ axo-spinous synapses are indeed a population of transient synapses. This constitutes, to our best knowledge, the first morphological identification of a population of transient synapses.

469.2

NEOCORTICAL SYNAPTOGENESIS: LOW DENSITY PRIMARY CULTURES AND USE OF HSV-1 VECTORS FOR GENE TRANSFER INTO POSTMITOTIC NEURONS AND GLIAL CELLS.

P.R.Lowenstein[1], P. Hodge[1,3], N.D. Stow[2], C.M. Preston[2], and M.G. Castro[3]*, [1]Dept. of Anatomy-Physiology, University of Dundee, Dundee DD1 4HN, [2]MRC Virology Unit, University of Glasgow, Glasgow G11 5JR, and [3]Dept. of Molecular-Life Sciences, Dundee Institute of Technology, Dundee DD1 1HG, Scotland.

Neocortical synaptic organization is very specific in terms of the post-synaptic targets of individual neurons, and the synaptic input onto individual cells. Although cortical neurones have 5 different membrane domains on which they could potentially receive synapses, mainly dendrites and cell bodies do receive synaptic input. Also, excitatory cell bodies only receive inhibitory synaptic input, while inhibitory somata receive both excitatory and inhibitory input. We now wish to examine the cellular and molecular basis of this synaptic specificity. Thus, utilizing a very low density primary culture system of neocortical neurons, based on the work of Banker, Kosik, and Ramakers, we determined that neurons: (a) survive long term in low density, defined medium, and absence of astrocytic contact; (b) develop proper morphological polarity (e.g. dendrites and axon); (c) after 3 weeks in vitro MAP-2 is found only in dendrites, while tau is localized to all cellular processes; (d) immuno-localization of synaptophysin combined with confocal microscopy suggests that the pattern of synapses in vitro is comparable to the in vivo one; (e) HSV-1 tsK vectors can be used to transfer foreign genes into both postmitotic neurons and glial cells in primary culture. Thus, in spite of its intrinsic complexity in vivo, the cellular and molecular basis of neocortical synapse formation can now be examined using a simple in vitro model.

DEVELOPMENT OF SYNAPTIC CONTACTS BETWEEN NEURONS OF BASAL FOREBRAIN AND CEREBRAL CORTEX IN ORGANOTYPIC TISSUE SLICE CULTURE

P.G. Distler & R.T. Robertson*, Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717

We have previously shown that AChE-positive neurons of rat basal forebrain project toward co-cultured cerebral cortex slices and, after entering the tissue, branch within the different cortical layers (Distler and Robertson, 1992). We are now investigating whether these projections also form synaptic contacts with neurons in the cortical target region.

Slices of neonatal basal forebrain tissue were co-cultured with 4 day old cerebral cortex tissue over a time period up to 4 weeks. Various developmental stages of the basal forebrain-cerebral cortex innervation were then investigated on the fine structural level. For identification of afferent projections, two different labeling techniques were applied: (i) placement of the lipophilic dye DiI on fixed basal forebrain tissue and subsequent DAB-photoconversion of stained fibers within cortical tissue, and (ii) AChE-histochemistry, a label which is known to be a reliable marker for cholinergic basal forebrain neurons.

The electron microscopical investigation revealed consistent results for both staining methods: First, basal forebrain afferent fibers form terminal synaptic contacts on dendritc shafts in the superficial cortical layers. Second, the observed synapses are of the symmetric type. Furthermore, both methods reveal the presence of clear spherical vesicles in the presynaptic profile. Within superficial cortical areas, stained synaptic contacts were evident as early as one week after beginning culturing.

In conclusion, the data reveal parallels to the cholinergic innervation in vivo, and provide further evidence about the significance of this model system for the study of the development of the cerebral cortex.

469.4

INTERRUPTION OF AXONAL GROWTH BY TARGET NEURONS IS ENHANCED BY NMDA.

D.H. Baird*, A.B. MacDermott[1], E. Trenkner[2], and C.A. Mason[3]. *Howard Hughes Medical Institute, Rockefeller Univ.; [2]NY State Institute for Basic Research in Developmental Disabilities; Depts. of [3]Pathology and [1]Physiology and Cellular Biophysics, College of Physicians and Surgeons of Columbia University, New York, N.Y. 10032.

Cultured cerebellar granule neurons interrupt the growth of their mossy fiber afferents originating from explants of basilar pontine nuclei (Baird et al. 1992 *J. Neurosci.*12:619-634). This "stop-growing signal" is afferent and target cell specific (Baird et al. *J. Neurobiol.* 1992 in press; Baptista et al, this volume). Action potentials and neurotransmitters play a role in the stop-growing signal as TTX, TTX + high magnesium, or kynurenic acid, an antagonist of glutamate receptors, all interfere with the stop-growing signal.

To determine which types of glutamate receptors might be involved in the stop-signal, explants of pontine nuclei were cultured on granule neurons for two days in the presence of glutamate agonists and antagonists specific for NMDA and non-NMDA receptors. The NMDA-specific antagonist D-AP5 interferes with the stop-signal, resulting in increased numbers of long pontine neurites extending over granule neurons compared to control cultures in ordinary medium. In the presence of 20μM NMDA the number of long neurites was reduced to less than 40% of controls. Pontine explants cultured without granule neurons but with NMDA showed a small increase in the number of long neurites produced. In contrast, explants co-cultured with granule neurons in 50μm AMPA (a non-NMDA agonist) showed little reduction in the number of long neurites produced. AMPA had no effect on the number of pontine neurites in the absence of granule cells.

These results suggest a role for NMDA receptors in regulating the growth of mossy fibers on target granule neurons and potentially in contributing to target cell specificity during the innervation of the cerebellum.

469.5

SPECIFICITY OF CEREBELLAR AXON-TARGET INTERACTIONS *IN VITRO*.

C.A. Baptista*, D.H. Baird, and C.A. Mason Dept. of Pathology, Coll. Physicians and Surgeons, Columbia University, New York, N.Y. 10032.

Granule neurons *in vitro* present a stop-growing signal for their appropriate afferents, the mossy fibers. This signal is afferent-specific since neither retinal nor inferior olivary fiber growth is arrested by granule neurons (Baird et al, J. Neurosci. 1992 12:619-634; J. Neurobiol., in press).

With the ability to purify Purkinje cells (Baptista et al. 1991 Soc. Neurosci. Abstr. 17:38), we examined the capacity of this cell type to regulate afferent growth. To study the growth of one afferent to Purkinje cells, the parallel fibers axons from granule neurons, we co-cultured reaggregates of purified granule cells with purified Purkinje cells. Purkinje cells stimulate and maintain the growth of parallel fiber axons, in line with the mode of growth of parallel fibers across the dendritic fields of multiple adjacent Purkinje cells. In turn, granule neurons and their axons maintain and promote the differentiation of Purkinje cells. Thus, Purkinje cells and granule cells may have different modes of regulating afferent growth, in some cases stimulating growth.

Second, we examined how an inappropriate afferent, the pontine mossy fibers, interact with Purkinje cells. Mossy fiber growth is abundant on a number of substrates and is not affected by co-culture with Purkinje cells. However, when purified Purkinje cells are added to granule neurons, mossy fiber growth is increased three fold compared to growth on granule cells alone. While it is not known if Purkinje cells stimulate mossy fiber growth directly, or disrupt the stop-signal for mossy fiber growth by interacting with granule cells, these results suggest that Purkinje cells do not send a stop-signal to mossy fibers and that the signal is target cell-specific.

The above paradigms will allow the analysis of mechanisms involved in the specificity of axon growth regulation, its maintenance by target cells and the establishment of specific synaptic connections.

469.6

SPATIAL DISTRIBUTION OF EXCITATORY AND INHIBITORY SYNAPSES ON A PURKINJE CELL IN A RAT CEREBELLAR CULTURE.

T. Hirano*, K. Kasono, Department of Physiology, Faculty of Medicine, Kyoto University, Yoshida Konoe-chou, Sakyo-ku, Kyoto 606, Japan.

Spatial distribution of synapses on Purkinje cells formed in a dissociated cell culture of rat cerebellum, were studied by intracelluar fluorescent stainings of pre- and postsynaptic neurons and by immunocytochemical staining of presynaptic terminals. Simultaneous whole-cell recordings were performed both on a presynaptic small neuron and on a Purkinje cell, and the property of synaptic transmission was determined. Inward excitatory synaptic currents were suppressed by CNQX, and outward inhibitory synaptic currents were suppressed by bicuculline, respectively. A presynaptic neuron was stained with intracellularly injected lucifer yellow and a Purkinje cell was filled with texas red. Axonal varicosities presumed synaptic terminals of excitatory granule cells on a Purkinje cell, were exclusively localized along dendrites, and presumed synaptic terminals of inhibitory interneurons such as basket or stellate cells were fond both along dendrites and on the soma. After the electrophysiological recordings, neurons were fixed and stained with an anti-synaptophysin monoclonal antibody in order to visualize overall distribution of synaptic terminals on a Purkinje cell. The staining confirmed that the varicosities are presynaptic terminals and that a Purkinje cell receives synaptic inputs both on a soma and on dendrites. Thus, differential spatial distribution of excitatory and inhibitory synapses on a Purkinje cell in a simple culture system was demonstrated. Synapses were also observed with a scanning electron microscope.

469.7

EVIDENCE FOR THAT GANGLIOSIDES ARE ESSENTIAL FOR SYNAPSE FORMATION BETWEEN CEREBRAL CORTICAL NEURONS; ENDOGLYCOCERAMIDASE INHIBITS *IN VITRO* SYNAPTOGENESIS. Kazuyo Muramoto*[1,3], Kazuo Kobayashi[1], Masahiro Kawahara[1], Makoto Ito[2], Tatsuya Yamagata[2] and Yoichiro Kuroda[1], [1]Dept. of Mol.and Cell. Neurobiol. Tokyo Metropol. Inst. for Neurosci., Fuchu, Tokyo 183, [2]Lab. of Glycoconjugate Res., Mitsubishi-Kasei Life Science Inst., Machida, Tokyo 194, [3]Dept. of Pharmacol., Fac. of Med., Univ. of Tokyo, Tokyo 113, Japan.

Synapse formation between cultured cerebral cortical neurons was observed by multi-site Ca^{2+} fluorometry (Muramoto,K., *et al., Proc.Japan Acad.Ser.B*, **64**, 319, 1988). Most neurons in the culture showed synchronous oscillations of the fluorescence intensity which correspond to spontaneous synaptic activity. Continuous application of K-252b, a protein kinase inhibitor, blocked the synchronous firing and significantly decreased the number of synapses identified morphologically using electron microscopy (Kuroda,Y., *et al., Neurosci.Lett.*, **135**, 255, 1992). Since K-252b does not permeate the cell membrane, the data strongly suggest that phosphorylation of cell surface by an ecto-protein kinase (Ehrlich,Y.H., *et al., Nature*, **320**, 67, 1986) is inhibited by K-252b. Since it has been reported that an ecto-protein kinase activity is regulated by a specific type of gangliosides (Tsuji,S., *et al., J.Biochem.*, **104**, 498, 1988), we applied purified endoglycoceramidase (EGCase) which can remove all carbohydrate moieties from any ganglioside but not from proteins and others (Ito,M., *et al., J.Biol.Chem.*, **264**, 9510, 1989) to the cortical culture. Continuous presence of EGCase together with its activator protein inhibited the occurrence of synchronous oscillation after 8 days in culture, when control culture showed oscillation which represents a significant amount of synapse formation between cerebral cortical neurons. The inhibition was dose-dependent and without any significant morphological changes of neurons and their neurites which was observed by phase-contrast microscopy and immunostaining of MAP 2 and neurofilament.

Supported by grant-in-aids for promotion area "gangliosides" (To Y.K. No.03255222) from ministry of Education, Science and Culture of Japan.

CHARACTERIZATION OF SYNAPSE FORMATION BETWEEN CNS NEURONS IN CULTURE: BINDING OF MONOCLONAL ANTIBODIES AND LECTINS TO LIVING HIPPOCAMPAL NEURONS. Kazuo Kobayashi*, Masumi Ichikawa, Masahiro Kawahara, Kazuyo Muramoto, Yoichiro Kuroda, Depts. of Molecular & Cellular Neurobiology, and of Anatomy & Embryology, Tokyo Metropol. Inst. for Neuroscience, Fuchu, Tokyo 183, Japan.

We have carried out quantitative analysis of synapse formation between cultured CNS neurons using multi-site Ca^{2+} fluorometry and electron microscopy (Kuroda et al. *Neurosci.Lett.* 133:255, 1992). Synaptophysin immunostaining using laser confocal microscopy demonstrated that neurons were connected by many synapses which matured during the culture (Ichikawa et al. *Neurosci. Res.* 12:452,1991). To investigate whether these synapses are formed between specific pairs of neurons in culture or not, we have attempted to identify different types of CNS neurons. We developed a library of monoclonal antibodies which bind to living PC12 cells differentiated by NGF treatment. At least 14 monoclonal antibodies in the library bound almost exclusively to living neurons from rat hippocampus in culture. We also screened a series of lectins to the living neurons. *Vicia villosa agglutinin* (VVA) binding appeared to be significant to multipolar neuron in the hippocampus after 2 weeks in culture. These neurons appear to be inhibitory, which identified in fixed hippocampal tissue(Drake et al. *Brain Res.* 554:176,1991).

469.9

DEVELOPMENT OF FUNCTIONAL SYNAPTIC TRANSMISSION BETWEEN CULTURED RAT HIPPOCAMPAL NEURONS. T.A. Basarsky, V. Parpura and P.G. Haydon*. Signal Transduction Training Group and Dept of Zoology and Genetics, Iowa State University, Ames, IA 50011.

The formation of a functional synapse requires the simultaneous expression of voltage-dependent calcium channels, calcium responsive secretory machinery, and post-synaptic receptors. In rat neonatal hippocampal cell cultures we find the presence of functional synapses is not detected until 5-8 days *in vitro*. Paired whole-cell recordings were used to assay the presence of evoked excitatory and inhibitory connections. To identify the rate-limiting element in synapse formation we have begun studying the developmental appearance of voltage-dependent calcium channels and postsynaptic receptors.

Internal calcium levels were monitored using the calcium indicator Fluo-3 AM (8 μM). Focal application of either 50 mM K^+ or 100 μM glutamate reliably elevated internal calcium in neurons 3 days *in vitro*, prior to the onset of functional synaptic transmission. The actions of high K^+ and glutamate were reduced in zero calcium saline.

These data indicate that calcium channels and glutamate receptors are present prior to the detection of functional synapses. However, further studies must examine the timing of appearance of specific channel types and their spatial relation to the synaptic terminal.

469.10

A PROTEASE INHIBITOR REDUCES ACTIVITY-DEPENDENT SYNAPSE ELIMINATION AT THE MOUSE NEUROMUSCULAR JUNCTION *IN VITRO*. Y.Liu*, R.D.Fields, S.Fitzgerald, W.Nyhus and P.G.Nelson, LDN, NICHD, NIH, Bethesda, MD 20892.

The possible involvement of proteolysis in the process of activity-dependent synapse elimination was studied in an *in vitro* model of the neuromuscular junction. Neurons of the superior cervical ganglion (SCG) and muscle cells were isolated from new born mice and cultured in a multicompartment system, the Campenot chamber. The SCG neurons were kept in the two side compartments; muscle cells in the center. Cholinergic synapses developed between neurons and muscle cells after 2-3 weeks. Functional synapses were monitored by the contraction of muscle cells in response to stimulating the afferent neurons.

The elimination of these synapses was activity-dependent. After 1-2 days of extracellular stimulation to the presynaptic axons, 52% of the synaptic connections were eliminated (n=275). When 50 μM leupeptin, a protease inhibitor, was added into the central compartment during the whole period of stimulation, only 35% of the synapses were lost (n=193). The difference between the effect of stimulation in the presence and absence of leupeptin was statistically significant ($p<0.001$). Synapse elimination in unstimulated controls was 8% (n=177). In the presence of 1 μM tetrodotoxin (TTX), stimulation did not cause synapse elimination (n=107).

In conclusion, the partial block of synapse elimination by this protease inhibitor suggests that proteolysis may play a role in the mechanism of activity-dependent synapse elimination.

469.11

A TROPHIC MODEL OF NEUROMUSCULAR SYNAPSE ELIMINATION: CORRELATION OF MOTOR UNIT SIZES WITH ACTIVITY. J.N.Carr and M.Morgan-Carr*, Dept. Of Biology, Bryn Mawr College, Bryn Mawr, PA. 19010

It has been proposed that neuromuscular synapse elimination is driven by pre-synaptic competition for a post-synaptically supplied trophic factor. This competition is activity dependent in that pre-synaptic uptake and/or post-synaptic supply of trophic factor requires activity in the respective element. Because pre-synaptic growth is tied to trophic factor uptake, such models predict that the most active motor neuron forms the largest motor unit, in direct contradiction with observation. This contradiction can be removed by postulating that each motor neuron desires to obtain the same total amount, or target value, of trophic factor from its axonal arbor.

Our model of synaptic dynamics is based on the biology of NGF. We assume that trophic factor is taken up pre-synaptically by a receptor mediated endocytotic mechanism; therefore, active motor neurons are capable of taking up more trophic factor than inactive counterparts. Growth or retraction of a given pre-synaptic element is based upon a net difference between factor taken up locally and a decay process that operates when a pre-synaptic element is active. Growth occurs when a given synapse obtains enough trophic factor to overcome the internal decay process. Internalized trophic factor is retrogradely transported to the soma where it regulates trophic factor receptor expression. If the soma concentration of trophic factor exceeds the target value, receptor expression is down-regulated; up-regulation occurs if the concentration is too low. Thus, a motor neuron that is obtaining too much trophic factor places all of its synapses at a competitive disadvantage by limiting the number of receptors each synapse has available.

Computer simulations demonstrate that this model correctly predicts both the time course of normal synapse elimination and the observation that less active motor neurons form larger motor units. The model also reproduces the effects of numerous experimental manipulations, including partial denervation and the effects of pre- or post-synaptic blockade. It is worth noting that trophic factor receptor regulation serves to produce motor units whose sizes display the observed dependence upon activity levels, but is not required for the removal of polyneuronal innervation.

469.12

SOMATOTOPIC ORGANIZATION OF OVERLAPPING MOTOR UNITS WITHIN A LARVAL FROG JAW MUSCLE. F.F. Omerza* and K.E. Alley Ohio State University, Columbus, Ohio 43210.

Individual myofibers within the larval jaw muscles of Rana pipiens are polyinnervated. This is due to the presence of multiple neuromuscular junctions (NMJs) as well as multiple axons within individual junctions. The purpose of this study was to determine whether this polyinnervation arises from more than one neuron and, if so, to investigate their central and peripheral organization. In order to examine the neuronal distribution at muscle, myofiber and NMJ levels, we employed a triple labeling technique utilizing standard AChE histochemistry and the anterograde fluorescent tracers DiI and DiA. This procedure allowed us to distinguish the distributions of two separate groups of axons to their respective NMJs. A second study used retrograde axonal transport of Fast Blue and DiI from injection sites at opposite ends of the muscle. This provided the location of motoneurons serving different regions of the same muscle. Results of the triple label study indicate that individual NMJs and myofibers may receive innervation from axons within different portions of the nerve root, and further, suggests a regional distribution for motor units. Results of the retrograde study demonstrate that neurons projecting to the rostral and caudal regions of the muscle are distinct. Our observations indicate that several neurons can project to the same myofiber or NMJ and that the resultant overlapping motor distribution is reflected in a somatotopic organization of motoneurons.

469.13

INITIAL EMBRYONIC EXPRESSION OF MOTONEURON TOPOGRAPHY IN THE RAT DIAPHRAGM MUSCLE. M. Laskowski* and Jesse Owens. WAMI Medical Program, University of Idaho, Moscow, ID 83843 and Program in Biomedical Science, University of Alaska, Anchorage, AK 99508, U.S.A.

In previous reports we have shown that motoneurons in the adult phrenic nucleus of the rat map across the surface of the diaphragm muscle in a distinct rostrocaudal pattern. In an effort to understand mechanisms responsible for the establishment of this rostrocaudal map, in this study we examined the pattern of innervation of the developing diaphragm. Focal extracellular end-plate currents (EPCs) were recorded from curarized embryonic diaphragm muscle while stimulating sequentially each ventral root (C_3, C_4, C_5 and C_6). This method offers high spatial resolution of synaptic activity without the biases introduced by intracellular recording. The first evidence of EPCs in the center of the diaphragm was observed at day E-15.5 when all roots (C_4, C_5 and C_6 and sometimes C_3) had synaptic input. By E-16 as the phrenic nerve grew into slightly rostral and caudal regions of the muscle, a distinct topographic preference could be detected. By E-18 when two-thirds of the muscle was innervated the topographic map was further sharpened. We conclude first, that topographic selectivity cannot be explained on the basis of a difference in arrival time of rostral vs caudal motoneurons. Second, a topographic bias is present soon after the earliest period of evoked synaptic activity suggesting that growing motoneurons respond to topographic cues on muscle targets at a very early stage of development. Supported by NIH grant NS 27024.

NUTRITIONAL AND PRENATAL FACTORS: ALCOHOL

470.1

EFFECT OF IN UTERO ETHANOL EXPOSURE ON THE MORPHOLOGICAL DEVELOPMENT OF THE OCULOMOTOR NUCLEUS IN THE RAT. R.C. Burrows; A.K. Shetty; D.E. Phillips*. Dept. of Biology Montana State University, Bozeman, MT 59717.

This study was designed to determine if exposures to ethanol can alter the development of brainstem nuclei controlling the extraocular eye muscles. Pregnant rats were fed throughout gestation with either an ethanol containing liquid diet, in which 37.5% of the total caloric content was ethanol derived, or with an iso-caloric diet. Male offspring were perfused on postnatal day 15 and the oculomotor nucleus was examined using plastic section light microscopy, Golgi-Cox staining, and stereologic analysis of electron micrographs. A decrease in the number of neurons as well as an increase in the number of astrocytes per unit area was found in the ethanol exposed animals, while the total number of cells per unit area remained relatively constant. There was an alcohol-induced decrease in the overall complexity of the dendritic ramifications, as well as in the total number of dendrites. The area of the neuronal soma was also decreased in the alcohol exposed animals, but there was no change in the area of the nucleus or nucleolus. These results may help explain some of the motor deficits associated with the visual system after developmental alcohol exposures.
Supported by NIAAA AA7042 and NSF EPSCoR RII-8921978.

470.2

TEMPORAL CONSTRAINTS ON ALCOHOL-INDUCED CORTICAL ASTROGLIOSIS DURING THE NEONATAL BRAIN GROWTH SPURT IN RATS. J.T. Leo, C.R. Goodlett* and J.R. West. Alcohol and Brain Research Laboratory, Dept. of Anatomy, University of Iowa, Iowa City, IA 52242.

It has previously been reported that alcohol exposure during the brain growth spurt (postnatal days [PD] 4-9), in a pattern yielding cyclic blood alcohol concentrations with high peaks and low troughs, produces a conspicuous reactive gliosis in the cerebral cortex. Radioimmunoassays have shown that the amount of GFAP is increased more than 300% above controls. Immunocytochemical studies indicated that much of the increased GFAP was associated with loci of reactive astrocytes surrounding some cortical blood vessels. These loci, scattered throughout the cortex, contained hypertrophied astroglia with thick fibrillary processes heavily labeled by GFAP.

The goal of this study was to determine if a similar pattern of alcohol exposure later in the neonatal brain growth spurt (PD 10-14) would stimulate astrogliosis comparable to exposure on days 4-8. Pups were gastrostomized either on PD 4 or PD 10 and were given either 4.5 g/kg of alcohol per day [delivered in 2 of 12 daily feeding as a 10.2% (v/v) solution in milk formula] or were given a calorically matched diet free of alcohol. Pups were perfused on postnatal day 9 or postnatal day 15 and 40-μm thick frozen coronal sections were processed for GFAP immunoreactivity using peroxidase-antiperoxidase immunocytochemistry. Matched sections from control and alcohol-treated pups were evaluated microscopically for reactive gliosis around cortical blood vessels.

In contrast to the prominent effect seen in pups exposed on PD 4-8, alcohol exposure on PD 10-14 did not result in the intense reactive astrogliosis surrounding cortical blood vessels. These results indicate the presence of a temporal window of vulnerability to alcohol-induced reactive gliosis elicited around cortical blood vessels. The critical period for this effect appears to end by postnatal day 10. Supported by grants #AA 07313 and #AA 05523)

470.3

DEFICITS IN BEHAVIORAL DEVELOPMENT AND OLIGODENDROCYTIC PERCENTAGES IN THE NEONATAL RAT DUE TO PRENATAL ALCOHOL EXPOSURE. C.A. Aquilino and K.M. Cianci*. Dept. of Psychology, Franklin & Marshall College, Lancaster, PA 17604.

Subjects were Sprague-Dawley pups of dams receiving a diet of either 35% ethanol-derived calories, 35% carbohydrate-derived calories (sucrose), or 100% lab chow during the 21 days of gestation. Twenty subjects were tested on reflex activity, stereotropic behavior, open-field activity, and wheelrunning on days 7-10, 11-14, 15-21, and six weeks of age, respectively. Significant differences were found between ethanol-exposed rats and controls in their development of righting reflex, suckling behavior, tactile stimulation, negative geotaxis, phototropism, stereotropic behavior, and rearing activity. Sucrose-exposed animals resembled the ethanol-exposed in behavioral delays. Twenty ethanol-exposed rats and 19 controls were sacrificed at postnatal day two to establish cultures of the hippocampi, cerebral cortexes, and brainstems. At five days in culture, relative percentages of oligodendrocytes and neurons were determined using the immuno-fluorescent labels anti-galactocerebroside and anti-neurofilament, respectively. Ethanol-exposed rats had significantly lower per-centages of oligodendrocytes and neurons than controls. They were significantly lower in the hippocampus, cerebral cortex, and brainstem. The ethanol group may have had a lower percentage of neurons in the cerebral cortex (approached significance). Research was supported by Franklin & Marshall College Committee on Grants.

470.4

ALTERED DEVELOPMENT OF DOPAMINERGIC NEURONS IN THE RAT SUBSTANTIA NIGRA FOLLOWING PRENATAL ETHANOL EXPOSURE. A.K. Shetty*, R.C. Burrows and D.E. Phillips. Dept. of Biology, Montana State University, Bozeman, MT 59717.

The development of dopaminergic neurons of substantia nigra pars compacta (SNPC) was investigated following prenatal ethanol exposure. Pregnant rats were either fed with an ethanol containing liquid diet (6.7% v/v) or were pair fed an isocaloric diet throughout gestation. Offspring were sacrificed on postnatal day 15 and the morphology of neurons was assessed by tyrosine hydroxylase (TH) immunocytochemistry and by Golgi-Cox staining. Compared to control offspring, ethanol exposed offspring had more closely packed and smaller TH positive cell bodies, thinner and fewer TH positive fibers, reduced numbers of second, third and fourth order dendrites, fewer total dendritic segments per cell, and an altered dendritic branching pattern. Some dysmorphic neurons with irregular cell body contours and fusiform and/or spheroidal enlargements in the dendrites were also encountered. These results suggest that prenatal ethanol exposure causes retardation of the development of SNPC neurons, especially of the growth and branching of dendrites. The underdevelopment of dendrites could result in altered development of neuronal circuitry which in turn could contribute to the abnormal motor functions reported after developmental alcohol exposures.

470.5

EFFECTS OF ALCOHOL EXPOSURE DURING DEVELOPMENT ON THE NEUROCHEMISTRY OF THE AMYGDALA. Sandra J. Kelly.* Department of Psychology, University of South Carolina, Columbia, SC, U.S.A. 29208.

Previous work from this laboratory has suggested that the amygdala may be affected by exposure to alcohol during the early postnatal period. This period is similar with respect to brain growth to the third trimester in humans. The alcohol exposure is given via an artificial rearing procedure in which the rats are exposed to either 5 or 3 g/kg/day of ethanol from postnatal days 4 to 10. Control groups consist of rats artificially reared but not exposed to alcohol and rats reared normally by dams. At 21 days of age, the rats were killed and their heads were immediately immersed in liquid nitrogen. The amygdala region was dissected free, sonicated in 0.2 M perchloric acid, and frozen until time of assay. At that time, the sonicated tissue was thawed and centrifuged for 15 min. The supernatant was injected on a C18 reverse phase column for HPLC with electrochemical detection. The mobile phase was 6.7% (v/v) methanol in 1 mM sodium monophosphate, .631 mM sodium octyl sulfate, 1.0 mM sodium EDTA and 2.49 mM triethylamine (pH 4.0). The supernatant was analyzed for noradrenaline, dopamine, DOPAC, HVA, 5-HT, and 5-HIAA content.

Exposure to alcohol during development alters the amygdala in 21 day old rats. The dopamine levels were altered in rats of both sexes and the 5-HT levels were increased in female rats. There were also a number of effects of artificial rearing on neurochemistry. (Supported by NIAAA Grant AA08080)

470.6

THE INFLUENCE OF CHRONIC PRENATAL ETHANOL EXPOSURE ON CHOLINERGIC DEVELOPMENT IN THE SEPTOHIPPOCAMPAL SYSTEM OF THE RAT D.J.Swanson, D.W. Walker, and M.B. Heaton*. University of Florida College of Medicine and V.A. Medical Center Gainesville, FL, 32610.

In animal models of Fetal Alcohol Syndrome (FAS) the hippocampus has been shown to be especially sensitive to the effects of prenatal ethanol exposure, exhibiting neuronal loss and alterations in neuritic process elaboration. We have begun to characterize the influence of chronic prenatal ethanol exposure on the development of the cholinergic neuronal population which projects to the hippocampus, the medial septal nucleus and nucleus of the diagonal band (MS/DB). On gestation days 1-22 pregnant dams were either fed an ethanol containing liquid diet, pair-fed a calorically equivalent sucrose-containing diet, or given rat chow *ad lib*. Preliminary evidence shows that chronic prenatal ethanol exposure produces a significant decrease in MS/DB ChAT activity at postnatal day 1 (P1; 18% reduction in ethanol exposed pups compared to pair-fed pups). Subsequently, at P7 ChAT activity expression in ethanol exposed pups approximately equaled that of pair-fed and chow control pups. Further experiments are in progress to examine additional developmental time points as well as the anatomical basis for this alteration in ChAT developmental expression. These studies will determine whether the early decline results from a developmental delay, or whether a reduction in cholinergic neurons coupled with up-regulation of ChAT expression may occur. Supported by AA05332, AA00200, a grant from the A.B.M.R.F., and the Dept. of Veterans Affairs.

470.7

EXPRESSION OF LHRH mRNA IN THE C57BL/6J MOUSE FOLLOWING ACUTE IN UTERO ETHANOL EXPOSURE. H.C. Scott*, R.T. Zoeller, P.K. Rudeen, Department of Anatomy and Neurobiology, University of Missouri School of Medicine, Columbia, MO 65212.

Previously we have shown that an acute dose of ethanol on gestational day 7 (G7) alters the number of neurons immunoreactive for LHRH peptide (Scott et al., Dev. Brain Res. 66:119, 1992). The effect of an acute dose of ethanol on G10 on the expression of LHRH mRNA was examined in this study. G10 corresponds to the day of development when LHRH neurons begin to differentiate as a single neuronal population in the medial olfactory placode of the mouse (Wray et al., Proc. Natl. Acad. Sci. USA, 86:8132, 1989). C57BL/6J mice were exposed to two doses of 25% ethanol (2.9 g/kg body weight) on G10. Control pups were intubated with water. Animals were sacrificed on G18 and frozen coronal sections cut at 12 μm. In situ hybridization histochemistry localized individual neurons containing LHRH mRNA. A Bioquant MEG IV imalge analysis system determined the area covered by grains for each neuron expressing LHRH mRNA in the diagonal band of Brocca/medial preoptic area. Fetal ethanol exposure does not appear to interfere with LHRH gene expression when given during an important period of LHRH neurogenesis. (Supported by NIAAA grants AA07458, AA05893 and AA00107)

470.8

ETHANOL EXPOSURE INCREASES GFAP mRNA AND PROTEIN IN DEVELOPING RAT CORTEX AND CULTURED CORTICAL ASTROCYTES. T.L. Fletcher* and W. Shain, School of Public Health, The University at Albany and Wadsworth Center, Albany, NY 12201.

Prenatal exposure to ethanol can result in Fetal Alcohol Syndrome (FAS). We have shown that brief ethanol exposure causes changes in expression of a limited number of genes in the developing rat CNS. We describe here ethanol's effect on glial fibrillary acidic protein (GFAP) expression. Artificially-reared rat pups received 3.3 g/kg/day in 2 doses from postnatal days 5-7 resulting in peak blood alcohol levels of 180 mg/dL Artificially-reared control pups received an isocaloric diet. Suckle control pups were reared by their dams. Two hours after the last dose of ethanol, mRNA was isolated from four brain regions of some pups. Other pups were fostered to control dams and mRNA was isolated at 14, 21, or 90 days of age. Northern and slot blot analyses demonstrated a transient 3-fold increase in GFAP, but not β-actin, mRNA in cortex. No changes in GFAP were observed in the hippocampus. Western blot analysis of 7 day cortex showed a comparable increase in GFAP protein. To determine if this increase was due to a direct action of ethanol on glial cells, primary cultures of cortical astrocytes were exposed to ethanol resulting in media concentrations equivalent to pup ethanol exposure. Ethanol exposure increased GFAP expression parallel to the *in vivo* observations. These results suggest that ethanol directly disrupts the regulation of specific genes in astrocytes during CNS development. (Supported by AA-07472)

470.9

FETAL ALCOHOL EXPOSURE (FAE) BLUNTS THE IMMUNOMODULATORY RESPONSE TO SWIM STRESS IN MALE RATS. M.L. Pilati, F. Chiappelli, D. Tio and A.N. Taylor*. Depts. Anat./Cell Biol. & Psychol., BRI, Psychoneuroimmunol., UCLA; and Brentwood Div., West LA VAMC, Los Angeles, CA 90024.

Maternal alcohol consumption (36% ethanol-derived calories during the last two weeks of gestation) produces long-lasting alterations in stress-induced neuroendocrine and neurobehavioral responses and in basal (non-stressed) neuroimmune responses in the offspring. In order to determine the effect of FAE on stress-induced immune responses, adult male Sprague-Dawley FAE and control rats were exposed to swim stress (5 periods of 3-min swim in 37°C water over 30 min, with tails weighted). One hr later thymuses were removed and their proliferative response to Concanavalin A was tested. The thymoproliferative response of swim-stressed control rats dropped by 69% compared to unstressed controls ($p<0.01$), while it decreased by only 41% in stressed FAE compared to unstressed FAE rats ($p>0.05$). The ontogenic and temporal profiles of this FAE-induced differential immunosuppressive response to stress are currently under investigation. (Supported by VA Medical Research Service.)

470.10

THE EFFECT OF EARLY POSTNATAL ETHANOL EXPOSURE ON LIGHT-DARK PREFERENCE IN PREWEANLING RATS. Janie H. Wilson* and Sandra J. Kelly. Department of Psychology, University of South Carolina, Columbia, SC 29208.

This experiment examined the influence of early postnatal ethanol exposure on light-dark preference and the effect of home-cage shavings versus clean shavings on this preference. Rats were artificially reared and exposed to either 3 or 5 g/kg/day of ethanol from postnatal days 4 through 10. Control groups consisted of rats artificially reared but not exposed to alcohol and rats normally reared by dams. All rats were reared by dams from postnatal day 12 to the time of testing on postnatal day 18. The testing apparatus consisted of two chambers: one was made of black Plexiglas and completely enclosed, and the other was made of white Plexiglas and open to bright lighting. A small door connected the two chambers. Each animal was placed in the white chamber facing away from the dark chamber. Latency to enter the dark chamber and total time spent there were recorded.

The presence of home-cage shavings resulted in more time spent in the white chamber. It is plausible that the presence of home-cage shavings reduced the stress associated with a novel environment such that the animal leaves the shelter of the black chamber. There was a distinct sex effect in that males spent more time in the dark chamber than females. High-dose and low-dose animals spent less time in the dark chamber than animals reared by dams. Both control groups spent the same amount of time in the dark chamber. Early postnatal exposure to ethanol may cause a decrease in the adaptive unconditioned fear response when placed in a novel environment. An alternate explanation is that there was an increase in exploratory behavior due to ethanol during development. (Supported by NIAAA Grant AA08080 to S.J.K.)

470.11

AUDITORY BRAINSTEM RESPONSES (ABR) IN RATS PRENATALLY EXPOSED TO ALCOHOL: EFFECTS OF CRITICAL PERIODS. M.W. Church*, G.W. Overbeck, P. Holmes, J. Tilak. Fetal Alcohol Research Center, Dept. Ob/Gyn, Wayne State University School of Medicine, Detroit, MI 48201.

Prenatal alcohol exposure can cause sensory disorders and other nervous system morbidities. Our interest concerns the auditory system. For example, children with the Fetal Alcohol Syndrome (FAS) have a variety of hearing disorders (Church & Gerkin, Pediatrics 82:147-154, 1988; Church & Eldis, Alc. Clin. Exp. Res. 16:380, 1992). Using an animal model, we have also observed congenital hearing loss (Church, Alcohol 4:231-239, 1987) and developmental delays in auditory maturation (Church & Holloway, Alc. Clin. Exp. Res. 8:258-263, 1984) as evidenced by the ABR. The degree and type of morbidities caused by prenatal drug exposure depends, in part, on the gestational age at the time of exposure. To study the effects of "critical periods" of exposure, Sprague-Dawley rats were prenatally exposed to alcohol by administering liquid diets containing either 0% or 35% ethanol-derived calories to pregnant dams from gestation day 7-14 or 15-22. Untreated control groups were also used. The earlier (organogenesis) period of exposure proved more critical in producing ABR maturational delays in the offspring than the latter (histogenesis) period. Supported by NIAAA Grant AA07606.

GLIA AND OTHER NON-NEURONAL CELLS IV

471.1

ASTROCYTE DEVELOPMENT AND CHONDROITIN-4-SULFATE EXPRESSION IN FETAL HUMAN SPINAL CORD F.J. Liuzzi[1]*, T. Bass[2] and M. Bergevin[3]. Departs. of Anatomy and Neurobiology[1,2], Pediatrics[2] and Pathology[3], Eastern Virginia Med. Sch., Norfolk, VA 23501.

Cervical spinal cords from premature infants were obtained at autopsy and immersion fixed in Zamboni's fixative. Transverse 60μm vibratome sections were cut and stained with antibodies to the glycosaminoglycan, chondroitin-4-sulfate (CS-4), vimentin (VIM) or glial fibrillary acidic protein (GFAP) using a biotin-avidin-peroxidase protocol.

In developing white matter, radially-oriented astrocytes are both GFAP and VIM positive before 33 weeks of gestation. Few stellate astrocytes are evident in the white matter prior to that time. Later, the predominant white matter astrocytic type is stellate and appears to express GFAP only. The distribution and density of these cells correlate with the degree of myelination. GFAP-positive astrocytes are evident in the gray matter at 28 weeks, but are more numerous and more ramified by 33 weeks.

CS-4 is distributed throughout white and gray matters at the gestational ages examined. In the regions of the unmyelinated corticospinal tracts, CS-4 immunoreactivity is associated with septae. These septae are also GFAP and VIM positive prior to 33 weeks of gestation, but only GFAP positive at later times.

471.2

DEVELOPMENTAL REGULATION OF A NON-SPECIFIC TRANSPORTER BY ASTROCYTES IN CULTURE R.E. Petroski*, V.Quiñones-Jenab, J.A. Connor[†], and H.M. Geller. Department of Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854 and [†]Department of Neuroscience, Roche Institute of Molecular Biology, Nutley, NJ 07110.

We have previously demonstrated that embryonic neurons growing on a substrate of rat cerebral cortical astrocytes were selectively labelled with the vital dye 5(6)-carboxy fluorescein diacetate (CFDA). Neurons displayed brilliant green somata as well as intensely labelled processes while the glial monolayer showed only a dim level of fluorescence. Using optical recording methods, we demonstrated that both neurons and astrocytes hydrolyze CFDA to the fluorescent free acid. However, once CFDA is removed from the medium, the astrocytes rapidly expel the dye with a time course of minutes as opposed to neurons which retain the dye for several hours. This has allowed the selective labelling of neurons with CFDA. When astrocytes are rinsed at 4°C, they retain the dye for several hours, suggesting that an active pump is responsible for the extrusion of the dye. The extrusion of the dye is also inhibited by reserpine in a concentration dependent fashion. Immature astrocytes were not able to expel the dye. However, the ability of embryonic astrocytes to pump out fluorescent dyes develops during the first week *in vitro*. Moreover, the immortalized V1 cell line from embryonic mouse hypothalamus, which expresses several mature astroglial properties, is able to expel the dye. This cell line will be used to investigate the properties of this membrane transporter. Supported by NIH NS 24168.

471.3

NEURONS FAIL TO INDUCE BRAINSTEM ASTROGLIAL CELL DIFFERENTIATION *IN VITRO* D.L. Cooper and M.E. Hatten* Department of Pathology and Center for Neurobiology and Behavior, Columbia University, New York, NY 10032

Tumors derived from cells of astrocytic lineage are the most common and devastating of the mammalian brain. Previous *in vitro* analyses, in which cerebellar astroglia and granule neurons were purified from early postnatal cerebellum and recombined, demonstrated that neurons provide a control mechanism for astroglial growth, inducing cerebellar astroglial glial differentiation via contact-mediated proteolytic activation of TGFβ1. In the present study, we have examined whether astroglial cells from the brainstem, a more primitive brain region where neuronal layers do not form, respond to neuronal regulatory signals and TGFβ1-induction of glial differentiation.

When neurons, purified from either brainstem or cerebellum, are co-cultured with brainstem astroglial cells, the neurons bind poorly to the astroglial cells and do not induce glial differentiation. Although neurons did not induce brainstem astroglial differentiation, brainstem glia had an augmented response to the TGFβs. In the absence of neurons or TGFβ, brainstem astroglial cell DNA synthesis was 2-4 times higher than that of cerebellar astroglial DNA synthesis. Addition of TGFβ1 or β2 (1-10 ng/ml) resulted in a 47-94% reduction in DNA synthesis in brainstem glia as compared with the 26-61% reduction seen with cerebellar astrocytes. At similar concentrations, both TGFβs induced glial differentiation, measured by Northern blot analysis of GFAP expression and the extension of glial processes. These experiments demonstrate the ability of TGFβ, but not neurons, to induce differentiation of brainstem glia, and suggest that the failure of neurons to induce differentiation may be related to neuron-glial binding.

DEVELOPMENT OF OLFACTORY NERVE GLIA. R. B. Norgren*, N. Ratner and R. Brackenbury. Depts. of Psychiatry and Anatomy and Cell Biology, Univ. Cincinnati Coll. Med., Cincinnati, OH 45267

The studies reported here were aimed at establishing an antigenic marker specific for olfactory nerve glia throughout development. We have recently developed a monoclonal antibody (1E8) that recognizes both myelinating and non-myelinating Schwann cells in the chick (Bhattacharyya, et al. 1991) but does not recognize astrocytes, oliogodendrocytes or neurons. In the current study, we used the 1E8 antibody and the avidin-biotin-HRP technique (Vectastain) on tissue sections of embyronic and adult chickens. 1E8 immunostained olfactory nerve glia both in early embryos and in adults indicating that olfactory nerve glia may be more closely related to non-myelinating Schwann cells than other glial cell types. Further, the pattern of immunostaining we obtained is consistent with the idea that most, if not all, progenitors of olfactory glia are derived from the olfactory placode rather than the neural crest. We also observed that immunostained glia were initially distributed around the perimeter of the olfactory nerve (late E4). By the end of E5, 1E8-immunostaining was found throughout the nerve. Finally, glia appear to enter the olfactory bulb with the olfactory nerve. In the adult, a thin rim of 1E8 immunopositive cells can be observed around the edge of the olfactory nerve layer. This work was supported by NIH grants NS30047 (RBN) and NS27227 (RB and NR).

GLIAL DEVELOPMENT IN PRIMARY CULTURES ESTABLISHED FROM X-IRRADIATED NEONATAL SPINAL CORD. D.L. Davies*, T.J. Sims, and S.A. Gilmore. Dept. of Anatomy, Univ. of Arkansas for Med. Sciences, Little Rock, AR 72205

X-radiation is a useful tool for manipulating the cellular composition of an organ and exploring the developmental consequences. Exposure of the spinal cord in 3-day-old rats to x-rays induces a profound yet incomplete depletion of astrocytes and oligodendrocytes (J. Neuropath. Exp. Neurol., 22:294-301, 1963; Exp. Brain Res. 75:513-522, 1989). This *in vitro* study addresses issues related to the vulnerability of specific cell phenotypes and maturational status. Lumbosacral spinal cords of rats were irradiated and removed within several hours to establish the cultures. Non-irradiated spinal cords from littermates provided the control cultures. Cells were cultivated for 8 days *in vitro* and a battery of immunocytochemical markers was used to characterize the cultures. In cultures derived from x-irradiated tissue, growth was markedly diminished and a significant portion of the surviving cells were GFAP-positive astrocytes. These cells were either stellate or epithelioid, and vimentin was colocalized in the majority of the epithelioid cells. Galactocerebroside, a marker for mature oligodendrocytes, was immunolocalized in an abundant population within control cultures but was virtually absent in cultures from x-irradiated rats. However, a small population within cultures from x-irradiated rats exhibited immunolocalization of A2B5 and 2',3'-CNP, markers of early oligodendrocytic lineage. This preliminary study demonstrated reduced survival and viability of glia in cultures derived from x-irradiated spinal cord. Moreover, the absence of mature oligodendrocytes suggested a specific vulnerability of a stage in this cell's lineage.

Supported by NIH Grant NS 04761.

IMMUNOCYTOCHEMICAL AND ULTRASTRUCTURAL CHARACTERIZATION OF GLIAL CELLS IN LONG-TERM CO-CULTURES. C. Andersson*, J. Brunso-Bechtold, and M. Tytell. Bowman Gray School of Medicine, Wake Forest University, Winston-Salem,NC 27101.

We examined a mixed glial culture containing type 1 astrocytes and O-2A lineage cells in fetal calf serum at 5 days in vitro (DIV), 12 DIV, and 30 DIV, using cell-specific immunocytochemical markers and electron microscopy. The flat type 1 astrocytes were polygonal, and GFAP+, GalC-, and A2B5- (specific markers for mature astrocytes and oligodendrocytes, and O-2A cells) at all three time points. From 5 to 30 DIV, the type 1 astrocytes increased in cell size. Ultrastructurally, the cytoskeleton changed dramatically over time, with the numbers of glial filaments increasing and microtubules decreasing.

At 5, 12, and 30 DIV, the O-2A lineage cells were multipolar, and A2B5+, GFAP-, and GalC-. Ultrastructurally, the O-2A lineage cells could not be regarded as either astrocytes or oligodendrocytes. These cells had a dense cytoplasm, a very small number of intermediate filaments, and a large number of vacuoles and dense bodies.

At no time were the differentiated type 1 astrocytes immmoreactive for HNK-1 and NCAM. O-2A lineage cells were HNK-1+ and NCAM+, further suggesting cellular immaturity.

The cytoskeleton of cultured type 1 astrocytes seems to develop comparable to astrocytes in vivo. Under these culture conditions, O-2A lineage cells were multipolar, but immature, and appear unable to differentiate.

471.7

EXPRESSION OF CD44 ANTIGEN ON HUMAN FETAL AND ADULT NEURAL CELLS IN CULTURE. G. Moretto* and S.U. Kim. Dept. of Neurology, Univ. of British Columbia, Vancouver, Canada.

CD44 is a 90 kDa lymphocyte glycoprotein that belongs to the family of cell adhesion molecules and therefore is likely to be involved in cell-cell and cell-matrix interactions. Its broad distribution in different tissues includes the fibrous astrocytes of normal white matter and reactive astrocytes in multiple sclerosis lesion. In this study, expression of CD44 antigen in primary neural cell cultures derived from fetal and adult human brains was investigated. By double staining with antibodies to human CD44 and to GFAP, we found that 70-75% of fetal and 90-95% of adult astrocytes expressed the CD44 antigen on the cell bodies and processes. Unlike in vivo where only fibrous astrocytes are CD44-positive, both flat and process-bearing astrocytes expressed CD44 in culture. CD44 was also detected on more than 50% of galactocerebroside-positive oligodendrocytes that were isolated from adult brains. Small fetal neurons, A2B5-positive and MAP2-positive cells, did not express CD44 at all. These results indicate that CD44 glycoprotein is restricted to a glial cell population in the human nervous system.

471.8

INSULIN-LIKE GROWTH FACTOR I (IGF-I) INDUCES ASTROCYTES TO ACQUIRE A RADIAL GLIAL-LIKE MORPHOLOGY *IN VITRO*. A. Casey and B.H.J. Juurlink*. Department of Anatomy, University of Saskatchewan, Saskatoon, SK, Canada S7N 0W0.

Insulin and IGF-I are known to have neuronotrophic effects; however, they can also affect astrocyte function. For example Dringen and Hamprecht have shown that they both affect glycogen metabolism (1992. J. Neurochem. 58:511) and we have shown that they affect astrocyte neuronotrophic activity (Ang et al. 1992. J. Neurol. Sci. in press). Since astrocyte morphology is intimately related to astrocyte function, our objectives were to determine whether insulin, and in particular IGF-I affected astrocyte morphology. Rat type-1 astrocytes were isolated using the McCarthy and de Vellis method. After two weeks in a serum-containing medium, the cultures were maintained on Bottenstein's G5 medium minus the insulin. On this medium the astrocytes maintained their flat fibroblast-like appearance. Addition of insulin (1-5μg/ml) or IGF-1 (10-100 ng/ml) resulted in a dramatic change in astrocyte morphology. In contrast, IGF-II (10-100 ng/ml) had no effect on astrocyte morphology. The insulin and IGF-I induced morphology consisted of a distinct soma from which emerged one long prominant and sometimes several long processes of narrower calibre. The processes were tightly packed with GFAP-containing intermediate filaments, whereas the somas had a lower density of intermediate filaments. This morphology is very reminiscent of that of radial glial cells. In the CNS, IGF-I mRNA as well as IGF-I receptors are expressed by both neurons and astrocytes in a stage-specific manner, i.e. the highest level of IGF-I expression occurring in embryonic and fetal development. It is likely, therefore, that IGF-I can act in a paracrine as well as in an autocrine fashion in the brain. We postulate that possibly IGF-I plays a role in the differentiation of radial glial cells. Furthermore, these paracrine and/or autocrine effects of IGF-I may be involved in the relationship of developing neurons and radial glia, which affects both neuronal migration and the differentiation of neurons and astroglia. *We thank Dr. B. Bhaumick for the gift of IGF-I and IGF-II.*

S100 AND ONTOGENESIS OF RADIAL GLIA-LIKE CELLS AND ASTROCYTES DURING DEVELOPMENT OF RAT BRAIN. S. Bledsoe* and F. C. Zhou. Indiana Univ. Sch. Med., Dept. Anatomy, Indianapolis, IN 46202

S100, an astrocytic marker in adult brain, appears predominately in the radial glia during early development of the brain. Immunocyto-chemical staining for S100 shows that it appears first in radial cells vertical to the neuraxis during early gestation stage of neural development. These cells appear in brainstem regions during E13-14 gestation stages of Sprague-Dawley rats, and then propagate from the brainstem center in two directions —rostrally to forebrain and caudally to spinal cord. In contrast, cells positive for glial fibrillary acidic protein (GFAP), a cytoskeletal marker for astrocytes, appear in a much later stage (E16) and do not overlap spatially with S100 immunostaining in adjacent sections. At the E17-19 stages, both GFAP and S100 appeared in the forebrain. The distribution of GFAP-positive cells is different from that of S100. This evidence reopens the hypothesis on ontogenesis of glial cells. In the brainstem and forebrain S100-positive cells at the early gestation stage represent a subpopulation of glial cells other than astrocytes, or radial glia-like cells develop into astrocytes in late gestation and postnatal stage. Further study of radial glia confirmation is in progress. (supported by NIH grant NS23027 to FCZ)

471.10

The Isolation of a novel oligodendrocyte specific c-DNA

C. Schaefer, N. Schaeren-Wiemers, C. Decavel* and M.E. Schwab.

Brain Research Institute, University of Zürich, August Forel Str. 1, 8029 Zürich -Switzerland-

Myelin contains a variety of unique proteins (e.g. MAG, MBP, PLP, CNPase). Only a few proteins seem to be selectively expressed by central nervous system (CNS) oligodendrocytes as compared to peripheral nerve Schwann cells. Myelin disorders that are specific for the CNS exist, however, and oligodendrocytes play important additional roles in CNS development and regeneration by their expression of neurite growth inhibitory proteins.

Here we demonstrate the isolation of a c-DNA encoding a novel oligodendrocyte specific protein. The c-DNA clone (p16.111) corresponds to a m-RNA of 4.9 kb. The presently available c-DNA (3.4 kb), including the poly-A-tail, does not show homology to any known oligodendrocyte or CNS c-DNA. The expression is restricted to the postnatal rat CNS (not detected in sciatic nerve (PNS), liver, lung, thymus, heart, kidney, spleen, skeletal muscle, testis) and is higher at P16-20 than in the adult spinal cord. *In situ* hybridisation shows a selective, strong expression in oligodendrocytes in myelinating regions of the brainstem, cerebellar white matter and corpus callosum. In cultured optic nerve oligodendrocytes p16.111 expression was localized in galC-positive oligodendrocytes.

471.11

THE GLIOARCHITECTONICS OF THE HUMAN NEOCORTEX.
T.I. Mandybur*, Department of Pathology and Laboratory Medicine, University of Cincinnati, Cincinnati, OH 45267-0529

It is well known that the normal cortex shows few fibrillary astrocytes except in the molecular layer where these cells are associated with external glial limiting lamina. We observed in old individuals and in Alzheimer's disease that astrocytes of the molecular layer also show long, straight, radial fibers which penetrate into the depth of the cerebral cortex down to the II and III layers.

We also describe the subcortical glial zone (of the white matter) astroglia. Also, these cells display straight fibers which penetrate deep into the cerebral cortex and could be traced up to the depth of the IV layer.

It was impossible to prove if these fibers penetrate through the whole thickness of the cortex, but in many aged individuals or individuals with Alzheimer's disease, perpendicularly running astroglial fibers were also seen in the mid-cortical layers.

We believe that these fibers represent a perpendicular glial fiber system that most likely is a remnant of the embryonal radial glia. We hypothesize that these fibers under normal circumstances are of the protoplasmic astroglia type and this is why they do not stain with GFAP in younger individuals. Another consideration is that these fibers represent a special type of isomorphic gliosis.

It was also observed that both the glia of molecular layer and subcortical zone seem to respond (proliferate) synchronically in aging and Alzheimer's disease.

MULLER CELL PHENOTYPE PRECEDES SENESCENCE OF VIRALLY TRANSFORMED CHICK NEURORETINAL CELLS.
G.M. Seigel*, E.L. Imperato, J.T. Hansen, and M.F.D. Notter. Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642.

The phenomenon of senescence has been an obstacle in obtaining permanent Rous sarcoma virus-transformed avian cell lines. Our previous studies analyzed this senescence phenomenon in Rous sarcoma virus-transformed chick neuroretinal cells (LA29NR) and demonstrated a decreased mitotic index accompanied by loss of transformed phenotype (Seigel and Notter, submitted, JVI 364-92). After four to five months in culture, immediately preceding cell death, unusual process formation is observed in LA29NR cell populations. We have now characterized these morphologically differentiated cells as immunoreactive for glial fibrillary acidic protein, S-100 antigen, and vimentin, while predominantly negative for neuron-specific enolase, as detected immunocytochemically. Electron microscopic observations revealed large, vacuolated cells packed with longitudinally-oriented intermediate filaments, extensive smooth and rough endoplasmic reticulum, as well as occasional myelin-like figures, characteristic of normal retinal Muller cells. However, unlike normal Muller cells, retroviral particles also were evident, both intracellularly and extracellularly. From these data, we conclude that despite continued retroviral expression, senescent LA29NR cells exhibit a Muller cell phenotype as a state of terminal differentiation at the end of their mitotic lifespan in culture.

UNIQUE GLIAL CELLS DEMARCATE NEUROMERES IN THE CENTRAL NERVOUS SYSTEM DURING METAMORPHOSIS IN *DROSOPHILA MELANOGASTER*.
D. Davis , R. Fehon , S. Artavanis-Tsakonas , and W. J. Costello*
Yale Univ., New Haven, CT and Ohio Univ., Athens, OH.

During metamorphosis in Drosophila, the central nervous system (CNS) is extensively remodelled. Adult nerves arise de novo or from modified larval nerves; inherent in the nerve formation is extensive pathfinding. Some glial cells may serve as landmarks to define pathways for developing neurites. At the boundary between neuropil and cortex, unique glial cells have an affinity for Notch antibodies (Ab) in third instar larvae (Fehon et al, J. Cell Biol. 113:657). In early pupae, Notch Ab affinity is most prevalent in the glial cells at the neuromeres where leg nerves are forming. By 48h, the affinity decreases and is barely evident at 72h; this period is coincedent with final leg nerve formation. Related mitotic activity, typical for many other Notch-positive cells, is absent in these glia. These neuromere glial cells are distinguished by intense synthetic activity in parallel with the peak Notch affinity (<48h pupae), as indicated by extensive rough endoplasmic reticulum.

471.14

IN VITRO CULTURE AND INITIAL CHARACTERIZATION OF PUTATIVE GLIAL CELLS FROM THE MOLLUSCS LYMNAEA AND HELISOMA.
R.L. Ridgway*, N.I. Syed, G.C. Hauser, and A.G.M. Bulloch. Dept. of Med. Physiol., Univ. of Calgary, Alta., Canada T2N 4N1 and Biol. Dept., Seattle Pacific Univ., WA, USA 98119.

In this study we have modified techniques for culturing neurons of pulmonate molluscs to obtain populations of cells having glial-like characteristics. The cells were isolated from the cortical regions of the central ganglia of the snails Lymnaea stagnalis and Helisoma trivolvis using proteolysis (see Ridgway et al., J. Neurobiol., 22: 377-390, 1991). The isolated cells were then cultured under sterile conditions in 50% Leibovitz (L-15) medium on various substrates. The putative glial cells displayed an elongate morphology (75-100 µm in length and 10-15 µm in width), the nucleus being situated midway along the cell axis. Lamellipodial processes extending from perimeter of the cells correlated with a high degree of motility in the first 6-12 h after plating. This motility was substrate dependent: on adhesive substrates (e.g., poly-L-lysine) cells decreased in motility after 12 h, whereas those plated on less adhesive substrates (e.g., bovine serum albumen) were motile for 48-72 h. Electrophysiological recordings made from less motile cells revealed resting membrane potentials ranging from -40 mV to -50 mV. The cells were responsive to both dopamine (0.1-1.0 µM) and FMRFamide (0.01-0.1 µM). Cells could be maintained for 4-5 days whereupon they became pycnotic and lost their membrane potentials; reasons for this cell death are under study.

471.15

CALCIUM OSCILLATIONS AND CONTRACTION WAVES IN INSECT GLIAL CELLS.
H. Jindrova#, J. Dallman+, J.W. Truman+ * and M.S. Cooper+, Institute of Parasitology, Branisovska 31, 370-05 Ceske Budejovice, Czechoslovakia# and Department of Zoology, University of Washington, Seattle, WA 98195+.

Agonist-induced Ca-oscillations, Ca-waves, and/or Ca-transients have been observed in glial cells from vertebrate cortex, hippocampus, optic nerve, and neuromuscular junction. To determine whether such intracellular signaling is found in the nervous system of invertebrates, we examined cytoplasmic Ca-dynamics in glial cells isolated from the brains of the insect, Manduca sexta. Primary explants of 5th instar larval brains were cultured on polylysine-coated coverslips, loaded with the Ca-indicator Fluo-3AM, and observed with time-lapse fluorescence video and confocal microscopy. Single Ca-transients, lasting approximately 10-200 seconds, occurred spontaneously in untreated cultures. When aluminum tetrafluoride (AlF_4^-), a general activator of G-proteins, was externally applied to cultures composed predominantly of glia, the following sequence of Ca-transients ensued: (1) an initial Ca-spike, lasting approximately 10 seconds; (2) a subsequent envelope of elevated Ca^{2+} lasting 400-500 seconds, which was often composed of Ca-oscillations whose period ranged from 20 to 170 seconds. Cytoplasmic contraction waves were also seen to propagate in Manduca glial cells, both spontaneously, and in response to externally applied agonists. These results suggest that an active transmembrane signaling system, involving G-proteins and cytoplasmic Ca-transients, exists in these invertebrate glial cells. (Supported by a Sloan Foundation Research Fellowship and NSF PYI Award DCB-9157132 to M.S.C.).

472.1

POSTBUBERTAL EMERGENCE OF MESOLIMBIC DOPAMINERGIC SUPERSENSITIVITY AFTER EXCITOTOXIC LESIONS OF VENTRAL HIPPOCAMPUS IN THE RAT. Barbara K. Lipska*, Ph.D., George E. Jaskiw, M.D., Ingrid Phillips M.A., Daniel R. Weinberger, M.D., Clinical Brain Disorders Branch, IRP, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

While early animal models of schizophrenia addressed primary changes in striato-limbic dopamine activity, they did not account for other phenomena associated with the illness (e.g. congenital temporal-limbic abnormalities, cortical deficits, vulnerability to stress, postpubertal onset). We have reported that ibotenic acid ventral hippocampal (VH) lesions in adult rats affected DA-related behaviors in a manner consistent with increased mesolimbic DA activity. These changes were paralleled by biochemical indices suggesting enhanced DA transmission in the nucleus accumbens, a reduction in DA turnover in the medial prefrontal cortex, and an inverse correlation between these (Brain Res., 1992). The behavioral response to pharmacological (FG-7142) or environmental (swim stress) stressors was not affected. In contrast, locomotor activity and response to amphetamine of rats lesioned as neonates (PD7) did not differ from controls 4 weeks after the lesion (PD35). However, 3 weeks later (PD56), the same rats became hyperactive in these conditions. Moreover, neonatally lesioned animals were hyperresponsive to stress. In summary, in rats with neonatal lesions of VH, augmented activity develops only after puberty. Neonatal but not adult-induced lesions also produce an exaggerated response to stressful stimuli. Homologous mechanisms could be involved in schizophrenia.

472.2

DEVELOPMENTAL EXPRESSION OF PARVALBUMIN mRNA IN THE CEREBRAL CORTEX AND HIPPOCAMPUS OF RAT. Lecea, Luis de[1,2], Eduardo Soriano[1], Jose A. del Rio[1], Sonja Forss-Petter[2*,1] Unit of Cell Biology. Faculty of Biology. University of Barcelona. Spain.[2] Dept. of Molecular Biology, MB10. The Scripps Research Institute. La Jolla. CA 92037

Parvalbumin is a calcium binding protein that is thought to play a major role in calcium buffering in metabolically active fast-firing cells. In adult cortex, parvalbumin is expressed in a subset of characterized GABAergic interneurons. The pattern of parvalbumin mRNA expression during the postnatal development of rat cerebral cortex and hippocampus was examined by means of in situ hybridization with an oligonucleotide probe. In animals aged P0-P6, no signals above background were observed in the cortex, although silver grains always occurred in the thalamic reticular nucleus. At P8-P10 a few cortical cells contained low numbers of silver grains in motor and somatosensory cortices and in the hippocampus. By P12, parvalbumin expressing cells were detected within all cortical regions. At P14 an overall increase both in the number of positive cells and in their intensity of labeling was observed. A further maturation pattern was seen at P16-P21 stages, which lead to the appearance of an adult like distribution in cortex and hippocampus. The appearance of parvalbumin mRNA expressing cells does not follow the usual inside out sequence of cortical maturation. Instead, hybridization is first observed in the middle cortical layers to thereafter expand to the immediate adjacent layers. Count of silver grains revealed that hybridization signals, increased progressively during postnatal development. In adult neocortex and hippocampus the distribution of parvalbumin mRNA containing cells is consistent with our previous immunocytochemical findings in rodent cortex. These data suggest that the developmental pattern of expression of parvalbumin follows the needs of calcium buffering and may reflect the functional maturation of cortical interneurons.

472.3

EFFECTS FROM EXPERIMENTALLY INDUCED HYDROCEPHALUS ON HIPPOCAMPAL EPENDYMAL LINING: AN ULTRASTRUCTURAL STUDY. R.M. Kriebel* and J.P. McAllister. Depts. Anatomy, Phila Col Osteopath Med and Temple Univ Sch Med, Phila PA 19131.

The neurological deficits found in infantile hydrocephalus have most often been explained by pathological changes in cerebral cortex. It has been the primary goal of our studies to provide a cellular basis for the residual neurological deficits observed even though surgical intervention may have relieved the effects of ventriculomegaly on the cerebral cortex. Previous studies have shown significant structural changes in cerebral cortex, basal forebrain region, especially in septal nuclei, and hippocampus. A primary difference in the structural alterations within these regions was the minimal increase in extracellular space in the hippocampus. In the present study we compared the ependymal surface adjacent to the cerebral cortex, basal forebrain region, and hippocampus. Kaolin injection induced hydrocephalus; aldehyde fixed brains were sectioned coronally with subsequent staining for cells and fibers. The ependyma underlying the cerebral cortex was thinned but appeared to remain intact. In contrast, the ependyma adjacent to the hippocampus was not altered in comparison to control tissues. The cuboidal shape as well as surface projections appeared normal. The potential relation of these structural differences to extracellular space in the neuropil is discussed. 472.4

CYTOARCHITECTURAL, NEURONAL MORPHOLIGIC AND MOLECULAR ASPECTS OF HUMAN HIPPOCAMPAL DEVELOPMENT

Steven E. Arnold* and John Q. Trojanowski, Departments of Psychiatry and Pathology, University of Pennsylvania School of Medicine

Cytoarchitecture, neuronal morphology and the expression of various neuronal cytoskeletal proteins were monitored in subfields of the developing human hippocampus. Fixed sections from the hippocampal formations of 18 cases from 10 weeks gestational age through 2 years were stained with cresyl violet for cytoarchitectural and morphologic analysis and processesed for immunohistochemistry. Monoclonal antibodies (mAbs) used were directed at components of the neuronal cytoskeleton that are believed to be important determinants of neuronal polarity. These included microtubule-associated proteins MAP2, MAP5 and tau, alpha and beta tubulins, and poorly, moderately and highly phosphorylated neurofilament (NF) isoforms. Differential patterns of cytoarchitecture and neuronal morphology were noted across time and both between and within anatomic regions. The expression of MAP2, MAP5, alpha and beta tubulins, NFM-P$^-$, and NFH-P$^+$ was evident at the earliest time point studied and persisted throughout development. Immunoreactivity to tau and NFH-P^{+++} appeared at subsequent points, with tau diminishing in intensity later on in development. MAP2, MAP5 and NFM-P$^-$ immuno- reactivity allowed recognition of nascent dendrites and pyramidal shaped neurons prior to their definition with conventional cresyl violet staining. At all times, there were differences in intensity of immunoreactivity between the different ammonic, subicular and entorhinal subfields. (Supported by NIMH grant 1 K20 MH00978-01)

472.5

CALBINDIN-D28K DISTRIBUTION IN HIPPOCAMPAL FORMATION OF LATE GESTATION FETAL SHEEP IS INDEPENDENT OF PLASMA GLUCOCORTICOID CONCENTRATION. T.J. McDonald* & R.H. Wasserman Department of Physiology, Cornell University, Veterinary Research Tower, Ithaca, NY 14850.

Glucocorticoids regulate the appearance of Calbindin-D28K in the granule cells of the dentate gyrus of adult rats with adrenalectomy causing complete loss of immunoreactivity in the granule cell layer after 4 weeks (Iacopino and Christakos, 1990. J.Biol.Chem. 265:10177-10180). In late gestation, fetal sheep undergo a logarithmic rise in peripheral plasma cortisol concentration that starts at approximately 125 days of gestational age (dGA) with baseline concentrations of 5-10 ng.ml^{-1} to peak at term with concentrations over 100 ng.ml^{-1} (Magyar et al. 1981. J.Ster.Biol. 14:1091-1099). This cortisol rise is driven by the pituitary and hypothalamic paraventricular nuclei and is indispensable for parturition to occur at normal term (Liggins et al., 1973. Rec.Prog.Horm.Res. 29:111-159; McDonald and Nathanielsz, 1991. Am.J.Obstet.Gynecol. 165:764-770). In this study the brains of fetal sheep at 105, 125, 135, 147 (in labor) dGA and newborn lambs were examined immunocytochemically. While Calbindin-D28K was found in diverse areas of the brain, eg. brainstem, cerebellum, neocortex, basal ganglia and hypothalamus, no Calbindin-D28K immunoreactivity was detected in the dentate gyrus or Ammons horn at the ages examined. However, many Calbindin-D28K immunopositive cells were found in the subiculum at all ages, but intensity of staining appeared to be independent of gestational age. It is concluded that unlike in adult rats, endogenous plasma glucocorticoids have no effect on the appearance immunocytochemical distribution of Calbindin-D28K in the hippocampal formation of the late gestation fetal sheep.

472.6

NEUROGENESIS OF THE VASOPRESSIN NEURONS IN THE BED NUCLEUS OF THE STRIA TERMINALIS AND MEDIAL AMYGDALOID NUCLEUS OF THE RAT. H.A. Al-Shamma* and G.J. De Vries. Program in Neuroscience and Behavior, Univ. of Massachusetts, Amherst, MA 01003.

The vasopressin-immunoreactive (AVP-ir) neurons of the bed nucleus of the stria terminalis (BST) and medial amygdaloid nucleus (MA) share many neurochemical and neuroanatomical characteristics, e.g., in their neurotransmitter content, cell morphology, and steroid sensitivity. It is unclear, however, how BST and MA neurons develop these similar characteristics. To get more information about the development of these cells, we determined the day of birth of these AVP-ir subgroups with the cell birth marker bromo-2-deoxy-5-uridine (BrdU).

Pregnant Long-Evans rats received intraperitoneal injections of BrdU on one of gestational days 14-20, day 1 being the day that a copulatory plug is found. At three months of age, the male offspring of these treated females were sacrificed and their brains were processed for both BrdU and AVP immunostaining. Approximately 20% of the AVP-ir cells in the BST and MA were also immunoreactive for BrdU, the majority of which were found in the BST and MA of animals exposed to the cell birth marker on embryonic day 16 and 14, respectively. These preliminary findings are in agreement with earlier studies using [^{3}H]thymidine autoradiography which suggest that most of the cells in the divisions of the BST and MA that contain the AVP-ir neurons are born on embryonic days 15-16 and 14-15, respectively.

472.7

PRE- AND POSTNATAL CHANGES IN THE EXPRESSION OF PROTO-ONCOGENES DURING THE DEVELOPMENT OF ROSTRAL CEREBRAL CORTEX. P.E. Kuhn* and M.W. Miller. Dept. Biology, Rutgers Univ., Piscataway NJ 08854, Res. Serv., V.A.M.C., Iowa City IA 52242, and Dept. Psychiatry & Pharmacology, Univ. Iowa Coll. Med., Iowa City IA 52242.

Zones containing post-mitotic cells and neurons forming neurites express proto-oncogenes. The change in the expression of c-*fos*, c-*neu*, c-*src*, and c-*ras*, was examined using immunoblots. Tissue from the frontal pole of rat cortex was harvested from fetuses and pups (between gestational day (G) 16 and postnatal day (P) 21) and in 3- to 5-month-old rats. Blocks of tissue were disrupted in buffer containing detergent and proteinase inhibitors. Standard gel electrophoresis and transfer techniques were used in producing immunoblots. Anti-c-*fos* identified 2 proteins, one with a molecular weight of 64 kD and the other 80 kD. c-*fos* expression (of both proteins) appeared on G16 and waned by P6 and peaked on G19. Anti-c-*neu* also labels 2 proteins, 65 kD and about 185 kD. The temporal expression of the 65 kD protein was similar to that of c-*fos*. On the other hand, the 185 kD protein appeared on the day of birth (P0) and virtually disappeared by P9; peak expression occurring on P3-P6. Anti-v-*src* identifies a doublet with molecular weights of 53 and 62 kD. The expression of both proteins begins as early as G16 and persists beyond P9. This expression was rather stable throughout this period. Trace amounts of each of these proto-oncogenes were detectable in the adult rat. The pattern of c-*ras* expression is quite different for it builds during the postnatal period to adult levels by P21. Based upon timing, the data are consistent with the concept of a cascade of events, c-*src* being related to cell proliferation or neuronal migration, c-*neu* and c-*fos* being related to neuronal differentiation and or death, and c-*ras* being related to neurite outgrowth, synaptogenesis, and the maintenance of neuronal integrity. Funded by DE 07734, AA 06916, and AA 07568.

MIGRATION OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) IMMUNOREACTIVE NEURONS TO RAT CORTEX. M.W. Miller*. Res. Serv., Iowa City V.A.M.C., and Dept. Psychiatry & Pharmacology, Univ. Iowa Coll. Med., Iowa City IA 52242

Most neurons migrate to cortex by an orderly inside-to-outside sequence. Accordingly, neurons in deep cortex are generated before those in superficial cortex. In visual cortex, this migrational pattern is followed by cortico-cortical projection neurons and by GABAergic local circuit neurons. A combined autoradiographic-immunohistochemical method was used to determine the time of origin of VIP immunoreactive neurons. VIP is expressed by a subpopulation of local circuit neurons, mostly small bipolar neurons, which do not co-localize GABA. The birth of neurons in each layer of cingulate cortex (areas 24 and 29), somatosensory cortex (area 3), and visual cortex (area 17) was examined by administering [^{3}H]thymidine on gestational day 13, 15, 17, 19, *or* 21 and sacrificing the pups on postnatal day 30. Although the timing differed slightly in each cytoarchitectonic area, the basic pattern of neuronogenesis was similar in all areas. VIP-positive neurons with a particular time of origin were not distributed in a tangential band of cortex; rather such neurons were distributed through the full depth of cortex. Such a pattern was evident regardless of the time of origin. Thus, VIP immunoreactive neurons migrate into cortex via a mode other than the standard inside-to-outside sequence. Funded by DE 07734, AA 06916, and AA 07568.

POSTNATAL DEVELOPMENT OF PROTEIN KINASE C GAMMA EXPRESSION IN RAT BRAIN. B. Buwalda, C. Nyakas, E.A. van der Zee, S. Cazaubon, P.G.M. Luiten*. Dept. of Animal Physiology, University of Groningen, P.O.Box 14, 9750 AA Haren, The Netherlands.

Protein kinase C (PkC) is a key enzyme in intercellular signal transduction, and can be activated through receptor-mediated hydrolysis of phosphoinositol. PkC activation has also been found to play a crucial role in cellular processes related to development. Here we examined the developmental changes in hippocampal and cortical expression of the gamma isoform of PkC. The PkC immunoreactivity was studied in rats on postnatal day 7 (PD7), 10, 14, 20, 30 and 47. PkC-gamma immunoreactive neurons on PD7 are visible in neocortical layer 5 and in the hippocampal subicular and hilar region. On PD10 PkC in the neocortex is increased and expression is also seen in layer 6 and in allocortical areas. Furthermore pyramidal cells throughout all parts of the cornu ammonis (CA) become immunoreactive. On PD14 PkC gamma expression is visible in cortical layers 2,3,5 and 6. Whereas on PD7 and PD10 the PkC immunostaining shows a relative uniform neuronal cytoplasmic distribution, the PkC immunoreactivity within hippocampal CA1 pyramidal cells and entorhinal cortical neurons on PD14 appears to become translocated to the cellular membrane. This translocation of PkC gamma is extended to cortical layers 2,3 and 6 on PD20. After PD20 PkC levels increase in dendritic fields and fiber systems. The translocation of PkC gamma to cellular membranes after PD14 may be related to the receptor linked activation of PkC and in this way reflect maturational processes of central nervous systems.

Corpus Callosum: EM Measures of Sex and Infantile Handling Effects. G. W. Boehm*, C. M. Mack, A. S. Berrebi and V. H. Denenberg. Biobehavioral Sciences Graduate Program, University of Connecticut, Storrs, CT 06269.

Findings of sexual dimorphism in the rat corpus callosum, using gross size measures, prompted the use of electron microscopic techniques to view ultrastructural parameters. Since neonatal handling has been shown to enhance certain differences between gross measures of female and male rat callosa, both handled and nonhandled rats were used to study this phenomenon. All rats were transcardially perfused at 110 days of age, and midsagittal sections were obtained. Based on previous findings, sampling was restricted to the first 20% of the genu, although the posterior portions of the callosa have been retained and embedded for possible analysis. Preliminary findings indicate a greater quantity of unmyelinated axons than myelinated axons in the areas sampled, and a distinct Sex x Handling interaction in total number of unmyelinated axons.

CHARACTERIZATION OF A NOVEL **ANTENNAPEDIA**-CLASS HOMEOBOX GENE ISOLATED FROM HUMAN 11 WK FETAL BRAIN LIBRARY. J.F. Leckman*, X. Lin, A. Swaroop, F.M. Vaccarino, M.T. Murtha, F.H. Ruddle. Child Study Ctr., Depart. of Biol., Psychiatry, and Pediatrics, Yale University, New Haven, CT 06510 and W.K. Kellogg Eye Ctr., Depart. Ophthalmol. and Human Genetics, Univ. Michigan, Ann Arbor, MI 48105.

A novel **Antp.**-class homeobox gene has been isolated from a human 11 wk. fetal brain cDNA library. PCR with two sets of oligonucleotide primers (specific for highly conserved regions of the **Antp.**-class homeobox) was used to amplify portions of homeobox genes present in the fetal brain library. Sequencing 100 clones identified 2 novel **Antp.**-class genes. Screening the fetal brain library with a probe specific for one of the novel genes led to the identification of a 1.7 kb cDNA containing the novel homeobox sequence. This clone encodes a protein of approximately 327 amino-acid residues. By Northern analysis, this cDNA detects multiple transcripts in the developing human CNS as well as other tissues. These observations suggest that in early mammalian development this homeobox gene may exert a spectrum of control functions in a variety of organ systems including the CNS.

ANALYSIS OF THE CONEL HUMAN DEVELOPMENTAL CORTICAL DATA USING OPTIMAL INTERPOLATION W.R. SHANKLE*, J.P. DeFIGUEREDO, B.H. LANDING, UCI 1617 MEDICAL PLAZA, IRVINE, CA 92717

We introduce a developmental neuroanatomical database from J.L. Conel as a potentially useful framework for computational models and analysis of the developing human brain to 6 years and its relation to developing behaviors. We have investigated the relation between functions related to gyri and anatomical measures of cortical thickness, cell density, cell body length, cell body width, # of axoms/ unit area across all layers and over 40 gyri. Using the analytical method, Optimal Multi layer Neural Network Interpolation, inputs consisting of the 6 variables per gyrus per layer were used to find the best separation of the gyral functions used the fewest variables possible. We wished to see which variables, layers and gyri mapped to gyral functions found anatomic correlations relevant to the given classes of gyral functions. Results will be presented. Also presented are data on total cortical thickness. Figure 1 graphs the total cortical thickness in mm., for the 37 loci for all eight age-points in his data. The curves for the majority of loci are not smooth, with many loci showing episodes of reduction in cortical thickness despite the general tendency to increased thickness with age. Figure 2 graphs the slopes (rates of change in cortical thickness per mm. per month) of the values for total cotical thickness, for the seven age-blocks the graph showing that all loci show appreciable change in cortical thickness, either positive (increasing in thickness) or negative (decreasing in thickness) over the age-block 0-1 month, with the rate of change in total cortical thickness per month generally decreasing with age.

472.13

CORRELATION OF CORTICAL GROWTH AND METABOLISM IN THE DEVELOPING RAT. D.R. Riddle*, K. Alexander, A. Richards, F. Zsuppan and D. Purves. Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710.

We have used enzyme histochemistry and digital image analysis to examine the relationship between regional metabolic activity and postnatal growth in the cerebral cortex. Juvenile (one week-old) and adult (10-12 weeks-old) rats were anesthetized and perfused with saline followed by 10% glycerol. The cortical mantle was then removed, flattened and rapidly frozen; serial tangential cryostat sections were stained for succinic dehydrogenase (SDH) or cytochrome oxidase (CO). Each section was digitized and the images corrected for shading errors. The density of the reaction product within defined regions of the primary somatic sensory cortex (SI) was determined using a computer-based image analysis system. A robust and consistent gradient of enzymatic reactivity was evident in juvenile but not adult rats. The density of the enzymatic reaction product (SDH or CO) was greatest in the representation of the anterior snout and least in the representations of the paws, particularly the hindpaw. This gradient of metabolic activity corresponds to the pattern of differential postnatal growth (Riddle et al., 1992; J. Neuroscience, in press). The covariance of growth and metabolism in juvenile rats must in part reflect the metabolic demands of increased biosynthesis; this gradient may also indicate higher average levels of electrical activity in those regions of the developing cortex that grow the most.

REGIONAL CEREBRAL BLOOD FLOW DURING VISUAL STIMULI PROCESSING IN TWO-MONTH-OLD ALERT INFANTS. N. Tzourio*, S. De Schonen, B. Mazoyer, A. Boré, U. Pietrzyk, B. Bruck, Y. Aujard, C. Deruelle. S.H.F.J, C.E.A, Orsay, 91406, and Lab. Cogn. Neurosci., C.N.R.S., Marseille, France, Max Planck Instit., Cologne, Germany.

Evidence for regional cerebral metabolic changes accompanying human brain maturation was first demonstrated in sleeping children using PET) and fluoro-deoxyglucose (FDG). In the present study, we have adapted the regional cerebral blood flow (rCBF) PET-[15O]-water activation method to investigate the brain regions involved in visual stimuli processing in awake infants.

Six neonates were recruited during their first week after birth from the R. Debré Hospital neonatalogy intensive care unit. All were suffering from acute fetal stress, birth asphyxia or neonatal convulsions. At the age of two months, rCBF was measured twice in the same session while infants were involved in the following tasks: 1- visual fixation of a circle of flashing diodes, 2- visual fixation of slides of female faces presented at .25 Hz (in two cases, only condition 2 was recorded). Tasks were started one minute before i.v. injection of [15O]-water (0.7 mCi/kg body weight) and a single 80 second scan was acquired on a high resolution PET camera (ECAT 953B/31). Individual magnetic resonance images were also acquired.

Overall, the rCBF cortical pattern at this age appeared similar to that observed with the FDG method. In addition, a right hemisphere dominance was observed during both visual tasks (right-to-left ratio = 1.017, p = 0.014, N = 10, t-test) with no overall significant difference between the two (p = 0.51). Besides demonstrating the feasibility of PET activation studies in alert babies, these preliminary results argue for (i) either differential sensitivity of the two hemispheres to perinatal stress, (ii) a time lag between the maturation rate of the two hemispheres, or, (iii) a right hemisphere advantage in visual attention. CHOLINE ACETYLTRANSFERASE IN THE CEREBRAL CORTEX OF NBM-LESIONED RATS RECEIVING CHROMAFFIN CELL GRAFTS. S. A. Welner* and Z.C. Koty. Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal, Quebec, Canada H4H 1R3.

Lesions of the nucleus basalis magnocellularis (NBM) in rats produce spatial memory deficits as well as changes to cholinergic markers in the cerebral cortex, the target area of projections from the NBM. We have previously reported that adrenal chromaffin cells transplanted to the cerebral cortex of rats with NBM lesions are able to ameliorate lesion-induced spatial memory deficits and increase acetylcholinesterase (AChE) staining in the host cortex (Welner et al., *Brain Research*, **527**: 163, 1990). In the present experiments, we test whether grafting chromaffin cells to the cerebral cortex of NBM-lesioned rats will have an effect on a different cholinergic marker in the cerebral cortex, choline acetyltransferase (ChAT), at various time points post-grafting. Sprague-Dawley rats received bilateral partial lesions in the NBM and, two weeks post-lesion, were either left unoperated or had suspensions of adrenal chromaffin cells grafted to six sites in their frontal and parietal cortices. A group of unoperated rats served as controls. ChAT activity was measured at 2, 6, 12 and 16 weeks post-graft. In the lesioned-alone group it was found that ChAT progressively decreased over time, whereas in the lesion plus graft group, ChAT levels were significantly decreased at 6 weeks and appeared to be increasing at the 12 and 16 week time points. These results support previous findings that the cholinergicity of cerebral cortex following grafting of chromaffin cells to the cortex of NBM-lesioned rats is increased. (Medical Research Council, Canada & Fonds de la Recherche en Santé, Québec.)

473.2

BASIC FIBROBLAST GROWTH FACTOR IN CHROMAFFIN CELL GRAFTS TO THE CEREBRAL CORTEX OF NBM-LESIONED RATS. E.S. Yuzda*, Z.C. Koty and S. A. Welner. Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal, Quebec, Canada H4H 1R3.

Chromaffin cell grafts to the frontal and parietal cortices of nucleus basalis magnocellularis (NBM)-lesioned rats can ameliorate the spatial memory deficits which result from the lesions; this is accompanied by an increase in staining for a cholinergic marker in the host cerebral cortex (Welner et al., *Brain Research*, **527**: 163, 1990). Since chromaffin cells of the adrenal medulla are known to contain basic fibroblast growth factor (bFGF), a known neuroprotectant, it is of interest to determine whether bFGF may be involved in the graft effects. As a first step, it is necessary to test whether bFGF is present in these grafts at various time points post-grafting. T-maze trained rats were lesioned and then administered either no graft, kidney cell grafts as a control or chromaffin cell grafts, two weeks post-lesioning. Rats were retested on the T-maze at various time points post-graft; subsequently, the density and distribution of bFGF in grafts and the area surrounding the grafts was measured using immunocytochemical techniques. Whereas the host cortex is virtually devoid of staining, bFGF was clearly visible in chromaffin cell grafts. As expected, control kidney cell grafts contained no bFGF. Further, the presence of bFGF in the grafts correlated with groups that showed behavioral recovery of spatial memory, as measured in the T-maze. These results indicate that bFGF may be involved in producing the effects of chromaffin cell grafts to cerebral cortex. (Supported by the Alzheimer Society of Canada and the Medical Research Council of Canada.)

473.3

HYPERTROPHY OF CALBINDIN-D_{28K}-POSITIVE AND PARVALBUMIN-POSITIVE CELLS IN INTRASTRIATAL CORTICAL GRAFTS. E.-C. Liu*[1], S.B. Dunnett[2] and A.M. Graybiel[1]. [1]Dept. Brain and Cognitive Sciences, MIT, Cambridge, MA 02139, USA and [2]Dept. Experimental Psychology, Univ. of Cambridge, Cambridge, CB2 3EB, UK.

Calbindin-D_{28K}- and parvalbumin-positive neurons in the frontal and temporal cortex are severely degenerated in Alzheimer's disease (AD) (Arai et al., 1987; Ichimiya et al., 1988). Degeneration of these cortical neurons is evidenced by the reduction of their numbers and perikaryal sizes. In the present study we report a finding of hypertrophy of calbindin-D_{28K}-positive (CB) and parvalbumin-positive (PV) cells in intrastriatal grafts derived from embryonic cortical primordia. Ibotenate lesions were made unilaterally in the host caudoputamen 7 days prior to grafting. At grafting, cell-suspensions were prepared primarily from ventrolateral or dorsolateral cortical primordia and then were injected into the damaged caudoputamen. Survival times for the grafted rats were 4 to 8 months. CB and PV cells were present in all cortical grafts. Substantial hypertrophy of CB and PV cells was found in the cortical grafts derived from the ventrolateral cortical primordia. They had well-stained processes and were larger than the CB and PV neurons in the host neocortex (ca. 25-56 μm vs. ca. 11-19 μm in diameter). By contrast, very few hypertrophied cells were found in the grafts derived from dorsolateral cortical primordia. The earliest and most affected regions in AD are in the ventrolateral cortical areas including medial temporal cortex in and around the olfactory areas, whereas the motor, somatosensory and primarily visual areas of the dorsolateral cortex are less affected. Our results suggest that the neurodegenerative striatum induced by ibotenate lesions may provide a trophic environment for CB and PV positive neurons in such ventrolateral cortical regions. Further study of the mechanisms underlying this hypertrophy thus has considerable interest for understanding the aetiology of AD. Supported by NSF BNS-8702475.

FUNCTIONAL AND MORPHOLOGICAL CHARACTERIZATION OF NGF-PRODUCING GRAFTS IMPLANTED INTO LESIONED RAT FIMBRIA-FORNIX. K.L. Eagle *, L.J. Fisher, G.R. Chalmers, and F.H. Gage. Dept. of Neurosciences, UCSD, La Jolla, Ca. 92093

Nerve growth factor (NGF) has been shown to sustain axotomized cholinergic neurons. Previous work from our group investigated the grafting within the rat CNS of primary fibroblasts genetically modified to produce NGF. When suspended in a collagen matrix and placed into the lesion cavity following bilateral fimbria-fornix (FF) ablation, such grafts promoted the survival of medial septal neurons, and induced sprouting of new processes into the graft and the hippocampal formation. We are investigating functional and morphological correlates of these graft effects. In the present study, unilateral FF lesions were used rather than bilateral lesions because the smaller lesion cavity causes less collateral damage to tissue, as well as allowing use of the contralateral side as a control. However, behavioral deficits have been difficult to elicit in unilaterally lesioned rats. We have used a paradigm which allows for behavioral analysis of these rats in the Morris water maze. Fischer rats were given unilateral aspirative lesions of the FF; they then received grafts of either NGF-producing or control ß-Galactosidase (ßGal)-producing fibroblasts, or no graft (lesion-only). After a 4 month recovery period, the rats were trained to find a hidden platform in a fixed location in the maze using spatial cues, given 4 trials a day for 10 days. After all rats had successfully learned the task, the platform location was reversed 180° from its previous location. Performance in learning the new location was measured by distance travelled in each trial before finding the platform. Over the course of 5 days, the mean distance travelled by ßGal-grafted and lesion-only rats was significantly higher than that of normal control rats, while NGF-grafted rats showed no difference from controls. These results suggest that the reversal paradigm exposes behavioral deficits in unilaterally lesioned rats, and that rats grafted with NGF-producing fibroblasts show attenuation of those deficits. Morphological analysis is under way.

FETAL CORTICAL GRAFTS: EVALUATION OF CONNECTIVITY BETWEEN GRAFTS AND HOST STRIATUM. A. Herranz*, H.E. Cannon-Spoor and W.J.Freed. NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032.

The major input to the basal ganglia is the excitatory input from the cerebral cortex to the medium spiny striatal neurons. The purpose of this investigation has been to reconstruct the cortical pathway by using fetal cortical tissue transplants. Frontal cortical lesions were performed by aspiration in adult rats. After 15 days animals received grafts of 16-day gestational cortical tissue into the lesion site. Connections from the graft to the host striatum were studied after 6 weeks using immunostaining for neurofilaments and anterograde tracing with DiI. SMI-31 and SMI-35 inmunoreactive neurites were found crossing the interface with corpus callosum and striatum with a relatively high frequency (13.7 and 29.8 per mm of interface respectively), but only rarely entering the adjacent cortex. DiI tracing demonstrated a large number of graft-derived neurites projecting from 0.5 to 0.8 mm into the host caudate putamen. It is concluded that fetal cortical grafts in adult animals send limited projections into the host caudate-putamen.

473.6

FETAL NEOCORTICAL TISSUE SURVIVES TRANSPLANTATION INTO A RAT MODEL OF NEONATAL HYPOXIC-ISCHEMIC BRAIN DAMAGE. M.H. Elsayed, T. F.Myers, C.L .Anderson and A.I. Castro*. Depts. of Pediatrics and Cell Biology, Neurobiology and Anatomy, Loyola Univ. School of Medicine, Maywood, IL 60153.

Several studies demonstrate that fetal neocortical tissue will survive, grow and form axonal connections with the host brain after transplantation into newborn rats with cortical aspiration lesions. In the present study fetal neocortical grafts were transplanted into Long-Evans, black-hooded rats that sustained hypoxic-ischemic brain damage at 7-8 days of age by permanent right common carotid artery occlusion under methoxyfluorane anaesthesia followed by hypoxic exposure (8% oxygen) for 2-2.5 hr. Twenty-one out of 25 animals survived this procedure. One week later, 1-2 mm^3 block neocortical grafts obtained from E13 fetuses were transplanted into the right hemisphere of these animals just caudal to the coronal suture at 1-2 mm from the midline. All animals survived the transplantation procedures and were sacrificed at 2 (n=8), 4 (n=6) and 6 (n=7) weeks after transplantation. Brains were cut frozen at 30 µm and processed for acetylcholinesterase (AchE) immunocytochemistry and Nissl stain. Generalized atrophy and shrinkage of the right cerebral hemisphere was seen in 20/21 animals. Various degrees of ischemic brain lesions with neuronal loss were observed in several structures including the cerebral cortex, thalamus, hippocampus, and striatum. Well developed transplants were found adjacent to the ischemic areas. AchE positive fibers were seen crossing the transplant-host interface providing evidence that the grafts became integrated into the host brain circuitry.

473.7

MORPHOLOGIC ASSESSMENT OF MONOAMINERGIC NEURAL TRANSPLANTS TO THE RAT FRONTAL CORTEX. C.E. Sortwell*, J.Sagen and G.D. Pappas. Dept. of Anat. and Cell Biol., Univ. of IL at Chicago, Chicago, IL 60612.

Monoaminergic neural transplants to the rat frontal neocortex have been demonstrated in our laboratory to alleviate depression in animal models. These findings suggest that neural transplants may provide a long term source of monoamines to correct the central imbalance of serotonin (5-HT) and norepinephrine (NE) functioning implicated as the cause of depression. In order to support this suggestion, grafted monoaminergic tissue must survive well and continue to produce high levels of monoamines. Using electron microscopy the ultrastructural characteristics of 5-HT-containing pineal gland tissue, NE-containing adrenal medulla tissue, cografted pineal and adrenal medulla tissue and control sciatic nerve were examined at least six weeks following transplantation. The transplanted pinealocytes maintained their characteristic *in situ* features of numerous and dense mitochondria, a highly convoluted nucleus and the presence of lipid droplets. Similarly, transplanted adrenal chromaffin cells retained their *in situ* cuboidal morphology and displayed numerous granules. Neither type of graft was highly vascularized. The cografted transplants contained collagen matrices separating the pinealocytes from the chromaffin cells. Immunohistochemical studies indicated that the surviving chromaffin cells continued to produce tyrosine hydroxylase and dopamine-ß-hydroxylase and the pinealocytes continued to produce 5-HT. Sixth month old pineal implants also appeared to sprout densely into the surrounding host parenchyma. These results demonstrate that the monoaminergic tissues retain many features of their *in situ* morphology when transplanted to the frontal neocortex of rats.

473.8

ANALYSIS OF ADRENERGIC RECEPTORS IN THE CORTEX SURROUNDING MONOAMINERGIC TRANSPLANTS IN RATS. D. Dougherty*, J.R. Unnerstall, C.E. Sortwell, and J. Sagen. Dept. Anat. and Cell Biol., Univ. IL at Chicago, Chicago, IL 60612.

Previous findings in our laboratory have indicated that the transplantation of monoaminergic tissue into the frontal neocortex of rats can reduce behavioral deficits in rodent depression models. If the reduction in behavioral deficits by the transplants is due to the release of monoamines, it should be blocked by specific monoaminergic antagonists. We have shown that both alpha and beta adrenergic antagonists not only reversed the effects of the transplants on the behavior but in fact exacerbated the deficit, suggesting changes in receptor sensitivity. This study investigates this effect at the receptor level. Monoaminergic tissue (adrenal medulla, pineal gland, or a combination of both) was transplanted into the frontal cortices of separate groups of rats. Sciatic nerve and muscle were transplanted as controls in other groups. Another group was treated with imipramine (15 mg/ml/kg/day; i.p.) for six weeks. Six weeks later animals were tested for behavioral deficits using the forced swimming test. Following testing, a small section (5 x 5 x 7 mm) of cortex was removed from around the transplant of each animal and the transplant was discarded. The remaining tissue underwent receptor binding studies. ^{3}H-prazosin was used as a ligand to investigate alpha-1 binding sites while ^{125}I-iodocyanopindolol was used for beta binding sites. In these initial studies, K_d concentrations of ligand were used to screen for any changes in binding site sensitivity or concentration. No significant differences in binding were seen between transplant and control groups for either ligand (prazosin: 3.6-4.1 fmoles/mg tissue wet wt; pindolol: 4.6-5.4 fmoles/mg tissue wet wt). However, binding was significantly reduced in imipramine treated animals. These results suggest that the previously noted behavioral and pharmacologic changes in the transplanted animals are not associated with a corresponding change in the number of monoaminergic receptor sites.

Morphological assessment of grafted cortical neurons, J. Lübke*, M. Wood and D. J. Clarke, Dept. of Human Anatomy, University of Oxford, South Parks Road, Oxford OX1 3QX, U.K.

The morphology of cortical neurons grafted near /or into the rat striatum was studied by means of intracellular Lucifer yellow injections in fixed slices. Rat donor cortical tissue (from postnatal day 1 old rats; AO-strain) as well as mouse donor cortical tissue (prenatal E 19; C3H/HE strain) was grafted as solid pieces (a volume of 4 µl of donor tissue was inserted via a Hamilton syringe) in 8-12 week old rats (AO strain). Animals with xenografts were immunosuppressed with an antibody against the interleukin-2 receptor. 40-60 days postoperatively animals were perfused with buffered 2% paraformaldehyde and 1% glutaraldehyde. 120 µm vibratome sections were taken at the site of the transplant. The graft could be identified by a surrounding rim of astrocytes after incubation of the slice in the DNA-stain DAPI for 10 min. Cortical neurons (over 50 neurons in each transplant) were intracellularly filled with Lucifer yellow, DAB-photoconverted, embedded in resin, photographed and drawn with the aid of a camera lucida. In addition, tissue was prepared for electron microscopy to study the ultrastructural morphology and synaptic inputs of the injected neurons. In general, no cortical lamination could be observed in the grafted cortical tissue, but neurons were loosely packed throughout the graft. Two major cell types could be identified. The majority were spiny neurons (95%), of which some could be described as pyramidal-like with somata, ranging in size between 10-20 µm in diameter. The remaining 5% resembled non-spiny neurons with a basket-like morphology. Dendrites of both cell types were never seen to cross the astrocytic border, but some main axons and axonal collaterals were found to leave the graft. On the basis of light microscopical observations no difference was found between mouse and rat grafted cortical neurons. In conclusion, we have shown that grafted neurons retain some characteristic features of cortical neurons, although there appears to be a greater preponderance of spiny neurons. This may reflect an immaturity of the graft tissue or a response to the striatal environment.

474.1

BEHAVIORAL IMPROVEMENTS PRODUCED BY INTRAOCULAR GRAFTS OF LIVING RETINAL CELLS ARE NOT DUPLICATED BY GRAFTS OF OTHER NEURAL CELLS OR CELL HOMOGENATES. M. del Cerro*, G. Bowen, J. Ison, D. Grover, E. Lazar, and C. del Cerro. Depts. of Neurobiology, Psychology, & Ophthalmology, University of Rochester, Rochester, N. Y., 14642.

In normal animals light flashes suppress acoustic startle reflexes. In light blinded animals inhibition is lost and replaced at certain intervals by an anomalous peak of excitation, which is not seen in enucleated rats. Fischer 344 rats (N=18) were blinded by exposure to continuous fluorescent light and half of the animals were grafted with dissociated fetal rat retinal cell into 1 eye. Compared to non-grafted controls, grafted rats showed both statistically significant reductions of anomalous facilitation and increases in inhibition (Exp. 1: del Cerro et al., NeuroReps, 2:529,1991). To test for the specificity of this effect, blinded rats were grafted with fetal retinal cell homogenates (Exp. 2, N=20), or dissociated perinatal cerebellar cells (Exp. 3, N = 19), with control rats left untouched in each experiment. In contrast to the grafted rats of Exp. 1, the grafted animals in Exps. 2 and 3 were not different from their controls. Histologically, clusters of photoreceptor cells were consistently found in the retinae of Exp. 1 animals, but not on those of Exps. 2 or 3. We conclude that only retinal grafts of living fetal retinal cells partially repair the blindness caused by the action of continuous light exposure.

(Supported by EY 05262, the Rochester Eye Bank, and private gifts).

A SMALL ANIMAL MODEL OF HIV-1 INFECTION OF NEURAL TISSUE: INTRA-OCULAR XENOGRAFTS OF HUMAN FETAL RETINA AND BRAIN. E. Lazar*, T. Cvetkovich, H. Gendelman[1], B. Blumberg, K. Dzenko, M. del Cerro, C. del Cerro, and L. Epstein. University of Rochester Medical School, Rochester, NY, 14642. and Walter Reed Army Institute of Research[1], Washington, D.C. 20307-5100.

Human immunodeficiency virus type 1 (HIV-1) infection is highly specific for its human host. To study HIV-1 infection of the human nervous system, outside of the human body, we have established a small animal model of the disease. Second trimester human fetal brain or neural retina is transplanted into the anterior chamber of the eye of adult rats immunosuppressed with Cyclosporine A. Tissue procurement was in strict accordance with established guidelines. The human xenografts vascularize, form a blood-brain-barrier, and differentiate forming neurons and glia. The xenografts can be infected with cell free HIV-1 or with HIV-1 infected human monocytes. Analysis by polymerase chain reaction (PCR) revealed HIV-1 sequences in DNA extracted from xenograft tissue exposed to HIV-1 virions, and in-situ hybridization demonstrates HIV-1 mRNA localized in macrophages and multinucleated giant cells. Pathological damage was observed only in neural xenografts containing HIV-1 infected human monocytes supporting hypothesis that these cells are neurotoxic. Interestingly, the host retinal neurons were unaffected. This animal model allows the study of the direct and indirect effects of HIV-1 infection on developing human fetal neural tissues, and may be useful in the evaluation of antiviral therapies, which must target HIV-1 brain infection.

HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL CHARACTERISTICS OF Y79 RETINOBLASTOMAS IN VIVO. D. DiLoreto Jr.*, G. M. Seigel, D.H. Brooks, E. Lazar, D.A. Grover, C. del Cerro, M. del Cerro, and G. Chader[1]. Department of Neurobiology, University of Rochester Medical School, Rochester, NY, 14642 and the National Institutes of Health[1] Bethesda, MD.

Retinoblastoma is the most common intraocular neoplasia of childhood. Continuous human retinoblastoma cell lines, such as Y79, have been used primarily for analysis of tumoral cell growth and phenotype in vitro. Recently, we developed a useful in vivo model of retinoblastoma which involves subretinal transplantation of Y79 cells into immunosuppressed Fischer 344 rats (ARVO 92). Thirty to sixty days following transplantation, we examined the histochemical properties of Y79 tumor-bearing retinal tissue. The tumors are formed by fast-dividing, pleomorphic cells which invade the host retina and vitreal cavity. These cells were immunoreactive for the neuronal markers PGP 9.5 and neuron-specific enolase, but remained negative for S-antigen. These tumors showed no sign of a glial cell phenotype in vivo, as the only GFAP immunoreactivity present was comprised of host-derived Muller cell fibers which traversed layers of tumoral tissue. Our results show that intraocularly grafted Y79 cells survive, actively grow, and exhibit a primitive neuronal phenotype in vivo. Furthermore, these cells, even as xenografts, fully retain the features of poorly differentiated, highly invasive, neuro-tumoral cells.

ENHANCEMENT OF SURVIVAL OF INTRAOCULAR NEURAL RETINAL GRAFTS BY ANTIGEN-SPECIFIC IMMUNE DEVIATION. Luke Qi Jiang* and J. Wayne Streilein, Department of Microbiology and Immunology, University of Miami, Miami, FL, USA.

The ultimate goal of our studies is to implant functional retinal grafts into the blind eye to restore vision. In order to explore the possibility of using immunological manipulation to enhance survival of intraocular retinal grafts, we implanted neural retinal grafts from newborn BALB/c mice into one eye of C57BL/6 mice, which induces immune deviation (ACAID). In parallel experiments, conventional immunity was induced by implanting similar grafts into the subconjunctival space. Control C57BL/6 mice received a sham operation. Two weeks later, a second graft (identical to the first) was implanted into the contralateral eye of all recipients. The results revealed that all control mice rejected the test graft by 36 pid, at which time the graft size was reduced to 24% of original size. Mice which received prior SCon grafts rejected BALB/c retinal test grafts sooner. In contrast, mice which developed ACAID maintained their retinal test graft for an extended time. In this ACAID group, the graft in the first eye retained 60% of its original size by 50 pid and the second graft in the contralateral eye maintained 63% of its original size by 36 pid. Microscopic examination showed the graft in the ACAID group to have well-differentiated cell layers which resembled the structure of the normal retina. In contrast, AC retinal grafts displayed obvious histologic regression in both control mice and in mice which developed a conventional immunity. These results suggest that 1) antigen-specific suppression (ACAID) can be used to enhance the survival of intraocular neural retinal allografts and 2) immunological manipulation may provide a novel way to prevent rejection of intraocular neural retina grafts.

SYSTEMATIC EXPRESSION OF CELL TYPE-SPECIFIC NEURAL GENES IN DEVELOPING AND MATURE TRANSPLANTED RETINAE. J.D. Radel*, F. Hoover†, D. Goldman† and M. Hankin§. *Univ. Pittsburgh, Pittsburgh, PA, †Univ. Michigan, Ann Arbor, MI and §Med. College of Ohio, Toledo, OH.

Retinae transplanted to intracranial locations develop many properties characteristic of normal retina and form anatomically and functionally appropriate connections in the host brain. While resembling normal retinae, the degree to which basic cell populations are represented in transplants (TPs) has not been addressed fully. Embryonic rat retinae (E12-15) were transplanted into newborn rats. After various post-transplantation (PT) periods (4-180 days), animals were perfused and the brains sectioned. Recipients with mature transplants were tested for pupillary responses to assess functional connections or stained with silver to show TP-derived projections to the host superior colliculus. Gene expression was assayed in the transplants using in situ hybridization. Two classes of genes were studied: (1) those encoding proteins involved in neural communication represented by the nicotinic acetylcholine receptor (nAChR) α-3 and β-3 subunits, glutamate receptor (GluR3) subunit, and opsin; and (2) a gene encoding a protein involved in axonal outgrowth (GAP-43). At 4dPT, GAP-43 and β-3 nAChR subunit gene expression was seen at the vitreal margin of the transplant, suggesting the presence of differentiated retinal ganglion cells. At 180dPT in situ hybridizations demonstrated that all genes examined were expressed in a normal spatial fashion. We detected RNA levels of GAP-43, nAChR α-3 and β-3 subunit genes in a heterogeneous population of soma in the ganglion cell layer (GCL) and inner part of the inner nuclear layer (INL). GluR3 RNA was expressed by >50% of cells in the GCL, suggesting that both ganglion and displaced amacrine cells express this gene. In addition, it appeared that the majority of INL soma expressed their GluR3 gene. Unlike normal adult retinae, however, β-3 and GluR3 gene expression was detected in cells located ectopically in the inner plexiform layer, perhaps the result of abnormal cell migration. Finally, opsin mRNA was expressed solely by rod photoreceptors in the outer nuclear layer. In summary we have assayed for the presence of cell-type specific genes in transplanted retinal neurons and report that these genes are expressed in a spatial and temporal pattern similar to the normal retina.

IMMUNOLOCALIZATION OF OLFACTORY MARKER PROTEIN (OMP), GROWTH ASSOCIATED PROTEIN (GAP-43), AND PLATELET DERIVED GROWTH FACTOR B-CHAIN (PDGF-B) IN THE TRANSPLANTED RAT OLFACTORY BULB. [1]I.N. Kott*, [3]E.W. Raines, [3]R. Ross, [3]M. Sasahara and [1,2]L.E. Westrum. Depts. of [1]Neurol. Surg., [2]Biol. Struct, and [3]Pathol., Univ. of Wash., Seattle, WA 98195.

We are examining the development of transplanted rat olfactory bulbs (OBs) using antibodies against OMP, GAP-43 and PDGF-B. OMP identifies mature primary olfactory neurons (ONs), GAP-43 is a marker for growing axons and PDGF-B is heavily localized in the specialized glia that ensheath the ON. Donor OBs are taken from fetuses of embryonic days 14-15 and transplanted directly into the cavity produced by removal of an OB in one day postnatal rats of the same strain.

Adjacent 8 μm paraffin sections are examined using the three antibodies. Both OMP and GAP-43 are common to many large fiber bundles within the transplanted OB. Fiber bundles in sections identified with GAP-43 antibody (AB) have sharply defined borders and are slightly smaller than homologous bundles in adjacent sections reactive with OMP AB. The borders of OMP reactive fiber bundles are diffuse and may represent collateral branches around the bundle. In adjacent sections reactive for PDGF-B, homologous bundles are often (but not always) surrounded or ensheathed by reactive cell bodies and fibers. Scattered PDGF-B reactivity is also seen within some fiber bundles. The relationships between fiber bundles identified with OMP, GAP-43 and PDGF-B AB remain similar at survival times ranging from 2 weeks to several months and generally recapitulate the patterns, but not the overall architecture, seen in the normal OB. Antibodies kindly provided by Dr. Frank Margolis (OMP) and Mochida Pharmaceutical Co. (PDGF-B).

OLFACTORY NERVE REINNERVATION PATTERNS CORRELATE WITH BEHAVIORAL RECOVERY IN OLFACTORY BULB TRANSPLANT AND OLFACTORY BULB LESION RATS. [1,2]K.R. Hendricks*, [2]J.N. Kott, [3]M. Gooden, [3]S. Harman, [3]M.E. Hanson, and [2,3]L.E. Westrum. Depts. of [1]Psychol., [2]Neurol. Surg., and [3]Biol. Struct., University of Washington, Seattle, WA 98195.

We are examining the anatomical correlates involved with potential recovery of function in the rat under the following conditions: neonatal olfactory bulb (OB) transplants (nOBT), neonatal olfactory bulb lesions (nOBL), and adult OBLs (aOBL). The nOBT and nOBL animals can eventually find hidden cookies as well as normal rats but the aOBL rat does not show recovery. Since the aOBL rat does not display general learning disabilities in passive avoidance tests, the loss of cookie-finding ability appears to be specific to olfactory ability. Histological analysis, blind of the behavioral results, was used to place the animals into groups. Techniques included: olfactory marker protein (OMP)* immunocytochemisty for olfactory nerve (ON) penetration, cell and fiber staining, and tritiated thymidine autoradiography for donor-labeled transplant verification. All animals with incomplete OBLs were excluded from the study. Innervation of brain tissues by ON was achieved only in the nOBL and nOBT but not the aOBL and correlated perfectly with recovery of olfactory ability. Analysis of ON fiber reinnervation patterns in the nOBL rat revealed that ON targets included olfactory peduncle (OP) and olfactory cortex (OC). Analysis of nOBT rats revealed that ON innervation of OBT was usually accompanied by innervation of OP and OC. These results suggest that in the absence of secondary OB neurons, ON connects directly with "tertiary" neurons in the pathway and that this novel connection in the nOBL rat may be responsible for recovery of olfactory ability. It is not possible at present to say whether it is ON innervation of OBT or OP/OC or both that is responsible for recovery of olfactory ability in the nOBT rat. (Supported by NIH Grant NS 09678. L.E.W. is an affiliate of the CDMRC). *OMP was kindly provided by Dr. F.L. Margolis.

474.8

RECONNECTIVITY OF TRANSPLANTED OLFACTORY BULBS IN RATS. [1]M.E. Hanson, [1]J.N. Kott, [1,3]K.R. Hendricks, [4,5]D.F. Farrell* and [1,2,5]L.E. Westrum. Depts. of [1]Neurol. Surg., [2]Biol. Struct., [3]Psychol., [4]Medicine (Neurol.), and [5]Child Devel. & Ment. Retard. Ctr., University of Washington, Seattle, WA 98195.

Using lesion-degeneration methods it has previously been shown that successfully transplanted (TX) olfactory bulbs (OB) send their axons to appropriate target areas in the adult host brain (Westrum et al., 1990 Neurosci. Lett.). We are using WGA-HRP transport to study reconnectivity in the developing TX OBs in Sprague-Dawley rats. Time-mated dams received subcutaneous injections of tritiated thymidine on embryonic days (E) 12-14. OBs from fetal rat donors of E 14-15 were immediately grafted into neonatal rats in the site from which the host OB had been removed. Following survival times of 2 weeks and longer, 0.1 µl of a 2 per cent WGA-HRP solution is injected into the TX OB and subjects are perfused after 24 hours. Alternate frozen sagittal sections are processed using TMB as the chromagen or olfactory marker protein (OMP)* immunolocalization. Autoradiography will be included to verify that the injections remained within the TX OB. WGA-HRP transport is seen in fibers from the TX OB into layer I of the host anterior olfactory nucleus (AON) and pyriform cortex (PC) and in cell bodies in layers II and III of the AON and PC. OMP material shows that primary fibers are seen within the TX OB and in the peduncle. These preliminary findings reaffirm that the axons from a TX OB make connections with some appropriate areas of the host brain, and also suggest that axons from cells in the target areas of the host brain innervate the TX OB. Supported by NIH Grants NS09678 and HD02274. LEW is a research affiliate of the CDMRC. *Anti-OMP kindly provided by Dr. Frank Margolis.

SYNAPTIC CONNECTIVITY OF SEROTONIN RAPHE TRANSPLANTS IN THE SUPRACHIASMATIC AND SUPRAOPTIC NUCLEI IN ADULT RATS. O. Bosler[1]*, S. Boulaïch[1], M. Geffard[2] and A. Daszuta[3]. [1]Lab. de Neurobiologie and [3]Lab. de Neurobiologie Cellulaire et Fonctionnelle, CNRS, Marseille, and [2] Lab. d'Immunologie et Pathologie, Univ. Bordeaux II, France.

We have previously reported that cell suspensions of fetal mesencephalic raphe, transplanted at mid-distance between the suprachiasmatic nucleus (SCN) and the supraoptic nucleus (SON) in adult rats after intraventricular administration of 5,7-dihydroxytryptamine, induced partial 5-HT reinnervation of the SCN vs hyperinnervation of the SON. We have further investigated the ultrastructural relationships of reinnervating vs normal 5-HT axon terminals in both nuclei following immunodetection and systematic sampling on ribbons of 4-12 consecutive sections. About 48% of the 5-HT positive terminals photographed in the ventral part of the normal SCN (n=77, from 4 animals), where they normally predominate, showed synaptic membrane specializations. Graft-derived 5-HT terminals in the same portion of the SCN (n=88, from 4 animals) showed a comparable synaptic incidence (around 46%). The frequency with which 5-HT varicosities made synaptic contacts was also found to be equally high in the SON from normal and grafted rats (more than 40%). These results indicate that the extent of reinnervation after grafting are not solely dependent on the mode of termination of normal 5-HT axons in the denervated territory. Target-specific trophic influences, i.e. target-derived stimulatory or inhibitory signals, should also be determinant in promoting graft-induced reinnervation. Such influences, together with innate programing of transplanted neurons committed to supply 5-HT fibers to the SCN and/or the SON, could also account for the fact that, irrespective of the extent of reinnervation (hypo- or hyperinnervation), the new 5-HT fibers in both nuclei re-established the same relational features as in control tissue.

THREE-DIMENSIONAL EXTRACELLULAR MATRIX AS PRIMARY CULTURE SYSTEM FOR FETAL HAMSTER HYPOTHALAMIC SCN CELLS. K.Z. Doll, P.W. Coates†, and M.N. Lehman*. Dept. Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH 45267; †Dept. Cell Biol. & Anat., Texas Tech Univ. HSC Sch. Med., Lubbock, TX, 79430.

Transplants of the fetal hamster hypothalamic suprachiasmatic nucleus (SCN), the site of a circadian pacemaker, restore rhythmic behavior to SCN-lesioned hamsters (Lehman et al., J. Neurosci. 7:1626). We explored the use of a three-dimensional (3-D) extracellular matrix consisting of hydrated native rat tail collagen (type 1) as an alternative method of culturing SCN cells for use in grafting studies. Fetal (E13) anterior hypothalamic cells were dissociated by a combination of gentle trituration and enzymatic treatment. Cells were rinsed and plated at 5 x10^5 cells/ml/16mm well on either the 3-D matrix or control poly-L-lysine coated coverslips. At various intervals following seeding (1, 4, 7 and 14 days) cultures were rinsed with serum-free media and fixed with 4% paraformaldehyde. The 3-D matrix was processed for immunocytochemistry (Dudley et al., Peptides 10:1205) to detect a variety of neuronal and glial markers. 3-D matrices contained far greater numbers of isolated neurons and few glia in contrast to the clusters of neurons and glia seen in poly-L-lysine cultures. A 4 days positive staining for neuron-specific tubulin (class III, type II) was abundant; at 14 days staining was decreased. Neurophysin immunostaining suggested that SCN neurons survived in the 3-D matrix. The matrix may be useful in providing a scaffolding for neuronal cultures to be used for grafting studies, including those in which isolated SCN neurons are tested for their ability to restore rhythmicity. TRANSPLANTATION OF FETAL SUPRACHIASMATIC NUCLEI (SCN) INTO MIDDLE-AGED RATS INFLUENCES LIGHT-INDUCED C-FOS EXPRESSION IN THE HOST SCN A.Cai[1], J.M. Lloyd[1], M.N.Lehman[2], and P.M. Wise[1]*. Dept. Physiology, U. Maryland Sch. Med., Baltimore, MD 21201[1] and Dept. Anatomy & Cell Biology, U. Cincinnati Coll. Med., Cincinnati, OH 45267[2].

Aging disrupts multiple diurnal rhythms that are regulated by the SCN. c-Fos expression in the SCN is induced by light, and may be part of the mechanism for photic entrainment of the circadian pacemaker in the SCN. The purpose of this study was to determine whether transplantation of fetal SCN into middle-aged rats can influence light-induced c-Fos expression in the host SCN. We transplanted fetal SCN tissue into the third ventricle of middle-aged female constant estrous rats (9-12 mo). Sham operated middle-aged and young (3-4 mo) rats served as controls. After one month, rats were ovariectomized (day 0) and treated with estradiol (day 7) to maintain a constant and similar hormone environment in both age groups. On day 11, rats were transcardially perfused within 90 min before and after lights on. Brains were prepared for immunocytochemical localization of c-Fos (Cambridge Research, OA-11-823). Young rats exhibited virtually no c-Fos expression in the SCN prior to lights on, and a dramatic increase in c-Fos by 90 min. In contrast, c-Fos-containing cells are evident in some middle-aged rats prior to lights on. Transplantation of the fetal SCN into middle-aged rats appears to reinstate the pattern of c-Fos expression observed in young rats; that is, no c-Fos expression was detectable before lights on. The results suggest a possible trophic influence of the donor SCN on the host SCN function. Supported by NIH AGO2224.

NANOASSAY FOR NEUROTOXIN–TARGET RECEPTOR BINDING BY FLUORESCENT LIGAND EXCLUSION ANALYSIS (FLEA). D. Yoshikami*. Dept. of Biology, Univ. of Utah, Salt Lake Cty, UT 84112

A simple and efficient approach has been developed to assess the binding of ligand with receptor in solution. The approach is called fluorescent ligand exclusion analysis (FLEA), and requires: 1) a fluorescently labeled ligand (**fL**); 2) a microscopic speck of a steric exclusion matrix, such as a polyacrylamide or dextran bead normally used for gel filtration chromatography, which is permeable to **fL** but not to receptor (**R**); and 3) a fluorescence microscope fitted with a video camera or photodetector to measure fluorescence within the semipermeable matrix. Whereas **fL** can permeate the matrix, **fL** bound to **R** cannot; hence, fluorescence within the matrix provides a direct measure of the free **fL** concentration which can be used to determine the equilibrium binding constant.

By use of a flow cell (internal volume, ≤ 150 nanoliters) containing an immobilized steric exclusion bead (diameter, ~ 50 microns), different solutions can be readily FLEA-assayed in quick succession (≤ 1 minute/sample). In addition, since **fL** can diffuse into (and out of) the bead relatively rapidly (time constant of seconds), the kinetics of binding of **fL** to **R** may also be examined. Thus in-line, as well as near-real time, binding assays can be performed by FLEA. Only nanomolar concentrations of reagents in nanoliter volumes are required, so FLEA is referred to as a "nanoassay."

The practicality of FLEA has been verified with experiments involving fluorescently labeled α-Bungarotoxin used in conjunction with acetylcholine receptors from *Torpedo*, and we are exploring the feasibility of examining other neurotoxin–target receptor interactions with FLEA. It should be noted that FLEA may also be used to examine the interactions of other biological molecules, including those of antibody with antigen, enzyme with substrate, and protein with each other as well as with nucleic acid.

IMAGING CELL VOLUME CHANGES IN RAT HIPPOCAMPAL SLICES. R.D. Andrew* and B.A. MacVicar. Anatomy Department, Queen's University, Kingston, Ontario and Department of Medical Physiology, University of Calgary, Calgary, Alberta.

Brain cell swelling is a consequence of seizure, ischemia or excessive rehydration therapy yet the process is difficult to study unless cells are isolated. By imaging light transmittance in the hippocampal slice, we studied how the signal is affected by osmotic manipulation of cell swelling where neuron-glia relationships are intact. Brief exposure to 20 mM K^+ (1-2 min, n=6) or hypo-osmotic saline (4-6 min, n=16) consistently and reversibly increased light transmittance. The increase was greatest in CA1 dendritic regions. Synaptic blockade using zero-Ca^{2+} saline did not alter the transmittance increases. In hypo-osmotic saline (-40 mOsm), an increase in the CA1 population spike (PS) evoked from Schaffer collaterals developed concomittantly with the transmittance increase. Both findings are consistent with a swelling-induced reduction of extracellular space. Hyperosmotic saline (+40 mOsm) using impermeant mannitol (n=9), but not permeant glycerol (n=5), consistently reduced light transmittance and PS amplitude. Recovery from mannitol (+40 mOsm) was markedly slower than from -40 mOsm ACSF although recovery could be accelerated by brief application of hypo-osmotic saline.

We conclude that increased light transmittance results primarily from reduced light scattering caused by cell swelling, particularly by astrocytes. This imaging technique may prove useful in examining brain cell swelling in epileptiform and excitotoxic states.

Supported by the Canadian MRC and the Queen's Faculty of Medicine.

GLIAL SWELLING IN CA1 STRATUM RADIATUM IN RESPONSE TO OSMOTIC AND ELECTRICAL STIMULATION. P. Osehobo*[1], B.A. MacVicar[2] and R.D. Andrew[1]. Anatomy Department[1], Queen's University, Kingston, Ontario and Department of Medical Physiology[2], University of Calgary, Calgary, Alberta.

Light transmittance in CA1 stratum radiatum (st. rad.) of rat hippocampal slices increases dramatically upon stimulation of Schaffer (Sch) collaterals (MacVicar and Hochman, 1991) or when saline osmolality is lowered (Andrew and MacVicar, this meeting). In both cases, we suspected that neuronal and/or glial swelling reduced light scattering, thus increasing transmittance. Previously we've shown that neither pyramidal cell intrinsic properties nor synaptic input were altered by lowering osmolality. Glial resting potentials in st. rad. in this study were unaffected by -40 mOsm ACSF (n=10) or -80 mOsm (n=4). A stimulus train to Sch. collaterals (10-100 Hz, 0.5 - 2.0 s) consistently increased light transmittance and depolarized glia in st. rad. The amplitude of the depolarization was increased in -40 mOsm ACSF (n=15) probably due to increased K^+ accumulation in the reduced extracellular space. Antidromic stimulation from alveus in ϕ Ca^{2+} saline caused only minor increases in light transmittance in CA1 stratum pyramidale where glia are sparce (n=4). Apparently rapid firing by neuronal somata without dendritic activation caused comparatively small increases in cell volume.

We conclude that glial swelling in regions of dendritic depolarization underlies the large change in light transmittance observed during orthodromic stimulation. However glial swelling, in itself, does not alter glial resting potential in hippocampal slices.

AFFERENT CONNECTIONS OF NUCLEUS RAPHE PALLIDUS. A STUDY WITH FLUORESCENT TRACERS IN RATS. M.I. Nogueira, L.E. Ribeiro do Valle*,Dep. de Fisiologia e Biofísica, and J.C.Bittencourt, Dep. Anatomia, Instituto de Ciências Biomédicas, USP. SP. 05508 - Brasil.

Nucleus raphe pallidus (NRP) has been implicated in the modulation of visceral and somatic activities. It is an important source of serotonergic innervation to the brain stem and the spinal cord. We are investigating in detail its afferent connections.

Fluorogold was injected iontophoretically in the NRP of male rats, after a survival time of 30 days the animals were sacrified and their brain processed. Marked cell bodies and dendrites were found mainly in the hypothalamus (preoptic, anterior and lateral areas), in the colliculus superior , in eye related movment nuclei, pretectal areas, in the central gray, in vestibular and coclear nuclei and in the spinal cord layer 10 and 7. These results should be confirmed by using an anterograde tracer technique.

The present findings contribute to a better understanding of the functional role of the NRP.

Grants from CNPq and FAPESP.

"Miniruby": A Fluorescent Biocytin Compound for Intracellular Labeling Of Neurons In Fixed Slices. W. -L. Liu, M. M. Behbehani[1] and M. El-Etri*, M. T. Shipley. Depts. of Anatomy & Cell Biology and [1]Physiol & Biophysics, University of Cincinnati College of Medicine, Cincinnati, OH 45267.

Intracellular labeling can be done not only in living, but also in fixed slices. Biocytin is useful for intracellular injection because it is highly soluble, has high affinity for avidin and high electrophoretic mobility. In fixed slices, membrane potential cannot be used to signify that a cell is impaled. Thus, it is necessary to inject cells with a fluorescent compound so that impalement and filling can be visualized. As biocytin does not fluoresce it cannot be used in fixed slices. Here, we report that a biocytin compound, "miniruby" (MR), dextran(MW~10K)-tetramethylrhodamine-biocytin, is a useful intracellular marker for injecting neurons in fixed slices.

Fixed adult slices (300-400 μm)of olfactory bulb, piriform cortex and periaqueductal gray were used. Slices were stained by 0.001% ethidium bromide so that cell bodies could be visualized under fluorescent illumination. A cell was impaled with a pipette containing 3-5% MR; positive pulsed constant current (2-5 nA ; 300-400 msec on- 600-700 msec off; ~10 min) was applied until the fine dendrites were brightly fluorescent. Slices were post-fixed for 6-12 hours, then reacted by ABC-DAB.

MR has several advantages: (1) It is easy to visualize the electrode in relation to the cell bodies. (2) The histochemical staining is very sensitive and is light stable. (3) Injected neurons, dendrites and axons are well visualized by brightfield microscopy. In addition, it should be possible to analyze MR filled cells at the EM level.

IMMUNOPEROXIDASE LABELING OF FLUORO-RUBY H. T. Chang* Department of Anatomy & Neurobiology, The University of Tennessee, Memphis, College of Medicine, 875 Monroe Ave., Memphis, TN 38163

Fluoro-Ruby (tetramethylrhodamine - dextran amine conjugate, Molecular Probe # D-1817) has been shown recently to be an effective anterograde tracer readily visible in brain sections using conventional fluorescence microscopy. However, several inherent disadvantages have limited the use of Fluoro-Ruby by many neuroanatomists. For example, since the fine fluorescent signals are difficult to resolve at low magnifications, the analysis of the macroscopic distribution of Fluoro-Ruby labeled fibers within tissue sections has been difficult. This is in contrast to the ease of using low magnification dark-field microscopy to analyze the distribution of fibers labeled by either the autoradiographic or the immunoperoxidase methods. On the other hand, high magnification analyses of Fluoro-Ruby labeled fibers also have been problematic due to the labile nature of the fluorescent signal and the lack of a convenient method to render the labeled fibers electron dense for electron microscopic analysis. In this study, I will present results which show that most of these inherent limitations of Fluoro-Ruby can be overcome by conventional immunohistochemical procedures using primary antisera raised against tetramethylrhodamine, the fluorescent moiety of the Fluoro-Ruby. Problems of false negative results associated with anterograde tracing methods revealed during the course of this study will also be discussed during the Annual Meeting.

BEHAVIOR OF LIPOPHILIC DYES IN THE EMBRYONIC MAMMALIAN VISUAL SYSTEM. J. Kelly Johnson[1] & Vivien A. Casagrande.[1,2] Depts. of Cell Biol.[1] & Psychol.[2], Vanderbilt Univ., Nashville, TN 37232-2175.

Lipophilic dyes have been used in studies of neuronal pathways since Godement et al (Development, 1987, 101:697-713). However, continued reports of cell:cell (transcellular) movement of the dyes have been made by a number of investigators since this time. The embryonic rat visual system was used to examine what conditions affect cell:cell movement of these dyes and which cell types and cellular interactions are involved.

Midgestation (E15.5) rat embryos were immersion fixed in buffered paraformaldehyde. DiI, DiA, or 4di10ASP (Molecular Probes; Eugene, OR) were placed in one eyecup, covering the optic disk. Brains were dark incubated 2-12 weeks at room temperature, sectioned biweekly, and mounted and photographed the same day.

All dyes label similar cell types, but at different rates (DiI/DiA at ~0.18 mm/day, 4di10ASP at ~0.21 mm/day). After incubating 2 wk , 1) DiI and DiA label a few optic axons from the opposite eye, 2) DiI labels a few, and DiA many, midline glia at the optic chiasm, 3) neither DiI, nor DiA, label glia along the optic tracts, 4) 4di10ASP labels a large number of optic axons, ganglion and Müller cells in the opposite eye, most midline glia at the optic chiasm and glia along both optic tracts. After 8 weeks, 4di10ASP labels optic radiations into cortex, and a glial compartment dividing dorsal and ventral thalamus. All dyes label more of the same cell types with longer incubations.

These results suggest that, 1) the dyes move cell:cell via specialized contacts between axons, and axons and glia, within the optic chiasm, diencephalon, and retina, and 2) the amount of transcellular labeling correlates with the rate of diffusion and length of incubation.

Supported by grant EY05038 (VAC), core grants EY08126 & HD15052.

475.8

RETROGRADE LABELING OF EMBRYONIC RAT SEPTAL NEURONS FOLLOWING IN VITRO HIPPOCAMPAL INJECTIONS OF FLUORESCENT TRACERS. B. Webb*, M.B. Heaton, M.A. King, and D.W. Walker. University of Florida College of Medicine and V.A. Medical Center, Gainesville, FL, 32610.

A technique was developed in which tracer substances were injected into isolated brains and retrogradely labeled cells were subsequently analyzed. Specifically, septal neurons that project to the hippocampus were retrogradely labeled using FITC, fluorescent microspheres, and Di-I in embryonic rat brains on days E18, E21, and P1. The embryonic rat brains were removed and immediately immersed in oxygenated Tyrode's Balanced Salt Solution. Dye was injected bilaterally throughout the rostral-caudal extent of each hippocampus. Each injection (total of 4/hippocampus) consisted of 0.1 ul of fluorescent dye delivered through a micropippette. Following 17 h of transport time in oxygenated Tyrode's, each medial septum was removed. The neurons were dissociated (DNAase and trypsin) and cultured (L-15 media, with fetal bovine serum (FBS), heat inactivated horse and FBS, glutamine, penicillin-streptomycin, and fungizone) in 35 mm dishes at medium density (1 septum/2 dishes). A hole had been drilled in the bottom of the dishes and covered by a coverslip with a grid. The neurons were followed daily with a low light video system (intensified CCD cameras) and images were digiitized daily for analysis. The number of labeled septal-hippocampal neurons increased progressively from E18 to P1 which is consistent with developmental studies of septo-hippocampal projections. The neurons showed considerable process outgrowth and differentiation during culture. The cultures were fixed (4%paraformaldehyde) and stored in phosphate buffer for immunocytochemical analysis. This technique will allow the identification and experimental manipulation of a subpopulation of medial septal neurons, in particular those septal neurons forming the septohippocampal pathway. Supported by the Veterans Administration, NIAAA AA00200, and A.B.M.R.F.

FLUORO-GOLD REVISITED: TOXICOLOGICAL AND PHARMACOLOGICAL PROPERTIES. L.C. Schmued[1]*, J.F. Bowyer[1], C. Beltramino[2], H.W. Broening[1] and W. Slikker Jr.[1] [1]Division of Neurotoxicology, NCTR/FDA Jefferson AR 75209-9502 and [2]Dept. of ENT, Univ. of Virginia, Charlottesville, VA 22908.

Since its introduction in 1985, Fluoro-Gold (FG, hydroxystilbamidine) has been widely used as a retrogradely transported fluorescent tracer to reveal neuronal connectivity. However, little is known regarding its neurotoxic or pharmacological properties. To address its neurotoxic potential, FG was injected into the rat striatum at different concentrations (2.5-10%), volumes (100-250 ηl), and vehicles (saline and .1M cacodylate). Survival intervals ranged from one week to one day. The tissue was processed according to a modified de Olmos' cupric-silver stain for degeneration. At the injection site degenerating neurons and neuropil could be observed at higher dye concentrations and volumes. Necrotic debris without any cellular profiles is seen at survival times exceeding 2 days. Examination of the substantia nigra indicated degenerating axon terminals in some cases, however no neurons retrogradely labeled with FG also stained for degeneration. The second phase of this study involved looking at the effects of FG on the dopamine (DA) release from striatal slices *in vitro*. Slices were first incubated in a medium containing [^{3}H]DA, and then exposed to 10^{-6} to 10^{-4}M [FG]. FG completely blocked the basal, 15 mM K^+-, and 1 mM glutamate- evoked [^{3}H]DA release in a concentration dependent manner. Basal and glutamate-evoked [^{3}H]DA release were inhibited by lower [FG] than K^+-evoked release. These studies indicate that high [FG] can be neurotoxic. However, since FG can also inhibit neurotransmitter release, it might be neuroprotective in some instances.

LABELING OF SPECIFIC CELL TYPES IN THE RAT CNS BY INTRAVENTRICULAR INJECTIONS OF BIOCYTIN. A.J. McDonald* and F. Mascagni. Dept. of Cell Biology and Neuroscience, Univ. of South Carolina Sch. of Med. Columbia, S.C. 29208.

Recent experiments performed in this laboratory have demonstrated that large injections of biocytin into the lateral ventricle (or brain) produce labeling of particular neuronal subpopulations in the rat CNS. Rats were perfused 24 hr following injection and brain sections were processed with the ABC technique. In many cases the staining of neurons was very complete and resembled that obtained with the Golgi technique. Regions containing labeled cells included the olfactory bulb, cerebral cortex, hippocampus, amygdala, striatum, hypothalamus, tectum, cerebellar cortex, and dorsal horn of the spinal cord. Only particular cell types were labeled in each of these regions (e.g., only nonpyramidal neurons were strongly labeled in the cerebral cortex; all neurons but Purkinje cells were labeled in the cerebellar cortex). Labeled cells in most brain regions appeared to be small local circuit neurons. Cases with short survival times (1-6 hr) exhibited strong labeling of glial cells and light labeling of a large percentage of neurons in many brain regions. Cases with 48 hr survival times exhibited no labeled cells. Injections of d-biotin did not produce neuronal labeling. Injections of biotinamide (neurobiotin, Vector Labs) produced a pattern of labeling that was much different from that produced by biocytin. The results of this study suggest that there is differential uptake and retention of biocytin by subpopulations of CNS neurons. This uptake system may be associated with biotin-dependent metabolic pathways in these cells. Double-labeling studies are in progress to further characterize neurons that exhibit biocytin uptake. Supported by NIH Grant NS19733.

ULTRASTRUCTURE OF PHYSIOLOGICALLY CHARACTERIZED CORTICAL NEURONS AND THEIR RELATION TO GABAERGIC AND CATECHOLAMINERGIC TERMINALS IN RAT BRAIN. R.L. Cowan*, S.R. Sesack, J. Chan, E.J. Van Bockstaele and V. M. Pickel. Div. of Neurobiology, Dept. of Neurology and Neuroscience, Cornell University Med. Center, New York, N.Y. 10021.

In vivo intracellular recording and immunocytochemical labeling were used to determine the ultrastructure and synaptic associations of physiologically characterized pyramidal neurons in the superficial layers of the rat frontal cortex. After each recording, individual neurons were filled with biocytin, and the animals were transcardially perfused with acrolein. Sagittal serially collected sections were processed for visualization of biocytin using avidin biotin peroxidase. Sections containing the filled neuron were processed using immunogold silver for detection of GABA or tyrosine hydroxylase (TH), a marker of catecholaminergic afferents. Filled neurons had branched and spiny dendrites as seen by light microscopy. At the ultrastructural level, filled perikarya and dendrites had irregular (ruffled) contours. Although these were densely filled with peroxidase, synaptic contacts were usually identifiable. In dually labeled sections, (i) GABA immunoreactivity was seen in perikarya, dendrites and terminals, some of which formed synapses on proximal filled dendrites, and (2) TH-labeling was seen in terminals in neuropil near the filled dendrites in the superficial layer. The combined use of *in vivo* intracellular labeling with ultrastructural identification of transmitters provides an important method for determining the synaptic basis for modulation of cortical activity. COMBINED ANALYSIS OF CALCIUM BINDING PROTEINS, GAMMA AMINOBUTYRIC ACID, ANTEROGRADELY TRANSPORTED WHEATGERM AGGLUTININ HORSERADISH PEROXIDASE AND ANTEROGRADE DEGENERATION IN THE CNS OF THE PRIMATE. Antonia M. Milroy,*Diane Daly Ralston and Henry J. Ralston, III. Department of Anatomy and the W.M.. Keck Foundation Center for Integrative Neurosciences, University of California, San Francisco, California, 94143.

Our laboratory has explored the use of several neuroanatomical techniques simultaneously to analyze projections in the primate central nervous system to neuronal populations that have been characterized for the presence of neurotransmitters and calcium binding proteins. As an example, one M. facicularis, as part of a series of studies in which our laboratory is currently involved, was injected with wheatgerm agglutinin-horseradish peroxidase (WGA-HRP) in somatosensory/motor cortices for anterograde transport in cortico-spinal/thalamic/rubral pathways and underwent ablation of the area of hand representation in the prefrontal cortex, area 4, for cortico/rubral/spinal afferents. According to protocol the animal was anaesthetized and perfused intracardially with 2% paraformaldehyde and 2% glutaraldehyde, pH7.4 at room temperature. The brain was kept in cold fixative for 4-5 hours , then transferred to cold phosphate buffered saline. Vibratome sections of 100µm, were 1) reacted with tetramethyl benzidine (TMB) for electron microscopy 2) incubated with the appropriate antibody for calbindin or for parvalbumin using the Avidin-Biotin method, reacted with either diaminobenzidine (DAB) or TMB. (Triton-X was not used in the Avidin-Biotin method). Areas for study were blocked for EM and placed in 1% OsO_4 overnight and then embedded according to standard EM procedures. Post embedding GABA immuno-gold was then applied to the tissue containing either transported HRP, anterograde degeneration, parvalbumin or calbindin. (Triton-X was used in low concentration in all solutions of the post-embedding GABA immuno-gold labeling instead of etching). We have found that these techniques can be employed in a variety of combinations to maximize the information while preserving the fine structural integrity of the tissue. Supported by NS-21445 and NS-23347.

LIGHT AND ELECTRON MICROSCOPIC STUDIES OF BOUTONS ON ISOLATED RAT NEURONS. W.Liu* and M.DeSantis. Dept. of Biological Sciences and WAMI Medical Program, University of Idaho, Moscow, ID 83843, USA

The size of axosomatic boutons was measured on isolated neuronal somas using scanning electron microscopy (SEM). Neuronal cell bodies were isolated from the trigeminal motor nucleus by ultrasonic disruption after perfusion of the anesthetized rat with aldehyde fixative and postfixation in osmium tetroxide. The isolated neuronal somas were first identified by light microscopy and then examined by SEM. They ranged in size from 23.0 to 41.6 um average diameter (n=23). Preparation for SEM resulted in an average shrinkage of the soma by 20% of its diameter. There was a direct relationship between the size of cell body and the amount of shrinkage. SEM revealed bulbous structures from 0.6 to 3.6 um in size at the surface of neuronal somas. Our interpretation that they were boutons was confirmed when transmission electron microscopy (TEM) was used to study the same somas after SEM. The surface of the isolated somas was generally free of adhering elements except for the boutons. (Supported by Idaho State Board of Education grant 92-010).

ULTRASTRUCTURAL LOCALIZATION OF GLIAL HYALURONIC ACID BINDING PROTEIN (GHAP). M.A. Hosley.* Spinal Cord Injury Research, V.A. Med. Ctr., West Roxbury, MA

GHAP (glial hyaluronic acid binding protein) is a 60 kDa glycoprotein which binds to hyaluronic acid in the CNS. Functionally, GHAP is thought to inhibit neurite adhesion and outgrowth. In this study, the ultrastructural localization of GHAP was performed in rat spinal cord and cerebellum, the two portions of the CNS with the highest GHAP staining. The localization was performed via an indirect immunoperoxidase staining with the monoclonal antibody 12C5 as the primary antibody. Animals were anesthetized and then perfused via a gravity flow system through the left ventricle, first with 50cc of PBS (phosphate buffered saline)at pH 7.3-7.4, containing 2% procaine-HCl and 3mg% heparin sulfate (169 units/ml). This was followed by fixation with 100-300cc of PBS at pH 7.3-7.4 containing 2.0% paraformaldehyde, 2.5% glutaraldehyde and 1% CPC (cetylpyridinium chloride); the CPC serves to stabilize the water soluble hyaluronic acid in the extracellular matrix to which the GHAP binds. After perfusion, the brain and spinal cord were removed and stored overnight (12-16 hrs.) in the same fixative. Vibratome sections were subsequently collected and stained by indirect immunoperoxidase using the DAB protocol of Streitt and Reubi (1977).

Electron micrographs will be presented to illustrate the labelling of GHAP in both the spinal cord and the cerebellum.

This research supported in part by NIH Grant NS 13034 and V.A. Gen. Res. Service Merit 0002.

A PRE-EMBEDDING TRIPLE-LABEL EM IMMUNOHISTOCHEMICAL METHOD AS APPLIED TO THE STUDY OF MULTIPLE INPUTS TO DEFINED NIGRAL NEURONS. A. Reiner*, K.D. Anderson and E.J. Karle. Dept. of Anat. & Neurobiol., Univ. of Tennessee, Memphis, TN, 38163.

Both dopaminergic and nondopaminergic neurons are present in the substantia nigra, and the substantia nigra receives input from both enkephalinergic (ENK+) striatal neurons and substance P-containing (SP+) striatal neurons. To determine the types of nigral neurons receiving these inputs and to determine whether such individual neurons receive input from both types of terminals, we have developed an approach for carrying out pre-embedding triple-label EM immunohistochemistry, using three distinct markers.

Following fixation with a paraformaldehyde-glutaraldehyde-acrolein fixative, vibratome sections were sequentially labeled for the localization of: 1) SP+ terminals using a PAP/DAB procedure with rat anti-SP; 2) ENK+ terminals using a 1nm gold-conjugated secondary with mouse anti-ENK; and 3) tyrosine hydroxylase-containing (TH+) neurons using a PAP/BDHC procedure with rabbit anti-TH. The sections were then osmicated and the immunogold labeling was silver intensified. Thin sections examined with EM showed that all three labels could be distinguished at the EM level. Although individual SP+ and ENK+ terminals contacted both TH+ and non-TH+ perikarya and dendrites, profiles receiving simultaneous contact from both SP+ and ENK+ terminals were typically non-TH+. These results show that pre-embedding triple-label EM immunohistochemistry is feasible, and that SP+ and ENK+ striatal terminals may be segregated on nigral dopaminergic neurons (i.e. on different neurons or different parts of the same neurons). Supported by NS-19620 & NS-28721 (A.R.)

PREDOMINANCE OF Na/Ca EXCHANGER (NCX) IMMUNOREACTIVITY IN SELECTED SYNAPTIC FIELDS OF RAT HIPPOCAMPUS. R.K. Yip*[1], A. Ambesi[2], G.E. Lindenmayer[2] and M.P. Blaustein[1]. [1]Dept. of Physiology, U. of MD Med. Sch., Baltimore, MD 21201 & [2]Dept. of Pharmacol., Med. U. of SC, Charleston, SC 29425.

The Na/Ca exchanger (NCX) is prevalent in neurons and appears to be concentrated at nerve terminals; the exchanger is also present in glia (*Ann. N.Y. Acad. Sci.* 639:254-274, 1991). Polyclonal antisera specific to canine cardiac NCX were used to localize the NCX in adult rat hippocampus. We compared the distribution of the NCX immunoreactivity to the distribution of synapsin I and synaptophysin (synaptic vesicle markers), and glial fibrillary acidic protein (GFAP; a glial marker). Immunostaining of 25 μm cryosections of hippocampus was performed by an indirect immunoperoxidase procedure. The anti-NCX antibodies labeled the strata oriens and radiatum most intensely, followed by stratum lacunosum-moleculare and the inner third of the dentate molecular layer where axons from both the ipsilateral and contralateral hilus terminate. The regions of the hippocampus where the neuronal cell bodies are located (the stratum pyramidale and the dentate granular layer) were poorly labeled by the anti-NCX antiserum. No specific labeling in any region of hippocampus was observed with preimmune serum. Immunostaining patterns for synapsin I and synaptophysin were similar to the NCX pattern although antibodies to synapsin I and synaptophysin, but not NCX, strongly stained the entire molecular layer of the dentate gyrus. The GFAP immunostaining pattern differed markedly from the NCX pattern. These results suggest that much of the NCX immunoreactivity is associated with synapses since synapsin I and synaptophysin are present in all nerve terminals. We concluded that the NCX is present in relatively high concentration in the hippocampus, and that it is especially prevalent in some synaptic fields where it may play an important role in Ca homeostasis.

CYTOCHROME OXIDASE SUBUNIT IV PRECURSOR POLYPETIDE: IMMUNOHISTOCHEMICAL LOCALIZATION IN THE RAT BRAIN S. Liu*and M. Wong-Riley. Dept. Cellular Biology & Anatomy, Med. Coll. Wis., Milwaukee, WI 53226

Cytochrome oxidase (C.O.) contains 13 subunits which are individually encoded by mitochondrial or nuclear genes. Nuclear-derived mitochondrial proteins are cytoplasmically synthesized as precursors carrying cleavable polypeptides (presequence) at the N-terminus, which functions as the targeting signal for directing precursors into the mitochondria. In order to determine if nuclear-derived precursors are localized mainly in neuronal cell bodies or in dendrites, we generated polyclonal antibodies against the presequence of the rat C.O. IV precursor. Immunoreactivity could be detected in all brain regions examined (cerebellum, hippocampus, brain stem, somatosensory barrel cortex, and olfactory bulb). There is a distinct heterogeneous immunohistochemical pattern among different brain regions, laminae, and cell types. The pattern of immunoreactivity for the precursor matched that for the mature enzyme and the pattern shown by C.O. histochemistry. Antisera were localized in both somata and dendrites in the hippocampus and the cerebellum, where somatic and dendritic layers are spatially segregated. This is the first evidence that precursors of the rat C.O. subunit IV are detectable immunohistochemically in the mammalian brain. (Supported by NIH grant NS 18122 to MWR)

QUANTITATIVE DIFFERENCES IN CALCITONIN GENE-RELATED PEPTIDE (CGRP)-IMMUNOREACTIVITY IN RAT SPINAL CORD MOTONEURONS INNERVATING FAST AND SLOW MUSCLES. J. Calderó, A. Sorribas, E. Hengesbach, V. Yuste, J.X. Comella* and J.E. Esquerda. Unitat de Recerca Neuromuscular, Departament de Ciències Mèdiques Bàsiques, Facultat de Medicina de Lleida, Universitat de Barcelona, E-25006, Lleida, Spain.

When CGRP is detected by immunocitochemistry a substantial variation on the intensity of the reaction is found among the spinal cord motoneuron population. The significance of such heterogeneity is unknown. We have explored whether or not motoneurons innervating fast or slow muscles shown correlative differential content in CGRP. Motoneurons innervating the slow soleus or the fast extensor digitorum longus (EDL) muscles from adult Sprague-Dawley rats were labelled by intramuscular injection of fluoresceinated-wheat germ agglutinin or cholera toxin (B subunit). CGRP-like immunoreactivity (CGRPLI) was evidenced by immunofluorescence using rhodamine as a label. The intensity of CGRP reaction was measured in traced neurons with a microspectrofluorimeter. Recorded data from each set of samples were analyzed by means of an automatized classification procedure for individual intensities in each neuronal population. The classification algorithm is based on a pattern recognition method with no initial membership defined for each individual cell. In female rats, an inverse frequency distribution of the intensities of CGRPLI was consistently observed when histograms from soleus and EDL-innervating motoneurons were compared: the strong CGRPLI was more frequent in the body of soleus-innervating motoneurons. When the same evaluations were done in male rats, the above mentioned clear-cut differences were not consistently observed. It is concluded that the type of motor units and/or metabolic state of the muscle fibers may influence the neuronal CGRP.

A SILVER-REDUCING AXONAL PROTEIN IN THE CENTRAL NERVOUS SYSTEM OF ADULT RATS. C.J.Tandler, A.Pellegrino de Iraldi* Instituto de Biología Celular, Facultad de Medicina, UBA. Paraguay 2155, (1121) Buenos Aires, República Argentina.

A selective "argentaffin" staining of nerve fibers after mercuric acetate postfixation was reported (20th Ann Meet Soc Neurosc, Abstract 28.9,1990). The technique (Hg-Ag) also stained specifically proteins within lateral components of triads and diads in striated muscle cells (Histochemistry 92:15,23, 1989). The axonal argentaffinity is dependent on both glutaraldehyde and mercuric ions. It is not suppressed after extraction of lipids, heating in 1N perchloric acid or incubation with alkaline phosphatase. Methylation of glutaraldehyde fixed tissues abolished the Hg-Ag reactivity indicating that carboxyl groups in protein are involved in the formation of the organic mercurial responsible for silver staining. The electron microscope shows that the silver-reducing protein localizes inside the axon. The procedure stained white and gray matter fibers in cerebrum, cerebellum and spinal cord but not the neuronal perikarya or their dendrites and proximal axons. In the cerebellum the basket cell axons were strongly reactive but not the parallel fibers. The possibility of the method to distinguish between functional stages of proteins in relation to cytotypic variations in cytoskeleton structures is suggested.

ANATOMICAL ORGANIZATION OF INTRINSIC NEURONS OF THE RABBIT TRACHEA

R.Hendriks, S.R.Knoper*, and D.L.Kreulen. Department of Pharmacology, College of Medicine, University of Arizona, Tucson, Arizona. 85724.

The mammalian trachea is likely to be under the efferent influence of both intrinsic and extrinsic neurons. Using a variety of neuronal markers, we have investigated the anatomy of intrinsic tracheal neurons of the rabbit. Individual trachea were variously labeled with *Neutral Red* (Sigma, USA) and antibodies to *Neuron Specific Enolase* (NSE) or *S-100* protein and were prepared for viewing either as wholemounts or tissue sections. All three markers clearly labeled intrinsic neurons of the rabbit trachea. The nerve cells were found to be organized into small ganglia containing less than ten cell bodies each. The ganglia were primarily between the cartilaginous rings and at the esophageal border. Most were found to lie at the surface of the tissue although occasionally ganglia could be found lying deep within the trachea. No clear plexus arrangements for these neurons were discernible. Individual fibers of some neurons could occasionally be followed to the mucosa. In conclusion, the intrinsic neurons of the trachea form a diffuse neural network that, accordingly, is likely to have a unique role in the functioning of this tissue. Support HL-46471.

CEREBRAL ATROPHY AND HYDROCEPHALUS IN CONTROL AND GANGLIONECTOMIZED SPONTANEOUSLY HYPERTENSIVE RATS. D. Livingstone, F. Hans, L. Wei, P. Brink*, J. DeMaro, W. Finnegan, and J. Fenstermacher. Dept. Neurological Surgery, SUNY, Stony Brook, NY 11794-8122.

The spontaneously hypertensive rat (SHR) is hypertensive, hyperactive, and hydrocephalic relative to Wistar-Kyoto rats (WKY). In young adults, glucose metabolism is lower in SHR than WKY and is elevated in SHR when one superior cervical ganglion is removed at 4 weeks of age. In view of these cerebral oddities, tissue volumes and neuronal density were measured in control, ganglionectomized (uGX), and sham-operated (sham) SHR and WKY. In control SHR the volume of the whole brain and of some areas was 5-10% less than in control WKY; ventricular (CSF) volume was nearly 2 times larger in SHR than WKY. Neuronal density was similar in control SHR and WKY. Relative to controls, the volumes of brain and all brain areas were 15-25% less in uGX and sham SHR as well as uGX and sham WKY. In both SHR and WKY, neuronal density in some areas tended to be less in uGX and sham rats. The uGX procedure at 4 weeks of age, but not ganglionectomy *per se*, seems to affect brain structure and function.

PHOSPHOTYROSINE-CONTAINING PROTEINS IN THE RAT BRAINSTEM AND SPINAL CORD. J.W. Unger*, W. Lange and J.N. Livingston[1]. Department of Anatomy, University of Munich, FRG, and [1]Department of Endocrinology University of Rochester, Rochester, NY 14642, USA.

The regulation of cell activity by a number of growth factor receptors and proto-oncogene products involves tyrosine kinases (TKs). The presence of phosphotyrosine-proteins (PY) is an index of the activity of Tks. Light- and electronmicroscopy demonstrated PY-immunoreactivity in numerous nuclei of the brainstem and spinal cord of the adult rat, including afferent and efferent nuclei, i.e. nucleus of the solitary tract, hypoglossal, lateral reticular nucleus, area postrema. Ultrastructural analysis revealed PY in the cytoplasm, in the perinuclear Golgi complex and at pre- and post-synaptic sites. Several receptor and cytosolic TKs may contribute to the PY-substrates, i.e. a high overlap was evident with the presence of insulin receptors. Our results suggest that protein tyrosine phosphorylation may play an important role for the regulation of neuronal function in the adult central nervous system. (Supported by the Walter-Schulz-Stiftung, NIH, and NATO Collaborative Research Grant).

BLOOD-BRAIN BARRIER I

476.1

PERMEABILITY COEFFICIENT-SURFACE AREA PRODUCTS OF THE BLOOD NERVE AND BLOOD BRAIN BARRIERS FOR NGF AND ALBUMIN. J.F. Poduslo,* G.L. Curran, and C.T. Berg. Molecular Neurobiology Laboratory, Departments of Neurology and Biochemistry/Molecular Biology, Mayo Clinic and Mayo Foundation, Rochester, MN 55905 USA.

Neurotrophic molecules will likely prove to be of importance in the treatment of neurodegenerative diseases of the peripheral and central nervous system. Although their administration to patients with Alzheimer's and other neurodegenerative diseases may represent a new era of treatment of these degenerative diseases, the development of a reliable, non-invasive, delivery system is clearly needed prior to the initiation of clinical trials. We have utilized the i.v. bolus injection technique in the catheterized brachial vein and artery of normal rats to quantify the permeability coefficient-surface area product (PS) for NGF across the blood nerve and blood brain barriers. The PS obtained for 2.5S NGF across the blood nerve barrier was $1.726 \pm 0.394 \times 10^{-4}$ ml/gm/second ($\bar{x} \pm$ S.D.). When compared to the PS for normal albumin (0.101 ± 0.088), a 17-fold increase was observed for NGF. Although a 5-fold M, difference exists between NGF and albumin, the PS for NGF was significantly higher suggesting a possible different mechanism of uptake into the nerve. Values obtained for different brain regions ranged from 12.7-32.5 fold higher for NGF compared to albumin. No changes were observed in the residual plasma volume for either the endoneurium or the different brain regions. Data will also be presented which suggest that selective modifications of NGF can enhance its permeability into the nervous system while still preserving biological activity of the protein. Such approaches might be useful in formulating a reliable delivery system of this and other neurotrophic factors for the potential treatment of Alzheimer's and other neurodegenerative diseases.

SATURABLE TRANSPORT OF TNFα ACROSS THE NEONATAL BBB. L.M. MANESS*, A.J. KASTIN, W.A. BANKS, and E.G. GUTIERREZ, Dept of Med and Neurosci Training Prog, Tulane Univ Sch of Med and VA Med Ctr, New Orleans, LA 70146.

The effects of tumor necrosis factor-α (TNFα) on the development of the CNS raise the possibility that circulating TNFα might enter the brain. We examined the blood-to-brain transport of recombinant murine TNFα across the blood-brain barrier (BBB) in 3 day old rat pups. ^{125}I-TNFα and ^{99m}Tc-albumin were injected IV, and the unidirectional influx constant (Ki) into the brain was calculated from the levels of radioactivity in the brain and blood. No entry of albumin was detected for the 30 min period tested, while the Ki for ^{125}I-TNFα was $8.12(10^{-4})$ ml/g-min. A 0.5 μg excess of unlabeled TNFα decreased the Ki to $0.79(10^{-4})$ ml/g-min, which represented an inhibition of over 90% of ^{125}I-TNFα entry [$F(2,7)=10.9$, $p<0.01$]. The excess TNFα, however, did not alter the brain/blood ratio of ^{99m}Tc-albumin (11.7±2.9 μl/g brain for controls vs 11.5±3.9 μl/g for excess TNFα). These results show that TNFα does not disrupt the neonatal BBB and support the existence of a blood-to-brain saturable transport system for TNFα in the neonatal rat.

476.3

THE IN VIVO TRANSPORT OF DOPAMINE AT THE LUMINAL SIDE OF THE BLOOD-BRAIN BARRIER IN GUINEA PIGS. C.L. Martel*, J.B. Mackic, M.H. Weiss, J.G. McComb and B.V. Zlokovic. Depts. Neurol. Surg. and Divn. Neurosurg. CHLA, USC Sch. Med., Los Angeles, CA 90033

Studies in animal models with high monoamine oxidase B (MAO-B) activity in cerebral microvessels have suggested that circulating dopamine (DA) is prevented from entering brain parenchyma by the enzymatic blood-brain barrier (BBB). In the present study, blood-brain DA transport is examined in an animal model with low BBB MAO-B activity - the guinea pig, Cavia porcellus, which in this respect is similar to humans. A vascular brain perfusion method [J.Neurochem. (1986) 46: 1444-1451] and a capillary depletion technique [J.Neurochem. (1990) 54: 1882-1888] were used to study BBB transport and/or binding of plasma derived DA. The initial rapid uptake (V_i), and rate of entry (K_{in}) of [^{3}H]-DA into the brain tissue were both found to be almost ten times higher than that of simultaneously infused [^{14}C]-sucrose, a metabolically inert cerebrovascular space marker. A substantial in situ DA binding to cerebral microvessels was also demonstrated. Brain uptake of [^{3}H]-DA (21 nM) was significantly inhibited in the presence of 500 nM unlabeled DA (by 49%); concentrations of 1-250 μM produced further inhibition (83%-92%). The D_2-receptor antagonist spiperone (25 μM) virtually abolished [^{3}H]-DA uptake, as evidenced by both brain homogenate and capillary-depleted tissue. In situ DA binding to cerebral microvessels was completely displaced by spiperone. The BBB DA transport and capillary sequestration were not affected by the MAO inhibitor pargyline (50 μM). These results suggest that DA is indeed transported across the BBB in guinea pigs by a specific MAO-independent mechanism. Brain uptake of circulating monoamine may be mediated by a capillary membrane D_2-receptor. (Supported by Childrens Hospital of Los Angeles grant 1102/3846).

476.4

OPIATES GIVEN DURING THE NEONATAL PERIOD ALTER THE BLOOD-BRAIN BARRIER TRANSPORT OF TYR-MIF-1. L.M. HARRISON*, A.J. KASTIN, and W.A. BANKS Dept of Med and Neurosci Training Prog, Tulane Univ Sch of Med and VA Med Ctr, New Orleans, LA 70146.

Tyr-MIF-1, a peptide with opiate-modulating properties, and Met-enkephalin are removed from the brain by a peptide transport system (PTS-1). Since morphine given during the neonatal period is known to alter opiate function, we examined whether PTS-1 was also affected. Neonatal rats were injected subcutaneously (SC) during the first week of life with either morphine sulfate (MS), MS+naltrexone (MS+Nal), MS+methyl naltrexone (MS+MNal), or vehicle at a dose for each drug of 50 μg/rat. On postnatal day 22, the brain-to-blood transport rate of ^{125}I-Tyr-MIF-1 was measured as previously described (Methods in Enzymology 168:652-660, 1989). Pups treated with MS had significantly smaller brain weights than controls ($p<.05$) or MS+MNal treated pups ($p<.001$). After correction for brain weight, transport of ^{125}I-TMIF-1 by PTS-1 in MS treated pups was over 21% faster than in control rats ($p<.01$) and 16% faster than in MS+MNal treated pups ($p<.05$). These results indicate that treatment with opiates during the neonatal period can affect the development of PTS-1.

476.5

BLOOD-BRAIN GLUTATHIONE TRANSFER IN GUINEA-PIGS OF DIFFERENT AGE. R.K. Kannan*, J.B. Mackic, N. Kaplowitz and B.V. Zlokovic. Dept. Neurol. Surg., Divns. Liver and GI Dis. and Neurosurg., CHLA USC Sch. Med., Los Angeles, CA 90033

Glutathione (GSH) is the major endogenous anti-oxidative agent in brain cells. Recently, it has been demonstrated that blood-brain transport of GSH may be of primary importance to preserve high levels of this cerebroprotective peptide in the central nervous system [J. Clin. Invest. (1990) 85: 2009-13]. In the present study, a vascular brain perfusion technique [J. Neurochem. (1986) 46: 1444-51] was used to examine blood-brain barrier (BBB) uptake of plasma-derived GSH in weanling (10 days) and 9 months old guinea-pigs. [^{35}S]-GSH (4 nM) was infused simultaneously with [^{14}C]-sucrose for 10 min, and blood-brain unidirectional transport rates (K_{in}) were estimated from uptake vs. time plots by single and/or multiple-time point graphic analysis. In weanling guinea-pigs, regional cerebrovascular permeability to GSH was 5 to 7 times higher than for sucrose. In older animals, however, there was no statistical difference between GSH and sucrose rates of entry into the brain. In both groups, K_{in} values for [^{14}C]-sucrose (cerebrovascular space marker) were comparable. Based on this preliminary evidence, it is suggested that blood-brain transport of GSH is guinea-pigs is lessened by aging possibly due to inefficient specific transport mechanism (Supported by VA funds).

GLUTATHIONE TRANSPORT ACROSS THE BLOOD-BRAIN BARRIER IN GUINEA-PIGS. J.B. Mackic*, M.N. Lipovac, R. Kannan, D. Tang, J.G. McComb, N. Kaplowitz and B.V. Zlokovic. Dept. Neurol. Surg., Divns. Liver and GI Dis. and Neurosurg., CHLA USC Sch. Med., Los Angeles, CA 90033

Glutathione (GSH) cerebroprotective function(s) involve detoxification of xenobiotics, reduction of hydrogen peroxide and lipid peroxides, and maintenance of thiol-disulfide status of brain cells. Although brain is rich in GSH, GSH level becomes significantly reduced under certain pathologic conditions (e.g., cerebral ischemia, focal seizures). Thus, strategies for GSH central delivery are of obvious therapeutic potential. The presence of GSH-specific blood-brain barrier (BBB) transporter that is independent of gamma-glutamyl transpeptidase (GGT), has recently been suggested in rats [J. Clin. Invest. (1990) 85: 2009-13]. In this study, we used the guinea-pig model with high BBB GGT activity to re-examine transport of circulating [^{35}S]-GSH across the BBB. Brain uptake index (BUI) technique confirmed original data in rats by demonstrating regional BUI values of 19.9% to 28.1% relative to [^{3}H]-water standard. GSH BUIs were not affected by 5 mM serine-borate (GGT inhibitor). Vascular brain perfusion technique [J. Neurochem. (1986) 46: 1444-51] revealed that regional rates of GSH blood-brain entry were 4-6 times higher relative to simultaneously infused sucrose (cerebrovascular space marker). There was no significant capillary sequestration of circulating GSH, but the uptake of [^{35}S]-GSH (4 nM) was abolished by 1.5 mM unlabeled tripeptide. HPLC analysis demonstrated that more than 95% of plasma-derived GSH in the brain was in its original form after a 10 min perfusion. It is concluded that intact GSH is transported across the BBB in guinea-pigs, by a mechanism that may be similar to that previously described in rats. (Supported by VA funds).

EXPRESSION OF THE mRNA FOR THE BASIC AMINO ACID TRANSPORTER (SYSTEM Y+) AT THE BLOOD-BRAIN BARRIER. I. Stoll*, K. C. Wadhwani and O. R. Smith
Laboratory of Neuroscience, National Institute on Aging, Bethesda, MD 20892.

Basic amino acids (Lys, Arg and Orn) are transported into brain from blood by a Na-independent, saturable carrier at the blood-brain barrier (BBB). The carrier is stereospecific and exhibits a Km for L-lysine of approx. 70μM. Recently, the cell-surface receptor for ecotropic murine retroviruses was shown to be a basic amino acid transporter with similar selectivity and affinity attributes (Wang et al., Nature (1991) 352, 729). To determine if the same protein is expressed at the BBB, transporter mRNA expression was assessed in purified rat brain capillaries and compared to expression in whole rat brain, brain parenchyma (brain minus capillaries) and desheathed rat sciatic nerve. We designed oligonucleotide primers based on the published sequence of the ecotropic retroviral receptor and used them to generate a cDNA from mouse brain total RNA by polymerase chain reaction. Partial sequence analysis of the amplified cDNA showed identity with the published sequence. Expression of the transporter mRNA in rat brain and peripheral nerve was observed by both Northern blot analysis or by RNAse protection, with the highest level observed in capillaries (greater than 10-fold higher than whole brain). These results suggest that the ecotropic murine retrovirus receptor may be the basic amino acid carrier of the BBB.

476.8

STRUCURE-ACTIVITY STUDY OF HIGH-AFFINITY NEUTRAL AMINO ACID TRANSPORT ACROSS THE BLOOD-BRAIN BARRIER. O. R. Smith*, Y. Takada, and N. Greig. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892.

Large neutral amino acids are transported from blood into brain by a saturable carrier at the blood-brain barrier (BBB). This carrier exhibits many of the properties of the amino acid "L System" including sodium-independent, BCH-inhibitable transport. Previous studies from our laboratory have identified several high affinity drugs that are also taken up into brain by this mechanism. In the present study we examined structure-activity relations for two series of drugs in order to better understand the molecular factors that influence binding and transport. Brain uptake was measured in pentobarbital-anesthetized rats using the in situ brain perfusion technique (Takasato et al., 1984). As previously reported for the natural, endogenous amino acids (Smith et al., 1987), transport affinity ($1/K_m$) for amino acid drugs was critically influenced by side chain hydrophobicity. However, other factors contributed as well, including the nature and location of side groups. For example, placement of a nitrogen mustard at the 7-position of 2-amino-1,2,3,4-tetrahydro-2-naphthoic acid enhanced affinity by >30 fold (K_m ~0.2 μM). In contrast, transfer of the same group to the 5-position or movement of the amino acid group to the 1-position reduced affinity by > 90%. Comparable differences were seen for structural analogues of phenylalanine, including melphalan and meta-L-sarcolysine. V_{max} varied among compounds and was quite low for some analogues. The results demonstrate that amino acid transport capacity and affinity are critically influenced by solute structure and that careful positioning of hydrophobic side groups can markedly enhance delivery to brain.

476.9

AMINO ACID TRANSPORT INTO MEMBRANE VESICLES ISOLATED FROM THE BLOOD-BRAIN BARRIER. M.M. Sánchez del Pino, R.A. Hawkins* and D.R. Peterson, Dept. Physiology and Biophysics. Univ. Health Sci./Chicago Med. Sch., North Chicago, IL 60064.

Luminal and abluminal membranes from bovine brain endothelial cells were separated on Ficoll gradients. The membranes formed sealed vesicles that were adequate for transport studies. Transport of N-(methylamino)-isobutyrate (MeAIB), a specific substrate of the A-system, and L-phenylalanine were studied in both membrane populations. Luminal vesicles showed a high affinity transport system for L-phenylalanine that was independent of Na^+ and H^+ gradients and inhibited by other large neutral amino acids, including D-phenylalanine; it was not inhibited by MeAIB. In contrast, abluminal vesicles contained a Na^+-dependent phenylalanine transport system that was inhibited by MeAIB. Similarly, uptake of radiolabeled MeAIB was stimulated by a Na^+ gradient in abluminal vesicles, whereas no significant effect of a Na^+ gradient was observed in luminal vesicles. The results provide direct evidence for the presence of the Na^+ dependent A-system exclusively in the abluminal membranes of the BBB. The data are consistent with the location of an L-type system in both membranes.

RECEPTOR-MEDIATED TRANSCYTOSIS THROUGH THE BLOOD-BRAIN BARRIER (BBB): FERRO-TRANSFERRIN AND ITS RECEPTOR. R. Broadwell, B. Baker, P. Friden, M. Tangoren and A. Wolf*. Div. of Neurosurgy, Univ. Maryland Sch. Med., Baltimore, MD 21201 and Alkermes, Inc., Cambridge, MA 02139

The potential for receptor-mediated transcytosis of ferro-transferrin (fTRF) and antibody against its receptor through BBB endothelia was investigated in Sprague Dawley rats. TRF, a blood-borne peptide, conveys iron to tissues and cells. BBB endothelia exhibit the receptor for fTRF on the luminal surface. Rats were injected into the carotid artery with fTRF conjugated to HRP (6mg/0.5ml; 1-3hrs) or intravenously with native HRP (50mg/0.5ml; 1hr), HRP-conjugated or non-conjugated antibody to the fTRF receptor (0X26; 200-700ug/ 0.5ml; 5mins-6hrs) and to Major Histocompatibility Complex Class I (0X27; 210ug/0.5ml; 6hrs) against the PVG rat strain; the latter antibody and native HRP were employed as controls. Non-conjugated antibodies were identified immunohistochemically. fTRF-HRP, each of the antibodies, and native HRP labeled BBB endothelia, perivascular phagocytes and pial surface macrophages. fTRF-HRP and OX26-HRP were seen ultrastructurally within perivascular clefts; fTRF-HRP only was observed in cells of the neuropil; OX26-HRP only was localized in saccules of the Golgi complex in BBB endothelia. Native HRP and OX27 labeling of perivascular and pial surface phagocytes occurs through extracellular routes circumventing the BBB. Potential transcytosis of blood-borne fTRF-HRP and OX26 through the BBB very likely occurs, but the exact intracellular pathways are elusive. Supported by NIH grant #NS18030.

IN VIVO LABELING OF BRAIN MICROVASCULAR TRANSFERRIN RECEPTORS USING COLLOIDAL GOLD-ANTITRANSFERRIN RECEPTOR ANTIBODY-COMPLEXES. J. Yang, U. Bickel, T. Yoshikawa, H. Weiner*, and W.M. Pardridge, Departments of Medicine and Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The transferrin receptor (TfR) is highly expressed at the plasma membrane of brain microvascular endothelial cells, which form the blood-brain barrier (BBB) in vivo. A monoclonal antibody to the rat TfR, OX26, has recently been evaluated as a model of brain transport vectors for drugs unable to pass through the BBB. Transcytosis of OX26 and OX26-drug conjugates could be demonstrated in pharmacokinetic studies, and OX26 was successfully used for brain delivery of a vasoactive intestinal peptide analog, resulting in a pharmacological response (increased cerebral blood flow).

To obtain ultrastructural information about the in vivo transcellular trafficking of OX26 at the BBB, a direct receptor labeling study with 5 nm-colloidal gold/OX26 complexes was performed. The complex was infused for 10 min into anesthetized Sprague-Dawley rats via the internal carotid artery (about 200 μg OX26/rat). Immediately after the end of the infusion, the animals were perfusion fixed via the ascending aorta with 2% glutaraldehyde. Vibratome and semithin sections of the brain were silver enhanced and examined at the light microscopic level. A widespread staining of brain capillaries was found. Selected regions were subsequently processed for transmission electron microscopy. A pattern of gold particles at the lumenal membrane of endothelial cells and intracellular clusters of gold particles in defined cytoplasmic compartments resembling endosomes was seen. In conclusion, this study presents a novel approach to in vivo receptor labeling and ultrastructural analysis.

PRESYNAPTIC MECHANISMS VI

477.1

A GABA-T BLOCKER SELECTIVELY ENHANCES PRESYNAPTIC INHIBITION. H. Golan and Y. Grossman*. Unit of Physiology, Faculty of Health sciences, Ben-Gurion University of the Negev, Beer-Sheva, 84105, Israel.

Blockers of GABA transaminase (GABA-T) elevate GABA concentration in the nervous system and increase convulsive threshold. In order to determine how administration of a GABA-T blocker influences synaptic transmission, we studied the effect of ethanolamine-O-sulfate (EOS), an irreversible blocker, on spontaneous and evoked PSPs in the opener muscle of the crayfish walking leg. EPSPs and IPSPs were recorded intracellularly; corresponding single axons were stimulated separately. EOS (1 mM) was applied to the cut end of the nerve in a suction electrode. Picrotoxin (0.05 mM) caused an increase in R_m by 24.7% (n=7) indicating tonic GABA release. EOS had no effect on R_m (n=3) and did not alter reversal potential or conductance of IPSPs. Inhibition was tested by delivering a short train of stimuli to the inhibitory axon 0-70 ms before evoking EPSPs. In 7 of 12 cells EOS enhanced inhibition by 15-60% without changing the time course of EPSP decay. In cells not sensitive to EOS, control inhibition was also weak. The data suggest that the predominant effect of the GABA-T blocker is to selectively enhance presynaptic inhibition.

477.2

GAP JUNCTIONS MEDIATE SELF AMPLIFICATION OF AFFERENT SIGNALS IN CRAYFISH. D. Cattaert, A. El Manira, F. Clarac*. CNRS NBM, 31 Chemin Joseph Aiguier BP 71, 13402 Marseille CEDEX 9 FRANCE.

Sensory information plays an important role in the control of motor behaviour. Nevertheless the strength of sensory-motor loops fluctuates during motor tasks. The modulation of reflexes not only involves neurones that are postsynaptic to the afferents, but sensory cells themselves, either at the periphery by neuromodulators that modify their sensitivity, or centrally by presynaptic inhibition. We present here evidences for a new type of presynaptic control of sensory afferents that involves electrical coupling between sensory terminals. This study has been achieved in the crayfish walking system in *in vitro* experiments. Sensory terminals from the coxo-basipodite chordotonal organ, were intracellularly recorded in the central neural network in the proximity of their synaptic endings. Paired recordings demonstrate electrical coupling between sensory terminals. The analysis of dye coupling (Lucifer Yellow) between those terminals by confocal microscope reveals large close apposition sites. The functionnal role of sensory coupling is discussed taking into account the enhancement of synaptic transmission from sensory terminals by subthreshold depolarizations, such as those produced by spikes in coupled terminals. By this mechanism only meaningfull sensory messages would be effectively transmitted.

ANALYSIS OF PRIMARY AFFERENT INPUT.TO RAT DORSAL HORN
S. Jeftinija*, Lj. Kojic, T.-H. Chen and L. Urban[1]. Dept. Vet. Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011, USA; Laszlo Urban, MD, Ph.D., [1]Present address, Sandoz Institute for Medical Research, Gower Place, London WC1E 6BN, UK.

Horizontal spinal cord slice preparation with attached dorsal root (DR) and dorsal root ganglion (DRG) was used to study the functional interaction of different afferent fibers at DH neurons. Brief perfusion of 50mM potassium to the DRG depolarized large sensory neurons (29±2.2 mV, mean ±SEM, n=32) and blocked firing of AP. Simultaneous intracellular recording from superficial DH neurons revealed that in cells receiving input from both small and large fibers, excitatory postsynaptic potentials (EPSP) evoked by electrical stimulation of large myelinated afferents (10-20V, 0.02ms) were selectively blocked during high potassium perfusion. Bath application of TTX (0.2-10μM) to the DRG blocked electrically-evoked APs in large DRG neurons and consequently EPSPs in DH neurons. Depolarizing effect of high potassium on DRG neurons and excitatory effect on DH neurons was not blocked by TTX. During this potassium-induced increased activity in DH neurons, EPSPs evoked by stimulation of small unmyelinated fibers were potentiated. Our data suggest that in large DRG neurons with TTX sensitive Na channels high K evoked depolarization inactivates the fast Na-current and blocks AP generation. As TTX resistant Na channels require higher levels of depolarization C-cells remain active in the presence of high K and maintain synaptic input to the DH. This difference could be responsible for the selective activation of C afferent fibers by high K which produced EPSPs in the spinal cord. This hypothesis is further supported by the finding that when Na ions in the DRG bathing media were totally removed in the presence of TTX, both high K and electrical activation of afferents were without effect on DH neuron. Work was supported by NIH Grant NS27751.

477.4

PURIFICATION OF β-LEPTINOTARSIN-h BY IMMUNOAFFINITY CHROMATOGRAPHY. R.D. Crosland*, T.H. Hsiao¶, and B.C. Lidgerding#. Toxinology Div. and #Virology Div., U.S. Army Med. Res. Inst. Infec. Diseases, Frederick, MD 21702 and ¶Biol. Dept., Utah State Univ., Logan UT 84322.

β-Leptinotarsin-h (β-LPT-h) is a proteinaceous toxin(s) that promotes Ca++ influx and neurotransmitter release at mammalian presynaptic nerve terminals. To date, the most purified preparations of β-LPT-h have been demonstrably heterogeneous. Our goal was to further purify β-LPT-h by immunoaffinity chromatography.

We immunized Balb/C mice with the heretofore most purified preparation of β-LPT-h. Monoclonal antibodies were generated by cell fusions with SP2/0 parent myeloma cells. Antibodies of interest were located by determining the ability of antibody + protein G-Sepharose to remove ^{45}Ca++ uptake activity from solutions containing β-LPT-h. We found four activity-binding antibodies, one of which (2C3-1-1) we chose for further study. 2C3-1-1 bound to only 80% of the activity in the preparation used for immunization, revealing the presence of at least two immunologically distinct Ca++ uptake activities. Column chromatography of β-LPT-h with 2C3-1-1 coupled to Affi-Gel 10 and subsequent SDS-PAGE chromatography revealed two bands of 55 kD and 60 kD.

THE EFFECT OF CALCIUM AND SODIUM ON THE EXTRACELLULAR CONCENTRATION AND RECOVERY OF DOPAMINE USING QUANTITATIVE MICRODIALYSIS. A.D. Smith* and J.B. Justice, Jr., Department of Chemistry, Emory University, Atlanta, Georgia, 30322.

The point of no net flux method was used to study the effects of varying the sodium (Na^+) and calcium (Ca^{2+}) concentrations (conc.) in artificial cerebrospinal fluid (CSF) on the in vivo probe recovery and extracellular conc. of dopamine (DA) in the nucleus accumbens of the rat. Anesthetized animals were implanted with 20 gauge guide cannula in the nucleus accumbens at coordinates AP +3.4, ML +1.5 from bregma and DV -7.2 from dura. The night prior to the experiment a 2 mm microdialysis probe was inserted and perfused with artificial CSF at 0.2 μl/min. On test day, dialysate samples were collected at 20-minute intervals and injected on a smallbore HPLC system. Samples were analyzed until stable levels of DA were obtained, after which time, depending on the experiment, the perfusate was changed to an artificial CSF solution containing 0, 1.2, 3.0, 5.0 or 7.2 mM Ca^{2+} or 0, 72.5, 145, or 217.5 mM Na^+. Each ionic conc. was run with 0 and 50 nM DA (n = 4 or 5). Linear regression was performed at each ionic conc. to obtain the extracellular DA conc. and probe recovery. The results indicate that DA increases with increasing Ca^{2+} conc. from 0 to 46.1 nM at 6.7 nM DA/mM Ca^{2+} and decreases with increasing Na^+ conc. from 18.3 to 1.8 nM at -0.07 nM DA/mM Na^+. There was no effect of Na^+ on recovery. However, the effect of Ca^{2+} on recovery was complex. Above physiological Ca^{2+}, the recovery tended to decrease, whereas below there was an increase in the recovery. Linearity of the method was confirmed using 0, 1.25, 2.5, 5, 10, 12.5, 25 and 50 nM DA in a separate group of animals (n = 12).

477.6

ELECTRICAL STIMULATION REPROGRAMS THE METABOLIC AND SYNAPTIC PHENOTYPES OF CRAYFISH MOTONEURONS. P.V. Nguyen* and H.L. Atwood. MRC Group in Nerve Cells & Synapses, Department of Physiology, Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

Can impulse activity in motoneurons determine metabolic efficacy? Using Rhodamine-123 (Rh) as a supravital, mitochondria-specific fluorochrome, we compared the mitochondrial activities and synaptic physiology of crayfish tonic and phasic abdominal motoneurons. Tonic flexor motoneurons showed greater activity-dependent resistance to synaptic depression than phasic extensor motoneurons. Axonal mitochondria from the former showed significantly higher mean Rh fluorescence intensities than did the phasic axons' mitochondria (as measured using confocal microscopy). Mitochondrial metabolic inhibitors (dinitrophenol, azide, CCCP) induced synaptic depression in tonic axons and reversibly abolished the Rh fluorescence of their mitochondria, suggesting that Rh fluorescence signals metabolic competence. In vivo stimulation of an identified phasic motoneuron significantly increased both neuromuscular synaptic stamina and mean axonal mitochondrial Rh fluorescence. Axotomy prior to conditioning stimulation abolished both changes. Thus, there exists a direct correlation between mitochondrial metabolic capacity and synaptic stamina in single living motor axons, while imposed electrical activity reshapes both metabolic and synaptic performance.

ELECTROGENIC Na-K PUMP IN SYMPATHETIC PRE-GANGLIONIC FIBRES IN BULLFROG LUMBAR SYMPATHETIC CHAIN. T.Hashiguchi[1], M.Hashiguchi[1], T.Tosaka[1] and A.L.Padjen[2]*. [1]Dept. of Physiology, Tokyo Medical College, Tokyo, Japan and [2]Dept. of Pharmacology and Therapeutics, McGill University, Montreal, Qc, Canada.

Excitability of nerve terminals in vertebrate nervous system is difficult to study in a direct way. We have used the sucrose gap technique applied on the sympathetic chain to measure membrane potential of preganglionic terminals of bullfrog sympathetic ganglia (X segment). A switching amplifier (T.Hashiguchi, Pflueg.Arch.406:540,1986) was used for simultaneous current injection and potential measurement.

Injection of a current pulse (200 - 400 ms) was followed by biphasic hyperpolarizing afterpotential (HAP) only after voltage displacement reached threshold for action potentials generation. HAP was unaffected by d-tubocurarine (10 μM) or atropine (1 μM), and thus not likely result of endogenous acetylcholine release. Removal of extracellular sodium (choline replacement), but not of Ca^{++} or Cl^-, abolished the HAP. Na,K-pump blockers (3-10 μM ouabain, Na-free lithium Ringer) as well as Na-azide blocked the HAP generation; however, 2,4-DNP (0.1 mM) only depressed it. Addition of cesium (.2 - 5 mM) caused a conc dependent increase in HAP amplitude (> 250%; 110% at ED_{60} of .7 mM Cs) and duration and slowing of the rate constant (control: 0.039/sec ± .014, n=12; 2 mM Cs: 0.017/sec ± .0024, n=4), more than could be explained by a depression of inward rectification. HAP was not accompanied by changes in membrane conductance.

These results suggest that HAP in preganglionic terminals results from activation of an electrogenic pump. (This work was supported in part by MRC and DHRC)

ALTERNATIVE SOLUTIONS OF AXONAL IMPULSE PROPAGATION INTO A LARGER-DIAMETER REGION. M.D. Goldfinger*, Dept. of Physiology & Biophysics, Wright State University, Dayton, OH 45401-0927.

Impulse propagation was simulated for unmyelinated axons whose diameter changed from 1 to 2-10 μm. The 1-dimensional cable equation was solved with a finite-difference discretization (1). The spatial integration step (Δx=3 μm) was constant; hence, the electrotonic step Δx/λ was geometry-dependent (2). The Hodgkin-Huxley equations (3) defined excitability. First-order differential equations were solved numerically with a second-order method which averaged the forward (explicit) and backward (implicit) Euler integrations over very small time steps (e.g., Δt = 0.1 μs) kept constant during each run (4). No predictor/corrector methods were used. The H&H temperature parameter was 10°C. It was assumed that Na, K, and leak maximal conductances and reversal potentials were geometry-independent. The point-to-point conduction velocity [CV(x)] was computed from the time of the action potential peak (T) at any point: $CV(i) = \Delta x/(T_i - T_{i-\Delta x})$ (2,4).

A single impulse propagated from the 1 μm-diameter region into a region with diameter d=2-10 μm. In the 1-μm region and within 200 μm of the diameter expansion, CV(x) changed axially: first increased, then slightly decreased, and finally increased at the expansion to a maintained value θ(d), where: $\theta(d) = \theta_{d=1}\sqrt{d}$. Impulse amplitude and duration were basically unaffected by the diameter expansion (cf 5). The CV(x) pattern was paralleled by axial changes in maximal negative membrane current density.

The CV(x) pattern with diameter expansion was due entirely to the decrease in axial load, since: (1) the pattern was duplicated in uniform-diameter axons with a reduction of internal resistivity instead of a diameter expansion; (2) the pattern reverted to a step change of CV(x) at the diameter expansion if the electrotonic step in the expanded region equalled that of the smaller-diameter region. Correcting the discretization for non-uniform diameter did not affect the result (6). However, the CV(x) pattern was sensitive to Δt and to inappropriate discretization.

MODULATION OF LOCAL ANESTHETIC BLOCKADE IN SINGLE FIBERS BY ACTIVATION OF NEIGHBORS IN PERIPHERAL NERVE. S.A. Raymond*, S.C. Steffensen, J.G. Thalhammer and G.R. Strichartz. Anesthesia Research, Brigham & Women's Hospital, Boston, MA 02115.

Single axonal units from isolated frog sciatic nerves recorded via suction electrodes were stimulated with current pulses (1.5-3 times the tonic threshold for the recorded unit) during exposure of the nerve to stable concentrations of the local anesthetic lidocaine, [lido]. At [lido] just below the concentration needed to produce "tonic" conduction failure for above-threshold stimuli at rates $\leq$0.5 Hz, units conducted impulses at a slowed velocity but with 100% fidelity. Increasing the number of neighboring units also firing to each stimulus by increasing the stimulus current by a factor of 10 further slowed the conduction velocity, or CV, in 28 of 28 fibers studied, and led progressively to a full block of conduction. The impulse slowing began after the first impulse at the tenfold intensity and then progressively increased over about 30 s. Slowing or block also persisted for at least 30 s after the stimulus intensity was returned to control. No cumulative increase in latency nor failure was observed without lidocaine. Instead, the tenfold stimulus intensity with [lido] = 0 increased the CV by about 10% (reduced latency by 0.3-0.5 ms).

The recovery time for latency to return to the tonic latency, recorded prior to the tenfold increase in stimulus intensity, depended on the number of stimuli given at the higher intensity. If the intensity was maintained at the high level, activating more neighboring fibers, then the slowing or block was likewise maintained. Repeated activation of conditioning bursts of 8 impulses at tenfold intensity produced conduction failure that persisted for more than 30 min. The cumulative slowing and block was observed only for fibers near blocking concentration since in cases where multiple fibers were recorded, the ones not near block did not slow when the intensity was increased. Because of the 30 s accumulation and recovery times and because of a transient increase we observed in the CV after tetanic conditioning, which is known to result in post-tetanic hyperpolarization, we attribute the modulation of block to a potentiation of lidocaine binding by a depolarization of the affected axon by its activated neighbors, possibly resulting from increased extra-axonal potassium.

A NOVEL TARGET OF NITRIC OXIDE-STIMULATED ADP-RIBOSYLATION.
L.G. Hammerland*, A.M. Ferro and B.M. Olivera. Dept. of Biology, Univ. of Utah, Salt Lake City, UT 84112

Nitric oxide (NO) has been implicated as a retrograde messenger necessary for the induction of long-term potentiation (LTP). Although it is not understood how NO acts in this pathway, the two known physiological effects of NO are the activation of a soluble guanylate cyclase and the stimulation of an ADP-ribosyltransferase that targets a group of 39-42 kDa proteins which are found in many tissues, including brain. Here we report the identification and partial characterization, in a neural preparation, of a novel target of NO-stimulated ADP-ribosylation.

Because NO likely acts via presynaptic mechanisms, the membrane-associated targets of NO-stimulated ADP-ribosylation were identified using a biochemical model of the synapse, a presynaptic membrane fraction isolated from electroplax of *Torpedo californica*. ADP-ribosylation (using ^{32}PNAD as the ADP-ribose donor) of *Torpedo* presynaptic membranes resulted in the labeling of several proteins. However, the ADP-ribosylation of just one protein (apparent Mr = 110 kDa) was enhanced in the presence of the NO-generating compound sodium nitroprusside. This enhancement of ADP-ribosylation by nitroprusside was dose-dependent and was blocked by calcium. Furthermore, the 110 kDa protein was photoaffinity labeled by 8-azido-GTP, suggesting that the target of NO-stimulated ADP-ribosylation also binds guanine nucleotides. These results suggest that the NO-stimulated ADP-ribosyltransferase and its 110 kDa target protein may modulate synaptic transmission.

INTERLEUKIN-1β (IL-1β) INHIBITS SYNAPTIC TRANSMISSION IN THE BASOLATERAL AMYGDALA (BLA). B-J.Yu, D.G.Rainnie and P.Shinnick-Gallagher*. Dept. of Pharmacology, Univ. of Texas Medical Branch, Galveston, TX 77555

IL-1β, a cytokine, has central actions including anticonvulsant activity. We analyzed IL-1β effects on synaptic transmission using intracellular recording in the rat BLA, a nucleus involved in limbic epilepsy. In the BLA, stimulating the stria terminalis (ST) or lateral amygdala (LA) elicits excitatory postsynaptic potentials (EPSPs) and fast- and slow-inhibitory postsynaptic potentials (f-and s-IPSPs) via both feed-forward and direct pathways. The ST- and LA-evoked EPSPs were reversibly depressed by IL-1β (2 ng/ml). F- and s-IPSPs evoked by stimulating the ST and LA were also reduced or completely blocked suggesting direct and indirect effects on GABAergic transmission. Furthermore, the reversal potential for the IPSP was not altered by IL-1β. Analysis of input-output relationships indicated that the inhibitory effect of IL-1β on synaptic transmission was not overcome by increasing the stimulus intensity. We tested whether IL-1β inhibition was due to a pre- or post-synaptic action by applying agonists exogenously. Muscimol responses were not altered by IL-1β suggesting presynaptic inhibition of the f-IPSP. Responses to AMPA were slightly decreased but the ST- and LA-evoked EPSPs were decreased to a greater extent; IL-1β effects on AMPA responses were not reversible. These data suggest that IL-1β inhibits excitatory and inhibitory transmission at a presynaptic site and provide evidence that IL-1β, a mediator of the immune response, has an inhibitory effect on synaptic transmission in CNS neurons. Furthermore, these results suggest that the BLA nucleus may be a neuronal substrate for interactions between the immune and central nervous systems.(supported by NS 29265).

ENDOGENOUS ADENOSINE MEDIATES NEUROMUSCULAR DEPRESSION WITHOUT AFFECTING CALCIUM CURRENTS IN THE FROG. R.S. Redman* and E.M. Silinsky. Dept. Pharm., Northwestern Univ. Med. School., Chicago Illinois, 60611.

Studies at normal levels of acetylcholine output have suggested that at selected nerve endings, a proportion of presynaptic neuromuscular depression in frog is mediated by adenosine released by active neuromuscular junctions (Meriney & Grinnell, J. Physiol 443:441-455). Under such conditions, presynaptic facilitation occurs concomitantly with depression, thus partly obscuring the action of adenosine. In addition, Ca currents cannot be measured, precluding an investigation as to mechanism of depression. We have found that simultaneous measurements of Ca currents and quantal ACh release may be made in normal Ca solutions with the addition of 3,4, diaminopyridine (DAP, 100 μM) to block a proportion of K currents in the motor nerve. In this study we examined the contribution of endogenous adenosine to evoked ACh release and Ca currents in the frog cutaneous pectoris muscle in Ringer containing DAP, using fast flow methods for the rapid application of adenosine receptor reagents to the neuromuscular junction. Nerve stimulation at 0.1 Hz causes a gradual decrease in ACh release that is consistently and rapidly reversed by the selective adenosine receptor blocker 8-cyclopentyltheophylline (CPT, 1 μM) or by adenosine deaminase (5 i.u.). The normal inhibitory effect of adenosine or 2-chloroadenosine is occluded during synaptic depression. All of these effects occur without changes in perineural Ca currents. The results suggest that endogenous adenosine mediates neuromuscular depression by a mechanism unrelated to changes in Ca entry. This work was supported by NIH grants T32 NSO7140 and R01 NS12782.

EXTRACELLULAR MESSENGERS PRODUCED BY ECTO-PROTEIN KINASE IN DEVELOPING NEURONS. H. Yang, M.V. Hogan and Y.H. Ehrlich*. CSI/IBR Ctr. Dev. Neurosci. CUNY at Staten Island, NY 10301 and the Biology Doctoral Program of CUNY Graduate School.

Ecto-Protein kinase (ePK) utilizes extracellular ATP to phosphorylate proteins localized at the external surface of the neuronal plasma membrane. To determine the role of ePK in neuronal development, we investigate primary neurons cultured from the telencephon of 7-day chick embryos. Phosphorylation reactions are carried out with cells attached to 48-well plates. For ePK assays we add [γ-^{32}P]ATP (0.1μM; 15μCi per well) and incubate for 10 min. To label intracellular proteins an equivalent dose (15μCi per well) of inorganic ^{32}Pi is added. We found that two proteins with apparent MW of 11.7K and 13K became rapidly phosphorylated upon addition of [γ-^{32}P]ATP to the medium, but were not labeled at all even after 1-2 hrs incubation with ^{32}Pi. These proteins have been identified as exclusive substrates of ePK. The extracellular phosphorylation of these proteins was found to peak at the onset of rapid neuritogenesis. In the present study, attached cells were rinsed three times with Krebs-Ringer buffer just prior to the ePK reaction, to remove all soluble components. Immediately after 10 min incubation with [γ-^{32}P]ATP, the medium was separated from the attached cells and spun at 1000 x g/5 min. A soluble fraction was prepared from this supernatant by high speed centrifugation (150,000 xg/90 min). The 11.7K and 13K phosphorylated substrates of ePK were found in the soluble fraction. Thus, during the extracellular phosphorylation reaction these phosphoproteins *detach* from the cell surface. In developing neurons this process may provide a unique, novel means of communication: a signal sent from growing neurites to target neurons, and/or for interaction with components of the extracellular matrix.

478.1

AMINO ACIDS REQUIRED FOR FAST Na^+ CHANNEL INACTIVATION.

J.W. West[1], D.E. Patton[2], T. Scheuer[1], A.L. Goldin[2], and W.A. Catterall*[1]. [1]Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195 and [2]Dept. of Microbiology and Molecular Genetics, Univ. of California, Irvine, CA 92717.

Previous work with site-directed and cut mutants has shown that the intracellular peptide loop between homologous domains III and IV (LSP 19) of the rat brain Na^+ channel α subunit may function as the inactivation gate. To further resolve the role of LSP 19 in inactivation, we constructed Na^+ channel cDNAs encoding extensive changes in the amino acid sequence of LSP 19 and analysed their effects by expression in oocytes and in mammalian cells. The results of the experiments presented here show that charged amino acids in LSP 19 are not essential for inactivation of the channel. Mutations of charged residues caused only small increases or decreases in inactivation rate. Rapidly inactivating Na^+ currents are recorded in oocytes expressing mutant Na^+ channels with 10 of the 12 basic amino acids and 2 of the 3 acidic amino acids substituted with glutamine. In contrast, substitution of three contiguous nonpolar amino acids within LSP 19 removes fast inactivation when expressed in oocytes. Furthermore, substitution of a single phenylalanine with glutamine removes most of the fast inactivation. Na^+ currents were also recorded in mammalian cells expressing the phenylalanine mutation. Single channel recordings from cell-attached patches on these cells reveal rapid transitions between open and closed states which continue throughout 100 ms depolarizations indicating nearly complete removal of inactivation. Slow inactivation is retained. Further analysis of the gating properties of these mutant Na^+ channels lacking fast inactivation is in progress.

478.2

BIPHASIC MODULATION OF SODIUM CHANNELS BY PHOSPHORYLATION AT TWO DIFFERENT SITES.

Randal Numann, James W. West, Ming Li, Raymond D. Smith†, Alan L. Goldin†, Todd Scheuer*, W.A. Catterall. Dept. of Pharmacology, U. of Washington, Seattle, WA; †Dept. of Microbiology & Molecular Genetics, U. of California at Irvine, Irvine, CA.

Phosphorylation of the voltage-dependent rat brain sodium channel by protein kinase C (PKC) has 2 effects: 1) Inactivation of the current is slowed and 2) Peak currents are reduced. We have previously shown that both effects are blocked by mutation of serine to an alanine in a PKC consensus site in the conserved intracellular loop between homologous domains III and IV of the α subunit (Numann et al, Science 254:115, 1991; West et al, Science 254, 866, 1991). Here we report that although phosphorylation at this site is necessary for both effects, a second site is also involved. Modulation by the protein kinase C activator 1-oleoyl-2-acetyl-*sn*-glycerol (OAG) was studied using cell-attached patches from Chinese hamster ovary cells stably expressing the rat brain type IIA sodium channel α subunit (CNaIIA-1 cells; West et al, Neuron 8, 59, 1992). Dose-response experiments showed that the slowing of inactivation saturated near 40 μM OAG whereas the reduction in peak current continued until doses of 70 to 80 μM OAG (n=44). Low concentrations of OAG (<10 μM) often produced slowing of inactivation with no reduction in peak current (n=8). These data suggested the involvement of at least two separate PKC phosphorylation sites. To identify the second site, we screened consensus PKC phosphorylation sites in the cytoplasmic loop connecting homologous domains I and II of the sodium channel α subunit. Mutation of serine to alanine at one site in this loop eliminates sodium current reduction by OAG but slowing of inactivation is unaffected (n=12). Similar mutation of a nearby phosphorylation site had no effect. The PKC system appears to cause biphasic modulation of sodium channels. Phosphorylation of serine 1506 by itself causes slowing of inactivation. Additional phosphorylation at a second site in the intracellular loop between domains I and II causes a reduction in peak sodium current.

478.3

CONVERGENT REGULATION OF BRAIN SODIUM CHANNELS BY CAMP-DEPENDENT PROTEIN KINASE AND PROTEIN KINASE C.

Ming Li*, James W. West, Todd Scheuer, William A. Catterall. Dept. of Pharmacology, U. of Washington, Seattle WA 98195

Direct application of the catalytic subunit of cAMP-dependent protein kinase (cA-PK) and ATP to the cytoplasmic surface of rat brain Na channels in excised inside-out membrane patches reduces channel activity. Protein kinase C (PKC) phosphorylation of Ser1506 in the conserved intracellular loop between domains III and IV of the α subunit slows inactivation and allows reduction of channel activity by phosphorylation at another site in the loop between domains I and II (Numann et al, preceding abstract). Since phosphorylation at Ser1506 is necessary but not sufficient for reduction of Na current by PKC, we examined whether it might also control reduction of channel activity by cA-PK. Na current recorded in 14 macro-patches excised from Chinese hamster ovary cells stably expressing Type IIA sodium channels with the mutation Ser1506Ala were unaffected by application of cA-PK and ATP. Application of cA-PK and ATP to 6 patches containing wild-type channels reduced the current by 40% in the same series of experiments. The reduction in wild-type channel activity by cA-PK cannot be due to phosphorylation at Ser1506 since: 1) this site is not phosphorylated by cA-PK in biochemical experiments and 2) phosphorylation at this site by PKC causes only slowing of inactivation. Evidently, phosphorylation of Ser1506 by PKC is necessary for reduction of Na channel activity by phosphorylation of a second site by cA-PK. The PKC consensus site at ser1506 was converted to a cA-PK consensus site by conversion of Lys1507 and Lys1508 to Gln. In contrast to wild-type, Na currents are slowed and reduced by cA-PK and ATP. The effects of cA-PK are similar to PKC in wild-type and consistent with the conclusion that phosphorylation of Ser1506 by PKC slows Na channel inactivation and regulates the reduction of Na channel activity by both PKC and cA-PK.

478.4

MUTAGENESIS OF THE RAT BRAIN SODIUM CHANNEL PROTEIN KINASE A PHOSPHORYLATION SITES.

R.D. Smith* and A.L. Goldin, Dept. of Microbiology & Molecular Genetics, U. California, Irvine, CA 92717.

We have previously demonstrated that induction of protein kinase A (PKA) in *Xenopus* oocytes results in an increase in sodium currents expressed from the rat brain type IIa sodium channel clone. We have now used site-directed mutagenesis to determine if the current enhancement by PKA was the result of direct phosphorylation of the sodium channel α subunit. The rat IIa channel has five consensus PKA phosphorylation sites located in the linker region between domains I and II. Phosphorylation at these five sites was either eliminated by replacing the serine residues with alanine, or was mimicked by replacing the serines with aspartates. All five of the serine to alanine substitutions resulted in functional channels in oocytes, with variable levels of current. The voltage-dependent properties and inactivation kinetics of all of the mutants were similar to that of the wild-type channel. All five of the mutant channels also showed some current enhancement following PKA stimulation, but the magnitude of the effect was quite variable and depended on the specific mutation. Four of the five serine to aspartate mutants have thus far been expressed and are similar to the wild-type channel in preliminary experiments. When all five PKA sites were replaced with alanine in a single mutant, however, the level of current was less than 100 nA, at least 1000 fold lower than that seen with the wild type sodium channel. This result implies that phosphorylation at some subset of the PKA sites is necessary for normal sodium channel function in *Xenopus* oocytes. To test whether phosphorylation at any single PKA site is sufficient for normal levels of current, each of the consensus sites in the composite mutant was reverted back to the original wild-type sequence. These mutants are currently being analyzed. Finally, we are examining a composite mutant with all five serines replaced by aspartates to test whether a negative charge at each position is sufficient for normal sodium channel function.

DEDUCED AMINO ACID SEQUENCE OF A PUTATIVE SODIUM CHANNEL FROM THE JELLYFISH *CYANEA CAPILLATA*.

Robert M. Greenberg*, Molly A. Holman and Peter A.V. Anderson, Whitney Laboratory, Univ. of Florida, St. Augustine, Fl 32086.

The Na^+ channel in *Cyanea* is a Na^+ channel physiologically but a Ca^{++} channel pharmacologically. Using PCR with degenerate primers based on conserved sequences from other Na^+ channels, we isolated a 900bp product with high sequence homology (60% identity) to known Na^+ channels. This fragment was used to probe a Northern blot of *Cyanea* mRNA, resulting in specific labelling of a 8.5kb band. Additional fragments of this putative Na^+ channel have now been obtained and sequenced, yielding a single open reading frame of 4.3kb. Residual portions at the 3' and 5' ends of the cDNA are currently being isolated. The deduced amino acid sequence from this cDNA shows high sequence homology with other Na^+ channels (35-45% identity, 76% conservation) particularly in the transmembrane spanning regions.

Scrutiny of this cDNA in regions corresponding to the verapamil binding site of Ca^{++} channels and the TTX binding site of Na^+ channels reveals important clues as to the amino acids involved in binding these important channel blockers.

Supported by NSF grant BNS-9109155 to PAVA and funds from the Univ. of Florida DSR.

478.6

CLONING AND SEQUENCE OF A PUTATIVE SQUID SODIUM CHANNEL cDNA AND A PROPOSED TERTIARY STRUCTURE MODEL.

C.Sato and G.Matsumoto* Electrotechnical Laboratory, Tsukuba, Ibaraki 305, Japan

With polymerase chain reaction and recombinant DNA techniques, we have cloned DNA complementary to RNA which seems to encode a sodium channel protein of the optic lobe of squid Loligo bleekeri. The total number of amino acid residues deduced from the cDNA is 1,522, about three-fourths of that of rat brain I, II and III (each being about 2,000) and an even greater proportion in eel (1,820). The estimated molecular weight of the squid sodium channel protein is 174,105 dalton. The squid sodium channel is basically quite similar to those of vertebrates, and consists of four domains I, II, III and IV, each containing five hydrophobic segments (S1, S2, S3, S5 and S6), one characteristic segment with strong positive charge (S4), and short intervening sequences. Both a negative charge and a positive one in S2, and a negative charge in S3 as well, are entirely conserved at identical positions in all the domains; but only 3 positive charges are serially repeated at every third position in II-S4. On the basis of the amino acid sequence data, we propose a tertiary structure model of the squid sodium channel.

478.7

CLONING AND CHARACTERIZATION OF *tip-E* GENE. L. M. Hall*, G. Feng, J. Pursey Lee, P. Deak and E. R. Reynolds. Department of Biochemical Pharmacology, SUNY at Buffalo, Buffalo, NY 14260.

The *tip-E* mutation is an ethylmethane sulfonate-induced recessive mutation which shows a temperature-sensitive paralytic phenotype. Biochemical and electrophysiological studies showed that *tip-E* is associated with reduced binding of saxitoxin to sodium channels and decreased sodium current density. These data suggest that *tip-E* affects the function or regulation of sodium channels. We have induced a chromosome deletion/translocation which gives same phenotype as *tip-E* and have cloned a genomic fragment containing the *tip-E* gene based on the chromosome deletion/translocation breakpoint. Northern analysis showed that this genomic region contains 4 different mRNAs (2.0, 3.2, 4.0, and 5.2 kb). A cDNA clone corresponding to the 4 kb mRNA was sequenced. It encodes a novel protein of 452 amino acids with two putative hydrophobic regions. We believe this is the *tip-E* gene because it is disrupted in the deletion/translocation which gives the *tip-E* phenotype. In addition, the sequence of genomic DNA from *tip-E* mutants showed a single nucleotide change resulting in a stop codon in the region corresponding to the open reading frame of the cDNA. This change would cause premature termination of the 4 kb mRNA encoded protein. Transformation experiments are in progress to determine whether the genomic fragment encoding the 4 kb mRNA can rescue the *tip-E* phenotype.

The SkM2 Na^+-Channel Gene Is Expressed In Rat Dorsal Root Ganglia L.M. Donahue*, K.A. Moffatt and N. Sueoka[1]. Dept. of Cell Biol. and Anat., Texas Tech Univ. H.S.C. Lubbock, TX 79430; [1]Dept. of Mol., Cell. and Dev. Biology, University of Colorado, Boulder, CO 80309.

Previous work by our laboratories has shown that SkM2 is the predominant Na^+-channel gene expressed by the neuronal derivatives of the RT4 cell line family. Since the RT4 family was derived from a rat peripheral neurotumor, our results presented the possibility that the SkM2 Na^+-channel gene might be important *in vivo* in the rat PNS. In addition our findings suggested that the RT4 system may derive from dorsal root ganglia (DRG) since small cell neurons from rat DRG have tetrodotoxin (TTX) resistant Na^+-current and the only known Na^+-channel gene thought to encode a TTX-resistant channel is the SkM2 gene. We are pursuing two lines of investigation: the first to ask whether SkM2 is expressed *in vivo* in rat DRG and the second to ask whether other markers of small cell DRG neurons are expressed by the RT4 neuronal cell types. We have examined the expression of SkM2 from newborn rats by RNase protection assay and detect low levels of SkM2 mRNA. We are currently in the process of examining DRG by *in situ* hybridization histochemistry to determine which DRG cell type(s) express SkM2. We have also determined that the RT4 neuronal derivatives do not express the three neurofilament proteins, as is the case for small cell DRG neurons. Small cell DRG neurons express the intermediate filament protein peripherin and we are presently examining whether the RT4 neuronal derivatives express peripherin.

478.9

ALTERED RELATIVE EXPRESSION OF TWO HUMAN BRAIN SODIUM CHANNEL mRNAS IN PATIENTS WITH EPILEPSY. A. J. Lombardo*, C. M. Lu, R. Kuzniecky and G. B. Brown. Psychiatry and Behavioral Neurobiology, Neurology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Voltage-gated sodium channels are important contributors to the intrinsic excitability properties of CNS neurons. The aim of this study was to determine whether the relative expression of human brain sodium channel (HBSC) subtypes I and II is altered in epileptic brains compared to those of normal controls. Previous studies have shown that the ratio of these two subtype mRNAs varies markedly between different normal brain regions along the neural axis, but for a given region the value is generally consistent between individuals (Lu *et al.*, FEBS Lett., in press).

Epileptic tissue was obtained at surgery from patients undergoing treatment for intractable seizures. Postmortem tissues matched for brain region, age and sex were used as normal controls. Following RNA extraction, the relative amounts of type I and II sodium channel mRNA was compared in these tissues using a modification of the ligase detection reaction as described previously (Lu *et al.*, FEBS Lett., in press). This protocol, combining high sensitivity and high specificity, proves useful for measurements of highly homologous messages such as HBSC I and II, since specificity is provided at the level of single nucleotide differences.

Compared to normal postmortem controls, the data reveal an increased range of the I:II ratio in epileptic tissues, with moderate relative increases in HBSC I-specific transcripts. Additionally, a I:II ratio of 0.43 was determined for normal temporal lobe, a region not previously characterized with respect to sodium channel mRNA expression. These results suggest a potential correlation between epileptic activity and alterations in the expression of subtypes I and II of the human brain sodium channel. Moreover, these results may lend insight into the control of neuronal excitability and its contribution to the state of hyperexcitability in epileptic tissue.

478.10

PORE-FORMING REGIONS ON VOLTAGE-SENSITIVE POTASSIUM AND SODIUM CHANNELS SHARE A COMMON SECONDARY STRUCTURAL MOTIF TARGETED BY STRUCTURALLY SIMILAR SCORPION TOXINS. John A. Schetz*, Department of Neuroscience and The Whitney Laboratory of the University of Florida, Gainesville, Florida 32610.

Secondary structure within the putative S5-S6 pore-forming regions of voltage-sensitive K^+ and Na^+ channels was compared and quantified with a statistical metric (SHC (C) version 6.10). The metric predicts that the α-scorpion toxin receptor region mapped to IS5-IS6 on rat brain II Na^+ channel and the charybdotoxin receptor region mapped to S5-S6 on the *Shaker* A K^+ potassium channel are structurally similar (overall fit = 92%), even though their amino acid sequences are sparingly homologous (18%). The striking secondary structural similarity between K^+ channel and Na^+ channel sequences in comparable S5-S6 regions demonstrates that scorpion peptide toxins target structurally similar channel receptor sites. This result, in combination with the fact that the peptide ligands, charybdotoxin and α-scorpion toxin Aa II, are themselves structurally similar (Bontems *et al* (1991), *Science*, 254, 1521-1523), invites the hypothesis that venomous peptide ligands of comparable structure bind "pore"/receptor regions of comparable structure.

478.11

BIOCHEMICAL EVIDENCE THAT THE TTX-INSENSITIVE SODIUM CHANNEL IN THE JELLYFISH *CYANEA CAPILLATA* IS A HIGH MOLECULAR WEIGHT PROTEIN WHICH BINDS THE CALCIUM CHANNEL BLOCKER AZIDOPINE. Peter A. V. Anderson* and John A. Schetz, Dept. of Neuroscience and the Whitney Laboratory, Univ. of Florida, 9505 Ocean Shore Blvd., St. Augustine, Florida 32086.

Previous electrophysiological studies of neurons from the jellyfish *Cyanea capillata* (Anderson (1987), *J. Physiol.*, 396, 86P) revealed the presence of a fast Na^+ current which is completely insensitive to the classic Na^+ channel blocker, TTX, but it is blocked by the L-type Ca^{++}-channel blockers known as dihydropyridines (DHP). Since *Cyanea* Ca^{++} currents are insensitive to DHPs, this unusual combination of channel pharmacology in *Cyanea* allowed biochemical analysis of the *Cyanea* Na^+ channel. Isolated membranes from nerve-rich tissue in *Cyanea* were digitonin-solubilized, applied to an azidopine affinity column and eluted with drug. Column eluates were concentrated, then size fractionated by SDS-PAGE. Silver staining revealed a distinct protein band with an molecular weight of approximately 200 KDa only in column fractions eluted with a concentrated DHP solution. This size is consistent with that deduced from a putative Na^+ channel cDNA isolated from *Cyanea*.

Special thanks to Dr. H. Glossman for providing Azidopine. Supported by NSF grant BNS 9109155 (PAVA).

NEUROANATOMICAL DISTRIBUTION AND BINDING CHARACTERISTICS OF SAXITOXIN SITES IN THE RAT AND TURTLE CNS. Y. Xia* and G.G. Haddad. Dept. of Pediatrics, Section of Respiratory Medicine, Yale Univ. Sch. Med., New Haven, CT

Although the literature on saxitoxin (STX) binding in the CNS is abundant, there is little data on the neuroanatomical distribution and STX binding properties in various brain nuclei. In the present study, we examined in detail the saturation profiles of STX binding at several CNS levels using a broad concentration range of ^{3}H-STX (up to 64 nM) and mapped STX sites at low (2 nM) and high (15 nM) concentrations of ^{3}H-STX. Since the density of STX binding sites (Na^+ channels) may be an important factor that determines resistance to anoxia, we also compared rat to turtle CNS. We found that 1) Scatchard plots were linear with Kd values around 5 nM for a number of areas including most cortical areas; 2) in some nuclei, especially in the brainstem, these plots showed an increase followed by a decrease in Bound/Free Versus Bound; 3) STX binding density was heterogeneous at both binding concentrations with a much higher density in rostral areas than in the brainstem; and 4) saturation patterns in the turtle brain were similar to those of the rat, but STX binding density was much lower (several to 10 fold) than in the rat. We conclude that a) STX binds mainly to a high affinity site and b) positive cooperativity occurs with STX binding in some areas. Since previous results from this lab have shown that Na^+ plays an important role during anoxia, we speculate that low binding density in the turtle brain may be partly at the basis of its hypoxic tolerance.

478.13

DEVELOPMENT OF THE SODIUM CHANNEL HIGH AFFINITY SAXITOXIN (STX) RECEPTOR IN RAT BRAIN. R. Villegas, C. Castillo, M. E. Póo, S. Schnell, C. Piernavieja, D. Balbi and G. M. Villegas*. Instituto Internacional de Estudios Avanzados (IDEA), Apartado 17606, Caracas 1015A, Venezuela.

The course of Na channel (NaC) gene transcription in Wistar rat forebrain was followed by measuring the levels of total NaC mRNA and types I, II and III NaC mRNAs, utilizing cDNA probes. Embryos (E) and postnatal (P) rats were studied. Total NaC mRNA increases steadily from E15 up to a maximun level at P14 (100%), declining then smoothly up to P90 (≈65%). Measurements of types I, II and III in E15, P0 and P15 reveal that: II, the most abundant, increases steadily up to P15 (100%); I increases after birth (10% of II at P15), and III increases until birth (21% of II at P15) and then declines. The amount of high affinity STX receptors, measured with ^{3}H-STX, rises to a plateau with a similar course to that observed for the total NaC mRNA, with some delay in the rising phase. Maximum binding (B_{max}) in pmoles/g wet weight and K_D in nM, determined in 200 mM NaCl (pH 7.4), are: 2.6 and 38.3 for E15; 26.3 and 3.1 for P0; 145.1 and 3.3 for P15. The STX affinity of batrachotoxin-modified NaC from E15, P0 and P15, incorporated into lipid bilayers in the same NaCl solution, was studied; the K_D(0 mV) in nM is 31.9 for E15; 9.9 for P0, and 3.9 for P15. Our results provide new information on the development of the high affinity STX/TTX receptor of rat brain Na channels.

Supported by research grants S1-2179 (C.C.) and S1-2180 (R.V.) from CONICIT, Venezuela; and donations from Prof. Betty G. Uzman, Fundación Polar and Fundación Pro Ciencia.

EFFECTS OF SCORPION VENOM, SEA ANEMONE TOXIN, GRAYANOTOXIN, AND DELTAMETHRIN ON TETRODOTOXIN-SENSITIVE AND TETRODOTOXIN-RESISTANT SODIUM CHANNELS. Mary-Louise Roy* and Toshio Narahashi, Dept. of Pharmacology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Dorsal root ganglion neurons acutely dissociated from 3-12 day old rats express TTX-sensitive (TTX-S, K_D~1 nM) and TTX-resistant (TTX-R, K_D~100 μM) sodium channels, which have been shown to differ in their biophysical and pharmacological properties. Leiurus quinquestriatus scorpion venom and sea anemone toxin ATX-II (1-100 nM) exerted no significant effects on TTX-S and TTX-R currents. Tissue dissociation procedures (collagenase-dispase, papain, trypsin, and mechanical dissociation) were systematically examined, each generating the same results. The binding region(s) of both toxins may thus be absent in these channels. α-Dihydro-grayanotoxin (GTX) and deltamethrin, however, each exerted differential effects on TTX-S and TTX-R channels. GTX (100 nM-10 μM) shifted TTX-S channel activation voltage slightly (-2.5 ± 4.1 mV, n=6), without affecting reversal potential. TTX-R current activation was minimally affected (-3.5 ± 4.3 mV, n=8) whereas the reversal potential was dramatically shifted (-17.9 ± 9.1 mV). Deltamethrin (1-100 nM), a type II pyrethroid, shifted activation and reversal potentials of the TTX-S current, without a significant effect on tail current. TTX-R tail current, however, was greatly prolonged, with τ_{slow} values of greater than 10 seconds. The differential properties of the TTX-R and TTX-S sodium channels continue to be of interest in CNS development and drug interactions. Supported by NIH grants F31 MH09839 and R01 NS14143.

DIFFERENCES IN THE NEUROEXCITATORY ACTIONS OF SODIUM CHANNEL SPECIFIC NEUROTOXINS IN RAT AND TROUT BRAIN SYNAPTOSOMES. J. T. Eells*, K. A. Pleyte, J. L. Rasmussen and P. A. Holman. Dept. of Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI 53226.

The effects of pyrethroid insecticides and other sodium channel specific neurotoxins on synaptosomal membrane potential were investigated in rat and trout brain synaptosomes using a membrane permeant, lipophilic cation [^{3}H]-tetraphenylphosphonium (TPP+). Concentration-dependent and tetrodotoxin-sensitive decreases in TPP+ accumulation indicative of membrane depolarization were produced by aconitine (Acn), veratridine (Vtd), scorpion (*Leiurus quinquestratus*) venom (ScV) and type I and type II pyrethroids in both species. Acn, Vtd and ScV were more potent and efficacious membrane depolarizing agents in rat synaptosomes than in trout synaptosomes. Type II (deltamethrin, cypermethrin and fenvalerate) pyrethroids produced similar depolarizing responses in rat and trout synaptosomes, however, the *1R,cis,αR* isomer of deltamethrin which had no effect on membrane potential in rat synaptosomes depolarized trout synaptosomes. In addition, the type I pyrethroid, permethrin, exhibited significantly greater efficacy in trout synaptosomes producing a maximal estimated membrane depolarization of 14 mV compared to 5 mV in the rat. These results provide evidence of interspecies differences in the membrane depolarizing properties of several sodium channel specific neurotoxins and suggest that some of the neurotoxin binding domains of the voltage-sensitive sodium channel in trout brain differ from those in mammalian brain. The hypersensitivity of fish to the neurotoxic actions of pyrethroid insecticides may be related to these differences. (ES05006 and ES01985)

THE SODIUM CHANNEL MARKS NEUROELECTROGENESIS IN EPILEPTIC MICE Hatch D.J., Smart M.L., Esplin M.S., Mouritsen C.L., & Litzinger M.J.* Depts. of Pediatrics and Physiology. University of Utah. SLC, Ut. 84132

Neuroelectrogenesis is the initiation of electrical activity in the central nervous system. Our study uses the sodium channel marker saxotoxin (STX) to follow the development of this ion channel in Swiss Webster (non-epileptic) and DBA (audiogenic seizure) mice. In 1972 ,Hafemann and Unsworth used tetrodotoxin, which also lables the sodium channel,to mark a critical period in the sodium spike generating system of Swiss Webster mouse brain. This critical period , postnatal days 10-15 ,corresponds to an increase in cortical width & weight, the maturation of dendritic spines for synapse formation and the onset of electrical activity (Himwhich, 1962). Hafemann and Unsworth concluded that the sodium channel was necessary though not sufficient for action potential propagation. Prior studies from this lab have shown differences in voltage sensitive calcium channel development between Swiss Webster and DBA mice during the critical period (Esplin, et. al., 1991).

Susceptibility of the DBA mice to seizure is greatest at juvenile ages (days 16-21) and dissipates thereafter. Data comparing binding of ^{3}H -STX in Swiss Webster and DBA mice on postnatal days 8 and 16, the critical period , show an increase in both groups. Swiss Webster shows a 33% increase; DBA shows a 20% increase. Hafemann & Unsworth showed a drastic increase (two fold) in tetrodotoxin binding during this time frame. Preliminary data in the DBA audiogenic seizure mice suggest a gradual increase in sodium channel development between days 3-16. This study suggest a difference in soudium channel development which may underlie the basic mechanism of audiogenic seizures. (This work was supported in part by NIH grant # HD00886.)

EFFECT OF SODIUM CHANNEL MODULATING DRUGS ON LOSS OF EPSPs FROM HYPOXIA/HYPOGLYCEMIA IN RAT HIPPOCAMPAL SLICES IN VITRO. C.P. Taylor* and M.L. Weber. Parke-Davis Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

Previous studies with phenytoin, lidocaine and tetrodotoxin in various models of ischemia have shown neuroprotection, suggesting the involvement of voltage-sensitive sodium channels in ischemic brain damage. We investigated this hypothesis with several modulators of voltage-sensitive sodium channels using rat hippocampal slices under conditions that mimic ischemia. Hippocampal slices were incubated under control conditions and then subjected to a 12-min period of "ischemia" from deprivation of oxygen and reduction of D-glucose from 10 mM to 2 mM. This treatment caused a loss of synaptic potentials over 2-5 min and a sudden negative shift in extracellular voltage corresponding to loss of ion homeostasis after about 8 min. Return of normal medium failed to recover EPSPs in any of 36 control experiments.

However, treatment with phenytoin (20 or 50 μM), lidocaine (50 or 100 μM), carbamazepine (50 μM), or verapamil (10 μM) significantly delayed the onset of negative voltage shifts and increased the number of slices that recovered EPSPs. These neuroprotective effects were seen at drug concentrations that did not alter presynaptic action potential amplitude, indicating that sodium channels were modulated but not blocked. Nimodipine at a concentration (1 μM) that modulates L-type voltage-sensitive calcium channels, had no effect. These results suggest that modulation of voltage-dependent sodium channels by anticonvulsant or local anesthetic drugs may be beneficial for treatment of cerebral ischemia.

IMPAIRED Na CHANNEL INACTIVATION PRODUCES MYOTONIA IN RAT SKELETAL MUSCLE. S. C. Cannon* and D. P. Corey, Department of Neurology and Howard Hughes Medical Institute, Massachusetts General Hospital, Boston, MA 02114.

The myotonias are a group of heritable muscle disorders that share the common phenotype of delayed relaxation after contraction due to enhanced electrical excitability of the muscle membrane. Several forms of myotonia have recently been postulated to arise from a defect in the inactivation of the Na current. In myotubes cultured from patients with a myotonic form of hyperkalemic periodic paralysis, a small elevation in extracellular [K] causes about 5% of the defective channels to gate in a non-inactivating mode (**Neuron** 6:619, 1991). We used both an *in vitro* assay and a theoretical model to test whether this degree of impaired Na channel inactivation was sufficient to cause myotonia.

Partial impairment of Na channel inactivation was obtained by applying a toxin from *Anemonia sulcata* (ATXII) to excised fast twitch fibers from the rat hindleg. With 10 μM ATX II, unitary Na currents recorded from bleb-attached patches had an average Popen of 0.02 in steady-state. With this degree of inactivation failure, twitch relaxation was slowed ten-fold and trains of repetitive discharges were elicited by 300 msec steps of current injection. Myotonic discharges continued after the end of the current injection. Detubulation by osmotic shock abolished the after-discharges which suggests they are driven by T-tubular K accumulation. Computer simulation predicted myotonic behavior when 1-2% of the Na channels fail to inactivate, and paralysis by depolarization block with ≥4%.

ANTIMYOTONIC ACTIVITY AND USE-DEPENDENT BLOCK OF SKELETAL MUSCLE Na^+ CHANNELS BY ENANTIOMERS OF TOCAINIDE AND MEXILETINE. A. De Luca*, C. Franchini, V. Tortorella, S.H. Bryant and D. Conte Camerino. Depts. of Pharmacobiology and Pharmacochemistry, Fac. of Pharmacy, Univ. of Bari, Italy and Dept. of Pharmacol. and Cell Biophysics, Univ. of Cincinnati, USA.

The use dependence of class I antiarrhythmic drugs, as tocainide, is related to high affinity receptor interaction during slow inactivation states of Na^+ channels (De Luca et al, Naunyn-Schm., 344: 596, 1991). In mammalian muscle cells this receptor has been described to be stereospecific (Tricarico et al., Pflügers Arch, 418: 500, 1991). To clarify the role of stereospecificity in the use-dependence of these drugs, the ability of enantiomers of tocainide and mexiletine to solve abnormal membrane excitability was evaluated "in vitro", by means of two intracellular microelectrodes technique, on rat extensor digitorum longus (EDL) muscle, made myotonic by previous incubation with 50μM anthracene-9-carboxylic acid (9AC), and on external intercostal muscle fibers from congenitally myotonic goats.On rat EDL, 30μM R(-) tocainide complitely antagonized the 9AC induced hyperexcitability, whereas 50μM S(+) inhibited only by 25% the myotonic repetitive firing. On the other hands, 50μM of R(-) and S(+) mexiletine inhibited 9AC hyperexcitability by 70% and 60%, respectively. On myotonic goats, 10μM R(-) tocainide fully restored normal membrane excitability, whereas 100μM S(+) was almost uneffective. These compounds were also tested on Na^+ currents recorded from frog semitendinosus muscle fibers by means of triple Vaseline gap voltage clamp. External application of 500μM of either R(-), S(+) and RS tocainide blocked Na^+ currents by 25-50%. Similarly, both enantiomers of mexiletine had an IC50 of about 300μM. Either enantiomers or racemates of tocainide and mexiletine were strongly use-dependent, i.e. they further cumulatively reduced peak Na^+ current (up to 50-70%) upon repetitive stimulation at 2Hz frequency. The present data suggest that the presence of a weakly stereospecific receptor (as in frog muscle), does not impair the use-dependence of Na^+ channel blockers. However, the presence of highly stereospecific site, as in mammals, modulates use dependence of drugs with pronounced stereoselectivity, as tocainide and this might have important therapeutical implications. (Granted by CNR 91.00226 and Telethon-Italy, 1991).

SODIUM CHANNEL BLOCKADE AND ANTICONVULSANT ACTIVITY OF SUBSTITUTED 2-AMINOBENZOTHIAZOLES. Sheryl J. Hays*, Michael J. Rice, Daniel F. Ortwine, Graham Johnson, Roy D. Schwarz, Denise K. Boyd, Laura C. Rodolosi and Peter A. Boxer. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor, MI 48105.

Modulation of sodium channels is a mechanism shared by the clinically useful anticonvulsants, phenytoin and carbamazepine. Riluzole, 2-amino-6-(trifluoromethoxy)benzothiazole was reported to be a potent anticonvulsant agent which initially was believed to function via a glutamatergic mechanism. Recent evidence suggests that riluzole is exerting its activity by a direct blockade of voltage-dependent sodium channels.

To understand the potential of 2-aminobenzothiazoles to function as anticonvulsants, a series of 4-, 5-, and 6-aryl-substituted benzothiazoles have been examined for their ability to inhibit sodium flux. Many of the compounds were found to be potent inhibitors of veratridine-stimulated influx of sodium into rat neocortical slices. A quantitative structure-activity relationship study has been completed on this set of benzothiazoles and suggests a trend toward increased potency with increasing lipophilicity, decreasing substituent size, increasing electron withdrawal capacity, and the absence of a 4- or 5-substituent. These compounds were further examined for anticonvulsant activity in a maximal electroshock (MES) model in mice. Anticonvulsant activity (as well as ataxia at higher doses) was observed in all potent sodium flux inhibitors.

SODIUM CHANNEL BINDING ACTIVITIES FOR DIPHENYLHYDANTOIN ANALOGS. M.L. Brown, W.J. Brouillette, G.B. Brown*, Departments of Chemistry , Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, AL 35294.

The anticonvulsant 5,5-diphenylhydantoin (Phenytoin or DPH) binds to the neuronal voltage-sensitive sodium channel in a voltage- and frequency dependant manner. Specific binding occurs at physiologically relevant concentrations, suggesting that the sodium channel may be an anticonvulsant "receptor site" for DPH. Previous studies from this laboratory suggested that the DPH binding site may require a specific phenyl ring orientation. We have been interested in determining an optimum phenyl ring orientation and possible stereoselective preference for this site. In order to investigate these possibilities, we have synthesized several spirocyclic hydantoins (general structure I) which restrain the 5-phenyl ring to different angular relationships with the hydantoin ring. Increased binding occurred for compounds able to adopt a phenyl ring orientation relatively "coplanar" to the hydantoin ring. The sodium channel binding activities for some enantiomers showed modest selectivity.

SPECIES DIFFERENCES IN THE PARANODAL DISTRIBUTION OF SODIUM CHANNELS. M.A. Ferguson, S. Tinkle, J.D. England, A. Koszowski, S.R. Levinson* Departments of Neurology and Physiology, University of Colorado, Denver, Colorado 80262.

A polyclonal antibody was raised against rat skeletal muscle sodium channel (M1 isotype) amino acid residues 1306-1324, a conserved sequence among all known vertebrate sodium channel isotypes. The specificity and high titre of these antibodies permit their reliable use with Western blot, RIA, and immunocytochemistry in a wide range of excitable tissues from fish and mammals. Using these site-directed antibodies for immunocytochemistry, we have demonstrated specific immunoreactivity (IR) at the nodes of Ranvier in both goldfish lateral line nerve and mouse sciatic nerve. In mouse sciatic nerve, but not goldfish nerve, we also observed specific IR on the paranodal myelin. Confocal microscopy demonstrates that this specific IR is patchy but localized to the outer loops of the paranodal myelin. These observations suggest that in mice sodium channels are present in paranodal myelin as well as at the nodes of Ranvier, whereas in fish sodium channels are present only at nodes. Thus, a species difference may exist for the presence of sodium channels within Schwann cells - myelin.

478.23

CHANGES IN THE DISTRIBUTION OF SODIUM CHANNELS DURING ACUTE TOXIC AXONAL INJURY. F. Gamboni, J.D. England, M.Ferguson, S.R. Levinson, Warren Wickelgren* Departments of Neurology and Physiology, University of Colorado, Denver, Colorado 80262.

Potassium tellurite (K_2TeO_3) is a neurotoxin known to cause acute demyelination in the peripheral nervous system of many experimental animals. When 3 ug of this agent is injected intraneurally into the posterior lateral line nerve of goldfish, demyelination is followed by profound axonal degeneration in the segment of nerve distal to the site of injection. The proximal segments of these nerves were analyzed on days 4,7,10,15, and 21 postinjection by both immunocytochemical and RIA methods, using an antibody specific for the sodium channel molecule (NaCh) in fish nerve. These studies showed a transient increase (0.5 to 5 fold compared to normal nerves) in the concentration of NaCh in the proximal nerve segments between days 7 to 10 postinjection. Furthermore, the immunocytochemistry showed that NaChs accumulated in the axolemma immediately proximal to the site of the lesions. These findings support the theory that NaChs in peripheral nerve are synthesized primarily in the neuronal perikaryon, transported down the axon, and then inserted into the axolemma.

COMPARISION OF THE FUNCTIONAL PROPERTIES OF HUMAN AND RAT NEOCORTICAL SODIUM CURRENTS.

T.R. Cummins[1*], Y. Xia[2] and G.G. Haddad[1,2]. [1]Interdepartmental Neuroscience Program and [2]Dept. of Pediatrics, Yale Univ. Sch. Med., New Haven CT 06510.

Rat and human brain sodium channels have a high degree of homology, but it is not clear how rat and human channels compare in terms of expression and function. We therefore studied the functional properties and STX-binding characteristics of sodium channels in adult human, adult rat and neonatal rat neocortex using whole-cell voltage clamp of acutely dissociated pyramidal neurons and quantitative autoradiography.

Adult human and rat neurons were very similar in terms of Na^+ current properties and current density (~700 and 1000 pA/pF, respectively), while neonatal rat neurons had a significantly lower current density (< 200 pA/pF). The STX binding site density was 10 fold lower in rat neonatal neocortex than in adult human and rat neocortex. In human and rat neocortex, only a single, high-affinity STX binding site was found in both neonatal and adult tissue (Kd ~ 4 nM). Data from our laboratory has shown that the sodium channel density in the adult rat brainstem is 3 fold lower than that found in adult rat neocortex. We conclude that, while in the rat significant regional and maturational differences are found in sodium channel density, human and rat adult neocortical sodium currents are similar in terms of function and level of expression.

NON-INACTIVATING, TTX-SENSITIVE Na^+ CONDUCTANCE IN RAT OPTIC NERVE AXONS: POSSIBLE PHYSIOLOGICAL AND PATHOLOGICAL ROLES. P.K.Stys*, H.Sontheimer, B.R.Ransom, S.G.Waxman. Dept. Neurology, Yale School of Medicine, New Haven, CT, 06510.

Sodium channels provide the rapid depolarization underlying axonal action potentials. Classical channel kinetics dictate that these channels quickly and completely inactivate at depolarized potentials, contributing to rapid termination of the action potential. We have used the *in vitro* rat optic nerve (RON) as a model to study the ionic mechanisms of anoxic injury in central myelinated axons. Anoxic injury in the RON is critically dependent on Na influx via a TTX-sensitive Na conductance. However, conventional Na channels should be inactivated at the depolarized membrane potentials that occur in anoxic tissue. We therefore hypothesized that a non-inactivating Na conductance must exist, which mediates pathological Na fluxes during anoxia. To test this prediction, we studied RONs with a modified grease gap technique. The recorded DC potential is a reliable fraction of true compound axonal resting potential (Vm), behaving as a linear function of trans-gap impedance. Nerves were studied at rest ([K]o=3mM) and at two levels of depolarization ([K]o=15 and 40 mM; at [K]o=40 mM, resting potential decreased to 44±9 % of control). A TTX-induced hyperpolarization was observed at each value of [K]o, indicating that a finite, non-inactivating Na conductance exists at rest and at depolarized membrane potentials in RON axons. PK:PNa ratios were estimated to be 39±16, 22±14 and 78±59 at [K]o=3, 15 and 40 mM, respectively. Following the TTX-induced hyperpolarization, Vm began to depolarize. We suggest that the depolarization was partly due to inhibition of the Na-K-ATPase secondary to depletion of intracellular Na. We conclude that myelinated axons of the RON possess a TTX-sensitive, non-inactivating Na conductance. This conductance may function as a source of intracellular Na for the Na-K-ATPase under physiological conditions. Under pathological conditions such as anoxia, this conductance plays a central role in mediating irreversible injury by admitting Na, raising [Na]i and driving the Na-Ca exchanger to import damaging quantities of Ca. This non-inactivating Na conductance may have unique pharmacological properties and its blockade may protect CNS white matter from anoxia without abolishing electrogenesis. *(PKS was supported by a Centennial Fellowship from the Medical Research Council of Canada).*

478.26

A NOVEL VOLTAGE-DEPENDENT, TTX-INSENSITIVE SLOW SODIUM CURRENT IN ACUTELY ISOLATED STRIATAL NEURONS K. Hoehn,* T.W.J. Watson and B.A. MacVicar. Neuroscience Research Group, University of Calgary, Alberta, Canada, T2N4N1

We have observed a novel voltage-dependent, TTX-insensitive slow Na^+ current which may be important in determining the firing patterns of neostriatal neurons. This current was investigated using whole-cell voltage clamp of neurons which were acutely isolated from rat (21-28 day postnatal) striatum using either trypsin-hyaluronidase or pronase. The pipette solution contained (in mM): trizma phosphate 70, trizma base 28, TEACl 40, EGTA 11, MgATP 2, NaGTP 0.3. The extracellular solution contained (in mM): NaCl 90, TEACl 40, HEPES 10, 4-AP 4, TTX 0.0012, Ca^{2+} 5 and Mn^{2+} 3. In addition to the fast TTX-sensitive Na^+ current, a slow Na^+ was present which was not affected by even a high concentration of TTX (12 μM). Activation threshold was noted around -50 mV and peak currents were observed at around 0 mV. This current decreased in amplitude with decreasing concentrations of extracellular Na^+ and was abolished when Na^+ in the extracellular medium was replaced with either TRIS-Cl, TEACl or sucrose. A small current was observed when 90 mM KCl was substituted for 90 mM NaCl, indicating some permeability to K^+. The slow Na^+ current was not diminished in 0 Ca^{2+} solution or when Ca channels were blocked by either cadmium (25 to 100 μM), cobalt (3 mM) or manganese (3 mM), indicating that it is not a Ca^{2+}-activated current nor a monovalent cation current through Ca channels. Activation of the slow Na^+ current could be fit by a single exponential with time constants ranging from 1400 ms at -40 mV to 200 ms at 0 mV. Deactivation of 'tail currents' could be fit to a single exponential with time constants ranging from 90 ms to 350 ms and revealed a bell-shaped dependence on voltage. A study of 'tail currents' at various times after onset of the slow Na^+ current revealed that the magnitude of the 'tail currents' corresponded closely to the magnitude of the inward current. This slow Na^+ current may underlie the depolarizing afterpotential observed in striatal neurons and may contribute to long-term changes in membrane-potential which have been observed in striatal neurons. (Supported by the M.R.C of Canada and AHFMR).

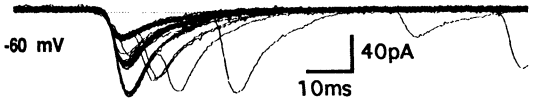
SPONTANEOUS TTX-INSENSITIVE Na^+ CURRENTS IN RAT SENSORY NEURONS MAY INVOLVE ALL-OR-NONE Ca^{2+}_i TRANSIENTS. H.-M. H. Saunders, J. Vautrin and J. L. Barker*. Lab. of Neurophysiol., NINDS, NIH, Bethesda, MD

Whole-cell patch clamp recordings in the presence of 1-3 μM tetrodotoxin (TTX) revealed spontaneous transient inward currents (STICs) in cultured (1-3 weeks) dorsal root ganglion cells dissociated from 19-20 day-old rat embryos. The amplitudes of STICs consistently showed preferred levels (see below). Their resting frequency was 2.4 events per minute at -60 mV, and increased as the holding potential was depolarized. Extracellular ATP (5-50 μM) increased the frequency of STICs in a dose dependent manner. Removal of extracellular Ca^{2+} decreased their frequency to 27 % of control, but did not eliminate STICs. Addition of 2.5 mM Mn^{2+} increased their frequency 7-8 fold, but preserved the preferred-amplitude characteristics. Replacement of extracellular Na^+ with N-methyl- D-glucamine reduced the frequency of STICs, shifted the distributions of peak amplitudes to lower levels, prolonged their time- to- peak, and decreased their rate of rise. Extracellular Na^+ -free reversibly eliminated STICs. When a membrane permeable Ca^{2+} chelator, BAPTA-AM, was added to the bath solution, the frequency of STICs decreased progressively to 6% of control. The properties of STICs suggest that these TTX-resistant Na^+ -dependent currents maybe activated by all-or-none Ca^{2+} transients released from intracellular stores.



478.28

REDUCED SODIUM CURRENT IN CULTURED HIPPOCAMPAL NEURONS FROM MOUSE TRISOMY 16, A MODEL OF DOWN SYNDROME. Z. Galdzicki *, E.J. Coan & S.I. Rapoport, LNS, NIA, NIH, Bethesda, MD 20892.

Action potentials in cultured hippocampal neurons from the trisomy 16 (Ts16) mouse have a slower depolarization rate than control neurons. This is likely due to differences in the voltage dependent sodium current. Primary cultures of hippocampal neurons were prepared from control and Ts16 mouse fetuses at day E15-16. Whole cell patch clamp recordings were obtained from 2-4 week old neurons. The extracellular medium included 130 NaCl, the intracellular medium included 5 NaCl. Currents were evoked with a 10 ms pulse in 10 mV steps between -50 mV to 90 mV from a holding potential of -60 mV. The mean membrane resistances were approximately 500 MΩ, the capacitances approximately 30 pF and the reversal potentials approximately +80 mV. None of these values were significantly different between control and Ts16 neurons. The mean maximum inward current was -125 pA/pF for control neurons (n=16) and -62 pA/pF for Ts16 neurons (n=16) (significant at $p < 0.01$), and was abolished by 1 μM TTX, but unaffected by 2 mM $CdCl_2$. This indicates that the current was a voltage-dependent sodium current, and likely explains the reduced depolarization rate of the action potential.

CORTISOL INDUCES SODIUM CHANNEL EXPRESSION IN CULTURED ASTROCYTES. B.K.Krueger#, D.S. Brougher# and P.J. Yarowsky ▮*. Depts. of Physiology# and Pharmacology & Exp. Therap. ▮, Univ of Maryland Sch. of Med., Baltimore, MD 21201.

We have previously shown (Yarowsky and Krueger, J. Neurosci 9: 1055, 1989) that substitution of serum-containing medium by serum-free G5 medium (A. Michler-Stuke et al., Int. J. Devl. Neuroscience 2:575, 1984) induces a rapid increase in high affinity STX binding in cultured rat astrocytes. We have now investigated whether one of the hormonal constituents of G5 (cortisol) induces high STX affinity Na channels. Serum-free medium was prepared containing DMEM/F12 with transferrin, biotin, sodium selenite, insulin, and fibronectin. Cultures from postnatal day 1 rat cerebral cortex were maintained in serum-containing medium for 4 DIV where a low, basal level of high affinity STX binding was measured. Cultures were then changed to serum-free medium with or without cortisol (10 nM). The astrocytes in cortisol-free medium continued to show the basal level of high STX affinity Na channels. An induction of Na channel expression by cortisol was evident after 24 hr, and was greater than 2.5 times the basal level 4 d after the change. This induction could be specifically blocked by the cortisol antagonist RU-38486 (200 nM and 2 μM) and it was also completely blocked by the transcription inhibitor actinomycin (20ng/ml). Thus, cortisol has a role in the control of Na channel expression during CNS development. Supported by NIH and NSF.

THE GAMBLER'S RUIN PROBLEM AND TRANSITIONS BETWEEN CLOSED AND OPEN STATES OF SODIUM CHANNELS. C.C. Chancey*[1], and S.A. George[2]. [1]Physics and Chemistry Depts., Purdue University Calumet, Hammond IN 46323, [2]Neuroscience Program, Amherst College, Amherst MA 01002.

Transition times between states of ion channels are generally assumed to be describable using classical statistical mechanics. However, the detailed connection between the distribution of these times and the dynamics of the gating mechanism is unknown. Assuming the models of Catterall and Guy, we have calculated times for sodium channel activation to occur through thermally-activated barrier hopping. We calculated coulomb interactions between the S4 α-helix and negative charges on nearest-neighbor helices, and included longer range interactions by adding a background electric field. Periodic pairing of charges between the S4 and adjacent helices in the model causes the resting and depolarized states of the channel to correspond to local minima in the S4 potential energy curve. Harmonic potentials closely fit the deviations from each local minimum, allowing the vibrational energies of the S4 helix about each minimum to be estimated. The thermally-induced stochastic fluctuations are modelled in terms of the classical Gambler's Ruin problem, producing a distribution of transition times.

ELECTROPHYSIOLOGICAL CHARACTERIZATION OF CATHa CELLS - A NEW CATECHOLAMINERGIC CNS CELL LINE. M. Lazaroff*, D.M. Chikaraishi, K. Dunlap. Neuroscience Program, Tufts Univ. Sch. of Med., Boston, MA 02111.

A CNS cell line (CATHa) was previously derived from a brain tumor from a transgenic mouse in which SV40 T antigen was under the transcriptional control of rat tyrosine hydroxylase 5' flanking sequences. The cells synthesize catecholamines and have neurofilament and synaptophysin proteins whereas glial fibrillary acidic protein is absent suggesting that the CATHa cells are neuronal in origin.

We have assayed for the presence of voltage-dependent ion channels by whole cell voltage-clamp recording. When CATHa cells are depolarized from a resting potential of -80 mV to between -40 and -20 mV, a fast-activating inward current is observed. Peak current is reached within 2 ms and is followed by a rapid, exponential inactivation (1.6 ms). Current-voltage relations show a maximum current near 0 mV. This current resembles that of the voltage-dependent Na^+ channels in other preparations. This was further confirmed by ion substitution experiments in which external NaCl was replaced with N-methyl-D-glucamine (NMDG); this substitution eliminated the current. In addition, 250 nM tetrodotoxin (TTX) blocked the current in a reversible manner. These findings suggest that CATHa cells express voltage-gated Na^+ channels.

When depolarized to -40 mV, a longer lasting inward current is observed in approximately 40% of the CATHa cells. This current is blocked by 100 uM cadmium and is carried predominantly by calcium ions. In other CATHa cells a long-lasting, more slowly activating outward "K^+- like" current is seen. Therefore, these transformed cells appear to possess voltage-gated sodium channels, calcium channels, and possibly potassium channels.

478.32

NA^+/K^+ ATPase INHIBITORS BLOCK PALYTOXIN INDUCED INACTIVATION OF IONIC CURRENTS IN FROG MUSCLE MEMBRANE. M.B. Rodríguez de Salzberg, S. Ortiz-Miranda and G. Escalona de Motta*. University of Puerto Rico Dept. of Biology and Institute of Neurobiology, San Juan 00901.

Palytoxin (PTX), isolated from zooanthids of the genus Palythoa (Cnidaria) and considered one of the most potent marine toxins, has been proposed to increase Na^+ permeability of cell membranes through a mechanism involving the Na^+/K^+ ATPase. In nM concentrations PTX depolarized frog sartorius muscle fibers in about 20 min. PTX (0.1-10 nM) completely inactivated ionic currents elicited by depolarizing voltage steps using the "loose" patch clamp technique. Holding membrane potentials at more negative values abolished this inactivation. Pretreatment of muscles with various cardiac glycosides produced a dose-related inhibition of PTX action. However, the inhibitory action of these glycosides was dependent on their chemical structure, monoglycosides being the most active inhibitors. These results confirm a relationship between the depolarizing effect of this toxin and the activity of the membrane Na^+/K^+ ATPase. (Work was supported by NIH grants GM08102, NS07464 and NOAA, USDC Sea Grant College Program at UPR).

CALCIUM CHANNEL MOLECULAR BIOLOGY

479.1

CLONING OF THE α1 SUBUNIT OF A VOLTAGE-DEPENDENT CALCIUM CHANNEL EXPRESSED IN THE ELECTRIC ORGANS FROM *NARCINE BRASILIENSIS*. M. Philip, J. Lin, C. Hashimoto, L. Shilo, S. Azhar, J. Fox*, J. Ramachandran and J. Bell. Neurex Corporation, 3760 Haven Avenue, Menlo Park CA 94025.

The electric organ of the fish *Narcine brasiliensis* is a rich source of molecules such as calcium channels involved in neuronal communication. Using two oligonucleotides from motif IV and the carboxy tail of the rabbit skeletal muscle calcium channel as primers, reverse transcribed cDNA from electromotor nuclei as template, and PCR, we cloned a 570 bp fragment and subsequently used it as a probe to screen a cDNA library made from electromotor nuclei. From the library, we isolated several overlapping clones covering almost the full length of the message. Upon sequencing, these clones showed high similarity to Class D channels (Snutch, T.P.*et. al.*, (1990) *Proc. Natl. Acad. Sci.* Vol 87, 3391; Williams, M.E. *et. al.*, (1992) Neuron, Vol 8, 71). Human and fish genes are highly conserved with 79% identity overall at the amino acid level. There is almost complete conservation of transmembrane domains and significant divergence in the intracellular regions between motifs I and II and between motifs II and III. In preliminary results, the C-terminal region of our fish clone is relatively short and diverges completely from the human clone 177 residues from the last transmembrane domain, perhapes suggesting alternate splicing in this region. It appears that the subtypes of calcium channels arose early in vertebrate evolution and are highly conserved among different species. We also obtained a presumptive splice variant, unique from other published sodium or calcium channels, which has two in-frame deletions of 129 bases and 66 bases corresponding to the IVS3 and IVS5 transmembrane domains.

479.2

MULTIPLE CALCIUM CHANNEL CLONES ISOLATED FROM A MARINE RAY. W.A. Horne*, P.T. Ellinor, I. Inman, M. Zhou, R.W. Tsien & T.L. Schwarz. Dept. Mol. Cell. Physiol., Stanford Univ., Stanford CA, Dept. Pharmacol., Cornell Univ., Ithaca NY.

In many neurons, transmitter release from presynaptic terminals is triggered by Ca^{2+} entry via DHP-insensitive Ca^{2+} channels (e.g. ω-CgTx-sensitive N-type channels). In an effort to understand the molecular properties of such channels, we have looked for Ca^{2+} channels in *Discopyge ommata*, a marine ray whose electric organ is the richest known source of binding sites for ω-CgTx. PCR was used to amplify putative Ca^{2+} channel sequences from the electric lobe which gives rise to nerve endings in the electric organ. PCR products were used to rescreen lobe libraries, yielding several clones with strong homology to known Ca^{2+} channels. We find one cDNA (doe-2) homologous to L-type, and another (doe-3) homologous to the BI channel of Mori et al. We also find additional clones (doe-1 and doe-4) with less similarity to L-type or BI channels. doe-4, which encodes a protein of 2326 amino acids, is more similar than the other doe clones to class B channels (Snutch). In all cases, the marine ray clones show higher homology to their mammalian counterparts in transmembrane domains than in external or cytoplasmic linkers. Northern analysis shows that doe-1 is more abundant in brain; doe-3 and doe-4 are more plentiful in the electromotor nucleus, and thus might play some role in motor nerve terminals. Evidently, the familial pattern of Ca^{2+} channel genes that has emerged for mammals also appears in this lower vertebrate.

479.3

CLONING AND CHARACTERIZATION OF A NOVEL α_1 SUBUNIT OF *DROSOPHILA* Ca^{2+} CHANNEL. W. Zheng, G-P. Feng, D.F. Eberl, D. J. Triggle* and L.M. Hall. Dept. of Biochemical Pharmacology, School of Pharmacy, SUNY/Buffalo, NY 14260.

The most abundant Ca^{2+} channels in *Drosophila* head membranes have different pharmacological properties than those of vertebrate L-type Ca^{2+} channels. These *Drosophila* Ca^{2+} channels have high binding affinity for phenylalkylamines, but are insensitive to dihydropyridines and to benzothiazepines whereas the vertebrate L-type channels are sensitive to all three classes of the Ca^{2+} channel antagonists. We report here a complete sequence of the Ca^{2+} channel α_1 subunit cloned from a *Drosophila* head cDNA library. This cDNA encodes a deduced protein estimated to contain 1964 amino acids. It exhibits 79.5, 72.2 and 71.2% sequence similarity to the α_1 subunits expressed in rat brain (D), rabbit skeletal muscle and heart respectively. A comparison of the Ca^{2+} channel sequences from *Drosophila* and vertebrates will be presented which provides important insight concerning the nature of phenylalkylamine and dihydropyridine binding sites. Northern analysis shows that this α_1 subunit mRNA is expressed as a single size class in leg (9.5kb) and body (9.6kb) but as three size classes (9.5, 10.2 and 12.5) in head.. This gene has also been localized on the left arm of chromosome 2 by *in situ* hybridization. Mutant analysis will define the physiological/developmental role of this channel in the whole organism. (Supported by NIH grants HL16003, HL39369 and GM42850-02).

479.4

PARTIAL SEQUENCE OF α_{1x}, A PUTATIVE NOVEL α_1 SUBUNIT OF A VOLTAGE-SENSITIVE CALCIUM CHANNEL L.M. Marubio*, L. H. Philipson, and R. J. Miller, Departments of Pharmacology and Physiology and Medicine,University of Chicago, Chicago, IL 60637

To date partial or complete sequences of five mammalian Ca^{2+} channel α_1 subunits have been reported, including skeletal muscle and $\alpha_{1A,B,C,D}$. In addition, some have areas of alternative splicing creating further variability. Whether this constitutes the complete set of such genes is uncertain. Using PCR amplification with degenerate primers designed to amplify a well conserved region in the fourth repeat domain of Ca^{2+} channel α_1 subunits, we have cloned a 320 bp fragment of a putative novel α_1 subunit channel (α_{1x}) from rat brain cDNA. Subsequent screening of a mouse brain cDNA library (Clonetech) with the 320 bp fragment as probe yielded a 1.1 kb fragment which contained a single open reading frame. Nucleotide sequence comparisons in the fourth repeat domain show it to be 72% identical to the A type Ca^{2+} channel and 65% identical to the C type. The deduced amino acid sequence shows the IV H5-H6 region to be approximately 85% identical to both the A and B type α_1 subunits. This cDNA has also been found in abundance in cDNA rat superior cervical ganglion neurons in culture, using PCR amplification of cDNA with primers designed specifically for this channel. Investigations to date have not revealed the transcript in PC-12 cells (differentiated and undifferentiated), NG108-15 cells, nor IMR32 cells.

479.5

MOLECULAR CLONING AND REGIONAL EXPRESSION OF A RAT BRAIN CALCIUM CHANNEL ALPHA-2 SUBUNIT. S.J. Dubel*, W.J. Tomlinson, T.V.B. Starr, S.R. Vincent# and T.P. Snutch. Biotechnology Laboratory and #Division of Neurological Sciences, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3.

Voltage-gated Ca channels are heteroligomeric complexes that include an alpha-1 subunit that serves both as a voltage sensor and ion conducting pore. In addition, exogenous expression studies demonstrate that other subunits (alpha-2, beta and gamma) can alter the physiological properties of the alpha-1 subunit. In the nervous system, the exact subunit composition of different neuronal Ca channel types has not been described and it is not yet known whether all Ca channel alpha-1 subunits are associated with ancillary subunits in vivo. Utilizing the skeletal muscle alpha-2 sequence as a probe we have isolated a 4.4 kb cDNA from a rat brain library. The cDNA encodes a 1091 amino acid protein (123 kDa predicted molecular mass) that shows 93% and 94% amino acid identity to rabbit skeletal muscle and human brain Ca channel alpha-2 subunits, respectively. The cellular localization of alpha-2 subunit expression was examined in adult rat brain using in situ hybridization with antisense oligonucleotides. Autoradiography reveals that the alpha-2 subunit is highly expressed in a subset of neurons in the cerebellum, olfactory bulb, hippocampus and cortex. The expression of the brain alpha-2 subunit does not correlate exactly with the expression of Ca channel alpha-1 subunits and suggests that only a subset of neuronal Ca channels are associated with an alpha-2 subunit.

479.6

cDNA CLONING OF A CALCIUM CHANNEL HIGHLY EXPRESSED IN THE HIPPOCAMPUS. T.-W. Soong and T.P. Snutch*. Biotechnology Laboratory, Univ. of British Columbia, Vancouver, B.C., Canada V6T 1Z3.

Screening of a cDNA library constructed from whole rat brain RNA identified four major subtypes of Ca channel alpha-1 subunits (classes A, B, C, and D; Snutch et al, PNAS 87:3391-3395). A number of studies indicate that the class C and D alpha-1 subunits encode distinct L-type Ca channels while the class A and B alpha-1 subunits are likely to encode P and N type channels, respectively. To identify Ca channels that may be involved in processes such as long-term potentiation, we have utilized the polymerase chain reaction (PCR) to amplify Ca channel sequences expressed in the hippocampus. Degenerate oligonucleotides were used to amplify hippocampus RNA isolated from adult rats and the PCR products were subcloned and analyzed by DNA sequencing. Of 18 clones examined, 15 were identified as previously characterized Ca channel alpha-1 subunits, while 3 encode a new class of Ca channel (designated class E). The deduced primary structure of the class E protein is most closely related to the brain class A and B alpha-1 subunits. Limited amino acid identity to the brain class C and D alpha-1 subunits suggests it is unlikely that the class E Ca channel corresponds to an L-type Ca channel. Northern blot analysis shows that the class E Ca channel is encoded by an approx. 12 kb mRNA that is expressed throughout the rat CNS and is most abundant in the hippocampus. This pattern of expression is distinct from previously cloned Ca channels and may reflect a unique physiological role for the class E Ca channel in the CNS.

CHROMOSOMAL LOCALIZATION OF MURINE GENES ENCODING α1, α2, AND β-SUBUNITS OF THE DHP-SENSITIVE L-TYPE CALCIUM CHANNELS. H. Chin[1]*, B. Mock[2], H-L. Kim[1], and C.A. Kozak[3]. [1]LMB, NINDS; [2]LG, NCI; and [3]LMM, NIAID, NIH, Bethesda, MD 20892.

Recent molecular cloning has indicated that a heterogeneous family of voltage-sensitive Ca^{2+} channels are expressed in mammalian brain, providing structural bases for the functional diversity of neuronal Ca^{2+} channels. As a first step toward understanding genetic bases for diversity of brain Ca^{2+} channels, we have begun mapping the genes encoding the α1, α2-d, and β-subunits of the dihydropyridine (DHP)-sensitive L-type Ca^{2+} channels. Previously, we and others localized two of the α1 subunit genes (*Cchl1a1* and *Cchl1a2*) on human and mouse chromosomes (Power et al., Genomics, 10:835-839, 1991; Chin et al., Genomics, 11:914-191, 1991). Here, we have determined the chromosomal location of the third subunit gene, *Cchl1a3*, which encodes the isoform predominantly expressed in skeletal muscle, to mouse Chr 1. Analysis of the progeny of an inbred strain cross positioned *Cchl1a3* 1.3 cM proximal to the *Pep-3* locus on Chr 1. In contrast to the α1 subunit which are encoded by 3 distinct genes located on separate chromosomes, the α2 and β subunits are encoded by a single gene, located on Chr 5 and 11, respectively. Analysis of Chr 5 alleles for several genes in an intersubspecies cross between NFS/N and C58/J mice shows that the α2 subunit gene, termed *Cchl2a*, can be positioned at the centromeric end of Chr 5, with gene order centromere - *Cchl2a* - *Il-6* - *Pgm-1*. Similarly, the gene for the β-subunit is mapped on Chr 11 with gene order centromere - *Sparc* - *Cchlb* - Gfap - *Pkca*. Our mapping data indicate that the DHP-sensitive Ca^{2+} channels genes are apparently dispersed in the mouse genome, unlike the Na^{+} channel whose genes are clustered on Chr 2.

479.8

THE β-SUBUNIT OF THE DHP-SENSITIVE CALCIUM CHANNEL: cDNA CLONING AND IDENTIFICATION OF mRNA IN ADULT AND DEVELOPING RAT BRAIN. H-L. Kim[1]*, H. Kim[2], H. H. Jung[1], and H. Chin[1]. [1]LMB, NINDS, NIH, Bethesda, MD 20892; [2]Dept. Anat., Coll. Med., Korea Univ., Seoul, Korea.

The dihydropyridine (DHP)-sensitive, L-type Ca^{2+} channel from skeletal muscle consists of 5 polypeptide subunits (α1, α2, β, γ, and δ). The α1 subunit of the Ca^{2+} channel can form the functional Ca^{2+} channels in *Xenopus* oocytes. However, coinjection of skeletal muscle α2-δ and β subunit mRNAs with the α1 subunit mRNA drastically changed the electrophysiologic characteristics of the expressed Ca^{2+} channels. These findings suggest that α2-δ and/or β subunits may play a modulatory role in regulating Ca^{2+} channel function. Previously, we cloned and characterized the molecular properties of the DHP-sensitive Ca^{2+} channel α1 and α2 subunits. Here, we report the primary structure of rat brain DHP-sensitive Ca^{2+} channel β subunit and tissue distribution of its mRNA. Two cDNA clones, BT11 and BT8, encoding the β subunit were isolated and characterized. The deduced amino acid sequenceof BT11 cDNA is very similar to that of the rabbit skeletal muscle β subunit, showing 96% amino acid identity. The BT8 clone is a spliced variant of BT11 with deletion of a 45-amino acid fragment. The distribution of rat DHP-sensitive Ca^{2+} channel β subunit mRNA was examined in prenatal (E16, E19), postnatal (P0, P6, P12), and adult rat brains as well as whole-body sections of E19 embryos. In adult rat brain, large amounts of β subunit mRNA were found in the hippocampus, dentate gyrus, and medial habenula. A high level of DHP-sensitive Ca^{2+} channel β subunit transcript was already expressed at E16, and transcript levels significantly changed in several areas during development.

479.9

DIFFERENTIAL EXPRESSION OF BRAIN L-TYPE AND P-TYPE CALCIUM CHANNEL mRNAs IN ADULT AND DEVELOPING RAT BRAIN H. Kim[1]*, H-L Kim[2], and H. Chin[2]. [1]Dept. Anat., Korea Univ. Coll. Med., Seoul, Korea; [2]LMB, NINDS, NIH, Bethesda, MD, 20892.

The four major types of voltage-sensitive Ca^{2+} channels present in the central nervous system (CNS) are classified as T-, N-, L-, and P-types. Our earlier localization study indicated that L-type Ca^{2+} channels are predominantly expressed in those brain regions important for neuroendocrine function (Chin et al., FEBS Lett., 299:69-74, 1992). Several studies suggest that the P-type channels, initially identified in cerebellar Purkinje cells, are distributed more widely throughout the brain. Here, we investigated mRNA expression patterns of the α1 subunit of L- and P-type Ca^{2+} channels of adult and developing rat brains by *in situ* hybridization histochemistry, using the specific cRNA probes. The L-type α1 subunit transcript was abundantly expressed in the olfactory bulb, dentate gyrus, pituitary and pineal glands, superior colliculus, and facial nucleus; whereas the P-type α1 subunit was highly expressed in the hippocampus (CA3 region), geniculate bodies, inferior colliculus, and cerebellum. Resolution at the cellular level disclosed differential labeling of distinct cell types in various brain areas, suggesting that L- and P-type Ca^{2+} channels may be localized in specific neuronal subpopulations. Consistent with this conclusion, relative L-type Ca^{2+} channel mRNA contents in different brain regions varied during development, whereas the P-type Ca^{2+} channel transcript gradually increased from very low levels during early embryogenesis (from E16), peaked to the highest level at P12, and decreased thereafter in adults. The data reveal that spatial localization and temporal expression patterns of L- and P-type Ca^{2+} channel mRNAs change developmentally, and suggest physiologic role(s) for these channels in mammalian CNS ontogeny.

479.10

CLONING AND EXPRESSION OF A HUMAN NEURONAL N-TYPE CALCIUM CHANNEL. S.B. Ellis, D.H. Feldman, M.E. Williams, P.F. Brust, A. Maroufi, S. Patthi, S. Simerson, G. Velicelebi*, M.M. Harpold. SIBIA Inc., 505 Coast Blvd. So., La Jolla, CA 92037

At least four different α_1 subunit genes are expressed in the central nervous system, designated α_{1A} through α_{1D}. We report the primary structure of the α_{1B} subunit and the functional expression of a human N-type voltage-dependent Ca^{2+} channel mediated by this α_1 subunit. Functional expression was achieved by transient coexpression of α_{1B} with human neuronal α_{2b} and β_2 subunits [Williams *et al.* Neuron 8:71 (1992)] in mammalian cell culture. Whole cell recordings revealed a high-voltage activated, inactivating channel that was sensitive to holding potential, insensitive to Bay K 8644 (1 μM) and irreversibly blocked by ω-conotoxin (0.5 μM) (see abstract by Feldman *et al.*). Transfected cells expressed a single class of high-affinity ω-conotoxin binding sites (K_d = 55 $\pm$ 18 pM; B_{max} = 25,000 $\pm$ 10,000 receptors per cell).

The predicted α_{1B} subunit structure consists of the characteristic twenty-four transmembrane topology determined for α_1 subunits. The predicted α_{1B} amino acid sequence is 64.1% and 43.0% identical to the rabbit BI (α_{1A}) dihydropyridine-insensitive and human α_{1D} dihydropyridine-sensitive subunits, respectively. α_{1B} has a characteristic large putative cytoplasmic loop between the IIS6 and IIIS1 transmembrane domains like the rabbit BI subunit but is only 29.3% identical through a majority of the loop. The α_{1B} primary transcript is differentially processed to produce at least two isoforms, α_{1B-1} (calculated molecular weight = 262,494) and α_{1B-2} (calculated molecular weight = 251,757). α_{1B-1} and α_{1B-2} differ at their carboxyl termini.

479.11

PHYSIOLOGICAL CHARACTERIZATION OF A CLONED HUMAN N-TYPE CALCIUM CHANNEL. D.H. Feldman*, M.E. Williams, P.F. Brust, G. Velicelebi, S.B. Ellis, M.M. Harpold. SIBIA Inc., 505 Coast Blvd. So., La Jolla, CA 92037.

N-type Ca channels, found in neurons but not in muscle, are irreversibly blocked by ω-conotoxin and are insensitive to dihydropyridines. Activation requires strong depolarizations from negative holding potentials, and inactivation occurs over tens to hundreds of msec. We have now isolated cDNAs encoding a human neuronal α_{1B} subunit [see abstract by Ellis *et al.*] that, when transiently coexpressed in transfected mammalian cells with previously isolated cDNAs encoding human neuronal α_{2b} and β_2 subunits [Williams *et al.*, Neuron 8:71 (1992)], expresses Ca channels with the properties of N-type channels.

Whole-cell recordings from transfected cells revealed Ba^{2+} currents up to several nA that were irreversibly blocked by ω-conotoxin (0.5-10 μM) at a rate dependant on concentration, consistent with rates measured in neurons. Activation began near -20 mV, and peaked near 10 mV. The currents usually activated within 10 msec and inactivated with a time course fit by the sum of two exponentials ($\tau_{fast} \simeq 0.1$ sec; $\tau_{slow} \simeq 0.4$ sec). Whereas τ_{fast} dominated inactivation at test pulses of 0 or 10 mV, τ_{slow} dominated at >10 mV. The currents were sensitive to holding potential, with half inactivation occurring at -60 to -70 mV, and 90% inactivation near -40 mV. Currents were reversibly blocked by 50 μM Cd^{2+}, and were not affected by dihydropyridines. Two observations suggest that the expressed channel is under tonic inhibition in the host cells: currents typically increased in magnitude 2 to 20-fold during the first several minutes of recording, and currents increased in magnitude when the test pulse was immediately preceded by a brief strong depolarization (+70 mV).

Thus, many of the properties attributed to N-type channels observed in neurons are exhibited by the recombinantly expressed channel.

479.12

CLONING OF A cDNA FOR A SYNAPTIC PLASMA MEMBRANE Na^+/Ca^{2+} EXCHANGER. **M.L. Michaelis*, J. Walsh, K. Kumar, J. Foye and G. Hadwiger. Dept. of Pharmacology and Toxicology, Univ. Kansas, Lawrence, KS 66045.**

The Na^+/Ca^{2+} exchanger is a plasma membrane protein which is believed to participate in the regulation of Ca^{2+} fluxes, particularly in excitable cells. We recently reported on efforts to purify exchanger activity from brain synaptic membranes and the development of Ab's to a 36 kDa protein which immunoprecipitated exchanger activity from solubilized brain synaptic membranes (J. Neurochem., 58:147-157, 1992). The Ab's were used to screen a brain cDNA expression library (Lambda ZAP) and several positive clones identified. One of those clones has been found to have an insert of ~1.6 kb and, following autoexcision and transfer of the phagemid pBS to E. Coli, the transfected bacteria expressed an ~40 kDa fusion protein which was recognized by the Ab's. The initial sequencing of the insert revealed a novel nucleotide sequence and the presence of a short COOH-terminal region with a high degree of homology to the voltage gated Ca^{2+} channel. Work is underway to express the protein transiently in cells with little or no endogenous exchanger acitivty. (Supported by PHS grant #AA04732 and the American Heart Assoc., KS Affiliate, grant #KS-91-G-07.)

ACETYLCHOLINE: CNS II

480.1

AF64A (ETHYLCHOLINE AZIRIDINIUM ION) PRODUCES OXIDATIVE STRESS: RELATION TO CHOLINOTOXICITY AND FUNCTIONAL DEFICITS. T.J. Walsh*, G. Woertwein, R. W. Stackman and S.C. Bondy[1], Dept. Psychology, Rutgers Univ., New Brunswick, NJ, 08903, and 1 Univ. of California, Irvine, CA, 92717.

AF64A produces (i) a persistent decrease in presynaptic cholinergic function, (ii) a loss of cholinergic neurons in the medial septum, and (iii) cognitive impairments. While AF64A inhibits high affinity choline uptake (HAChU) the mechanisms responsible for its long-term neurotoxicity are not well-characterized. The following experiments examined the potential role of oxidative stress in the cholinotoxicity and functional deficits induced by AF64A. Male Sprague-Dawley rats were bilaterally injected icv with artificial CSF or 3.0 nmoles of AF64A. Rats were sacrificed two days following surgery and it was determined that AF64A increased the production of conjugated dienes, an index of lipid peroxidation and oxidative stress, and decreased the activity of choline ChAT in the hippocampus (HPC). Furthermore, there was a significant correlation between the degree of cholinergic toxicity and the extent of lipid peroxidation. In a subsequent study rats were pre-treated with saline or 50 mg/kg of the anti-oxidant Vitamin E acetate (VE) at 24 hrs and 15 min prior to icv injection of artificial CSF or AF64A (3 nmoles/side). Vitamin E prevented the AF64A-induced (1) deficits in acquisition and retention in a Morris-water maze task and (2) the decrease in HAChU in the HPC. Therefore, while the structure of AF64A leads to its accumulation in cholinergic neurons oxidative stress might significantly contribute to the cholinotoxicity and functional deficits induced by this compound. Supported by a Busch Grant to TJW.

CHRONIC EEG CHANGES IN RATS TREATED WITH THE CHOLINERGIC NEUROTOXIN ETHYLCHOLINE AZIRIDINIUM (AF64A). H.Hörtnagl, E.Groll-Knapp, G.Khanakah and O.Hornykiewicz*. Institute of Biochemical Pharmacology and Institute of Environmental Hygiene, University Vienna, A-1090 Vienna, Austria

The effect of a neurotoxic lesion of the cholinergic septo-hippocampal pathway on cortical EEG activity was studied. Male Sprague Dawley rats received bilateral stereotaxic infusions of 2nmol AF64A or vehicle into the lateral ventricle. Four months after AF64A Ag/AgCl electrodes were chronically implanted in epidural position over frontal and parietal regions of both hemispheres. One month after implantation various EEG parameters were analyzed. In the AF64A-treated rats a reduction of the amplitude of the spontaneous EEG in rest and activated conditions and of the main peak amplitude of visual and acoustic evoked potentials was observed (click evoked potentials: AF64A: -7.3 ± 3.0 μV, n=11; control: -32.1 ± 5.9 μV; n=9; $p < 0.01$; flash evoked potentials: AF64A: -29.6 ± 2.7 μV; control: -47.0 ± 5.6 μV; $p < 0.02$). Additionally, a diminution of the slow potential shifts evoked by physiologically meaningful vocalizations occurred. Neurochemical analyses of the brain revealed a specific reduction in the activity of choline acetyltransferase in the dorsal (42%) and ventral (52%) hippocampus. The data indicate that treatment with AF64A results in a chronic decrease in general central nervous activity and disturbance in higher nervous integrative processes, which appear to be linked to the specific deficit of the cholinergic transmission in the hippocampus.

EXCITOTOXIC LESIONS OF THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS IMPAIR RADIAL-ARM MAZE PERFORMANCE

Larry L. Butcher *, Justin D. Oh, and Cheryl Cesarz.
Laboratory of Chemical Neuroanatomy and Dept. Psychology, UCLA, Los Angeles, CA 90024-1563, U.S.A.

Lesions of the pedunculopontine tegmental nucleus (PPT) lead to reduced choline acetyltransferase (ChAT) immunoreactivity in cholinergic basal forebrain nuclei (Oh et al., *Soc. Neurosci Abstr.*, 15, 782, 1989). In order to assess possible effects of PPT lesion on spatial memory, 10 female Sprague-Dawley rats with excitotoxin lesions were trained and tested on an 8-arm radial maze. After rats (n=5) reached a 0% error rate defined as no entries into an arm already entered, 3.8 nmol kainate (0.1 μl, total injection time = 4.5 min) was injected unilaterally into the PPT. Five additional rats served as controls and were injected with 0.1 μl of saline into the PPT. Starting on the day after surgery, and for an additional 6 days, rats were tested on the maze and the behavioral data was statistically analyzed with a 2-way mixed-design ANOVA. Lesioned rats, but not controls, showed a significantly greater impairment in spatial memory performance [$F(10,2) = 12.143$, $MsE = 0.623$, $p<0.05$]. These data suggest that excitotoxic lesions of the cells in the PPT nucleus have a deleterious effect on the spatial memory of rats.

RADIAL-ARM MAZE PERFORMANCE IN RATS IS IMPAIRED BY VESAMICOL [(-)-TRANS-2-(4-PHENYLDIPERIDINO) CYCLOHEXANOL], A POTENT INHIBITOR OF ACETYLCHOLINE ACTIVE TRANSPORT BY SYNAPTIC VESICLES.

Justin D. Oh*, Sonja Bockenhauer, Antoine Keller, Stanley M. Parsons, Gary A. Rogers and Larry L. Butcher. Laboratory of Chemical Neuroanatomy and Dept. Psychology, UCLA, Los Angeles, CA 90024-1563, U.S.A. and Dept. of Chemistry, University of Californis, Santa Barbra, CA 93106.

Effects on both choline acetyl-transferase (ChAT) immunohistochemistry and 8-arm radial maze performance were found for the drug Vesamicol, a potent inhibitor of acetylcholine (ACh) active transport by synaptic vesicles. Female rats (n=20) were randomly assigned either to vesamicol group or vehicle control group. Rats received bilateral injections of 1 (ng) vesamicol (2.0 ul X 0.5 mM) dissolved in PBS (pH=7.2) containing DMSO and acetic acid intraparenchymally in the nucleus basalis of Meynert (n=5) or intraventicularly (n=5). Rats injected with vesamicol showed significantly reduced numbers of ChAT-immunopositive cells in the basal forebrain 7 days following surgery. Staining for both Nissl and the nerve growth factor receptor revealed no actual cell loss or morphologic abberation in these cholinergic neurons. As measured by entries to repeat, radial-arm maze choice accuracy was significantly impaired in the vesamicol group compared to the control group ($p<0.05$). Paralleling the time-course of ChAT-immunoreactivity decrement, the effects of vesamicol on maze performance were significantly different from control 6 and 7 days post-surgery. [Support: USPHS grant NS 10928 to L.L.B.].

SELECTIVITY OF AN AFFINITY LIGAND, HEMICHOLINIUM MUSTARD, FOR THE HIGH AFFINITY CHOLINE TRANSPORT SYSTEM. K.H. Gylys* and D.J. Jenden *Department of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024.*

Hemicholinium mustard has been shown to be an irreversible inhibitor of high affinity choline uptake (HACU) in several preparations. (Smart, 1981, 1983; Gylys et al., 1990). In the present experiments the specificity of these irreversible effects was examined with respect to other cholinergic proteins and other sodium-dependent transport systems. To measure the effects of HCM on choline acetyltransferase (ChAT), synaptosomes were incubated in HCM, then washed. The synaptosomes were lysed and ChAT activity was measured. Treatment with 50 μM HCM, a concentration that inhibits 100% of synaptosomal HACU, results in a 24% decrease in ChAT activity. In other experiments, rat brain membranes were incubated with 1 μM HCM and then washed before saturation studies with the muscarinic receptor ligand [^{3}H]-NMS were carried out. HCM pre-incubation showed no significant effect on either the affinity or number of muscarinic receptors. Dopamine (DA) transport is also relatively unaffected by HCM pre-treatment: 10 μM HCM, which inhibits HACU in synaptosomes by >90%, inhibits DA transport by 11%. These results support the use of HCM as an affinity ligand for HACU. (Supported by MH 17691)

480.6

PRESYNAPTIC CHOLINERGIC MARKERS: CHANGES FOLLOWING DRUG ADMINISTRATION AND BEHAVIORAL TESTING IN RATS. L.K.Gorman*, V.Rodriguez, S.Golski & D.S.Olton. Psych Dept.,Johns Hopkins Univ., Balto., MD 21218.

Presynaptic functioning of the cholinergic system has been assessed by three different measures: choline acetyltransferase (ChAT) measures the activity of ChAT, the synthetic enzyme for acetylcholine; sodium dependent high affinity choline uptake (SDHACU) measures both the activity and the number of presynaptic HACU sites; hemicholinium-3 (HC-3) binding measures the number of HACU sites. CHAT, HC-3 and SDHACU were measured in dorsal and ventral hippocampus of the same rat following either systemic drug administration or behavioral testing. Preliminary data indicate that scopolamine decreased CHAT activity, whereas physostigmine increased CHAT activity; HC-3 binding and SDHACU activity were not changed by these drugs. In behaviorally tested rats, HC-3 binding was increased following performance on a spatial working memory task; ChAT was not altered by behavioral testing in previous experiments. These data indicate that different experimental manipulations differentially alter presynaptic cholinergic markers.

480.7

CHOLINE RESTORES BLOOD PRESSURE IN HYPOTENSIVE RATS: INVOLVEMENT OF VASOPRESSIN. V.Savcı, I.H.Ulus* S.Gürün, B.K.Kıran and L.R.Büyükuysal. Dept.of Pharmacology, Uludağ Univ. Medical School., Bursa, TURKEY.

Left carotid artery of rats (280-350 g) was cannulated with PE 50 tubing to monitor blood pressure and animals were made hypotensive by bleeding (2 ml/100 g of body weight) or by treatment with histamine (10 mg/kg; ia), hekzamethonium (15 mg/kg; ip), phentolamine (5 mg/kg; ia) or 6-hydroxydopamine (50 mg/kg;iv). Intracerebroventricular (ICV) injection of choline (50-150 ug; rat) to these animals increased and restored blood pressure within 1-5 minutes after the choline treatment. Choline's effect was abolished by pretreatment of rats with mecamylamine (50 ug). Pretreatment of rats with atropine (10 ug; ICV) failed to alter the effect of ICV choline. ICV choline (50 ug) also failed to increase and restore blood pressure when rats were pretreated with hemicholinium-3 (20 ug; ICV) 15 minutes before ICV choline. The increase in plasma levels of vasopressin was associated with the increase in blood pressure in ICV choline treated hypotensive rats. When animals were treated with an antogonist of vasopressin (10 ug/kg; ia) five minutes after ICV choline (150 ug) blood pressure decreased immediately to the pre-choline or to near pre-choline levels. These data indicate that ICV choline can increase and restore blood pressure in hypotensive rats by increasing the central cholinergic nicotinic neurotransmission. The increase in plasma levels of vasopressin involves in this effect of ICV choline.

480.8

EFFECTS OF APNEA ON BRAIN CHOLINE PRODUCTION IN RATS. O.U. Scremin* and D.J. Jenden. West L.A. V.A. Medical Center and UCLA School of Medicine, Depts of Physiology and Pharmacology. Los Angeles CA 90024.

Free choline (Ch) concentration in brain tissue results from a balance between synthesis and hydrolysis of acetylcholine (ACh), synthesis and degradation of Ch containing phospholipids and exchange with plasma. Since the ability of brain tissue to synthesize Ch *de novo* is negligible, losses of this base through the circulation can have serious consequences for phospholipid and ACh metabolism. We tested the hypothesis that the energy deprivation associated with apnea would enhance the loss of Ch. Experiments were performed in rats, mechanically ventilated with a N_2O/O_2 mixture. Ch in plasma of aorta (Ch_a) minus that of retroglenoid vein (Ch_v) multiplied by cerebral blood flow in the same vein represented the cerebral metabolic rate of Ch (CMRCh, nmoles/min) that reached -0.14±0.06 prior to apnea. Apnea of 1.5 min duration was followed by negative CMRCh values (-0.72±0.06 at 3 min post-apnea), returning to control after 16 min. Apnea of 3 min duration was followed by CMRCh values not different from zero during the initial 15 min followed by negative values (-0.52±0.11 at 60 min). Apnea of 6 min duration was followed by positive CMRCh initially (1.12±0.1 at 6 min) with negative values later (-0.74±0.23 at 64 min). Total Ch loss (nmoles) during 1 hr was related to the duration of the apnea episode that preceded it (1.5 min= -12.05 ±3.57; 3 min= -17.09±6.13; 6 min= -27.32±4.15; Controls (no apnea)= -6.99±2.25. This enhanced Ch loss took place in spite of increased Ch_a. Peak Ch_a (nmoles/ml) after apnea were: 1.5 min= 11.2±1.47; 3 min= 18.8±1.26; 6 min= 30.6± 1.07; Controls= 8.44±.21. It is concluded that apnea induces a significant loss of brain free Ch that could have metabolic consequences. Supported by the US Department of Veterans Affairs and USPHS MH 17691.

ONTOGENY OF CHOLINERGIC SENSITIVITY IN AN ANIMAL MODEL OF DEPRESSION: TOLERANCE DEVELOPMENT AND NEUROTRANSMITTER SYSTEM INTERACTION. L.C. Daws, G.D. Schiller, D.H. Overstreet*, School of Biological Sciences, Flinders University, Adelaide 5001, Australia.

The Flinders Sensitive and Resistant Lines (FSL, FRL-control line of rat) have been selectively bred for differences in cholinergic sensitivity. The FSL rat exhibits increased behavioural and physiological responses to cholinergic agonists. Thus, it is a an animal model of depression because an increased sensitivity of the cholinergic system has been postulated to be a trait marker of depression. The present studies aimed to investigate the development of responsiveness to the muscarinic agonist, oxotremorine, and its antagonist, scopolamine. FSL rats were consistently more sensitive to the hypothermic effects of oxotremorine by 20 days postpartum (dpp), whereas the development of sensitivity to scopolamine (as indexed by increased locomotor activity) was not different between the two lines. The early ontogenetic appearance of a substantial difference in sensitivity to muscarinic agonists suggests that cholinergic hyperfunction is a trait marker of predisposition towards depressive tendencies in FSL rats. However, since FSL rats are not different from FRL rats in their response to antagonists, it is suggested that the mechanisms underlying cholinergic supersensitivity are downstream from the muscarinic receptors. Subsequent studies showed that tolerance to oxotremorine emerged by 31 dpp when injected every third day from 10 dpp. Both lines exhibited tolerance suggesting that FSL rats have the capacity to maintain normal plasticity of the cholinergic system, although they are inherently more sensitive. A significant cross-tolerance to quipazine and salbutamol occurred in the FSL, but not the FRL rats. This strain-dependent cross-tolerance to noncholinergic drugs in FSL rats is consistent with the hypothesis advanced above that the mechanisms underlying their cholinergic supersensitivity are beyond the receptors.

AUTORADIOGRAPHIC LOCALIZATION OF MUSCARINIC CHOLINERGIC RECEPTOR (MCR) SUBTYPES IN CAT BRAIN STEM. H.A. Baghdoyan*, M.T. Roth, R.B. Duckrow, and D.C. Mash. Dept. of Anesthesia, Penn State Univ. Col. of Med., Hershey, PA 17033, and Dept. of Neurology, Univ. of Miami Sch. of Med., Miami. FL 33136.

Brain stem cholinergic mechanisms are involved in generating REM sleep, but the role of specific MCR subtypes is not clear. The goal of the present study is to map the distribution of MCR subtypes likely to be important for sleep cycle control. Using the technique of Flynn et al., (Neurosci. Abs. 17:586, 1991) which utilizes the kinetic properties of N-[^{3}H]-methylscopolamine to differentially label MCR subtypes, we are localizing M1, M2, and M3 subtypes throughout the cat brain stem. Receptor density is quantified using CCD-camera-based image analysis. Preliminary results show that the feline medial pontine reticular formation (mPRF), a non-cholinergic, cholinoceptive region involved in REM sleep generation, contains very few M3 receptors (4.0 fmol/mg tissue). The pedunculopontine tegmental nucleus (PPT), which provides cholinergic input to the mPRF, also has few M3 receptors (7.4 fmol/mg). In contrast, the laterodorsal tegmental nucleus (LDT) has 18.8 fmol/mg of M3 receptors. Relatively high levels of M3 receptors were also localized to the periaqueductal gray (15.4 fmol/mg) and the substantia gelatinosa (22.0 fmol/mg). M1 and M2 subtypes in mPRF, LDT, and PPT are being quantified. *Support: Dept. of Anesthesia, HL47749, MH45361 (HAB), NS24109 (RBD), NS25785 (DCM).*

COMPARISON OF CHOLINERGIC PROPERTIES AND MUSCARINIC RECEPTOR SUBTYPES PRESENT IN TWO NEURONAL CLONAL CELL LINES. M.A. BUCK,*L.A.TAYLOR, V. RUPERTO, C.E. TEDFORD and R.D. McQUADE, CNS Pharmacology, Schering Plough Research Institute, Bloomfield, NJ 07003.

Two cholinergic containing cell lines were investigated for various markers of cholinergic activity as well as characterized for muscarinic receptor subtypes. Muscarinic receptor characterization and identification in a neuronal cell model is of considerable interest to better understand muscarinic receptors and their mode of interaction in the central nervous system. Cells of the homogeneous hybrid line of mouse neuroblastoma X rat glioma (NG108-15) were compared with the PC12 phaeochromocytoma cell line derived from the rat adrenal medulla. PC12 and NG108-15 cells both demonstrated various levels of cholinergic activity. NG108-15 cells had higher levels of enzymatic activity for choline acetyltransferase (ChAT, 27.4 vs 13 nmoles/mg protein) and acetylcholinesterase (AChE, 1216 vs 376 nmol/mg protein) than PC12 cells. In contrast, functional measurements of high affinity choline transport (HAChT) indicated that PC12 cells contained almost double the activity. HAChT was sensitive to hemicholinium-3 (HC-3) and was modulated in both cell lines by muscarinic receptor agonists.

Muscarinic receptor characterization of the two cell lines was performed using saturation and competition binding studies with ^{3}H-N-methyl-scopolamine (^{3}H-NMS). Similar studies were performed in transfected Chinese hamster ovary (CHO) cell lines expressing the human muscarinic receptor subtypes, m1-5. Covalent labelling of the neuronal and transfected CHO cells with the muscarinic ligand, ^{3}H-propylbenzilylcholine mustard (^{3}H-PrBCM) and the mobilities of the mustard labelled species of these cells on sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) confirm the existence and identity of muscarinic cholinergic receptor subtypes in these cell lines.

ALKALOIDS ISOLATED FROM TROPICAL MARINE SPONGES BIND TO MOLECULAR TARGETS IN RAT BRAIN MEMBRANES. G.E. de Motta, R. Rosa, A.D. Rodríguez, W. Silva and C. Jiménez*. Institute of Neurobiology and Depts. of Chemistry and Biology, U. of Puerto Rico and Dept. of Pharmacology, U. Central del Caribe.

Four structurally related $C_{11}N_5$ compounds isolated from sponges of the genus *Agelas* exhibited both stimulatory and inhibitory activities in frog skeletal and smooth muscles. Potential target sites for these compounds were evaluated for their interaction with muscarinic acetylcholine receptors (mAChR) and tetrodotoxin (TTX)-sensitive sodium channels using rat brain synaptosomal membranes and radioligand assays. Competition experiments using tritiated quinuclidinyl benzylate (^{3}H-QNB) to label mAChRs revealed the following rank order of potency : sceptrin > oroidin ≥ dibromosceptrin ≥ clathrodin. Competition experiments using tritiated saxitoxin (^{3}H-STX) as a sodium channel marker showed the following rank order of potency : sceptrin = dibromosceptrin > oroidin > clathrodin. Scatchard analyses demonstrated that sceptrin, the most potent member of this group, was a competitive inhibitor of both ^{3}H-QNB and ^{3}H-STX binding. TOXIC EXTRACTS FROM THE BENTHIC DINOFLAGELLATE Ostreopsis lenticularis BIND TO RAT BRAIN MUSCARINIC RECEPTORS. J. Mercado, G.E. de Motta, W. Silva, T. Tosteson and R. Blanco*. Inst. of Neurobiology and Depts. of Biology and Marine Sciences, U. of Puerto Rico, and Dept. of Pharmacology, U.Central del Caribe.

Methanolic extracts prepared from clonal cultures of Ostreopsis lenticularis, a benthic dinoflagellate, were toxic to mice by i.p. injection. Reverse phase HPLC separation using isocratic methanol as the system solvent, produced two major fractions. Fraction I, with a retention time (R_t) of 2.04 min, contained apparently only one component while Fraction II consisted of a major component (R_t = 3.69 min) and several minors components. Using radioligand assay methods we studied the effect of the crude extracts and both HPLC fractions on muscarinic acetylcholine receptors (mAChR) in rat brain synaptosomal membranes. Preincubation of membranes with crude extracts (500 µg/mL), fraction I (500 µg/mL) and II (200 µg/mL) displaced binding of tritiated quinuclidinyl benzylate by 97.39 ± 3.7%, 64.285 ± 3.5% and 61 ± 1.51%, respectively. In frog gastric muscle strips, a preparation we have shown to contain M_3 mAChRs, crude extracts elicited contractions similar to those induced by acetylcholine in this muscle. (Supported by GM08102 and NS07464, NIH, and NOAA, UPR Sea Grant Program)

m1-TOXIN RECOGNIZES AND STABILIZES LIGANDED m1 MUSCARINIC RECEPTORS. S.I. Max*, J.S. Liang, and L.T. Potter. Molecular and Cellular Pharmacology, University of Miami School of Medicine, Miami, FL 33101.

m1-Toxin is the only ligand known which specifically identifies the extracellular face of m1 muscarinic receptors. By comparison, antagonists like pirenzepine show only partial selectivity, and antibodies recognize the third intracellular loop of m1 receptors. When applied before other ligands, m1-toxin blocks the binding of ^{3}H-antagonists only to m1 receptors (Max *et al.*, Neurosci Abstr 17:389). However, antagonists do not block the binding of m1-toxin. Membranes and soluble receptors were prepared from CHO-K1 cells transfected with the gene for m1 receptors. When applied after ^{3}H-N-methylscopolamine (NMS) or ^{3}H-pirenzepine, m1-toxin slowed the dissociation rates of these ligands from membranes at 25°C about four-fold. In digitonin, the dissociation of ^{3}H-NMS changed from a $T_{1/2}$ of about 100 minutes to zero. The implication of these results is that m1-toxin binds over the receptor pocket which holds traditional ligands, and does not project significantly into this pocket. Tetrahydroaminoacridine can similarly block m1 receptors and stop the dissociation of ^{3}H-NMS (Potter *et al.*, Mol Pharm 35:652), but this ligand is not specific for m1 receptors, and probably does not stabilize many of the extracellular loops of these receptors. Antibodies can bind to liganded m1 receptors (Levey *et al.* J Neurosci 11:3218; Wall *et al.* Mol Pharm 39:643), but have not been shown to stabilize the receptor pocket or the binding of other ligands. The specific, allosteric and nearly irreversible nature of the binding of m1-toxin may prove to have a number of uses. m1-Toxin can stabilize pure liganded (and unliganded) receptors for structural studies. Nonradioactive toxin can be used to increase the specific binding of ligands like ^{3}H-pirenzepine. Toxin-based affinity techniques may permit the isolation of pure already-labelled m1 receptors, even in detergents more effective and less expensive than digitonin. And m1-toxin may permit the study of agonist-receptor-G protein complexes which have so far proved too unstable to identify.

3-HEXYLOXY ANALOGS OF 3(1,2,5-THIADIAZOL-4-YL-1,2,5,6-TETRAHYDRO-1-METHYLPYRIDINE, TZTP) ARE POTENT AND SELECTIVE M1 AGONISTS IN VIVO. F. Bymaster*, D. Wong, C. Mitch, J. Ward, D. Calligaro, H. Shannon, B. Sawyer, S. Quimby, M. Sheardown, P. Olesen, P. Suzdak, P. Sauerberg. Lilly Research Laboratories, Indianapolis, IN 46285 and Novo Nordisk CNS Division, Malov, Denmark.

3-Hexyloxy-TZTP (TZTP-A) and 3-hexen-5-yl-TZTP (TZTP-B) are selective m1 agonists in vitro. In vivo, TZTP-A decreased the ex vivo binding (bdg) in cortex of 3H-pirenzepine (PZ), with an ED50 of 3 and 32 mg/kg, sc and po.; thus, TZTP-A penetrated into the brain. TZTP-A was a weaker inhibitor of bdg to M2 receptors with an ED50 of 14 mg/kg sc. TZTP-A and TZTP-B increased levels of the dopamine metabolite, dihydroxy-phenylacetic acid (DOPAC) in striatum up to 50%, presumably via M1 heteroreceptors. The increases in DOPAC were antagonized by M1-selective trihexyphenidyl. Both drugs transiently elevated acetylcholine (ACh) levels in striatum up to 60% and did not antagonize the large increases in ACh induced by oxotremorine, suggesting the increase in ACh was not via M2 receptors. TZTP-A inhibited PZ ex vivo bdg with a t1/2 of 3 hours and DOPAC levels were elevated up to 3 hours, but no changes were evident at 6 hours. Salivation via M3 receptor was not induced by TZTP-A up to 100 mg/kg po. Thus, TZTP-A entered the brain after systemic or oral administration, and was of moderate duration. Furthermore, TZTP-A and TZTP-B were efficacious M1 agonists in vivo, had low efficacy for M2-M3 receptors and are suitable for development as M1 agonists.

481.7

HEXYLOXY-TZTP:A POTENT AND SELECTIVE M1 AGONIST IN-VITRO. C.H. Mitch*, F.P. Bymaster, D.O. Calligaro, S. J. Quimby, B. D. Sawyer, H.E. Shannon, J.S. Ward, P.H. Olesen, P. Sauerberg, M.J. Sheardown, P.D. Suzdak. Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46285 and Novo Nordisk, CNS Division, MålØv, Denmark.

Hexyloxy-TZTP (3-(4-hexyloxy-1,2,5-thiadiazole-3-yl)-1,2,5,6-tetrahydro-1-methylpyridine) inhibited 3H-pirenzepine binding in rat hippocampus and 3H-oxotremorine-M binding in rat cortex with IC50 values of 7 nM and 10 nM, respectively. In cloned cells expressing human m1 receptors, hexyloxy-TZTP increased phosphoinositide turnover, and the potency and efficacy differed dependent upon the cell type in which the receptors were expressed (CHO>A9L>BHK). In cloned cells expressing m2, m3, m4 or m5 receptors, hexyloxy-TZTP was considerably less active. Hexyloxy-TZTP also was selective for M1 receptors in isolated tissues. At M1 receptors in rabbit vas deferens, it inhibited twitch height with an IC50 of 8 pM. Pirenzepine blocked the effects of hexyloxy-TZTP in rabbit vas deferens and had a Kb value of 10 nM. At M2 receptors in guinea pig atria, hexyloxy-TZTP had an IC50 of 5 μM. Hexyloxy-TZTP was a partial agonist in guinea pig ileum. In guinea pig bladder, it was neither an agonist nor an antagonist. The present results demonstrate that hexyloxy-TZTP is a potent, efficacious and selective M1 muscarinic agonist in-vitro.

481.8

EVIDENCE THAT M1 MUSCARINIC RECEPTOR SUBTYPE MEDIATES THE EFFECTS OF OXOTREMORINE ON MASCULINE SEXUAL BEHAVIOR.

S. Retana and J. Velazquez-Moctezuma*. Depto. de Biología de la Reproducción. Universidad Autónoma Metropolitana Iztapalapa, 09340 Mexico D.F., Mexico.

It has been shown that oxotremorine (OXO), a muscarinic receptor agonist, has a facilitatory effect on masculine sexual behavior in rats. Muscarinic receptors have been divided in several subtypes. This study analyzes the possible participation of M1 muscarinic receptor subtype in the mediation of OXO effects on masculine sexual behavior. Two groups of male rats received seven doses of the specific M1 antagonist trihexyphenidyl (TRI, 0.1, 0.2, 0.4, 0.8, 1.6 and 6.4 mg/Kg, i.p.) 30 min before assessing sexual behavior. Latency and frequency of mount, intromissions and ejaculation were recorded as well as hit rate and inter-intromission interval. No changes in these parameters of sexual behavior were observed following TRI administration. In a different group of male rats, five doses of TRI were administered before OXO (0.4 mg/Kg, i.p.). The facilitatory effect of OXO was completely prevented even with the smallest dose of TRI. These results strongly suggest the notion that cholinergic facilitation of masculine sexual behavior is mediated through the M1 muscarinic receptor subtype.

481.9

MODULATION OF ACETYLCHOLINE RELEASE BY MUSCARINIC RECEPTORS IS ALTERED FOLLOWING LESION OF CHOLINERGIC INPUTS WITH THE NEUROTOXIN AF64A.

B. Thorne* and P.E. Potter. Dept. Anesthesiology, Albert Einstein College of Medicine, Montefiore Medical Center, Bronx NY 10467.

The effects of cholinergic agonists on the evoked release of ^{3}H-acetylcholine (ACh) were studied in male Sprague-Dawley rats in which hippocampal cholinergic terminals were lesioned with the neurotoxin AF64A (ethylcholine mustard aziridinium, 2 nmoles/ventricle). Two weeks after AF64A infusion, choline acetyltransferase activity was decreased by more than 40%. ACh release was evoked from superfused hippocampal slices by electrical stimulation (1 or 2 Hz, 2 min). The nicotine dose response curve was shifted to the left following treatment with AF64A. The EC_{50} was shifted from 40 μM (controls) to 3.7 μM (AF64A). This change in response to nicotine was not due to changes in nicotinic binding sites. When the muscarinic receptors were blocked by atropine the nicotine dose response curve of control tissue, was shifted to the left (EC_{50} 4.1 μM). Atropine had no effect on the nicotine dose response curve of AF64A treated rats. In contrast, the dose response curve for inhibition of ACh release by the muscarinic agonist oxotremorine, was shifted to the right following AF64A treatment. This change in response to muscarinic drugs was reflected in a change in muscarinic M_2 but not M_1 binding sites.

481.10

LIGHT AND ELECTRON MICROSCOPIC LOCALIZATION OF m2 MUSCARINIC RECEPTOR PROTEIN IN RAT SEPTUM AND HIPPOCAMPUS.

A. Levey*, S. M. Hersch and S. M. Edmunds. Dept. of Neurology, Emory University School of Medicine, Atlanta, GA 30322

Pharmacological studies indicate that muscarinic acetylcholine receptors presynaptically regulate the release of neurotransmitters. However, the precise identity of presynaptic genetic subtypes is unknown. The cellular and subcellular distribution of m2 receptor in medial septum and hippocampus was determined using subtype-specific antibodies (Levey et al., 1991), avidin-biotin-peroxidase immunocytochemistry, and light and electron microscopic analysis. In medial septum, m2 immunoreactivity was present in both noncholinergic and cholinergic perikarya, and was more dense and punctate in the neuropil. At the ultrastructural level, m2 immunoreactivity was associated with the cytoplasmic face of the plasma membrane in perikarya, and in dendrites and postsynaptic densities; m2 was also present in many terminals. In hippocampus, m2 was present in cell bodies and processes of large neurons in the stratum oriens and hilus. Neuropil immunoreactivity was abundant in the pyramidal neuron layer, the polymorph layer of dentate gyrus. At the ultrastructural level, immunoreactivity primarily was in dendritic spines and rare axon terminals. Labeled spines contained reaction product within cytoplasm and within their postsynaptic densities. Contrary to current dogma, these findings indicate that in the septal region, m2 receptors are presynaptic (as well as postsynaptic), and that in hippocampus, most m2 receptor immunoreactivity is postsynaptic. Supported by Alzheimer Association Faculty Scholar Award (AIL), NS 01387, and NS 30454.

MUSCARINIC RECEPTOR SUBTYPES INVOLVED IN CONTRACTION OF THE GUINEA PIG ILEUM.

E. A. Thomas* and F. J. Ehlert. Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

Muscarinic receptor subtypes involved in smooth muscle contraction were investigated in the guinea pig ileum. The muscarinic agonist oxotremorine-M (Oxo-M) caused concentration-dependent contractions of the isolated ileum (IC_{50}=38 nM) with pharmacology consistent with that of an M_3-mediated response. In order to inactivate the M_3 muscarinic receptors selectively, ilea were pre-treated with the irreversible M_1/M_3 selective muscarinic antagonist 4-DAMP mustard (N-(2-chloroethyl)-4-piperidinyl diphenylacetate) (40 nM) for 1 hr in the presence of the reversible M_2-selective antagonist AFDX-116 (1 μM), and then washed extensively. This treatment caused a 22-fold rightward parallel shift in the concentration-effect curve for Oxo-M. In separate experiments, ilea were pre-treated with histamine (0.3 μM) and isoproterenol (1 μM) before measuring oxo-M-induced contractions. The resulting concentration-effect curve was biphasic consisting of high (0-50 nM) and low (> 50 nM) affinity components. Similar treatment with 4-DAMP mustard and AFDX-116 only slighty shifted the high affinity component, while producing a much greater shift in the low affinity component of the curve. Treatment with AFDX-116 (1 μM) abolished the high affinity component producing a monophasic concentration-effect curve. 4-DAMP mustard (10 nM; 1 hr) also prevented M_3-receptor mediated stimulation of phosphoinositide hydrolysis in the longitudinal muscle of the rat ileum, resulting in a 6.6-fold increase in the EC_{50} value with a 65% reduction of the maximal response. In contrast, this treatment only blocked M_2-receptor mediated inhibition of adenylate cyclase by a 2-fold increase in EC_{50}, without affecting maximum inhibition. These results support the hypothesis that the M_2 muscarinic receptors present in smooth muscle may influence contraction, perhaps by inhibiting relaxation induced by other receptors. *Supported by N.I.H. Grant NS 26511*

THE (+) OPTICAL ISOMER OF [(Z)-2-PCE] SELECTIVELY BLOCKS M_3 (ILEAL) BUT NOT M_2 (CARDIAC) MUSCARINIC RECEPTORS,

E.B. Thompson, M. Lu, S.M. Vogel and N.P. Plotnikoff*. Depts. of Pharmacodynamics, and Med. Chem. College of Pharmacy; and Pharmacology, College of Medicine, U.I. Chgo, IL 60612.

Studies in our laboratory have utilized muscarinic antagonists as probes for exploring topographical areas of the muscarinic receptors . In these studies, direct clues as to the actual binding conformation of the hydrophobic partion of structurally flexible molecules (such as atropine and QNB) have been provided by use of synthetic analogues which are structurally locked into certain desired conformations. Our earlier studies (Lu et al., 1991) showed that the racemic compound 2-phenyl cyclohexyl diethylamino ethyl ether [(Z) -2-PCE] was more potent in ileal (PA_2 = 7.15) than in atrial (pA_2 = 4.96) preparations. This suggests that the Z isomer is one of the most ileal selective muscarinic antagonist reported to date. In this study the optical isomers of the above compound were synthesized and evaluated pharmacologically on isolated rat atria and ileum preparations. Ileal selectivity of the optical isomers was similar to that of the racemate. The (+) isomer was found to be a potent competitive antagonist by a factor >100 fold, for the ileal but not the atrial muscarinic receptors. Conversely, the (-) isomer appeared to be non-competitive in this ileum. The results indicate that the competitively antagonistic activity of the racemate is due to the (+) optical isomer.

481.13

PROPERTIES OF STRIATAL m4 MUSCARINIC RECEPTORS. S.L. Purkerson, H.E. Hanchett, and L.T. Potter*. Molecular and Cellular Pharmacology, University of Miami School of Medicine, Miami, FL 33101.

The rat striatum expresses an unusually high concentration of m4 muscarinic receptors, many m1 receptors, and a few m2 receptors (Levey *et al.* J Neurosci 11:3218). m1-Toxin quantitatively blocks the m1 receptors, and 95% of the residual receptors are m4 receptors (Purkerson *et al.* Neurosci Abstr 17:390). This approach permits the first binding studies of m4 receptors coupled to normal amounts of native G-proteins. The order of antagonist affinities was NMS, trihexyphenidyl, biperiden, silahexocyclium, hexahydrodifenidol, methoctramine, himbacine, pirenzepine, gallamine and AFDX 116. Five of these ligands bound with the same affinity to rat striatal m4 receptors and human m4 receptors expressed in CHO-K1 cells. Agonist binding curves showed equal populations of GppNHp-sensitive high affinity (K_H) sites and GppNHp-insensitive low affinity (K_L) sites in both striatal and CHO-cell membranes. These studies suggest that m4 receptors, like m1-m3 receptors (Potter *et al.* Mol Pharm 39:211), may be dimeric. The order of K_H affinities was oxo-M, oxotremorine, acetylcholine, pilocarpine, carbachol, methacholine and arecoline, and K_H and K_L affinities were very similar in striatal and CHO cells. The order of K_L/K_H ratios (which often correlate with agonist efficacies) was oxo-M, carbachol, acetylcholine, methacholine, oxotremorine, arecoline and pilocarpine, which would suggest that quaternary agonists work better than tertiary agonists. These data do not correlate well with the K_d values and efficacies found for agonists by McKinney *et al.* (Mol Pharm 40:1014) for the inhibition of cAMP levels in rat striatum. In their studies oxo-M showed high affinity and efficacy, but so did several tertiary agonists. Possible reasons for the different binding and functional data include effects of activating m1 receptors on cAMP levels, and the high activity of tertiary agonists on m2 receptors. Autoradiographic studies of m1 and m4 receptors confirm their wide distribution within the striatum, and indicate their distinct cellular locations.

481.14

ALLOSTERIC MODULATION OF MUSCARINIC RECEPTORS BY BASIC PROTEINS IN RAT CEREBRAL CORTEX AND HEART. J. Hu and E.E. El-Fakahany *. Division of Neuroscience Research in Psychiatry, University of Minnesota Medical School, Minneapolis, MN 55455.

Allosteric interactions of arginine or lysine-rich proteins, such as histones, myelin basic protein (MBP) and dynorphin A (1-13), with muscarinic receptors were investigated in rat cerebral cortex and heart using radioligand receptor binding assays. These basic proteins inhibited binding of the muscarinic ligand [^{3}H]NMS at equilibrium and altered kinetics of its dissociation from the receptors. Histone VIII (rich in arginine) showed an inhibition constant value of 1.4 μM and a cooperativity value (α) of 5.4 in cerebral cortex. It also decreased the rate of dissociation of [^{3}H]NMS with an IC_{50} of 0.9 μM and a maximal inhibition of 60%. No significant difference was observed between its effects in cerebral cortex and heart. MBP also inhibited [^{3}H]NMS binding at equilibrium in a concentration-dependent manner with a lower α value (3.3 in cortex and 1.9 in heart). Maximal inhibition of specific [^{3}H]NMS binding by MBP was reduced from 45% to 16% by increasing the concentration of [^{3}H]NMS from 0.04 nM to 0.8 nM. The allosteric nature of MBP was also demonstrated in kinetic studies. The small basic peptide dynorphin A also exerted an allosteric effect on muscarinic receptor which was dependent on the number of basic residues. Our data suggest that positively charged amino acid residues in endogenous proteins might play a role in the regulation of the conformation of muscarinic receptors.

481.15

PHOSPHATIDYLCHOLINE-SPECIFIC PHOSPHOLIPASE D IS COUPLED TO RECEPTOR OCCUPANCY IN A9 CELLS TRANSFECTED WITH THE M3-MUSCARINIC RECEPTOR. P.G. Holbrook*, J. Wess# and C.C. Felder, NIMH and #NINDS, National Institutes of Health, Bethesda, MD 20892

In the presence of ethanol, phospholipase D (PLD) catalyzes a transphosphatidylation reaction producing phosphatidyl-ethanol (PEt). PEt formed in A9 cells stably transfected with the rat *m3* muscarinic receptor and stimulated with carbachol (1mM) was isolated and analyzed by fast atom bombardment mass spectrometry. It had a molecular species profile identical to that of phosphatidylcholine (PC) from unstimulated cells. In cells labeled overnight in serum free media containing ^{3}H-palmitic acid, the carbachol (100 uM) stimulated formation of ^{3}H-PEt required extracellular calcium (1mM) and was blocked by atropine (10 uM). TPA stimulated formation of ^{3}H-PEt in the presence and in the absence of extracellular calcium. EC_{50}s for carbachol stimulated ^{3}H-PEt and ^{3}H-PA formation were respectively: 8.8×10^{-6} and 5.5×10^{-7} M. Experiments with receptor chimeras produced by switching the third cytoplasmic loops of the *m3* and *m2* receptors suggest that g-protein coupling is necessary for PLD-activation. Occupancy of muscarinic receptor subtypes that couple to PI-specific PLC leads also to activation of a PC-specific PLD.

481.16

DIFFERENCES IN CARBACHOL BINDING AND PI TURNOVER BETWEEN THE DORSAL AND VENTRAL HIPPOCAMPUS. H. Ladinsky[1]*, A. Garcia[2], M. Zambelli[2], G. Schiavi[1] and S. Consolo[2]. Department of Biochemistry, Boehringer Ingelheim Italia, Milan 20139 and Mario Negri Institute, Milan, Italy 20157.

The full agonist CARB was more effective in stimulating PI turnover in the ventral (VH) than in the dorsal hippocampus (DH) while the partial agonist oxotremorine was similarly weak in both regions. No differences in density or distribution (≈20% M1, 50% M3, 30% M4) of muscarinic receptor subtypes between DH and VH were found to explain the effect using several selective antagonists in competition experiments. From the affinities of pirenzepine (K_H 6.1 nM; K_L 757 nM) and DAU 6202 (4-hydroxy-3-(tropyl) oxycarbonyl-3,4-dihydro-1H- quinazoline-2-one)(Kb 2.5 nM) to antagonize CARB-stimulated PI turnover, it appeared that about 50% of the response was activated by M1 and the other 50% by M3 receptors in either region. In binding studies against [^{3}H]NMS, CARB recognized three agonist affinity states (SH, H, and L) in the VH and two (H and L) in the DH. Gpp(NH)p converted the SH and H to the L state in both regions. Thus, regional differences in types or concentrations of G proteins may account for the complexity with which CARB binds to muscarinic receptors and stimulates PI turnover in the areas.

481.17

EVIDENCE FOR INTERACTION BETWEEN THE PHOSPHOINOSITIDE AND ADENYLATE CYCLASE SIGNAL TRANSDUCTION PATHWAYS IN THE RAT PAROTID GLAND. E. H. Gerstin, Jr. and F. J. Ehlert* , Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

In this study, we investigated whether an increase in cyclic AMP levels could modulate muscarinic receptor-mediated phosphoinositide hydrolysis in the rat parotid gland. Slices of the gland were incubated with the muscarinic agonist, oxotremorine-M (OXO-M), in the absence and presence of the adenylate cyclase-stimulator, forskolin. OXO-M at concentrations of 10 and 100 μM caused 6.98- and 13.6-fold increases in phosphoinositide hydrolysis over basal values, respectively. Forskolin (75 μM) caused significant 19.3 ± 5.01% ($P < 0.01$) and 19.0 ± 7.05% ($P < 0.05$) inhibitions of the phosphoinositide hydrolysis elicited by OXO-M at concentrations of 10 and 100 μM, respectively In preliminary experiments, OXO-M stimulated PI hydrolysis with an EC_{50} of 2.76 μM; the maximal effect was a 4.36-fold increase over basal value. The effect of forskolin (75 μM) was to increase the EC_{50} of OXO-M to 23.83 μM, which represents an 8.6-fold increase. We conclude that the forskolin-mediated increase in c'AMP results in a decrease in the OXO-M mediated phosphoinositide hydrolysis. These results suggest that receptors which increase c'AMP levels in the parotid gland may dampen muscarinic receptor-mediated phosphoinositide hydrolysis.

COMPARISONS BETWEEN HUMAN MUSCARINIC RECEPTOR SUBTYPES COUPLED TO PHOSPHOLIPASE C AND THOSE COUPLED TO ADENYLYL CYCLASE: EFFECT OF RECEPTOR RESERVE. L.L. Lauffer, R.D. Schwarz*, R.D. . and C.J. Spencer.
Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

Muscarinic receptors have been shown to exist as five distinct proteins which are functionally coupled through G proteins to phospholipase C (m1, m3, and m5) and adenylyl cyclase (m2 and m4). Stable expression of human receptors in CHO cells yielded cell lines with B_{max} values ranging from 210-2450 fmoles/mg protein and K_d values of 0.11-0.63nM (whole cell [^{3}H]-NMS binding). The use of these lines has allowed the pharmacological selectivity of various muscarinic agonists and antagonists to be determined using receptor binding and second messenger assays. Previous results obtained measuring PI hydrolysis, showed that both efficacy and potency of muscarinic agonists were markedly affected by receptor number, while antagonist results were not. However, it was not known whether similar effects occurred in cyclase linked receptors. In the present study, alkylation of Hm2 and Hm4 receptors was performed in order to determine the effect of receptor number on agonist/antagonist-induced changes in cAMP formation. These results are compared to those obtained measuring PI turnover under similar conditions in Hm1, Hm3, and Hm5 cells.

PROTO-ONCOGENE INDUCTION IN THE CNS OF LONG- AND SHORT-SLEEP MICE MEDIATED VIA MUSCARINE ACETYLCHOLINE RECEPTOR ACTIVATION. L. Tsiokas* and M. Watson. Dept. of Pharmacology, UMDNJ-N.J. Med. Sch., Newark, NJ 07103-2714.

Induction of several immediate early genes (IEGs) was studied in brains of long- and short-sleep (LS/SS) mice after activation of muscarinic receptors (mAChR) by oxotremorine (OXO;5mg/kg;ip) treatment (Rx). Brains were excised at t=0,15,30,45,60,90,120 and 180m after OXO Rx. Total RNA was extracted from LS/SS brains and processed for Northern analysis via cRNA probes for c-fos, c-jun, jun-B, jun-D and egr-1/NGFI-A as was described. c-fos mRNA (2.2 kb) shows no basal but a dramatic induction with peak levels at 60-90m in both strains. c-jun mRNA show rapid peak accumulation at 60m in both. Basal c-jun mRNA levels are significant with two transcripts of 2.9 and 3.6kb in murine CNS. The egr-1/NGFI-A gene was also induced by OXO and its mRNA (3.2kb) reaches a peak at t= 90 and 120m in LS and SS, respectively. Basal expression of the egr-1/NGFI-A gene is also seen in the murine CNS. jun-D expression is extremely robust and constitutive in nature, yet the significance of induction of jun-B is not certain. Induction of c-fos and c-jun genes show a characteristic dose-response with 1-5mg/kg OXO Rx producing increased c-fos and c-jun mRNA levels. Activation of mAChRs in vivo induce rapid and transient genomic responses via induction of several IEGs that might account for long-term changes in cellular phenotypes. (MH-43024).

EXCITATORY AMINO ACIDS: EXCITOTOXICITY V

482.1

USE OF A HERPES SIMPLEX VIRUS (HSV-1) VECTOR SYSTEM TO INTRODUCE GENES INTO CULTURED CORTICAL NEURONS WHICH ARE USED TO ASSESS EXCITATORY AMINO ACID NEUROTOXICITY. Dean Hartley*, Rachael Neve, Matthew During, and Alfred Geller. Div. Endocrinology, Childrens Hosp, McClean Hosp, and Harvard Med. Sch. Boston MA; Yale U. Sch. Med. New Haven CT.

Glutamate has been implicated in the pathophysiology of numerous neurodegenerative diseases, including Stroke, Huntington's disease and Alzheimers disease. Glutamate-induced neurotoxicity is mediated by the influx of calcium, however the biochemical pathways subsequent to calcium influx are poorly understood. Therefore, it would be useful to specifically alter calcium activated processes. Our laboratory has previously described a HSV-1 vector system which is capable of introducing genes into mature neurons (Science 241:166, 1988; TINS 14:428, 1991). We are exploiting this vector system to genetically alter signal transduction pathways to elucidate intracellular mechanisms mediating glutamate neurotoxicity. Our initial studies characterized the ability of the HSV vector system to deliver genes into cortical neurons which have been previously used to assess glutamate neurotoxicity (Hartley and Choi, JPET 250:752, 1989). The prototype vector pHSVlac expresses E.coli B-galactosidase from the constitutive HSV IE 4/5 promoter. Following infection of these cortical cultures with pHSVlac, B-galactosidase expression was readily detected in 30-50% of the neurons, as well as in glia cells. Because of the importance of calcium in mediating glutamate neurotoxicity, we are expressing genes that affect calcium mediated processes and assessing their ability to alter glutamate mediated neurotoxicity.

482.2

DELAYED ADMINISTRATION OF MEMANTINE (MTE) PREVENTS NMDA RECEPTOR-MEDIATED NEURONAL DEATH. James W. Pellegrini*, H.-S. Vincent Chen, Frances E. Jensen, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Progr. in Neurosci., Harvard Medical School, Boston, MA 02115.

Increasing evidence indicates that escalating levels of excitatory amino acids are responsible for neuronal cell death in a variety of neurological conditions including hypoxia-ischemia. The predominant form of neurotoxicity appears to be mediated by the NMDA subtype of glutamate receptor. Recently, using rat retinal ganglion cell (RGC) cultures, we found that the anti-Parkinsonian drug MTE blocks NMDA-activated current by a mechanism of open-channel blockade (IC_{50} = 1 μM). Here, using single channel recording, we demonstrate that 12 μM MTE reduced the frequency of NMDA-elicited channel opening by 87%, shortened the mean open time by 30%, but did not change the unitary channel conductance. We had previously shown that MTE prevents NMDA receptor-mediated neurotoxicity when administered coincident with the insult *in vitro* or *in vivo*. We have now tested whether delayed administration of MTE can prevent neurotoxicity. Cultured RGCs were exposed to toxic (25 μM) glutamate levels in high Ca/low Mg medium and compared with control cells. By the next day, this insult resulted in neuronal survival of 35%. In sibling cultures, MTE (12 μM) was added at 0-7 h after glutamate exposure. Survival at 24 h was close to control levels when MTE had been administered at 0 or 1 h, and approached 80% after treatment at 4 h. Presently, we are using 7-10 day old Long-Evans rats in a bilateral carotid ligation stroke model. In 7/11 litter-matched pairs, animals treated 1 h after insult with MTE (20 mg/kg) had substantially smaller strokes by MRI and histopathology after 48 h.

482.3

HALOPERIDOL AND RIMCAZOLE PREVENT INDUCTION OF THE HSP70 HEAT SHOCK GENE IN NEURONS INJURED BY PHENCYCLIDINE AND MK801. F.R. Sharp*, S. Wang, M. Butman, J. Koistanaho, S. Graham, L. Noble, S.M. Sagar, P. Berger, F.M. Longo. Dept. Neurology, UCSF School Medicine, SFVAMC, San Francisco, CA 94121.

The non-competitive NMDA receptor antagonists, PCP and MK801, produce abnormal vacuoles in posterior cingulate and retrosplenial cortical neurons (Olney et al. Science 1989). We show that PCP and MK801 induce *hsp70* mRNA and HSP72 heat shock protein in these injured neurons, and PCP induces the hsp70 gene in injured layer 2,3,5, and 6 neocortical neurons. The drug induced injury in cingulate and neocortex: occurs in 30 day and older rats, but not in 0-20 day old rats; and is prevented by prior administration of the antipsychotic drugs haloperidol (>5mg/kg) and rimcazole (>60mg/kg). It is suggested that the vacuolar injury that occurs following blockade of NMDA receptors reflects denatured proteins that induce the *hsp70* gene. Since haloperidol, rimcazole, M1 antagonists, and GABA agonists (Olney et al., Science 1991) prevent the injury, this suggests multiple receptors might mediate the injury. Alternatively, NMDA receptor blockade might activate sigma receptors which mediate the injury since haloperidol, rimacazole, and M1 antagonists have all been reported to block sigma receptors.

482.4

A TRANSGENIC MOUSE MODEL TO ASSESS THE NEUROPROTECTIVE EFFECT OF HSP70 IN THE CA1 AND CA2 REGION OF THE HIPPOCAMPUS

J.B. Uney, S. Pickering, K. Staley, M.H. Johnstone, T.H. Rabbitts[1], and M.V. Sofroniew*. Department of Anatomy, University of Cambridge, and [1]MRC Laboratory of Molecular Biology, Cambridge, U.K.

Heat shock proteins (HSPs) are induced rapidly in the mammalian brain following exposure to excitotoxins and ischaemia. Correlative evidence from several studies suggests that HSPs (particularly HSP70) may play a role in enhancing neuronal survival after stress. HSP70 proteins mediate the transport of newly synthesized precursor proteins across intracellular membranes. Cells expressing high concentrations of HSP70 may be more resistant to toxic insults due to the rapid replacement of damaged proteins. To test this possiblity, we have made a DNA construct in which the expression of HSP70 is driven by promoter 1 of the rhombotin gene. This promoter has previously been shown to direct LacZ expression to specific subpopulations of neurons in the hippocampus of adult mice, notably in the CA1 and CA2 regions. Thus far, injections of the contruct into the pronuclei of fertilized mouse eggs have resulted in the generation of 6 founder mice, which are currently being tested for expression. Lines of expressing mice will be used to assess the neuroprotective effects of HSP70 in specific hippocampal neurons following exposure to various insults, both in vivo and in vitro.

482.5

A SHORT EPISODE OF SEIZURE ACTIVITY PROTECTS CA3 NEURONS FROM PROLONGED SEIZURE ACTIVITY-INDUCED DEATH.

I. Najm*, S.S. Schreiber, A. Bruce, G. Tocco, and M. Baudry, Neuroscience Program, USC, Los Angeles, CA 90089-2520.

Systemic administration of kainic acid (KA) produces recurrent seizure activity and the loss of selectively vulnerable neuronal populations, in particular pyramidal CA3 neurons. We investigated the effects of a short episode of seizure activity on CA3 neuronal death following subsequent prolonged seizure activity. One group of adult rats was subjected to 1 hr of KA-induced seizure activity which was terminated by pentobarbital anesthesia, and treated again 16 hrs later with KA. Another group received KA twice at 16 hrs interval, while a third group received only one injection of KA. Animals were sacrificed at 16 hrs or 5 days after the last KA administration. Animals which were subjected to a short seizure episode exhibited a marked protection against delayed neuronal death in CA3 neurons resulting from a subsequent KA-induced episode of seizure activity. Histological examination of the brains of animals sacrificed 5 days after the last KA administration indicated a total absence of neuronal loss in CA3 as compared to animals which had been treated with one or two KA injections and which showed extensive neuronal loss. Immunocytochemistry of heat shock protein 72 (HSP72) performed 16 hrs after a short episode of seizure activity indicated that this period was sufficient to cause an increase of HSP72 in CA3 pyramidal cells suggesting that HSP72 could participate in the neuronal protection observed under these conditions. This phenomenon of "seizure tolerance" might therefore be viewed as an analog of the phenomenon of " ischemic tolerance" described in the gerbil brains.

482.6

CORTICAL NMDA TOXICITY *IN VITRO* IS DECREASED BY ETHANOL EXPOSURE.

K.L. Rogers*, R.A. Glover. Department of Psychiatry, University of Iowa College of Medicine, Iowa City, IA 52242.

Among the many actions of ethanol on the central nervous system are interactions with the N-methyl-D-aspartate (NMDA) receptor complex leading to inhibition of cyclic GMP production, altered ion currents, decreased neurotransmitter release and diminished NMDA-induced intracellular Ca^{2+} increases. Cortical cultures obtained from gestational day 19 rat embryos were employed to investigate a possible ethanol inhibition of NMDA toxicity. Cultures exposed for 30 minutes to NMDA in Mg^{2+}-free buffer with and without ethanol were compared using release of lactate dehydrogenase (LDH) as an assay for cytotoxicity. Cultures exposed to NMDA in the presence of ethanol released significantly less LDH than those exposed without ethanol, although considerable LDH release was seen following both conditions. These findings are consistent with other ethanol-induced changes in NMDA receptor function and suggest a possible protective role for ethanol in NMDA toxicity *in vitro*.

482.7

SELECTIVE ANTAGONISM OF JORO SPIDER TOXIN (JSTX) AGAINST QUISQUALATE (QUIS)-INDUCED LESION IN THE HIPPOCAMPUS.

H. Kanai , N. Kato,* N. Ishida , K. Satoh, A. Masui, M. Sadamatsu ,and T. Nakajima . Dept.of Psychiatry, Shiga Univ. of Medical Science, Otsu 520-21, Japan.

QUIS, a non-NMDA agonist, is known to provoke seizures with a selective cell loss in the hippocampus, indicating a suitable neurotoxin for a specific experimental model of epilepsy. We reported that a JSTX analogue, 1-naphthyl-acetylspermine (1-NA-Spm), exerts a potent and selective suppression of hippocampal epileptic discharges induced by QUIS (Brain Res., in press).

The present study was conducted to evaluate whether 1-NA-Spm selectively antagonized against histological changes induced by QUIS as well. Male Wistar rats were injected icv with 1-NA-Spm followed by either QUIS or quinolinate (QUIN), a NMDA agonist. After behavioral changes were observed, the animals were subjected to histological examination. QUIS (30ug) resulted in the loss of CA3 pyramidal cells in the injection side, which was completely blocked by 1-NA-Spm (50 ug) pretreatment. Contra-lateral side remained intact irrespective of history of repetitive seizures. JSTX analogue alone (80 ug) had virtually no effect on the cellular architecture in the hippocampus. QUIN (30 ug) induced CA1/4 lesion which was refractory to JSTX pretreatment. In several rats, JSTX appeared to exacerbate QUIN-induced changes.

482.8

LOW POTENCY OF COMPETITIVE NMDA ANTAGONISTS AGAINST GLUTAMATE NEUROTOXICITY DUE TO ASTROCYTE UPTAKE.

E.K. Speliotes*[1], K.A. Hartnett[2], E. Aizenman[2], and P.A. Rosenberg[1]. [1]Children's Hosp & Harvard Med Sch, Boston MA 02115; [2]Univ Pgh Med Sch, Pgh, PA 15261.

A puzzling feature of the pharmacology of glutamate neurotoxicity is the low potency of competitive NMDA antagonists compared to what would be expected on the basis of radioligand binding studies. These experiments were performed in order to examine the role of glutamate uptake in determining the apparent pharmacology of competitive antagonists in tissue culture models of glutamate neurotoxicity.

The potencies of APV against the transported agonist glutamate and the non-transported agonist NMDA in astrocyte-rich and astrocyte-poor cortical cultures were determined. Both agonists were used at approximately 5 times their EC50. The IC50 of APV against glutamate (1mM) in astrocyte-rich cultures was approximately 1500 μM compared to 25 μM against NMDA (200 μM). The difference in potency disappeared in astrocyte-poor cultures in which the IC50 for APV against both glutamate (20 μM) and NMDA (200 μM) was 60-70 μM.

These results are best explained by a model in which glutamate uptake plays an important role, and in which toxicity at the dendrite and at the cell body can be differentiated.

482.9

PICOLINIC ACID MODULATES KAINIC ACID INDUCED GLUTAMATE RELEASE FROM RAT STRIATAL SLICES.

L.C. Vrooman, K. Jhamandas*, R.J. Boegman, R.J. Beninger. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Picolinic acid (PIC), a pyridine monocarboxylic acid and metabolite of tryptophan, protects neurons from excitotoxic damage that is dependent on the presence of intact glutamatergic input. It is hypothesized that PIC may produce its effect by inhibiting glutamate (Glu) release. In the present study, we examined the effect of PIC on kainic acid (KA) (1 mM) induced Glu release from rat striatal slices. Endogenous Glu release was analyzed by HPLC with fluorescence detection. A dose response relationship was observed for the inhibition of KA-induced Glu release by PIC. PIC (100 μM) was found to maximally inhibit KA-induced Glu release by 65%, an effect similar to that produced by the selective non-NMDA receptor antagonist DNQX (500 μM). PIC only inhibited the calcium dependent component of releasable Glu. Nicotinic acid and isonicotinic acid, two structural analogues of PIC, showed similar profiles. PIC alone was found to significantly increase basal release of Glu by 44%. These results suggest that PIC has a stimulatory as well as an inhibitory action on striatal Glu release.

482.10

SIGMA LIGANDS PROTECT CULTURED RAT SPINAL CORD NEURONS FROM NMDA-INDUCED TOXICITY.

J.B. Long[1]*, R.J. Gaspari[1], M.A. DeCoster[1], and B.R. de Costa[2]. [1]Neuropharm. Br., Dept. of Med. Neurosci., Div. of Neuropsych., Walter Reed Army Inst. of Res., Washington, D.C. 20307 and [2]Lab. of Med. Chem., NIDDK, Bethesda, MD 20892.

The NMDA receptor complex has been implicated as a primary mediator of excitotoxic neuronal injury due in part to the protective effects of a variety of competitive and PCP-related noncompetitive NMDA receptor antagonists. Recent evidence with neuronal ischemic injury in vivo suggests that salutary effects of several non-competitive NMDA receptor antagonists might involve actions at σ binding sites in addition to the PCP binding component of the NMDA receptor complex. We therefore examined the protective effects of several σ cross-reactive NMDA receptor antagonists [dextromethorphan (DM), ifenprodil (IF) and (+)-SKF 10,047 (SKF)] in comparison with several highly selective and potent σ receptor ligands [including (+)-pentazocine (PEN), DTG, (+)-PPP, and BD 1008 (BD)] during exposure of primary cultures of rat spinal cord neurons to excitotoxic concentrations of NMDA (50-200 μM). After 8-10 days in culture, neurons were treated for 1 hr with NMDA/drug combinations in Locke's solution from which $MgCl_2$ and glucose were omitted. The following day, cell damage was quantitatively assessed using a tetrazolium salt colorimetric assay. DM, IF and SKF dose-dependently (and at highest doses completely) prevented NMDA-induced loss of cell viability. Not all σ ligands were protective; however, at concentrations ranging from 0.1-100 μM, PPP, DTG, PEN, and BD (which by themselves had no effect on measures of cell viability), also significantly, dose-dependently protected against NMDA neurotoxicity. These results indicate a potential usefulness of σ receptor ligands in the treatment of CNS neuronal injury.

482.11

AMANTADINE INHIBITS EXCITOTOXICITY IN CEREBROCORTICAL CULTURES. H.S. Lustig, K.L. von Brauchitsch, J. Chan and D.A. Greenberg*. Department of Neurology, University of California, San Francisco, CA 94110.

Excitatory amino acids (EAAs) have been implicated in the pathogenesis of acute and chronic neurodegenerative processes, and EAA antagonists protect against excitotoxicity in a variety of *in vivo* and *in vitro* disease models. Certain antiparkinsonian drugs, including amantadine, inhibit EAA responses mediated through *N*-methyl-D-aspartate (NMDA)-preferring EAA receptors and compete for [^{3}H]MK-801 binding sites on NMDA receptor-gated ion channels. Therefore, such drugs might not only reduce parkinsonian symptoms, but also modify neurodegeneration. Using neuron-enriched cultures from embryonic rat cerebral cortex, we investigated the effect of amantadine on NMDA-induced toxicity, determined by lactate dehydrogenase (LDH) release, and on NMDA-stimulated elevation of intracellular Ca^{2+} (Ca^{2+}_i), measured by fluorescence video imaging with fura-2. LDH release from control cultures (25±2% of total LDH) was unaffected by amantadine alone at concentrations as high as 300 μM (23±3%). LDH release, measured 24 hr after exposure for 20 min to 100 μM NMDA, was increased to 46±3%. Pretreatment for 10 min with amantadine (10-1000 μM) inhibited the toxicity of 100 μM NMDA, with half-maximal inhibition at 30 μM and complete inhibition at 300 μM. Amantadine (100 μM) also reduced the rise in Ca^{2+}_i produced by NMDA. These findings indicate that amantadine and other antiparkinsonian drugs with NMDA receptor antagonist properties may protect against excitotoxic neuronal injury.

482.12

4-CHLOROKYNURENINE AS A PRECURSOR OF 7-CHLOROKYNURENIC ACID IN RAT AND HUMAN BRAIN. W. Schmidt*, H.-Q. Wu, R. Schwarcz, [1]F. Salituro, [1]B. Baron, [1]M. Palfreyman and [1]T. McDonald. Maryland Psych. Res. Center, Baltimore, MD 21228 and [1]Marion Merrell Dow Res. Inst., Cincinnati, OH 45215.

7-Chlorokynurenic acid (7-Cl-KYNA), a selective antagonist of the glycine site associated with the NMDA receptor, is neuroprotective in experimental test systems. Since the compound penetrates poorly into the brain, it is difficult to explore its therapeutic potential for excitotoxic brain diseases. We have now examined if 4-chlorokynurenine (4-Cl-KYN), which should have easier access to the brain, can serve as a bioprecursor of 7-Cl-KYNA. Purified preparations of rat (Brain Res., 534:37, 1990) and human (Brain Res., 542:307, 1991) kynurenine aminotransferase (KAT) were used to investigate the conversion of 4-Cl-KYN to 7-Cl-KYNA. Enzymatic production of the latter was confirmed in all cases. In kinetic experiments with rat KAT, 4-Cl-KYN behaved like an effective competitive inhibitor, thus further indicating its ability to serve as a substrate of KAT. Preliminary evidence suggests that conversion of 4-Cl-KYN to 7-Cl-KYNA can also take place in the rat brain in vivo. Since (rat) brain KAT is predominantly localized in astrocytes which are often seen in apposition to excitatory synapses, 4-Cl-KYN administration may provide a means to produce 7-Cl-KYNA in situ in anatomically distinct and pharmacologically relevant foci.

Supported by grants NS 16102 and NS 28236 (to RS).

482.13

EXCITOTOXIC HIPPOCAMPAL DAMAGE AND NEUROPROTECTIVE AGENTS. G. Wolf, G. Keilhoff, S. Fischer, P. Hass and W. Schmidt.* Inst. of Biology, Med. Acad., D(O)-3014 Magdeburg, Germany.

Glutamate agonists, such as quinolinate, kainate, N-methyl-D-aspartate (NMDA), quisqualate, and AMPA were injected intracerebroventricularly in rats to induce convulsive reactions and hippocampal damage in order to model glutamate-mediated brain injury. Animals showed typical convulsive effects and heavy lesions of hippocampal tissue. In rats treated systemically with non-competitive glutamate agonists magnesium sulfate, MK 801, ketamine, or the adamantane derivative memantine, a reduction in neuropathological signs was observed. Depending on the dose and the application schedule even complete protection was observed. Factors of the glutamate transmitter metabolism were found to be affected in lesioned areas, most prominent the activity of aspartate aminotransferase. The vulnerability of neurons containing nitric oxide synthase (NADPH-diaphorese stained) was observed to be related to the type of glutamate agonist used as a noxious stimulus.

482.14

REPEATED EXPOSURE TO GLUTAMATE ALTERS BOTH ITS POTENCY AND EFFICACY AS AN EXCITOTOXIN. J.M. Dubinsky.* Department of Physiology, University of Texas Health Sciences Center, San Antonio, Texas 78284-7756.

Transient increases in extracellular glutamate (GLU), associated with ischemic events *in vivo*, are thought to contribute to the eventual neuronal loss observed several days later. One hypothesis explaining this delayed excitotoxicity states that normal synaptic release of GLU becomes toxic following the initial ischemic event. To test this hypothesis, in vitro toxicity experiments were performed on cultured hippocampal neurons experiencing two successive GLU insults. In the first toxic exposure, all cultures received 5 min of mildly toxic concentrations of GLU. Dose-response curves for the percentage of surviving neurons were constructed for varying doses of GLU applied during the second 5 min exposure, 2 hr after the first. Control dose-response curves following simple solution changes as a first exposure were characterized by an EC_{50} of 55 μM. When 30 μM GLU was used as the first exposure, the EC_{50} for the second exposure dropped slightly to 49 μM. When 100μM GLU was applied during the first exposure, the EC_{50} decreased to less than 5 μM. However, the amount of survival in both experiments was greater than expected from the control dose-response curve. The increase in both efficacy and potency indicate complex interactions may be involved in understanding GLU toxicity following an ischemic event. This work was supported by NIH #AG10034.

482.15

N-METHYL-D-ASPARTATE (NMDA) EXPOSURE BLOCKS GLUTAMATE TOXICITY IN CULTURED CEREBELLAR GRANULE CELLS. D.-M. Chuang*, X.-M. Gao and S.M. Paul. Biological Psychiatry & Clinical Neuroscience Branches, NIMH, Bethesda, MD 20892

Exposure of cultured cerebellar granule cells to glutamate results in a concentration-dependent (EC_{50}=22.7 ± 0.04 μM) and delayed (24-72 hr) neurotoxicity, which is blocked by the NMDA receptor antagonists APV and MK-801, but is unaffected by the non-NMDA receptor antagonists CNQX and DNQX. Pretreatment of cerebellar granule cells with subtoxic concentrations of NMDA markedly antagonizes the neurotoxic actions of glutamate with an IC_{50} of 55 ± 4 μM. The NMDA-induced neuroprotection requires a preincubation time of approximately 120 min to be fully manifest and does not require the presence of NMDA during glutamate exposure. These data demonstrate that NMDA receptors mediate both neurotoxicity and neuroprotection in cerebellar granule cells. Among four glutamate receptor agonists tested, only NMDA was able to provide a complete neuroprotection against glutamate toxicity. Quisqualate was neither neurotoxic nor neuroprotective. Ibotenate, which was also nontoxic, induced a small degree of neuroprotection. In contrast, exposure to kainate resulted in a weak neurotoxicity but also resulted in significant neuroprotection. Since preincubation of these neurons with NMDA fails to alter NMDA receptor-mediated phosphoinositide hydrolysis or the specific binding of [^{3}H] MK-801 to NMDA receptors, it appears that the neuroprotective effects of NMDA are not due to NMDA receptor desensitization.

482.16

CONTRIBUTION OF Na^+/Ca^{2+} EXCHANGE AND Na^+/K^+ ATPase IN Ca^{2+} HOMEOSTASIS: ROLE IN GANGLIOSIDE PROTECTION AGAINST GLUTAMATE NEUROTOXICITY. L. Kiedrowski*, G. Brooker, E. Costa, and J. T. Wroblewski. Fidia-Georgetown Institute for the Neurosciences, Georgetown University, Washington, D.C. 20007.

In cerebellar granule cells the concentration of free intracellular calcium ($[Ca^{2+}]_i$) and sodium ($[Na^+]_i$) was studied using the respective fluorescent probes Fura-2 and SBFI. Application of glutamate (1 μM), in the absence of Mg^{2+}, led to the increase of both $[Ca^{2+}]_i$ and $[Na^+]_i$. In the presence of extracellular Na^+ (154 mM) the increase of $[Ca^{2+}]_i$ after glutamate (1 μM) withdrawal was always followed by a rapid return to normal level and no neurotoxicity was observed. When extracellular Na^+ was replaced with *N*-methyl-D-glucamine, neurotoxicity and persistent elevation of $[Ca^{2+}]_i$ was observed with 1 μM glutamate. These results indicate that the activity of Na^+/Ca^{2+} exchanger might be operative in maintaining $[Ca^{2+}]_i$ homeostasis following glutamate receptor stimulation by nontoxic glutamate concentrations (1 μM). Application of excitotoxic doses of glutamate (50 μM) led to a sustained elevation of $[Ca^{2+}]_i$ which persisted after glutamate removal. In contrast, in cells pretreated for 2h with ganglioside GM_1 (100 μM), glutamate (50 μM) was not toxic, and $[Ca^{2+}]_i$ homeostasis was restored after glutamate removal. Additionally, GM_1 pretreatment attenuated glutamate-evoked $[Na^+]_i$ increase and accelerated the restoration of the basal $[Na^+]_i$ after glutamate removal. These effects of GM_1 were not observed in the presence of the Na^+/K^+ ATPase inhibitor, ouabain (1 mM). These data indicate that the pretreatment with GM_1 might facilitate Na^+/K^+ ATPase activity which, in turn, improves the function of the Na^+/Ca^{2+} exchanger. Moreover, these data suggest that in calcium-dependent glutamate neurotoxicity the elevation of $[Na^+]_i$ may impair the Na^+/Ca^{2+} exchange leading to $[Ca^{2+}]_i$ homeostasis destabilization.

482.17

AGE DEPENDENCY OF NMDA ANTAGONIST NEUROTOXICITY NB Farber, MT Price, J Labruyere, TA Fuller* and JW Olney, Washington Univ., St. Louis MO 63110.

Antagonists of the NMDA subtype of glutamate receptor, including phencyclidine (PCP), MK-801 and ketamine, protect neurons against excitotoxic injury in conditions such as ischemia, hypoglycemia and status epilepticus. However, in rats these agents cause neurotoxic side effects (pathomorphological changes in cerebrocortical neurons), and in humans, both PCP and ketamine are known to cause acute schizophrenia-like psychotic symptoms. The psychotic reaction associated with ketamine anesthesia, known as an "emergence" reaction, is suppressed by certain drugs (barbiturates and benzodiazepines) that also block the neurotoxic reaction in rat cortex, suggesting a relationship between the neurotoxic and psychotomimetic actions of these agents. The ketamine "emergence" reaction, like schizophrenia, is peculiarly age-dependent – typically, susceptibility is greatest in early to mid adulthood, and pediatric populations are not vulnerable. Here we report that susceptibility to the cerebrocortical neurotoxic reaction is also age-dependent with rats being non-susceptible to MK-801 neurotoxicity at 1 month of age, weakly susceptible at 2 months and not fully susceptible until 3 months. Thus, a similar age-dependency profile characterizes: 1) the neurotoxicity of NMDA antagonists in rats, 2) the psychotomimetic effects of NMDA antagonists in humans, 3) onset of schizophrenic psychosis, and 4) susceptibility to other adult-onset neurological disorders. Our findings suggest the possibility that some or all of these phenomena may be mechanistically related, and that NMDA antagonists may be safer for use as neuroprotectants in infancy than in adulthood. Supported by DA 06454, DA 05072, AG 05681 and RSA MH 38894 (JWO).

THE NMDA RECEPTOR ANTAGONIST MK-801 IS TOXIC TO VENTRAL HORN NEURONS IN ORGANOTYPIC CULTURES OF SPINAL CORD. D.M. Saroff AND J.R. Delfs*. Laboratory of Neurodegenerative and Aging Studies, New England Deaconess Hospital, Geriatric Medicine Program, Boston, MA. 02215.

We have previously demonstrated that the competitive N-methyl-D-Aspartic Acid (NMDA) antagonist D-2-amino-5-phosphonovaleric acid (D-AP5) has only a partial protective effect against NMDA-mediated neurotoxicity. These findings appeared to be due to a neurotoxic effect of D-AP5 itself on ventral horn acetylcholinesterase-positive neurons (VHANs) in organotypic rollertube cultures of spinal cord (OTC-SCs) (Saroff et al., Soc. Neurosci. Abstr., Vol. 17, Part 1, p. 787, 1991). In vivo studies have reported the specific non-competitive NMDA antagonist (+)-5-methyl-10,11-dihydro-5H-dibenzo [a,d]cyclohepten-5,10-imine maleate (MK-801) to have toxic effects on neurons in cingulate cortex (Labruyere et al.,Soc. Neurosci. Abstr., Vol. 15, Part 1, p. 761, 1989).

In the present study we examined the effects of MK-801 on VHANs in the OTC-SC system. Dose-response studies with MK-801 were carried out on OTC-SCs after 2 weeks in vitro. Cultures were exposed for 72 hours to either control media or media with MK-801 at concentrations of 1μM, 10μM, 100μM, or 1mM. MK-801 aplication produced a marked toxic effect on VHANs in culture. This toxicity was evident even at the lower concentrations studied. These results suggest that antagonists of excitation at the NMDA receptor, whether competitive or non-competitive, may cause neurotoxic effects on ventral horn acetylcholinesterase-positive neurons (VHANs). These studies support caution in the use of NMDA antagonists in clinical trials. (Supported by NIH Grant NS27685-03)

CALPAIN I INHIBITION DOES NOT BLOCK EXCITATORY AMINO ACID-INDUCED NEUROTOXICITY IN MURINE CORTICAL CULTURES. V.M.G. Bruno* and R.G. Giffard. Dept. of Anesthesia, Stanford Univ. Sch. of Med., Stanford, CA 94305.

Activation of the Ca^{2+}-dependent protease calpain I has been implicated in neuronal responses to excitatory amino acids in such diverse settings as long term potentiation and ischemic brain damage. Spectrin breakdown subsequent to Calpain I activation by increased intracellular calcium has been related to neuronal death, but reports of its involvement in the development of excitatory amino acid neurotoxicity has varied in different systems. We investigated the effect of Calpain I inhibitors in cortical cultures injured by exposure to maximal and submaximal concentrations of the glutamate receptor agonists N-methyl-D-aspartate (NMDA), kainate and AMPA. Injury was assessed by release of lactate dehydrogenase. We studied both calpain inhibitor I and MDL 28170 which has high specificity for the enzyme, both up to 100μM. Neither inhibitor protected neurons from brief exposure to NMDA (100μM-500μM) or 24 hr exposure to NMDA (12.5μM-500μM), kainate (30μM-300μM) or AMPA (10μM-100μM). MDL 28170 has been shown to inhibit CA^{2+} ionophore A23187-induced proteolysis of spectrin in erythrocyte ghosts. We then investigated the effect of the drug on A23187-induced toxicity in our cultures. Cells exposed to the ionophore for 20 minutes were moderately injured when assessed at 24 hr. MDL 28170 reduced the neuronal damage by about 30%. Activation of calpain I does not appear to be a major source of injury in excitatory amino acid-induced neurotoxicity in neocortical cultures.

L-trans-2,4-pyrrolidine dicarboxylate (L-PDC), an Inhibitor of High Affinity Glutamate Uptake (HAGU), is Neurotoxic in Neonatal Rat Brain. John D.E. Barks* and Faye S. Silverstein. University of Michigan, Departments of Pediatrics and Neurology, Ann Arbor, MI 48109

Strong evidence of the neurotoxicity of endogenous glutamate (GLU) in mammalian brain was provided by the observation that DL-threo-3-hydroxyaspartate (THA), an HAGU inhibitor, was neurotoxic in adult rodent striatum (J Neurochem 44:247); however, THA did not elicit neuropathologic changes in neonatal brain. The absence of injury was interpreted as evidence that immaturity of glutamatergic innervation limited the potential toxicity of endogenous GLU at this developmental stage. Yet, there is considerable support for the hypothesis that endogenous GLU can be neurotoxic in the developing brain. To address this issue, we assessed the neurotoxicity of the selective HAGU inhibitor L-PDC (J Med Chem 34:717) in 7 day old rats. L-PDC (pH 7.4) was injected into right anterior striatum (STR) (568 nmol, n=2) or through dorsal hippocampus into posterior STR (568 nmol, n=4, 150 nmol, n=2). Neuropathology was assessed in animals killed 5 days later. After anterior injections, focal neuronal necrosis was evident in dorsal STR. High-dose posterior injections caused prominent hippocampal lesions with CA_{1-3} pyramidal layer thinning and focal necrosis in dorsal thalamus; 150 nmol produced small foci of pyramidal cell loss. Focal cortical necrosis and callosal cysts were apparent adjacent to the injection track. Preliminary autoradiographic 3H-GLU binding assays were also done; L-PDC (10^{-7} or 10^{-5} M) did not displace 3H-GLU, suggesting that L-PDC lacked intrinsic agonist properties. Thus, L-PDC-induced brain injury provides direct support for the hypothesis that endogenous GLU may be neurotoxic in the developing brain.

DISCOVERY OF A HIGH AFFINITY, SODIUM-DEPENDENT L-PROLINE TRANSPORTER EXPRESSED IN SUBPOPULATIONS OF PUTATIVE GLUTAMATERGIC NEURONS

R.T. Fremeau, Jr.[1,*], M.G. Caron[2], and R.D. Blakely[3] Depts. of Pharmacology,[1] Neurobiology[1], Cell Biology,[2] and HHMI,[2] Duke Univ. Med. Ctr., Durham, NC 27710 and [3]Dept. of Anatomy and Cell Biology, Emory Univ. Med. School, Atlanta, GA.

We have used PCR with degenerate oligonucleotides derived from two conserved regions of the norepinephrine and GABA transporters to identify novel sodium-dependent transporters expressed in rat brain. One PCR product hybridized to a 4 kb RNA concentrated in subpopulations of putative glutamatergic neurons. Prominent *in situ* hybridization signals were observed over mitral cells of the olfactory bulb, pyramidal cells of layer V of the cerebral cortex, pyramidal cells of the piriform cortex, and pyramidal cells of field CA3 of the hippocampus. In contrast, background labeling was observed over granule cells of the dentate gyrus, caudate-putamen, white matter tracts, choroid plexus, and ependymal cells of the cerebral ventricles. Transient expression of the cognate cDNA conferred sodium-dependent, high affinity (K_m=9.7 μM) L-proline uptake in HeLa cells which exhibited a pharmacological profile similar to that for high affinity L-proline transport in rat brain slices. The cloned transporter cDNA predicts a 637 amino acid protein with 12 putative transmembrane domains and exhibits 44-45% amino acid sequence identity with other members of the emerging family of neurotransmitter transporters. These findings support a synaptic role for L-proline in specific excitatory pathways in the CNS and provide the basis for a direct molecular analysis of the presynaptic components of these excitatory projections.

483.2

CHANGES OF pH DURING GLUTAMATE UPTAKE. M. Bouvier*, M. Szatkowski, A. Amato and D. Attwell. Dept of Physiology, University College London, Gower St, London WC1E 6BT, UK.

Uptake of glutamate into glial cells and neurones ultimately terminates the post-synaptic action of the neurotransmitter. The glutamate uptake carrier is known to be powered by the co-transport of an excess of Na^+ ions (at least 2) and it also counter-transports one K^+ ion.

When L-glutamate or D-aspartate uptake was activated in whole-cell clamped Müller cells from the salamander, a pH sensitive electrode outside the cell detected an alkalinization of the extracellular medium, and intracellular BCECF detected an internal acidification. If intracellular Cl^- was replaced by ClO_4^-, the magnitude of the uptake current evoked by glutamate was increased but the external alkalinization was reduced. Using microelectrodes sensitive to perchlorate, it was possible to monitor ClO_4^- efflux when uptake was activated with ClO_4^- inside the cell. These data suggest that a pH changing anion such as OH^- or HCO_3^- is transported out of the cell by the uptake carrier and that ClO_4^- can be transported in place of this anion. Inhibition of carbonic anhydrase by acetazolamide had no effect on the intracellular acidification nor on the extracellular alkalinization, suggesting that HCO_3^- is not counter-transported on the carrier.

We therefore propose an uptake stoichiometry in which one glutamate ion is transported into the cell together with 2 Na^+ ions, and one K^+ ion and one OH^- are counter-transported, per cycle of the carrier.

DIFFERENTIAL LOCALIZATION OF THE METABOTROPIC (mGluR1) AND NMDA RECEPTORS IN THE BRAIN. M. Fotuhi*, A.H. Sharp, S.H. Snyder, and T.M. Dawson. Depts. Neuroscience and Neurology, Johns Hopkins Univ. Sch. Med., Baltimore, MD, 21205.

The G-protein-linked mGluR1 and the ion-channel-complex of the NMDA receptor mediate slow and fast responses of neurons to glutamate, respectively. We have compared the distribution of the two forms of mGluR1, alpha and beta, with NMDA receptors in the rat brain by immunohistochemistry and by in situ hybridization. We find that both mGluR1 and NMDA receptors are widely distributed. However, in a number of brain regions, they occur in distinctly different neuronal populations.

For instance, mGluR1 predominates in the non-pyramidal neurons of the cerebral cortex, stratum oriens of CA1 and CA3 of the hippocampus, islands of Callaje, subthalamic nucleus, lateral hypothalamus, mammillary bodies, and the molecular layer of the cerebellum. In contrast, the NMDA receptor predominates in the pyramidal neurons of the cerebral cortex and the hippocampus, medium spiny neurons of the striatum, paraventicular nucleus of hypothalamus, and the granule cell layer of the cerebellum.

These findings, in combination with reports of the distribution of other glutamate receptors, suggest that while many neurons are equipped to mediate both slow and fast responses to glutamate, many others are speciallized to have either a slow or fast response.

DISTRIBUTION AND MORPHOLOGY OF NEURONS EXPRESSING THE GLUR 2/3 SUBUNIT IN FOUR NEOCORTICAL AREAS OF MONKEYS. Fiorenzo Conti*, and Andrea Minelli. Institute of Human Physiology, University of Ancona, Via Ranieri, I-60131 Ancona (Italy).

In the last few years, several non-NMDA ionotropic glutamate (Glu) receptor subunits (GluR) have been cloned. Four of these, GluR1-4 (or GluR A-D), have pharmacological properties of AMPA receptors and appear to form heterometric receptor complexes. Recent data show that the GluR 2 subunit appears to be dominant in determining the properties of the receptor complex, since its presence is required for Ca^{++}-impermeability. Here we report on the distribution and morphology of neurons expressing the GluR 2/3 subunit in four neocortical areas of the monkey brain as studied using a subunit-specific antibody produced and characterized in Dr. Wenthold's lab (*Wenthold et al., J. Biol. Chem., 267: 501-507, 1992*). Under deep barbiturate anaesthesia, animals were perfused transcardially with phosphate buffer followed by 4% paraformaldehyde, the brains were removed, and postfixed. Small blocks from the primary somatic sensory (areas 3a, 3b, 1, and 2), the primary visual (area 17), the primary motor (area 4), and the posterior parietal (area 5) cortices were cut on a Vibratome in 15-μm thick sections, and processed for GluR-ICC (Ab 25) using the ABC method. Immunostaining was present both on cell bodies (excluding the nucleus) and on the major dendrites, and in the neuropil (mostly on dendritic processes).The pattern of GluR 2/3-positive neurons was basically similar in the four areas studied and was characterized by the presence of numerous small and medium sized pyramidal neurons in layer II and upper layer III, sparse non-pyramidal neurons in lower layer III and in layer IV, and some pyramidal and non-pyramidal neurons in layers V-VI. Some differences were, however, present when comparing the four areas: the number of positive neurons in layer IV was highest in areas 17 and 5, whereas the number of pyramidal neuron in layers V-VI was highest in area 4. The identity of immunoreactive non-pyramidal neurons could not be determined at the light microscope, and experiments are in progress to define the ultrastructural features of these neurons.

EVIDENCE FOR GLUTAMATERGIC NONPYRAMIDAL NEURONS IN THE RAT HIPPOCAMPUS: GOLGI STAINING COMBINED WITH POSTEMBEDDING IMMUNOCYTOCHEMISTRY. E. Soriano[1], H.-D. Hofmann[2]* and M. Frotscher[2]. [1]Unit of Cell Biology, Faculty of Biology, Univ. Barcelona, Spain 08028; [2]Inst. Anat., Univ. Freiburg, D-7800 Freiburg, FRG.

Nonpyramidal neurons of the hippocampus are known to be inhibitory using GABA as a transmitter. They control the principal cells, granule cells and pyramidal neurons, which are excitatory. By using postembedding immunocytochemistry in combination with Golgi staining, we provide evidence here that at least two types of nonpyramidal neurons in the rat hippocampus use glutamate as transmitter.

Mossy cells in the hilus and a novel type of spiny nonpyramidal cell in the mossy fiber termination zone of CA3 were Golgi-stained, gold-toned, and processed for postembedding immunocytochemistry using glutamate and GABA antibodies. At the electron microscopic level, both cell types were seen to receive massive input from the mossy fibers. When adjacent semithin sections through the cell body region of Golgi-stained neurons were immunostained, both cell types reacted for glutamate, like the pyramidal neurons and granule cells, but did not stain for GABA. In contrast, many other local circuit neurons were GABA-positive but could not be immunostained with the glutamate antibody. Excitatory glutamatergic nonpyramidal cells that are integrated in the main excitatory pathway of the hippocampal formation may play a hitherto underestimated role in hippocampal circuitry.

PHOSPHATE-ACTIVATED GLUTAMINASE mRNA EXPRESSION IN RAT SPINAL CORD. B. Srinivasan* and K.E. Miller. Dept. Anatomical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190

Phosphate-activated glutaminase (PAG) is the enzyme responsible for converting glutamine to glutamate in glutamatergic and GABAergic neurons. We have examined PAG mRNA in rat spinal cord using RNA blots and *in situ* hybridization. Spinal cords, kidneys, and brains from male rats were removed, total RNA was extracted, and slot blots were prepared. ^{32}P-labelled PAG cDNA (ATCC; Banner et al.,Molec.Br.Res 3:247,'88) was used to probe RNA blots. PAG mRNA was expressed in spinal cord similar to brain and kidney. To localize PAG mRNA to neurons, *in situ* hybridization was performed on sections from cervical, thoracic, and lumbar spinal cord and dorsal root ganglia (DRG). ^{32}P-labelled PAG cDNA was used for autoradiographic localization and digoxigenin-labelled PAG cDNA or 20mer PAG oligoprobes were used for nonradioactive localization. In the DRG, most neurons were labelled. In addition to intensely labelled motor neurons, other labelled spinal neurons were found in the intermediolateral cell column, lateral spinal & cervical nuclei, marginal zone, substantia gelatinosa, and central gray region (lamina X). The results from this study indicate that PAG mRNA is expressed in specific neurons of rat DRG and spinal cord, including some neurons not traditionally considered glutamatergic or GABAergic. Supported by NS27213 (KEM).

THREE SUBPOPULATIONS OF CORTICAL GABAERGIC INTRINSIC NEURONS IN THE RAT. Y. Kubota* and E.G. Jones Laboratory for Neural Systems, Frontier Research Program, RIKEN, Wako, Saitama 351-01, Japan and Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Recent studies have revealed that the cortical GABAergic neurons contain a wide variety of other neuroactive substances and specific calcium binding proteins. In this study we demonstrated the subpopulations of GABAergic neurons in different cortical area of the rat with double immunohistochemical methods. In all areas of the neocortex, intrinsic GABAergic neurons are subdivided into at least three types based on the selective colocalization of parvalbumin, calbindin D 28kDa or choline acetyltransferase (ChAT). All calbindin D 28kDa/GABA immunoreactive cells show somatostatin immunoreactivity and a small number of calbindin D 28kDa containing cells also show neuropeptide Y immunoreactivity and NADPH-diaphorase staining. All ChAT/GABA immunoreactive cells also show VIP immunoreactivity. In the piriform cortex and entorhinal cortex, these three subpopulations of GABAergic intrinsic neurons have slightly different characteristics. GABAergic parvalbumin containing neurons always contain calbindin D 28kDa but about half the calbindin D 28kDa containing neurons do not show parvalbumin immunoreactivity.

GLUTAMATE, GABA AND SUBSTANCE P IN THE PARAVENTRICULAR NUCLEUS OF THE THALAMUS (PV): AN IMMUNO-EM STUDY IN THE RAT. G. Balercia, S. De Biasi°, A. Amadeo° and M. Bentivoglio (SPON:ENA). Institute of Anatomy, University of Verona and °Dept. of General Physiology and Biochemistry, University of Milano, Italy.

PV is part of the midline group of thalamic nuclei and its synaptic organization and neurochemical features are still largely unknown. Immunopositivity for GABA and glutamate (Glu) in the rat PV was here revealed by a post-embedding immunogold procedure, and that for substance P (SP) by a pre-embedding method, using polyclonal antisera. Glu-, GABA, SP-immunoreactive (ir) terminals were observed, whereas only Glu-immunopositivity was also detected in neuronal perikarya, thus confirming the extrinsic origin of the GABAergic and SPergic innervation of the rat PV. Glu-ir terminals contain round clear vesicles and occasionally large granular ones; they make asymmetric synaptic contacts with proximal and distal dendritic arborizations. GABA-immunolabeling is in small to medium-sized terminals that contain clear pleomorphic vesicles and make symmetric synapses on dendrites of different caliber and frequently on cell bodies; some of them also contain several large granular vesicles. SP-immunoreactivity is present in small, dome-shaped terminals contacting distal dendrites, and in medium- to large-sized terminals contacting proximal dendrites and their spines. SP-ir terminals make asymmetric synaptic contacts and contain round clear vesicles and a variable number of large granular vesicles.

GLUTAMATE-IMMUNOREACTIVE CLIMBING FIBERS IN THE RAT CEREBELLAR CORTEX. P. Grandes, F. Ortega, L. Hennequet, J. Gondra and P. Streit*[1]. Dept. of Neuroscience, Basque Country University, E-48080 Bilbao; [1]Institut für Hirnforschung, University of Zürich, CH-8029 Zürich.

The nature of the climbing fiber transmitter is still a matter of debate. To determine whether glutamate-immunoreactive profiles with the morphological characteristics of climbing fibers could be found in the rat cerebellar cortex, an immunocytochemical study was performed at the levels of light (LM) and electron microscopy (EM). A monoclonal 'anti-glutamate' antibody was used in combination with postembedding staining. At the LM level, strongly labeled fibrous profiles and chains of interconnected varicosities appeared, often in close apposition to principal Purkinje cell dendrites. In EM preparations, some immunoreactive presynaptic elements were varicosities and elongated profiles that were 3-4 times more heavily labeled than their postsynaptic partners. These results show that a subset of climbing fibers and their terminals contain relatively high levels of glutamate-like immunoreactivity and provide additional evidence for a role of glutamate as transmitter in these cerebellar afferents.

[3H]D-aspartate labeling of Calbindin immunoreactive striato-pallidal and striato-nigral projection neurons. H.D. Hodges, L.E. White, K.M. Carnes, J.M. Dubinsky, & J.L. Price* Dept. Anatomy & Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO and Dept. of Physiology, Univ. Texas Health Science Ctr., San Antonio, TX.

The medium spiny neurons that project from the neostriatum to the globus pallidus and substantia nigra are immunoreactive for gamma-aminobutyric acid (GABA) and its synthetic enzyme glutamic acid decarboxylase (GAD). In addition, a subpopulation of these cells are co-labeled by retrograde transport of [^{3}H]D-aspartate injected into the globus pallidus or substantia nigra. [^{3}H]D-aspartate is taken up at axon terminals through the high affinity glutamate/aspartate uptake system found in neurons that use these excitatory amino acids as neuro-transmitters. Thus, both inhibitory and excitatory neurotransmitters may be present in the same striatal neurons (Carnes et al., Soc Neurosci Abs., 1991).

In this study, we tested whether cells that can be labeled with [^{3}H]D-aspartate are also immunoreactive for calcium binding proteins, parvalbumin and calbindin. Parvalbumin has been shown to be present in medium to large aspiny interneurons that are scattered throughout the striatum. Our findings show that parvalbumin does not colocalize with cells labeled by injections of [^{3}H]D-aspartate, even in cases in which the injection involved the striatum directly. Calbindin immunoreactivity is present in medium spiny projection neurons and defines the matrix compartment in the patch/matrix organization within the neostriatum. Most of the striatal cells labeled by [^{3}H]D-aspartate were also immunoreactive for calbindin. However, some [^{3}H]D-aspartate positive, calbindin negative cells are also found possibly because [^{3}H]D-aspartate cells are found in both matrix and patch compartments. Supported by the National Parkinsons Foundation and NIH grants DC00093 and GM07200.

AMINO ACID IMMUNOCYTOCHEMISTRY OF PRIMARY AFFERENT TERMINALS IN DEEP LAMINAE OF THE RAT DORSAL HORN

K.D. Phend*, R.J. Weinberg, J.G. Valtschanoff and A. Rustioni. Dept. of Cell Biology & Anatomy, University of North Carolina, Chapel Hill, NC 27599.

As part of a broader investigation we tested whether terminals of large fibers mediating low-threshold cutaneous input are enriched in glutamate or aspartate. Four to 7 days after injection of HRP conjugated to B subunit of cholera toxin in the sciatic n., rats were perfused with 2.5% glutaraldehyde/0.5% paraformaldehyde/0.1% picric acid. Vibratome sections of lumbar spinal segments were cut, reacted for TMB and embedded in plastic. Blocks from lamina IV were cut out; thin sections were stained with glutamate and aspartate antisera separately or in combination using different sizes of gold particles. Quantitative EM methods were employed to compare the density of gold particles coding for either antiserum in labeled terminals. To help define background, sections were also stained for GABA.

Mean staining level for glutamate was above background in primary afferent terminals in lamina IV compared with staining in dendrites, glia and GABA-positive terminals. Staining for aspartate was only marginally higher than background in afferent terminals and was elevated in dendrites as well. Density of staining for both amino acids in primary afferent terminals in lamina IV was lower than that in terminals of primary (unmyelinated and small myelinated) fibers in lamina II (Phend et al., Neurosci. Abst.1991).

483.12

AN ELECTRON MICROSCOPIC STUDY OF GLUTAMATE-LIKE IMMUNOREACTIVE (GLU) PERIKARYA AND PROCESSES IN THE DORSAL RESPIRATORY GROUP (DRG) OF THE FELINE MEDULLA. **V.J.Massari*, Z.Z. Song, H.M. Rhee# and P.J. Gatti. Dept. Pharmacology, Howard Univ. Coll. Med., Washington, DC and #FDA, Rockville, MD.**

We have previously observed GLU neurons and processes in the ventrolateral subnucleus of the tractus solitarius (vlNTS) using light microscopy. In this study, we have attempted to define the types of immunoreactive processes which are found in the vlNTS. Adult mongrel cats were anesthetized and perfused through the descending aorta with a combination of 4% paraformaldehyde and 0.3% glutaraldehyde. Vibratome sections were processed by an avidin-biotin based immunoperoxidase method utilizing a mouse anti-glutamate antiserum (INCSTAR). We have observed several small GLU perikarya with a large invaginated nucleus and a thin rim of immunoreactive cytoplasm. In addition, we have seen a few large GLU neurons with similar characteristics. Numerous large GLU dendrites receiving primarily asymmetric synapses from unlabeled nerve terminals were also seen. GLU axons were observed and unmyelinated. As yet, we have not observed any GLU nerve terminals in the vlNTS. These data suggest that some of the inspiratory neurons which predominate in the DRG utilize glutamate as an excitatory neurotransmitter, however, as yet the data do not indicate a role for glutamatergic nerve terminals in the regulation of the activity of DRG neurons. Supported by NIH HL 1RO1-44922 and the American Heart Association.

GLUTAMATE AND ASPARTATE IMMUNOREACTIVITY IN CORTICOSTRIATAL NEURONS OF THE RAT - R. Giuffrida* - Ist. Fisiologia umana, University of Catania, I-95125, Catania ITALY

The aim of the present work was to test whether corticostriatal neurons are immunostained by antisera raised in rabbits against glutamate and aspartate conjugated to hemocyanin by glutaraldehyde (Hepler *et al.*, J. Histochem. Cytochem, 1988, 36: 13-22). Corticostriatal neurons were identified by the retrograde transport of a tracer (colloidal gold-labeled WGA-apoHRP; Basbaum and Menétrey, J. Comp. Neurol., 1987, 261: 306-318) pressure-injected in the caudate-putamen; antisera were visualized by peroxidase immunocytochemistry using the ABC method. The bulk of corticostriatal neurons was observed in layer V of frontal and parietal areas, mainly in the ipsilateral hemisphere. In a sample of 1012 corticostriatal neurons in sections processed for Glu-antiserum, 595 (or 59%) were immunostained; in a sample of 1470 corticostriatal neurons in sections processed for Asp-antiserum, 837 (or 57%) were immunostained. Since it has been previously demonstrated that the two antisera largely reveal distinct populations of cortical neurons, results obtained combining Glu- and Asp-immunocytochemistry indicate that the entire population of corticostriatal neurons contains elevated concentrations of Glu or Asp in their cell body.

GLUTAMATERGIC RAPHESPINAL EXCITATION OF SPINAL MOTOR OUTPUT IN CATS. S.J. Fung*, R.H. Liu, V.K. Reddy and C.D. Barnes. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

The nucleus raphe pallidus (NRP) has been described to evoke, upon electrical stimulation, a rapid depolarization and action potential discharges in cat hindlimb motoneurons of both flexor and extensor origins (Fung and Barnes, 1989, *Neurosci. Lett. 103:* 185-190). We sought to answer two fundamental questions pertaining to such findings: (1) whether the motor excitation is caused by raphespinal neurons or other descending systems traversing through or adjacent to the medullary sites of stimulation; (2) is the fast, excitatory glutamate (Glu) transmitter involved in the bulbospinal excitation of hindlimb motoneurons?

Using the simultaneous, dual (Glu and serotonin) immunofluorescence method in combination with retrograde tract-tracing technique (by unilaterally injecting FITC-labeled microspheres to L7 ventral horn), spinally projecting neurons arising from NRP and nucleus raphe obscurus (NRO) were frequently found to contain either or both antigens, with more triple-labeled compared to double-labeled cells. Electrical stimuli (4 pulses of 50 μs duration, 500 Hz, 50-150 μA) applied to these medullary sites, in decerebrate cats, potentiated the L7 monosynaptic reflex (MSR). That the NRO or NRP neurons (instead of adjacent fiber systems) were the main source of the MSR enhancement was confirmed by a similar potentiation of the MSR upon chemically stimulating these raphespinal neurons with 0.2-0.5 μl of 0.5 M glutamate. Microinjections of the vehicle to the same sites were without effect on the MSR. Electrical stimulation of the NRP or NRO also induced ventral root responses signifying motoneuron discharges. These effects were reversibly antagonized by intraspinally injecting a non-NMDA antagonist CNQX (8x0.2 μl injections of 0.1M solution along the L7 ventral horn). Vehicle injections caused no changes on the ventral root responses. These data support a role of glutamate in raphespinally induced excitation of lumbar cord somatomotor outflow in cats.

483.15

EVIDENCE FOR A DESCENDING GLUTAMATERGIC CONTROL OF LUMBAR MOTONEURONS BY LOCUS COERULEUS COMPLEX NEURONS IN THE CAT. R.H. Liu, V.K. Reddy, S.J. Fung and C.D. Barnes*. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

Glutamate (Glu) is considered to be a major excitatory neurotransmitter in the central nervous system. Previously reported presence of Glu-like immunoreactive (Glu-LI) somata in the rodent catecholaminergic nucleus locus coeruleus (LC) raises two questions: (1) Are there any Glu-LI neurons in the catecholaminergic coerulospinal system of the cat? (2) What is the physiological role, if any, of Glu in LC control of spinal motoneurons?

In this study we used simultaneous immunofluorescence technique to identify tyrosine hydroxylase (TH) and Glu immunoreactivities in neurons that were retrogradely labeled by spinal (L7 ventral horn) injections of fluorescent microspheres (Zhuo et al., 1992, *J. Chem. Neuroanat.* 5:1-10). We found a widespread coexistence of Glu and TH in most (>80%) descending neurons and they were distributed randomly throughout the rostrocaudal extent of the LC complex. Electrical stimulation (4 pulses of 50 *us* duration at 500 Hz, intensity = 50-200 *uA*) of the LC complex, in decerebrate cats, consistently induced L7 motoneuron discharges recordable ipsilaterally as ventral root responses. The LC evoked ventral root responses were reversibly reduced (>50%) upon intraspinal injecions of the non-NMDA antagonist CNQX (in a total of 4 pene trations along the L7 ventral horn, each penetration consisted of 2 injections of 5 ng/0.2 *ul*). Vehicle injections were without any significant effect on the LC evoked ventral root responses. These results support that Glu has a pivotal role in mediating coerulospinal excitation of lumbar motoneurons in cats.

DISTRIBUTION OF THE NMDA RECEPTOR ANTAGONISTS [3H]-CGS 19755 AND [3H]MK-801 AFTER INTRATHECAL INJECTION IN MICE. J. Näsström*, É. Böö, M. Ståhlberg and O.-G. Berge. Astra Pain Control, Preclinical Research, Södertälje, Sweden.

The tissue distribution of [3H]CGS 19755 and [3H]MK-801 was investigated for up to 6 h after single lumbar spinal i.t. injection. [3H]CGS 19755 redistributed slowly from its injection site towards brainstem and cortex. In the cortex, the radioactivity peaked 3-4 h after injection. At no time did the level in frontal cortex exceed 10 % of the level in lumbar spinal cord. The highest peripheral level of [3H]CGS 19755 was found in kidneys. [3H]MK-801 redistributed rapidly from the spinal cord injection site to peripheral organs. The highest peripheral levels of [3H]MK-801 were found in lungs and liver, where the radioactivity peaked between 10 and 30 min after the injection. The levels of [3H]CGS 19755 were consistently higher in CNS tissues (except for the first 15 min in frontal cortex) and blood than the corresponding levels of [3H]MK-801. The opposite relationship was true in liver, lungs, kidneys, stomach, intestine, spleen and heart. The effect of these antagonists on response latency in the hot-plate test was quantified in the same animals immediately prior to sacrifice for the distribution study. For the first hour after the injection, the effect of CGS 19755 in the hot-plate followed the temporal distribution of this antagonist to the lumbar region of spinal cord. MK-801 was substantially ineffective in the hot-plate test even at 100 times the effective equimolar dose of [3H]CGS 19755. The marked difference in the distribution profile of [3H]MK-801 and [3H]CGS-19755 in the spinal cord does not appear to explain the lack of effect of MK-801 in the hot-plate test.

484.2

EFFECTS OF GLYCINE ON DIZOCILPINE-INDUCED CHANGES IN ACOUSTIC STARTLE. R.S. Mansbach* Dept. of Pharmacology & Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

Noncompetitive N-methyl-D-aspartate (NMDA) antagonists such as dizocilpine (MK-801) block central glutaminergic neurotransmission by binding to a site within the NMDA receptor-associated cation channel. Application of exogenous glycine has been shown to improve NMDA-stimulated binding of ligands to the noncompetitive antagonist (PCP) site and to potentiate NMDA-induced responses. These effects are thought to be mediated by a strychnine insensitive glycine binding site associated with the NMDA receptor complex. In the present study, effects of glycine and a lipophilic glycine prodrug, milacemide, were examined on the acoustic startle reflex in rats, both alone and in combination with a dose of dizocilpine (0.5 mg/kg) known to alter startle responses. Following injections, rats received 40 ms, 122 dB broad-band acoustic stimuli. These startle-inducing stimuli were presented alone or were preceded by 80 dB prepulses. When vehicle alone was administered, significant decreases in startle amplitude were produced by prepulses (pre-pulse inhibition). Dizocilpine significantly elevated startle magnitude and eliminated prepulse inhibition, but glycine (17 and 56 mg/kg) and milacemide (10-100 mg/kg) had no effect. Moreover, administration of these compounds did not affect changes in response magnitude and pre-pulse inhibition produced by dizocilpine. A higher dose of glycine,170 mg/kg, had no effect on startle magnitude but in combination with dizocilpine killed 42% of the subjects tested. Except for the lethal effects of glycine-dizocilpine combinations, these preliminary results do not indicate that behavioral effects of NMDA antagonists acting at the PCP receptor are modified by exogenous glycine. Further work with glycine antagonists and selective agonists at the strychnine-insensitive glycine binding site will explore other possible interactions with PCP-like drugs. Supported by PHS grant MH-46631.

NOVEL ANALOGS OF DEXTROMETHORPHAN ANTAGONIZE NMDA CONVULSIONS IN RATS. L. Robles, J. Taylor, +A. Newman* and F. Tortella. Walter Reed Army Inst. Res., Washington, DC 20307 and +NIDA Addiction Res. Ctr., Baltimore, MD 21224.

Dextromethorphan (DM) and its major metabolite dextrorphan (DX) possess significant anticonvulsant activity. We have previously reported on the anticonvulsant effects of a novel series of 3-substituted DM analogs to protect rats against maximal electroshock-induced convulsions. To date, three analogs have been synthesized which are more potent anticonvulsants than DM. In this study we explored the potential anticonvulsant nature of these DM analogs in a rat model of NMDA (12.5 nM, i.c.v.) convulsions. Pretreatment with DM (20-80 μg, i.c.v.) delayed the onset to NMDA-induced "popcorn" convulsions, while having little effect on the incidence of convulsions. DX (2.5-20 μg, i.c.v) attenuated both latency and incidence. Of the three analogs tested, the ethylether derivative of DM, AHN1036 (20-80 μg, i.c.v.), was the most potent anticonvulsant affording complete protection against NMDA convulsions. The isopropyl ether and primary amine derivatives were at least as potent as DM. These results will be discussed relative to receptor mechanism of action, behavioral side effects and possible clinical usefulness.

484.4

CONANTOKIN PEPTIDE FROM *CONUS GEOGRAPHUS* MODULATES [^{3}H]THIENYLPIPERIDINE (TCP) BINDING TO THE NMDA CHANNEL AND REDUCES NMDA RECEPTOR CURRENT. L. L. Coughenour, D. M. Rock, C. Hanchin, J. Hawley and G. W. Campbell*. Parke-Davis Pharmaceutical Res. Div., Warner-Lambert Co., Ann Arbor, MI 48106-1047.

Conantokin-G (CT-G) is a seventeen amino-acid peptide extracted from the venom of the marine snail *Conus geographus*. It previously has been shown to interact with the NMDA subtype of glutamate receptors. In well washed Triton-treated rat brain membranes the binding of [^{3}H]TCP was markedly enhanced upon the addition of the NMDA channel agonists, glutamate and glycine. The maximal enhancement caused by glycine (no added glutamate) was reduced in the presence of CT-G (2 μM). The maximal enhancement by glutamate (no added glycine) was unaffected, but the concentration-response curve for glutamate enhancement was shifted to the right by CT-G. In addition, CT-G did not affect the binding of [^{3}H]AMPA or [^{3}H]kainate to non-NMDA receptors. This data suggests a selective effect on the glycine site of the NMDA channel.

In cultured rat cortical neurons CT-G (2-20 μM) reduced the amplitude of whole-cell NMDA receptor currents and the frequency of NMDA-evoked single-channel openings in excised outside-out patch clamp recordings. Onset of the reduction of whole-cell and single-channel current by CT-G was slow, and the reductions were not readily reversible.

KINETIC ANALYSIS OF NMDA MODULATORS ON [^{3}H]MK-801 BINDING. D.P. Carrozza*, K. Williams and P. B. Molinoff. Dept. of Pharmacol., Univ. of Penn., Phila., PA 19104.

The NMDA receptor complex contains a distinct binding site for polyamines, including spermine, which enhance the binding of [^{3}H]MK-801, to a site within the ion channel. In the present studies, analysis of the kinetics of association of [^{3}H]MK-801 was used to investigate potential mechanisms of action of polyamines. Experiments were performed to determine whether specific modulators alter the conformation or dynamics of the receptor, which might be detected as an increase in the observed association rate (K_{obs}). The observed association rates were biphasic in the presence of glutamate and glycine (gg) or gg plus spermine and were not altered by preincubation of membranes with these modulators before addition of [^{3}H]MK-801. This suggests a mechanism that involves a change in the duration of opened and closed states rather than a persistent change in the conformation of the receptor. In other experiments, the rates of association (fast and slow) were independent of the concentration of [^{3}H]MK-801 in the presence of gg plus spermine (30 uM), a condition which results in maximal changes in equilibrium binding. These results, which were an unexpected finding, suggest that the limiting factor of [^{3}H]MK-801 binding even under these conditions, involves access of ligand to its binding site. This phenomenon may involve changes in the dynamics of channel opening initiated by activation of the polyamine site (supported by USPHS grant GM34781 and NS30000).

484.6

DIAMINES INHIBIT NMDA RECEPTOR RESPONSES THROUGH A CHANNEL-BLOCKING MECHANISM. S. Subramaniam*, S.D. Donevan and M.A. Rogawski. Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

It has been proposed that the inhibitory actions of the diamines diaminodecane (DA-10) and diaminododecane (DA-12) on NMDA-receptor responses is due to their actions as inverse agonists at the polyamine site. Recently, we and others have observed that the polyamines spermine and spermidine can block the NMDA receptor through an open channel mechanism. In this study we examined whether diamines could affect NMDA channels through a similar mechanism. In whole-cell recordings from cultured rat hippocampal neurons (V_H = −60 mV), the diamines inhibited NMDA currents in a concentration-dependent fashion. The potencies of the diamines increased with increasing length of the carbon chain. Thus, DA-12, the longest diamine tested, was the most potent (IC_{50} = 7 μM), whereas diaminopropane (DA-3), the shortest diamine tested, produced only partial inhibition (~70% at 10 mM). The blocking action of the polycationic diamines decreased at positive holding potentials supporting a channel blocking mechanism. In outside-out patches, DA-12 produced a flickery block of NMDA-induced single-channel currents whereas the shorter diamine putrescine (DA-4) produced an apparent reduction in channel amplitude. The ability to resolve flickering with DA-12 but not with the less potent shorter chain diamine DA-4 may reflect differences in binding kinetics but we cannot rule out the possibility of a distinct mechanism of block for the shorter diamines. These observations indicate that diamines antagonize NMDA currents through an open channel mechanism, and therefore it may not be necessary to invoke inverse-agonist properties of these compounds to explain their inhibitory actions on NMDA receptor responses.

484.7

NEUROCHEMICAL TOLERANCE TO MK-801 (DIZOCILPINE) IN THE MOUSE. P.H.Hutson*, L.J. Bristow, K. Flatman, L. Thorn and M.D. Tricklebank, Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex CM20 2QR, U.K.

In addition to anticonvulsant and neuroprotective effects, acute administration of the non-competitve NMDA receptor antagonist, MK-801 (dizocilpine) stimulates the turnover of dopamine in corticolimbic brain. We now show that chronic treatment with MK-801 decreases the neurochemical response to the compound in the nucleus accumbens, but not in the medial prefrontal cortex (mPFCX).

Dihydroxyphenylacetic acid (DOPAC) was determined in mouse brain regions by HPLC and electrochemical detection. In mice killed 60 min after drug administration (n = 5 per group), MK-801 (0.4 mg/kg, s.c.) increased the concentration of DOPAC (ng/g tissue) by 66 % and 85 % in mouse nucleus accumbens and medial prefrontal cortex respectively (Table 1). Forty eight hours after the last of 21 daily injections of 0.4 mg/kg MK-801, this same dose given 60 min before death again markedly increased DOPAC concentration in the medial prefrontal cortex (89 %), but led to a much reduced response in the nucleus accumbens (18 %). Neither acute nor chronic drug treatment altered striatal DOPAC concentration.

Table 1

	Chronic saline		Chronic MK-801	
	saline	MK-801	saline	MK-801
N. Accumbens	727	1206	813	956
s.e.m.	±24	±86	±55	±47
mPFCX	39	72	39	74
s.e.m.	±5	±11	±2	±8

Thus, mesolimbic and mesocortical dopaminergic neurones appear to be differentially affected by chronic treatment with MK-801.

484.8

IFENPRODIL SELECTIVELY POTENTIATES NMDA-INDUCED DEPOLARIZATIONS IN THE RAT CORTICAL WEDGE *IN VITRO*. *P.L.Herrling* and D.A. Lowe*. Sandoz Research Institute, P.O. Box,CH 3006 Bern, Switzerland.

Ifenprodil, an agent thought to interact with the polyamine site of the NMDA receptor (Carter et al. Europ. J. Pharmacol. 164:611, 1989), was studied in cortical wedges as described by Lowe et al.(Neurosc.Letters 113:315, 1990). Excitatory amino acids (EAAs) were added to ACSF perfused into the chamber containing the cortical layers. Effects were quantified by determining the area under the curve of EAA-induced depolarizations. In Mg^{++}-free ACSF Ifenprodil (10 to 100uM) potentiated NMDA-induced depolarizations by 50 to 187% over controls (mean±SD: 97±52). This potentiating effect was not observed in ACSF containing 1mM $[Mg^{++}]_o$ and was attenuated at 0.2 mM $[Mg^{++}]_o$. The potentiation was fully reversed by 5uM 7-chloro-kynurenic acid (7Cl-KYAC). If the potentiation was established before 7-Cl-KYAC application it reappeared after washout of the antagonist. Depolarizations elicited by non-NMDA EAA agonists such as AMPA and quisqualate were not affected by Ifenprodil. The potentiating effect of Ifenprodil is therefore NMDA specific and the experiments with Mg^{++} and 7Cl-KYAC suggest a site of action deep within the NMDA operated channel.

484.9

PUTRESCINE OVERPRODUCTION EFFECTS ON THE LEARNING & MEMORY AND THE SEIZURE THRESHOLD. [1]T. Halonen*, [1]J. Sivenius, [1]R. Miettinen, [2]L. Alhonen, [2]M. Halmekytö, [3]S. Syrjänen, [3]K. Syrjänen, [2]J. Jänne, and [1]P.J. Riekkinen. Depts of [1]Neurol., [2]Biotechnol., and [3]Pathol., A.I.Virtanen Institute, Univ. of Kuopio, 70211 Kuopio, Finland.

Polyamines appear to modulate excitatory synaptic transmission mediated by N-methyl-D-aspartate (NMDA) reseptor. We tested the effect of increased putrescine levels in transgenic mice line that overexpresses human ornithine decarboxylase on the spatial learning/memory and on the epileptic seizure threshold. Concentrations of putrescine in the different brain areas of transgenic mice increased from undetectable (limit 5 μmol/g) to more than 60 μmol/g compared with their nontransgenic littermates. Contents of spermidine and spermine remained unchanged. Transgenic mice had impared acquisition in water maze task (expressed using escape latency). Transgenic mice had also increased seizure threshold to clonic phase of pentylenetetrazol-induced seizures and to tonic phase of corneal electroshock convulsions. The effect against electroshock convulsions was potentiated when putrescine content was further increased by adding 5-fluoromethyl ornithine to drinking water. These results suggest that putrescine may play an important role in the excitatory neurotransmission.

484.10

EFFICACY OF SYNTHETIC POLYAMINES IN MODULATING NMDA-MEDIATED INCREASES IN INTRACELLUALR CALCIUM. J.M. Fahey*, G.A. Pritchard, L.G. Miller. Dept. of Pharmacology and Experimental Therapeutics and Neuroscience Program, Tufts Univ. School of Medicine Boston, MA 02111.

The endogenous polyamines spermine and spermidine potentiate N-methyl-D-aspartate (NMDA) receptor ionophore-mediated events. We have previously shown that both spermine and spermidine are able to potentiate NMDA-mediated increases in intracelluar calcium (Ca_i) of cultured chick cortical neurons using the calcium sensitive fluorescent dye Fura2. The present study characterizes structurally related synthetic polyamines. IBPA (3,3' imino-bis-propylamine) and AEPD (N-(2-aminoethyl)-1,3 propanediamine) are triamines which differ from spermidine in the length of one aliphatic chain between central terminal amines. IBPA potentiated NMDA-medited increases of Ca_i at concentrations of 100 , 250, 500 and 1000 μM. Its effects at these concentrations were also approximately 40% greater than effects of spermidine. AEPD produced an increase of Ca_i only at1mM. Diaminodecane(DA10) is a putative inverse agonist at the NMDA receptor ionophore and in this system decreases NMDA-mediated increases of Ca_i. No other diamine tested(DA5-DA8) had a similar effect. Only DA5(cadaverine) at 1 mM significantly altered NMDA-mediated responses by increasing, not decreasing, Ca_i. As previously reported, the presence of a proapnediamine moiety may predict the functional efficacy of a synthetic polyamine but it is strongly influenced by the properties of other sidechains.

484.11

MK-801-INDUCED IMPAIRMENT ON A MEMORY TASK IS COUNTERACTED BY SCOPOLAMINE. DF Wozniak*, M McEwen, G Brosnan-Watters and JW Olney. Washington Univ, St. Louis, MO, 63110.

NMDA antagonists, such as MK-801, block induction of hippocampal long term potentiation (LTP) and impair the performance of rats on various behavioral tasks, especially acquisition of spatial learning/memory tasks. NMDA antagonists also have neurotoxic side effects. Two hours after subcutaneous injection of a single low dose of MK-801, pathomorphological changes appear in neurons of the posterior cingulate cortex. A muscarinic cholinergic receptor is implicated in this neurotoxic reaction in that the reaction is blocked by certain antimuscarinic drugs, including scopolamine. Since this neurotoxic reaction affects cingulate but not hippocampal neurons, the question arises whether the memory impairing effects of MK-801 might reflect a functional disturbance in cingulate rather than hippocampal neurons. If this were the case, scopalamine might block the memory-impairing action just as it blocks the neurotoxic action of MK-801 on cingulate neurons. Using a hole board test and cross-over design, we found that MK-801 (0.05 mg/kg ip), compared to scopolamine (0.025 mg/kg ip) or saline, significantly impaired the ability of male rats to learn which of 4 holes contained a food reward. However, when scopolamine (0.025 mg/kg ip) was coadministered with MK-801 (0.05 mg/kg ip), rats performed like saline controls and better (marginally nonsignificant; $p = .077$) than MK-801-treated rats. Moreover, significantly more animals were unable to learn the task under the influence of MK-801 alone (7/23) compared to MK-801 + scopolamine (0/23). These findings suggest, contrary to popular assumption, that the locus of action of NMDA antagonists in causing a performance deficit in learning tasks may be the cingulate cortex rather than the hippocampus. If so, it may be necessary to reinterpret prior behavioral studies in which performance deficits in learning tests have been attributed either implicitly or explicitly to an action of the drug on LTP-linked mechanisms in the hippocampus. Supported by RSA MH 38894 (JWO), DA 05072, DA 06454 and AG 05681.

484.12

SIGMA RECEPTOR LIGANDS REDUCE NMDA-EVOKED DEPOLARIZATIONS AND ELEVATIONS OF INTRACELLULAR CALCIUM IN HIPPOCAMPAL NEURONS E.J. Fletcher, [1]J. Church* and J.F. MacDonald. Dept. Physiology, Univ. Toronto, Toronto, ONT. M5S 1A8 and [1]Dept. Anatomy, Univ. British Columbia, Vancouver, B.C. V6T 1Z3

Magnesium and the dissociative anaesthetics ketamine and phencyclidine block the ion channel associated with the NMDA-subtype of glutamate receptor in a characteristically voltage-dependent manner. The psychosis induced by the anaesthetics is similar to that induced by *sigma* receptor ligands and a common site of action has been debated for some time. The *sigma* ligands DTG and 3-PPP were reported to potentiate NMDA-evoked responses and may interact with polyamine binding sites. Interestingly, the polyamine antagonist ifenprodil also has affinity for *sigma* ligand binding sites.

The *sigma* receptor ligands tested here were potent and selective antagonists of NMDA-evoked responses in whole-cell, voltage-clamped hippocampal neurons in culture (V_h=-60mV). The potency of the compounds as NMDA antagonists was (Kd [μM]): (+)-SKF(10,047) [0.8] > ifenprodil [2.3] > dextromethorphan [2.8] > (+)-pentazocine [8.4] > DTG [35] ≈ (-)-44 [35] > caramiphen [98] > carbetapentane [188] > (+) and (-)-29 [200] > 3-PPP [360]. The antagonism was not competitive in nature, nor could it be reversed with 10μM glycine or 100μM spermine, but it was voltage-dependent (except for ifenprodil). The *sigma* receptor ligands also reduced NMDA- and high K^+-evoked increases in intracellular calcium in Fura-2 loaded hippocampal cells at similar potencies and reduced voltage-activated calcium currents. As *sigma* receptor ligands can reduce calcium influx into cells through two distinct mechanisms they may have great value as therapeutic agents in disease states involving over-activity of neurons and potentially damaging elevations of intracellular calcium.

484.13

INTRACEREBRAL INJECTION OF DOPAMINE IN A DENERVATED STRIATUM REVERSES CIRCLING INDUCED BY THE NMDA ANTAGONIST MK-801. J.A. St-Pierre, L. Grégoire and P.J. Bédard*. Centre de Recherche en Neurobiologie, Hôp. de l'Enfant-Jésus, Laval University , Québec City, Canada.

Carlsson and Carlsson (*J. Neural. Transm.* 77: 65-71, 1989) have shown that systemic administration of a dopamine agonist potentiates the behavioral response to the NMDA antagonist MK-801. The goal of the present study was to investigate whether a similar potentiation would be observed after direct intrastriatal injection of dopamine.

Ovariectomized female rats were lesioned with 6-OHDA in the left medial forebrain bundle. Fifteen days later, they were tested with apomorphine (0.25mg/kg s.c.). Microinjections of different doses of dopamine (1, 5, 25 or 50 μg/1.0 μl) were performed by guide-cannulae implanted stereotaxically into the striatum. Dopamine induced a contralateral circling response, in a dose-dependent manner, when injected into the lesioned side. Similarly, microinjection of dopamine into the lesioned side followed by systemic injection of MK801 (100 μg/kg i.p.) 20 minutes later, produced a contralateral circling response. However, this circling response persisted with a duration 4-fold that of the circling response induced by dopamine alone.

As previously reported in unilaterally lesioned rats, MK801 alone, produce an ipsilateral circling response (St-Pierre *et al., Soc. for Neurosc.* 1991) whereas microinjection of dopamine combined with MK801, reverses the circling response. Taken together, our results suggest that the potentiation seen in the present experiment cannot be explained by increased release of dopamine. In addition, the circling response induced by the suppression of the glutamatergic neurotransmission seems to be facilitated by dopamine receptor activation.

ELECTROPHYSIOLOGICAL EVIDENCE FOR THE EXISTENCE OF NMDA, KAINATE (KA) AND AMPA RECEPTORS ON VENTRAL TEGMENTAL (VTA) DOPAMINE NEURONS IN THE RAT. T.Wang*and E.D.French. Dept.Pharmacology, Univ. Arizona, Coll. Med. Tucson, AZ 85724.

Three ionotropic receptors (NMDA, KA and AMPA) which bind L-glutamate are present in various CNS structures. However, their existence on mesocorticolimbic dopamine (DA) neurons is less clear. Information on the factors controlling the excitability of these neurons may provide some insight into the neurobiology of schizophrenia, and the reinforcing properties of drugs of abuse. In midbrain slices extracellular recordings were made from VTA DA neurons identified by location, pacemaker-like firing, a rate of < 5 spikes/s, and action potential durations >2 ms. Superfusion with NMDA, KA and AMPA produced dose-dependent reversible excitations of all 52 neurons tested. The threshold for NMDA (N=17) activation was 1-3 μM, with 10 and 30 μM increasing rates by 1.7 and 3.0 spikes/s. The threshold for KA (N=25) was 300 nM-1 μM, with increases of 1.5 and 2.4 spikes/s occurring at 3 and 10 μM. AMPA (N=10) was the most potent excitant, with a threshold at 100 nM and increases of 3.4 spikes/s at 1 μM. Also, none of the agonists changed the firing pattern from regular to bursting activity. The effects of NMDA were antagonized by 30 μM CGS 19755, while KA and AMPA were selectively blocked by 10 and 1 μM NBQX. The antagonists did not affect spontaneous firing. These data indicate that the excitability of VTA neurons is under the influence of the three glutamate receptor subtypes with a rank order of potency of AMPA > kainate > NMDA.

484.15

THE ROLES OF EXCITATORY AMINO ACID (EAA) RECEPTORS IN THE CONTROL OF EXCITABILITY OF SYMPATHETIC PREGANGLIONIC NEURONES (SPN) D. Spanswick, A.E. Pickering, I.C. Gibson and S.D. Logan. (SPON:Brain Research Association) Dept. of Physiol., Univ. of Birmingham, B15 2TT, U.K.

Intracellular and whole-cell recordings were obtained from SPN in neonate rat spinal cord slices. Focal electrical stimulation of the dorsal horn or laternal funiculus evoked an EPSP which was both voltage-dependent and potentiated in magnesium-free ACSF. The EPSP was partly reduced by the selective NMDA receptor antagonists APV, CPP or MK801 and was completely abolished by the non-NMDA receptor antagonist CNQX . Superfusion of the selective EAA receptor agonists AMPA, kainate, quisqualate, NMDA and ACPD induced concentration-dependent depolarisations in all neurones tested. AMPA, kainate and NMDA-induced responses were blocked by a cocktail of both NMDA (APV, CPP or MK801) and non-NMDA (CNQX or DNQX) antagonists, whereas responses to quisqualate and ACPD persisted. Depolarising responses to quisqualate and ACPD were associated with an increase in neuronal input resistance and decreased in amplitude with increased membrane hyperpolarisation. In a subpopulation of cells, quisqualate and ACPD induced oscillations in membrane potential which gave rise to rhythmic burst firing at higher agonist doses .

We conclude that both AMPA and NMDA subtypes of receptors mediate synaptic transmission in SPN. Glutamate can also act via a metabotropic receptor to excite SPN by reducing a potassium conductance, and in some SPN to induce rhythmic activity.

KYNURENIC ACID MODULATES EXCITATORY AMINO ACID-INDUCED EXCITATION OF DOPAMINE-CONTAINING NEURONS IN RAT SUBSTANTIA NIGRA. H.-Q. Wu*, R. Schwarcz and P.D. Shepard. Maryland Psychiatric Research Center, Baltimore, MD 21228

Kynurenic acid (KYNA), an endogenous antagonist of ionotropic excitatory amino acid (EAA) receptors, was tested for its ability to modulate NMDA- and AMPA-induced excitation of dopamine (DA)-containing neurons in the rat substantia nigra (SNc). Experiments were conducted using conventional extracellular recording techniques in conjunction with an *in vitro* brain slice preparation. Bath application of NMDA (1-20 μM) or AMPA (1-10 μM) produced a concentration-dependent increase in the firing rate of SNc DA neurons. The highest concentration of both agonists produced a rapid and reversible cessation of activity that was attributed to acute induction of depolarization block. KYNA (10 μM - 1 mM) inhibited the excitatory effects of NMDA in a concentration-dependent fashion (EC_{50} ≈ 100 μM) without affecting basal firing rate. KYNA (100 μM) proved slightly more potent in inhibiting the effects of AMPA. Perfusion of tissue slices with low Mg^{2+} Ringers (0.12mM) increased the NMDA-induced excitation of DA neurons but failed to affect the ability of KYNA to antagonize the effects of NMDA. Addition of glycine (up to 100 μM) or kynurenine (3 mM), the immediate precursor of KYNA, to the bathing solution had no effect on either basal firing rate or the increase in firing produced by concomitant application of NMDA. However, co-application of D-serine (100 μM) partially attenuated the ability of KYNA to block the excitatory effects of NMDA. Thus, the ability of KYNA to block NMDA-induced excitation of SNc DA neurons may be mediated by an interaction with the glycine allosteric site on the NMDA receptor. Taken together, these data suggest that endogenous KYNA may play an important role in regulating DA cell excitability by modulating EAA neurotransmission.

484.17

INFLUENCE OF MK-801 AND NBQX ON ACUTE RECOVERY OF CEREBRAL METABOLISM IN PIGLETS AFTER HYPOTHERMIC CIRCULATORY ARREST. M. Aoki, F. Nomura, R.A. Jonas, M. Stromski, M.K. Tsuji, J.C. Fackler, P.R. Hickey, D.H. Holtzman*, Children's Hospital and MIT, Boston, MA 02115

Neuroprotective effects of MK-801 and NBQX were evaluated in 34 4-week old piglets (10:MK-801, 10:NBQX, 14:controls) undergoing cardiopulmonary bypass (CPB) and hypothermic circulatory arrest at 15°C nasopharyngeal for 1 hour as used clinically for repair of congenital heart defects. MK-801 (0.75 mg/kg) or NBQX (25 mg/kg) were given I.V. before CPB. Equivalent doses were given to the CPB prime plus infusions after reperfusion (0.15 mg/kg/hr or 5 mg/kg/hr). High energy phosphate (HEP) metabolism was analyzed by magnetic resonance spectroscopy (4.7 Te, horizontal bore) in 17 animals and cerebral blood flow by microspheres and cerebral metabolic rate (CMR) by oxygen and glucose extraction were studied in 17 until 225 min after reperfusion. CMR was depressed relative to control by both MK801 and NBQX at baseline. Recovery of phosphocreatine ($p = 0.01$), ATP ($p = 0.03$) and pH ($p = 0.004$) was accelerated by MK-801 and retarded by NBQX over the first hour of normothermic reperfusion. Final recovery of ATP at 3 hours 45 minutes reperfusion was significantly ($p = 0.025$ [ANOVA]) reduced by NBQX (44 ± 30% baseline, mean±S.D.) vs control (81 ± 19%) and MK-801 (75 ± 10%). CMR02 recovered to 105 ± 30% baseline in group MK-801 but only to 61 ± 22% in group NBQX (control 94.0 ± 32%) ($p = 0.07$). **Conclusion:** MK-801 accelerates recovery of CMR and HEP metabolism after CPB and hypothermic circulatory arrest in the immature animal. At the dose used, NBQX exerts an adverse effect.

EFFECTS OF ANIRACETAM AND BMS 181168 (BMY 21502) ON EXCITATORY AMINO ACID RESPONSES. S.I. Dworetzky*, M.C. McKay, C.G. Boissard and V.K. Gribkoff. Dept. of Biophysics and Molecular Biology, Bristol-Myers Squibb Pharm. Res. Inst., 5 Research Parkway, Wallingford, CT 06492.

Modulation of NMDA and non-NMDA EAA receptors by the substituted pyrrolidinones BMS 181168 and aniracetam was studied using the Xenopus oocyte receptor expression system, whole cell patch clamping of hippocampal neurons in culture, and extracellular recording of evoked hippocampal synaptic potentials in hippocampal slices. Hippocampal poly(A)$^+$mRNA was isolated from 2-3 week old rats and microinjected into defolliculated Xenopus oocytes. After 3-5 days of incubation, cells were tested for receptor expression using two electrode voltage clamp. The results showed that aniracetam significantly enhanced a fast component of the AMPA-induced inward current in oocytes, and potentiated EPSC's in hippocampal neurons, but did not effect responses to kainate and NMDA. This confirms observations seen by other laboratories (Vyklicky et al., Neuron 7, 1991:971-984). However, BMS 181168 was seen to have a qualitatively different effect on EAA-induced inward current, in comparison to aniracetam. BMS 181168 had only a small effect on the fast AMPA-induced current component, but greatly potentiated and prolonged a late, slow inward current component. BMS 181168 had little direct potentiating action on hippocampal synaptic potentials, but has been shown to prolong hippocampal LTP (Gribkoff et al., Neuropharm. 29, 1990:1001-1009).

EXCITATORY AMINO ACIDS: RECEPTORS VI

485.1

GLUTAMATE AND GLYCINE ACT SYNERGISTICALLY TO STIMULATE [^{3}H]MK-801 BINDING TO NMDA RECEPTORS. J. C. Marvizón* and M. Baudry. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

In well-washed membranes, glutamate and glycine increased each other's efficacies to stimulate [^{3}H]MK-801 binding to NMDA receptors, with no detectable effects in their potencies. Glutamate was virtually unable to enhance [^{3}H]MK-801 binding in the absence of glycine or in the presence of glycine antagonists, confirming the idea that occupancy of the glycine site is an absolute requirement for NMDA receptor activation. Conversely, the efficacy of glycine to stimulate [^{3}H]MK-801 binding was greatly reduced in the absence of glutamate and in the presence of glutamate antagonists. However, [^{3}H]MK-801 binding was stimulated by high concentrations (1 mM) of glutamate or glycine acting independently of each other. These low affinity components for glutamate and glycine are probably due to an agonist action of glutamate at the glycine site and of glycine at the glutamate site, respectively. In agreement with this idea, glutamate inhibited [^{3}H]glycine binding, and glycine inhibited [^{3}H]glutamate binding, each at millimolar concentrations. Moreover, the potency of the low affinity component for glycine was reduced by glutamate antagonists, but not by glycine antagonists. These results indicate that 1) simultaneous occupancy of the glutamate and glycine sites is necessary to activate NMDA receptors, and 2) glutamate and glycine at millimolar concentrations can act as agonists at the high affinity site for the other compound in the NMDA receptor.

485.2

Magnesium interacts with the NMDA receptor by two distinct mechanisms. **J.O.McNamara*, G.C.Yeh and D.W.Bonhaus. Duke and V.A. Med. Ctr. Durham, NC 27710. Taipei Med.Col. Taiwan, Syntex Res. Palo Alto CA.**

Depending upon concentration, magnesium can either inhibit or potentiate binding of the NMDA channel blockers [^{3}H]MK-801 or [^{3}H]TCP. To determine how magnesium produces these effects, we examined the action of magnesium on ligand binding to three distinct sites of rat hippocampal NMDA receptor: glycine, glutamate, and the [^{3}H]TCP binding sites (a.k.a. phencyclidine receptor). As previously reported by others, magnesium produced biphasic effects on [^{3}H]TCP binding; magnesium exerted potentiating effects at lower concentrations and inhibitory effects at higher concentrations. Both effects required agonist occupancy of the glutamate and glycine binding sites. The inhibitory effect of magnesium on [^{3}H]TCP binding was paralleled by an inhibitory effect on the apparent affinity of the [^{3}H]TCP binding site. The potentiating effects of lower concentrations of magnesium were associated with a concentration dependent increase of both the association and dissociation rate of [^{3}H]TCP without change in either the K_D or B_{max} of [^{3}H]TCP binding. Magnesium also increased the affinity of [^{3}H]glycine at concentrations comparable to those that increased [^{3}H]TCP binding. Magnesium did not modify NMDA-displaceable [^{3}H]glutamate binding. These findings support the idea that magnesium has two distinct effects on the NMDA receptor: 1) the apparently competitive interaction between magnesium and [^{3}H]TCP binding which likely corresponds to the well characterized channel blocking action; 2) a potentiation of NMDA channel activation likely mediated by the increased affinity of glycine binding.

485.3

Polyamine interacts with NMDA receptor by two distinct mechanisms. **G.C.Yeh*, D.W.Bonhaus and J.O.McNamara. Taipei Med.Col, Taiwan, Syntex Res. Palo Alto CA, Duke and V.A. Med.Ctr Durham, NC 27710.**

NMDA receptor mediated neurotransmission is regulated by polyamines. To examine the direct interaction of polyamines with the NMDA receptor we determined the effects of the polyamines spermine (SPM) and spermidine (SPD) on the binding of the NMDA channel blocker, [^{3}H]TCP. Both SPM and SPD produced biphasic effects on nonequilibrium binding of [^{3}H]TCP. Both the potentiating and inhibitory effects of polyamines required agonist binding at both the glutamate and glycine binding sites. The potentiating effect, detected at concentrations of polyamines less than 30 uM, was associated with increases of both the association and dissociation rates of [^{3}H]TCP binding. The inhibitory effect of polyamines, detected at concentrations of polyamines greater than 100 uM, was associated with a decrease of the apparent affinity of [^{3}H]TCP binding. This study suggests that SPM and SPD both have two distinct actions on the NMDA receptor: 1) the apparently competitive interaction between polyamines and [^{3}H]TCP binding which likely corresponds to the voltage-dependent block of NMDA channels described by MacDonald et al (Mol. Pharmacol.1992); 2) a potentiation likely due to an increase of NMDA channel activation which may correspond to the increased channel open frequency described by MacDonald et al.

485.4

THE NMDA ANTAGONIST [^{3}H]IFENPRODIL BINDS TO HETEROGENOUS POLYAMINE-SENSITIVE SITES IN RAT BRAIN. **H. Schoemaker, S. Pigasse and B. Zivkovic*. Department of Biology, Synthélabo Recherche, 31 Av. P.Vaillant-Couturier, 92220 Bagneux (France).**

The noncompetitive NMDA antagonist and cerebral anti-ischaemic properties of ifenprodil have been ascribed to its blockade of polyamine-stimulatory effects on the NMDA receptor complex. In support of this hypothesis, a polyamine-sensitive [^{3}H]ifenprodil binding site was demonstrated in the rat cerebral cortex (Schoemaker et al; Eur. J. Pharmacol. 176, 249-250, 1990). The present study further examined the pharmacology of polyamine-sensitive [^{3}H]ifenprodil binding in rat brain.

Specific [^{3}H]ifenprodil binding to the rat cerebral cortex, determined as described by Schoemaker et al. (1990) in 5 mM Tris-HCl buffer, is fully sensitive to inhibition by unlabeled ifenprodil (IC_{50}= 0.015 µM), SL82.0715 (IC_{50}= 0.041 µM), spermine (IC_{50} = 3.3 µM) and spermidine (IC_{50}= 8.0 µM). The competitive NMDA antagonist CGP 37849 partially inhibits [^{3}H]ifenprodil binding to 17 % of control values with an IC_{50} of 3.8 µM. L-Glutamate fails to affect [^{3}H]ifenprodil binding under control conditions, but reverses the inhibition of binding produced by CGP 37849.

In the adult rat cerebellum, [^{3}H]ifenprodil binding is only inhibited by higher concentrations of unlabeled ifenprodil (IC_{50}= 0.22 µM), SL82.0715 (IC_{50}= 1.8 µM), spermine (IC_{50}= 28 µM) and spermidine (IC_{50}= 63 µM) and is not affected by CGP 37849 (100 µM). Conversely, in the immature cerebellum, [^{3}H]ifenprodil binding is inhibited by low concentrations of ifenprodil (IC_{50}= 0.029 µM) and spermine (IC_{50}= 5.9 µM), and partially sensitive to CGP37849 (IC_{50}= 1.5 µM).

The present data demonstrate that polyamine-sensitive [^{3}H]ifenprodil binding sites in the rat cerebral cortex and immature cerebellum form part of the NMDA receptor complex and are allosterically coupled to the glutamate/NMDA recognition site. Polyamine-sensitive [^{3}H]ifenprodil binding sites in the adult rat cerebellum present a different pharmacology and may not be part of the NMDA receptor complex.

7-CK-DEPENDENT AND -INDEPENDENT EFFECTS OF POLYAMINES ON NMDA RECEPTOR ACTIVATION. S.R. Zukin*, D.C. Javitt, R. Sircar, M. Frusciante, Depts. of Psychiatry and Neuroscience, Albert Einstein College of Medicine and Bronx Psychiatric Center, Bronx, NY 10461.

Activation of *N*-methyl-D-aspartate (NMDA) receptors is regulated at distinct sites by polyamines and glycine. In order to determine the differential effects of polyamines and glycine on NMDA receptor activation, kinetics of [^{3}H]MK-801 binding were measured in the absence and presence of L-glutamate, the polyamine agonist spermidine and the putative glycine antagonist 7-CK. Two components of association were found: a fast component (not observed under control conditions) reflecting binding to the activated conformation of the NMDA receptor complex and a slow component reflecting binding to agonist-associated closed conformations. Addition of L-glutamate (0.3 - 100 mM) alone led to a dose-dependent 3-fold increase in total [^{3}H]MK-801 binding but did not significantly increase binding manifesting fast kinetics. Spermidine significantly potentiated the degree to which L-glutamate stimulated total steady-state binding and also led to a large increase in the percentage of total steady-state binding that was attributable to the fast component of association. 7-CK attenuated the degree to which spermidine increased the percentage of binding attributable to the fast component without affecting the spermidine-induced increase in total binding. These findings suggest that the glycine site primarily regulates the interconversion between open and closed conformations of the NMDA receptor complex, whereas the spermidine site regulates both the total number of non-desensitized complexes and the interconversion between open closed conformations.

485.6

SUBCELLULAR DISTRIBUTION OF [^{3}H]IFENPRODIL BINDING IN RAT BRAIN K. Hashimoto, C.R. Mantione,* M. Spadda[1], J.L. Neumeyer[1] and E.D. London, Neuropharmacology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224 and [1] Research Biochemicals Inc., Natick, MA 01760.

Ifenprodil has been shown to be cytoprotective in animal models of focal ischemia. It has been suggested that ifenprodil exerts this action by antagonism at polyamine modulatory sites on the N-methyl-D-aspartate (NMDA) receptor. In the presence of 3 μM GBR 12909 to mask σ receptor binding, [^{3}H]ifenprodil labels polyamine-sensitive binding sites in rat cerebral cortex at 0-4°C (Schoemaker H. et al., *Eur. J. Pharmacol.* 176, 249 (1990)). However, at 37°C, [^{3}H]ifenprodil binding to cortical membranes has a pharmacological profile similar to that of a σ receptor ligand (Schoemaker H. et al., *Br. J. Pharmacol.* 100s, 316 (1990)). σ receptors, labeled with (+)-[^{3}H]SKF-10,047, exhibit a unique distribution in rat brain subcellular fractions (McCann D.J. & Su T.P., *Eur. J. Pharmacol.* 188, 211 (1990)). The present study examined the subcellular distribution of [^{3}H]ifenprodil binding at 4°C in the presence of 3 μM GBR 12909 and at 37°C in the absence of 3 μM GBR 12909.

In the presence of GBR 12909, [^{3}H]ifenprodil binding at 4°C was enriched in synaptosomal and mitochondrial fractions, suggesting that polyamine binding sites occur in these fractions. This distribution of [^{3}H]ifenprodil binding at 4°C was similar to that of [^{3}H]MK-801 binding. In contrast, in the absence of GBR 12909 [^{3}H]ifenprodil binding at 37°C is enriched in microsomal and myelin fractions, consistent with subcellular distribution of σ receptors. These finds support the view that, at 4°C, [^{3}H]ifenprodil labels polyamine sites on the NMDA receptor. Subcellular distribution at 37°C indicate binding to σ receptors, therefore, effects of ifenprodil *in vivo* appear to involve σ receptors. Thus, it is likely that [^{3}H]ifenprodil may label σ sites in rat brain at 37°C. Therefore, ifenprodil may exert its pharmacological effects through the σ sites *in vivo*.

SPERMINE MAY MODULATE PRESYNAPTIC N-METHYL-D-ASPARTATE RECEPTORS. F. Della Vedova*, L. Facheris, R.G. Fariello, A. Bianchetti and C. Speciale. Farmitalia Carlo Erba-Erbamont Group, CNS/CV Research Group, 20014 Nerviano, Italy.

Previously, we showed a dual effect of spermine (SPM) on the N-methyl-D-aspartate (NMDA)-evoked [^{3}H]noradrenaline (^{3}HNA) release in hippocampal slices (Facheris et al., Soc. Neurosci. 17:108.13). This was possible by distinct evaluation of the release bursted directly by NMDA, in fractions with the agonist (NMDA fractions), and indirectly, in later fractions in the absence of the agonist (tail fractions), collected up to 25 min. We now demonstrate that tetrodotoxin (TTX), a blocker of synaptic transmission, discloses the enhancing SPM effect on the NMDA fractions, while the tail fractions-related effect is insensitive to TTX. In all experiments sliced hippocampi from Wistar rats (200-225 g) were used. Fractions (5 min each) were collected and fractional release (FR) expressed as percent of the ^{3}HNA present in the tissues at the corrispondent times. 500 μM NMDA evoked 7.08±0.86% FR. TTX (2 μM) inhibited NMDA fractions of approximately 90% ($P<0.01$). 1 mM SPM, per se inactive, restored FR to 3.71±0.37% ($P<0.01$). Moreover, the increasing effect of SPM on the tail fractions was not modified by TTX. 400 μM D(-)2-amino-7-phosphonoheptanoic acid significantly prevented SPM effect (1.62±0.26% FR, $P<0.01$), in the presence of TTX. Our data suggest that SPM may modulate the NMDA-induced ^{3}HNA hippocampal release by acting on presynaptic NMDA receptors.

485.8

INTERACTIONS BETWEEN THE GLUTAMATE AND GLYCINE RECOGNITION SITES ON THE NMDA RECEPTOR COMPLEX. T. Priestley, L.L Iversen* and J.A. Kemp. Merck Research Laboratories, Terlings Park, Harlow, Essex, U.K., CM20 2QR.

Concentration-jump experiments on voltage-clamped rat cortical neurones in culture have previously indicated an allosteric interaction between the glycine- and glutamate-recognition sites on the NMDA-receptor complex (Kemp & Priestley, Mol. Pharmacol., 39, 1991, 666-670) Thus, glutamate dissociates more slowly from its recogition site on the NMDA-receptor complex when glycine is bound to the glycine recognition site than when the low efficacy partial agonist, (+)-HA 966, is bound. We have extended these observations of interactions between these two co-agonist recognition sites by evaluating the effect of a range of agonists with differing levels of efficacy and affinity binding at one of the sites on the kinetics of agonists acting at the other.

The dissociation rate for glutamate in the presence of (+)-HA 966 is significantly faster than that seen in the presence of glycine. Similar, but progressively smaller effects were seen with D-cycloserine, ACPC (Aminocyclopropanecarboxylic acid) and L-alanine. A reciprocal effect on glycine kinetics was found to occur with several NMDA receptor agonists. Thus, the dissociation rate for glycine was slowest in the presence of glutamate and became progressively faster in the presence of NMDA, quinolinic acid and cis-2,3-PDA (piperidine dicarboxylic acid).

These results suggest that co-agonists acting at the NMDA and glycine recogition sites on the NMDA receptor complex influence each others affinity by an allosteric interaction the extent of which appears to correlate with the level of efficacy of the agonist rather than its affinity.

485.9

OPPOSITE EFFECTS OF ZINC ON AGONIST AND ANTAGONIST BINDING TO THE NMDA RECEPTOR RECOGNITION SITE IN RAT HIPPOCAMPAL FORMATION. D.D. Savage, L.L. Paxton and S.A. Queen* Dept. Pharmacology, University of New Mexico School of Medicine, Albuquerque, NM, 87131-5316.

Monaghan *et al.* (PNAS 85:9836, 1988) have shown that glycine alters the ability of NMDA receptor agonists and antagonists to bind to the NMDA-glutamate recognition site on the NMDA channel complex. Glycine produces a dose-dependent increase in NMDA-sensitive [3H]-glutamate binding and decreases binding by tritiated NMDA receptor antagonists. We conducted similar studies investigating the effect of zinc on NMDA agonist and antagonist binding.

Histological sections of brain containing dorsal hippocampal formation were incubated with either [3H]-glutamate (150 nM) or [3H]-CGS 19755 (33 nM) in the presence of 18 different concentrations of zinc ranging from 20 nM to 1 mM. NMDA-sensitive [3H]-glutamate binding was defined as the difference between [3H]-glutamate binding in the absence and presence of 100 μM unlabelled NMDA. Specific [3H]-CGS 19755 binding was defined as the difference between [3H]-CGS 19755 binding in the absence and presence of 10 μM unlabelled CGS 19755.

NMDA-sensitive [3H]-glutamate binding was increased in the presence of zinc concentrations between 50 nM and 5 μM. Maximum zinc-stimulated increase in NMDA-sensitive [3H]-glutamate binding (30%) occurred at 5 μM. At concentrations above 5 μM, zinc stimulation of NMDA-sensitive [3H]-glutamate binding diminished. Zinc produced an opposite effect on NMDA antagonist binding. Specific [3H]-CGS 19755 binding was decreased between 50 nM and 5 μM zinc. At 5 μM zinc, specific [3H]-CGS 19755 binding was decreased to about 25% of [3H]-CGS 19755 binding in the absence of added zinc. At concentrations above 5 μM, the inhibitory effect of zinc on [3H]-CGS 19755 binding diminished.

These data suggest that zinc, like glycine, may affect the function of the NMDA receptor-operated ion channel complex by altering the affinity of the NMDA receptor recognition site for glutamate. Increasing concentrations of zinc up to 5 μM may enhance the ability of glutamate to activate the NMDA channel. At concentrations above 5 μM, zinc may diminish the ability of glutamate to activate the NMDA channel. (Supported by AA06548)

GLYCINE BINDING TO CEREBRAL CORTICAL MEMBRANES FROM DEVELOPING AND ADULT MICE: INTERACTIONS WITH ß-ALANINE. P. Saransaari* and S.S. Oja. Tampere Brain Res. Ctr, Dept. Biomed. Sci., Univ. Tampere, Finland.

It is well established that glycine potentiates responses mediated by *the N-methyl-D-aspartate (NMDA) subtype of the glutamate receptor.* We have characterized with [^{3}H]glycine these strychnine-insensitive binding sites in cerebral cortical membranes isolated from adult and 7-day-old mice. The binding was saturable, consisting of only one component in both age groups studied. The maximal binding capacity B_{max} was significantly higher in immature mice than in adults. The binding constant K_D was greater in immature mice, indicating lower affinity of the binding sites for glycine. The binding was most strongly inhibited by glycine itself, followed by serine and ß-alanine in both immature and mature cerebral cortex. ß-Alanine was found to cause a mixed type of inhibition in glycine binding. The binding of ß-[^{3}H]alanine to cerebral cortical membranes was also saturable, consisting of one component. The binding constant K_D for ß-alanine was of the same order of magnitude as K_D for glycine, whereas the binding capacity B_{max} was smaller. The binding of ß-alanine was inhibited by glycine, NMDA and glutamate but not by strychnine. The results point to the possibility that ß-alanine could act at the glycine modulatory site in the NMDA receptor complex in both developing and adult cerebral cortex. (Supported by the Emil Aaltonen Foundation, Finland).

DIFFERENTIAL EFFECTS OF L-GLUTAMATE ON [^{3}H]MK-801 BINDING IN PCP-TREATED WEANLING RATS COMPARED TO SALINE-TREATED CONTROLS. R. Sircar*, Depts. of Psychiatry and Neurology, Albert Einstein College of Medicine, Bronx, NY.

The developing rat brain is more susceptible to *N*-methyl-D-aspartate (NMDA) receptor-mediated neurotoxicity compared to adults. We have earlier shown that Scatchard analyses of [^{3}H]MK-801 binding isotherms indicate lower density of binding sites in weanling rats treated postnatally with phencyclidine (PCP) compared to saline-treated rats; [^{3}H]MK-801 binding was used as a marker for NMDA channel activation. Here we report characterization of L-glutamate-induced NMDA receptor activation on [^{3}H]MK-801 binding in postnatal PCP-treated rats. Rat pups were treated with PCP (5 mg/kg) for eleven days. Controls received saline injections. [^{3}H]MK-801 bindings were measured in forebrain synaptosomal membranes prepared from PCP and saline-treated animals, both in the absence and presence of increasing concentrations of L-glutamate (0.1-100 μM) with or without added glycine (10 μM). In the absence of added glycine, incubation in the presence of L-glutamate lead to a dose-dependent increase in specific [^{3}H]MK-801 binding both in the PCP- and saline-treated rats but neither mean EC_{50} values nor maximum [^{3}H]MK-801 bindings were different in the two groups. When binding was carried out in the added presence of glycine, maximal binding in the PCP-treated rats were lower than in the saline-treated controls. The mean EC_{50} value for L-glutamate-stimulated [^{3}H]MK-801 binding was reduced in both experimental and control rats but there was no apparent difference in the mean EC_{50} values between the two groups. These findings suggest that PCP treatment during early postnatal period in rat alters the agonist-induced regulation of the NMDA channel activation.

Probing the Molecular Interactions between PCP-like Ligands and the PCP Binding Site of the NMDA Receptor Complex: Evidence for the Heterogeneity of PCP Binding Sites. Y.-P. Pang and A. P. Kozikowski*, Neurochem. Research, Mayo Clinic, 4500 San Pablo Rd., Jacksonville, FL 32224.

To further delineate the topography of the phencyclidine (PCP) binding site of the *N*-methyl-D-aspartate (NMDA) receptor complex, six oxygenated analogues of (+)-1,2,3,4,4a,9a-hexahydro-4a-fluorenamine (HFA) were designed and synthesized to serve as probes of the hydrogen bonding interaction postulated to exist between a substituent located at the *meta*-position of the phenyl group of the PCP-like ligand and its binding site. In addition, these oxygenated HFA analogues can serve as probes of topography to provide information about the possible heterogeneity of the PCP binding sites (for the conjecture that there are two subclasses of PCP-like ligands binding sites, namely the MK-801 site and the PCP site, on the NMDA receptor complex, see A. P. Kozikowski and Y.-P. Pang, *Mol. Pharmacol.*, 37:352, 1990; for the synthesis of these analogues, see Y.-P. Pang and A. P. Kozikowski, *J. Org. Chem.*, 56:4499, 1991). From the binding affinities measured for these HFA analogues, the existence of the putative hydrogen bonding interaction between the phenyl ring substituent of the HFA analogues and their binding sites appears unlikely, a result which stands in marked contrast to the increased binding affinities reported for the *meta*-hydroxy and *meta*-methoxy substituted derivatives of PCP. This discrepancy can be explained by assuming that the structural requirements for the binding of the MK-801 types of ligands (or HFA and its analogues) with smaller molecular volumes to the "MK-801 site" are different from those of the PCP-site preferring ligands with larger molecular volumes. The new data serve to support our previous conjecture that the PCP site and the MK-801 site are co-localized but are not identical. In addition, the binding results reveal the existence of unoccupied space which can accommodate certain functional groups in the vicinity of the 6-position of the phenyl ring of HFA, which therefore allows for the incorporation of an electrophilic alkylating group or a photoaffinity labeling group capable of irreversible labeling of the binding site. A more detailed "enzyme-excluded" volume of the MK-801 binding site has thus been defined.

DEVELOPMENT OF PHOTOAFFINITY PROBES FOR THE NMDA-ASSOCIATED GLYCINE BINDING SITE. *A.C. Nichols*, K.L. Yielding. and L.D. Snell. Dept. of Pharmacology, Univ. of Texas Medical Branch, Galveston, TX 77555.*

The photolabile acyl azide function was placed at the 2-position of 7-halogenated kynurenic acid derivatives to determine their usefulness as photoaffinity probes for the glycine modulatory site on the NMDA receptor complex. Similar derivatives were synthesized from 5,7-dichlorokynurenic acid and 4-(methylamino)-5,7-dichloroquinoline-2-carboxylic acid. The acyl azide of 7-chlorokynurenic acid was the most promising derivative. In dark experiments this compound could displace ^{3}H glycine binding from rat cortical membranes with relatively high affinity (K_i = 2.4 +/- 0.2 uM) in an apparently competitive fashion (nH = 0.90 +/- 0.08). When membranes were UV irradiated in the presence of 10 uM of the acyl azide, washed, and then assayed for glycine enhancement of ^{3}H- TCP binding, the maximal enhancement was reduced by 30%. This was taken as evidence of irreversible binding of the probe to the glycine receptor. Use of a radioactive precursor in the synthesis can provide a probe capable of radiolabeling NMDA-associated glycine binding sites irreversibly.

GLUTAMATE SENSITIVE BINDING OF [^{125}I]MK-801 TO INTACT CEREBELLAR GRANULE CELLS. T.F. Murray* and V.J. Caldwell. Oregon State Univ., College of Pharmacy, Corvallis, OR 97331.

Efforts to label NMDA receptors in membrane preparations derived from rat cerebellum have yielded conflicting results. Although unsuccessful attempts to detect specific binding of [^{3}H]TCP and [^{3}H]MK-801 in rat cerebellar membranes have been reported, a demonstration of specific [^{3}H]MK-801 labeling of cerebellar membranes has recently appeared (Ebert et al., Europ. J. Pharmacol.-Mol. Pharmacol. Sect. 208, 49, 1991). These cerebellar binding sites are distinct inasmuch as the affinity for [^{3}H]MK-801 is substantially lower than that of NMDA receptors in forebrain structures. To further explore the characteristics of cerebellar NMDA receptors, we have investigated the binding of [^{125}I]MK-801 in intact cultured cerebellar granule cells. The binding of [^{125}I]MK-801 was inhibited in a concentration-dependent manner by glutamate (1-300μM). The glutamate inhibition of [^{125}I]MK-801 binding to intact granule cells was reversed by Mg^{++} in concentrations ranging from 1 to 10,000μM. Similarly, the glutamate-induced inhibition of binding was antagonized by the competitive NMDA receptor antagonist AP-5. Noncompetitive NMDA receptor antagonists such as MK-801, phencyclidine and dextrorphan produced biphasic effects on [^{125}I]MK-801 binding with low concentrations stimulating and high concentrations inhibiting binding. Equilibrium saturation analysis of [^{125}I]MK-801 binding resulted in a K_D value of 77nM and a B_{max} value of 5.3pmol/plate. Companion experiments indicated that glutamate exerted similar negative modulation of cerebellar NMDA receptors labeled with [^{3}H]dextrorphan. These results suggest that intact cerebellar granule cells in culture express functional NMDA receptors. (Supported by PHS Grant DA07218)

485.15

DIFFERENTIAL REGULATION OF [^{3}H]DEXTRORPHAN AND [^{3}H]MK-801 BINDING TO SLIDE-MOUNTED RAT BRAIN SECTIONS BY MODULATORS OF NMDA RECEPTOR-CHANNEL FUNCTION. P.H. Franklin* and T.F. Murray, College of Pharmacy, Oregon State University, Corvallis OR 97331

Although structurally unrelated to either MK-801 or arykycloalkylamines such as PCP, the analgesically inactive dextrorotatory morphinan, dextrorphan(DX), has been found to possess significant NMDA antagonist efficacy in vivo and in vitro. Although DX clearly antagonizes NMDA-mediated excitation in a noncompetitive manner in the hippocampal slice, in contrast to the prototypical noncompetitive NMDA antagonist MK-801, DX blocks NMDA-mediated excitation in a use-independent manner(Cole *et al.*, Neuropharmacol., 28:249 '89). We have found that [^{3}H]DX, like [^{3}H]MK-801, labels a site in rat brain membranes in the domain of the NMDA-operated cation channel (Franklin and Murray, Mol. Pharmacol., 41:134-146, '92). Accordingly, [^{3}H]DX binding is modulated by the level of activation of the NMDA receptor-channel and thus is increased under "open channel" conditions and, conversely, inhibited by pharmacological antagonists of NMDA receptor function. Unique aspects of the regulation of [^{3}H]DX binding by Mg^{2+} and the polyamines, however, suggest that [^{3}H]DX labels a site in the channel which does not coincide with those of either [^{3}H]MK-801 or [^{3}H]TCP. In order to address this issue in the context of the apparent heterogeneity of NMDA receptors in the CNS we have compared the regulation of [^{3}H]DX and [^{3}H]MK-801 binding in slide-mounted sections of rat brain binding as a prelude to quantitative autoradiographic analysis of the binding of these radioligands. In HEPES/EDTA(1mM/10mM; pH 7.4) treated coronal sections of rat brain, taken rostral to the anterior commisure, we find that glutamate(1-100μM) stimulates both specific [^{3}H]MK-801 and [^{3}H]DX binding in a concentration-dependent manner. Glycine(1-1000μM), in contrast, stimulated the binding of [^{3}H]MK-801 only moderately, while exerting a concentration-dependent inhibition of specific [^{3}H]DX binding. The basis for these observations will be addressed using quantitative autoradiography.

EVIDENCE THAT HIGH AND LOW AFFINITY AMPA BINDING SITES REFLECT MEMBRANE-DEPENDENT STATES OF A SINGLE RECEPTOR. R. Hall, M. Kessler* and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

AMPA-type glutamate receptors are the primary mediators of excitatory neurotransmission in mammalian forebrain and are also thought to be central to the form of synaptic plasticity known as long-term potentiation (Staubli *et al., Psychobio.* 18:377, 1990). Binding of [^{3}H]AMPA (DL-α-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid) to lysed rat brain membranes in the presence of potassium thiocyanate resulted in curvilinear Scatchard plots which could be resolved by regression analysis into a large low affinity component (K_D=200-1000 nM; approx. 90% of the total number of sites) and a small high affinity component (K_D=10-40 nM; approx. 10% of the sites). Treatment with 0.4% Triton X-100 resulted in a solubilized fraction which contained 74% of the sites recovered after solubilization. These sites were uniformly of the high-affinity type with a K_D of 29 ± 5 nM. The total number of these sites was three to four times higher than the number of high affinity sites which was present in the starting material. Solubilization thus appears to convert low affinity into high affinity receptors; it follows from this that the two affinity states represent interconvertible forms of the same receptor rather than separate receptor types. Moreover, high-affinity sites were found to be greatly reduced in number in lysed synaptic plasma membranes: they accounted for only 1% of total binding in SPMs as compared to 10% in regular lysed membranes. This suggests that it is some factor in the synaptic environment which keeps receptors in a low affinity state and that it is the loss of this factor during solubilization which allows receptors to revert to a high affinity state. (Supported by NS 21860 and AFOSR 89-0383).

RAPID VISUALIZATION OF NMDA RECEPTORS; CHARACTERIZATION OF (+)-3-[^{125}]IODO-MK801 BINDING TO THIN SECTIONS OF RAT BRAIN. W. Jacobson* and G.A. Cottrell Department of Obstetrics and Gynecology and Department of Pharmacology, University of Toronto, Toronto, Ontario, M5G 1L7.

We have developed and characterized a method for the rapid autoradiographic determination of receptor sites for the non-competitive NMDA receptor antagonist MK801, using an iodinated form of the compound, (+)-3-[^{125}]-Iodo-MK801. The binding site was shown to exhibit those criteria necessary for its definition as a receptor site, i.e. the binding was saturable, of high affinity, easily reversible, and stereospecific. Saturation analysis of binding to thin brain sections revealed a B_{max} of 108.1±10.5 fmole/mg protein and a K_d of 383±67 pM. The pharmacology of the interaction of the ligand with the binding site yielded good correlation between the potency of various substances to compete for the binding site and their ability to act as antagonists of NMDA. Autoradiographs of thin coronal brain sections using (+)-3-[^{125}]-Iodo-MK801 yielded high quality images in 24-48 hours with a distribution of binding sites paralleling that reported for the tritiated form of the ligand, i.e. with high densities in the hippocampus, cerebral cortex and lateral septum. Other areas with significant binding included parts of the thalamus, the amygdala and the olfactory tubercules. Furthermore, due to its high specific activity, this ligand lends itself to the study of regions not rich in MK801 binding sites, such as the diencephalon. Supported by the Medical Research Council of Canada, MA-10911.

DEVELOPMENTAL CHANGES IN HYPOTHALAMIC EXCITATORY AMINO ACID RECEPTORS IN THE RAT. G.A. Cottrell * and W. Jacobson. Department of Obstetrics and Gynecology & Department of Pharmacology, University of Toronto, Toronto, Canada, M5G 1L7.

Using an iodinated form of the non-competitive NMDA receptor antagonist MK-801 (IMK) which labels a site on the NMDA receptor, as well as [^{3}H]-Kainic acid (KA), we have examined the development of excitatory amino acid (EAA) binding sites in the hypothalamus of young male and female rats during the pubertal transition. Coronal brain sections were obtained from rats of both sexes at d15, d25, d32 and d37 of life, and autoradiograms were generated using both ligands. In the female, IMK binding increased in all regions examined (MPOA, Lat Sept, BNST, VMH, and Striatum) over the course of development. Such was not the case in males, where increases were not seen in the BNST, VMH or Striatum. The ontogeny of KA binding sites in the median eminence was also sexually dimorphic, in that males demonstrated a transient elevation at d25 and d32 of life, while females did not show an increase until d32, and this was maintained at d37 of life. Significant KA binding was not measured in any other hypothalamic region in either males or females. These findings are considered in light of suggestions that EAA play a role in the control of the onset of puberty. Supported bty the Medical Research Council of Canada, MA-10911.

MATERNAL VITAMIN B-6 DEFICIENCY ALTERS POSTNATAL DEVELOPMENT AND ZINC REGULATION OF ^{3}H-MK801 BINDING TO CORTICAL NMDA RECEPTOR-ION CHANNELS. T.R. Guilarte* and R.C. Miceli Dept. of Environmental Health Sciences, The Johns Hopkins University School of Hygiene and Public Health, Baltimore, MD.

Vitamin B-6 (B6) deficiency during development results in reduced function of NMDA receptor-coupled ion channels in the cerebral cortex (CTX) of 14 day old rats (Guilarte TR. *Neurosci. Lett.* 121: 207-210, 1991). The present investigation extends the previous findings and indicates that B6 deficiency during development reduces the number of ^{3}H-MK801 binding sites and increases the level of zinc (Zn) required to inhibit ^{3}H-MK801 binding.

Long Evans female rats (125-150 g) were fed either a normal (7.0 mg/kg pyridoxine.HCL [PN.HCl]) or marginally deficient B6 diet (0.7 mg/kg PN.HCl) two weeks prior to mating. Dams and progeny (weaned at 21 days of age) were fed the same diet throughout the study. ^{3}H-MK801 binding to cortical membranes was assayed at postnatal day (PN) 7, 14, 21, 28, and 56 as described (Guilarte TR. *Ibid*). Rats fed a normal diet, had a transient increase in the Glu or Gly-dependent ^{3}H-MK801 binding to PN14 CTX, relative to all other ages. This transient increase in ^{3}H-MK801 binding sites was significantly reduced in rats fed the marginally deficient B6 diet. The effect of the NMDA receptor endogenous modulators Zn and magnesium (Mg) on ^{3}H-MK801 binding was also measured as a function of age. Cortical membranes from PN7 rats were significantly more sensitive (IC50= 0.91 mM) to the inhibitory effects of Mg than any other age tested (combined IC50= 2.93 mM). There were no significant effects of diet. In normal rats, Zn showed a transient increase in the IC50 (112 µM) at PN14 relative to PN7, 21, and 56. (IC50= 27.3, 30.7, and 45.9 µM, respectively). However, B6 deficient membranes at PN21 and 56 required greater amounts of Zn to produce the same inhibitory effect on ^{3}H-MK801 binding relative to age matched controls. These results suggest that vitamin B-6 deficiency can influence the postnatal development and regulation of NMDA receptor-coupled ion channels in the rat cerebral cortex (Grant # HD20939).

NMDA-RECEPTOR mRNA EXPRESSION IN THE CORTEX AND HIPPOCAMPUS OF CYCLING AND LACTATING RATS. R. Abbud,* B. Attardi, G.E. Hoffman, and M.S. Smith. Department of Physiology, University of Pittsburgh, Pittsburgh, PA 15261.

Using cFos expression as a marker of neuronal activation, we observed an inhibition of cortical and hippocampal activation in response to NMA, but not kainate, in lactating rats. This lack of responsiveness to NMA in lactating rats could be due to a decrease in the number of NMDA receptors (R) in these areas. To examine this hypothesis, we examined the expression of NMDA-R mRNA in cycling and lactating rats. *In situ* hybridization was performed using a ^{35}S-labeled riboprobe recognizing 1.4 kb of the NMDAR1 mRNA. Areas of silver grains were analyzed in the parietal cortex, the piriform cortex, the CA1 region of the hippocampus, and the dentate gyrus, using the Optimas Image Analysis System. NMDA-R mRNA was abundant in all areas of the brain examined. Differences in NMDA-R mRNA expression between cycling and lactating rats were observed only in the CA1 region of the hippocampus (18% decrease in the lactating rats). Differences in NMDA receptor expression were not detected by Northern Blot assays of tissue isolated from the cortex or hippocampus. These data suggest that the changes in NMDA-R mRNA expression in the lactating rat are very subtle, suggesting that alterations in NMDA receptors in the regions examined might not explain the functional deficits in cortical activation in response to NMDA. Other possible explanations are that a small but key subpopulation of neurons is altered in the cortex, or that changes in NMDA receptors occur within the brainstem or spinal cord rather than in the cortex. It is also possible that suckling may inhibit activation of brainstem pathways necessary for cortical activation. Supported by NIH Grant HD14643.

GABA RECEPTORS: FUNCTION IV

486.1

BACLOFEN INHIBITS THE INCREASE IN CYCLIC AMP INDUCED BY HIGH FREQUENCY ELECTRICAL STIMULATION IN THE DENTATE GYRUS OF RAT HIPPOCAMPAL SLICE. M.J. Bonnet* and J.M. Sarvey, Department of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, Maryland 20814.

Activation of second messenger systems is implicated in the induction and maintenance of long-term potentiation (LTP), a form of synaptic plasticity. A high-frequency train (HFT; 100 Hz, 2 sec) of electrical stimuli was applied to the medial perforant path in the dentate gyrus of rat hippocampal slices. After HFT the dentate gyrus was cut from the rest of the slice, and cAMP levels in the dentate were determined by a protein binding assay. Each treatment group consisted of 3 slices from each of 6 rats. One min after HFT, cAMP levels increased to 240% of levels in slices that did not receive an HFT. Immediate post-treatment exposure of slices to baclofen (10, 100, 1000 µM) for 1 min resulted in concentration-dependent inhibition of HFT-stimulated cAMP levels. Levels of cAMP were reduced by 50% by 10 µM baclofen compared to levels produced post-HFT without baclofen. A high concentration (1000 µM) of baclofen post-HFT suppressed cAMP to basal levels. Pre-treatment of slices with 100 µM baclofen for 20 min before HFT also inhibited the HFT-induced increase in cAMP to a similar degree to post-HFT baclofen. However, pre-HFT treatment with 10 µM baclofen did not produce any significant suppression of HFT-stimlated cAMP. These results suggest that the baclofen-sensitive GABA-B receptor can regulate stimulated cAMP levels in the dentate gyrus.

***IN VITRO* AND *IN VIVO* EFFECTS OF BACLOFEN ON cAMP OVERFLOW IN RAT CEREBRAL CORTEX.**

A.R.Knight*, P.Whitton and N.G.Bowery, Dept of Pharmacology, School of Pharmacy, 29-39 Brunswick Square, London, U.K.

The dual effect of baclofen upon cAMP production in brain tissue *in vitro* is well documented. The purpose of the present study is to elucidate and compare its effects *in vivo*.

In vitro experiments where performed by incubating aliquots of rat cross chopped cortical slices for 10 min with either 10 µM forskolin or 100 µM norepinepherine to stimulate adenylate cyclase (AC) activity. *In vivo* experiments were performed by implanting a concentric dialysis probe into rat frontal cortex, 100 µM forskolin was administered in the dialysing medium as two pulses, the first (S1) to standardize the preparation, the second (S2) for experimental manipulation. Radioimmunoassay was used to quantify the cAMP accumulated in the supernatant or the dialysate as a measure of AC activity. *In vitro* baclofen (0.01 to 100 µM) had no effect on base line cAMP production but was found to dose dependently inhibit forskolin stimulated AC activity (pIC_{50} 6.07 ± 0.29) and to augment the maximum stimulation obtained with norepinepherine (pIC_{50} 5.04 ± 0.17). *In vivo*, 10 µM baclofen also failed to alter base line cAMP. However, when baclofen (10µM) was administered simultaneously with forskolin during S2, cAMP overflow was not reduced when compared to control S2, but instead appeared to increase the stimulation produced by forskolin (S2/S1 ratio = 1.59 ± 0.27, control = 0.57 ± 0.07). The reasons for this are currently under investigation.

486.3

EFFECT OF (-)BACLOFEN ON cAMP FORMATION AND SUBSTANCE P RELEASE FROM RAT SPINAL CORD.

N.G. Bowery* & M. Malcangio Dept. of Pharmacology, School of Pharmacy, Univ. of London, London WC1N 1AX.

It has been proposed that baclofen may induce antinociception in rodents through an action on $GABA_B$ receptors localized in the spinal cord. In this study we have investigated the effect(s) of (-)baclofen on stimulated cAMP formation in rat spinal cord slices (350x350 μm) and on substance P release evoked by electrical stimulation (15 V, 10Hz, 1ms) of dorsal roots attached to rat spinal cord slices. (-)Baclofen, dose dependently (10-100 μM), inhibited forskolin (10 μM)-induced formation of cAMP (maximal inhibition 58±9.5% at 100 μM, n=3 rats) but this was not prevented by CGP 35348 (concentrations up to 1.5 mM). By contrast with cerebral cortical slices (-)baclofen (1-100 μM) failed to enhance noradrenaline (100 μM)-induced formation of cAMP. Evoked release of substance P-LI was completely inhibited by (-)baclofen (IC_{50} ~ 4.5 μM). Whilst $GABA_B$ mediated analgesia may stem from a reduction in primary afferent neurotransmitter release it seems unlikely that an alteration in cAMP production is implicated.

DIFFERENTIAL DISCRIMINATIVE-STIMULUS EFFECTS OF ANXIOLYTICS AND HYPNOTICS IN RATS TRAINED TO DISCRIMINATE LORAZEPAM (LRZ), DIAZEPAM (DZP), OR PENTOBARBITAL (PB).

N.A. Ator* and R.R. Griffiths, Div. of Behav. Biol., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21224.

Under two-lever drug vs. no-drug discrimination procedures, the LRZ training condition previously was shown to be unique among benzodiazepine (BZ) training conditions studied to date in that rats did not generalize to pentobarbital reliably, even when training dose and tolerance to its rate-decreasing effects were manipulated (Ator and Griffiths, Psychopharm., 1989, 98, 20). Subsequently, generalization profiles for LRZ, DZP, and PB training conditions have been directly compared in Long-Evans rats in tests with a range of BZ agonists and partial agonists, barbiturates, and other anxiolytics or sedatives. Rats in all three training groups generalized to BZ, but greater selectivity in generalization to barbiturates and other sedative/anxiolytic compounds occurred in rats trained to discriminate LRZ than DZP. Rats trained to discriminate LRZ failed to generalize reliably to any barbiturate or other non-BZ sedative/anxiolytic, but the profiles for rats trained to discriminate DZP and PB were comparable. Among novel BZ-receptor ligands, abecarnil occasioned drug lever responding under all conditions; zolpidem did so in the PB and DZP conditions but not as reliably in the LRZ condition; and bretazenil occasioned the drug response in the DZP and PB, but not the LRZ, conditions. ALTERATIONS IN TBPS BINDING IN THE LIDOCAINE-KINDLED RAT MODEL OF EPILEPSY.

Marc S. Abel* and Daniel E. Carney, Department of Cell Biology and Anatomy, UHS/The Chicago Medical School, North Chicago, IL.

This autoradiographic study examined regional $GABA_A$ receptors in chemically kindled rats. [^{35}S]t-Butyl bicyclophosphorothionate (TBPS), which binds in or near the $GABA_A$ receptor chloride channel, was used as a ligand to identify $GABA_A$ receptor complexes. Male Sprague-Dawley rats were injected daily with lidocaine (65 mg/kg, i.p.). Control rats received an equal volume of saline vehicle. Seizure activity was evaluated using the Racine Scale of 5 behavioral stages. The animals displayed a gradual increase in the severity of behavioral indices and by day 20 greater than 50% were in Stage 4 or 5. Midway through the injection regimen some animals exhibited a gradual regression toward less severe behavioral stages; these animals were considered 'compensated'. After 25 injections the animals were killed, the brains removed and 30 μm sections incubated with 2 nM [^{35}S]TBPS. Brain paste standards were prepared and included in the autoradiographic process. After appropriate exposure, the developed films were analyzed using a computer based imaging system. Binding was decreased in the subiculum, posterior lateral thalamic nuclei, hippocampal regions CA_1 and CA_3, and cerebellar nuclei in sections from kindled animals as compared to controls. Sections from rats that 'compensated' during the kindling process had normal or slightly elevated [^{35}S]TBPS binding in those regions. These data support the hypothesis that alterations in the $GABA_A$ receptor occur during the kindling process.

486.6

GABA EFFECTS ON ASCENDING AND DESCENDING TRACTS IN ISOLATED DORSAL COLUMNS OF NEONATAL RAT SPINAL CORD.

O. Honmou*[1], K. Sakatani[2] and W. Young[1]. [1]Dept. of Neurosurgery, New York University Medical Center, 550 First Avenue, New York, NY 10016 and [2]Dept. of Neurosurgery, Sapporo medical college, South- 1st West-16th Chuoku, Sapporo Japan 060.

We compared the effects of GABA and related drugs on axonal conduction in of neonatal rat spinal cords *in vitro*. In addition, we evaluated the effect of GABA-evoked extracellular K^+ concentration changes on axonal conduction in these spinal tracts, using double-barrelled K^+-sensitive microelectrodes. The compound action potential evoked by supramaximal stimuli was recorded with glass micropipettes or reference barrels of K^+-sensitive microelectrodes. GABA (10^{-4} M) reversibly depressed the compound action potential amplitude and prolonged the latency of the ascending tracts. In contrast, GABA had little or no significant effects on the compound action potential of the descending tract. The GABA-A receptor agonist isoguvacine (10^{-5}-10^{-4} M) reduced compound action potential amplitudes and increased response latencies of both ascending and descending tracts. However, these effects were far less pronounced in the descending tract. GABA (10^{-4}-10^{-3} M) increased extracellular K^+ concentrations in the ascending tracts with a depression of the compound action potential in a concentration-dependent manner. The GABA-induced compound action potential changes correlated only partially with the extracellular K^+ concentration changes. Furthermore, compound action potential changes induced by elevation of extracellular K^+ concentrations were far less than those induced by GABA. GABA (10^{-3} M) also caused a similar discrepancy of extracellular K^+ concentrations and compound action potential changes in the descending tract. These results suggest that extracellular K^+ concentration increases induced by GABA play a minor role in GABA actions on axonal conduction in the ascending and descending tracts.

The present results indicate that GABA-A activation modulated axonal conduction of both ascending and descending tracts in the neonatal rat spinal cord. However, the effects were much less on the descending tract compared to the ascending tracts. In addition, GABA-evoked extracellular K^+ concentration changes contributed only partially to the GABA-A mediated conduction changes.

486.7

PHASE SHIFT OF LLD IN DIFFERENT AREAS OF THE HIPPOCAMPUS: MULTI SITE RECORDING OF SPONTANEOUS AND EVOKED LLD FROM AN IN VITRO RODENT SLICE.

C.M. Coussens*, A.M. Borroni, T.J. Teyler. Dept. of Neurobiology, N.E. Ohio Univ. College of Med., Rootstown, OH. 44272.

A depolarizing bicuculline sensitive response can be elicited in slices of hippocampus and neocortex under various conditions. This response is not effected by the antagonism of excitatory amino acid receptors and seems to occur throughout the tissue. This response also occurs spontaneously in the presence of 4-AP, and does not seem to propagate but occurs simultaneously throughout the tissue. It can be shown that there is some delay in the occurrence of the response between the distal CA3 dendrites and the subiculum. The delay across 2mm of tissue is approximately 150 msec suggesting there may be a synaptic component to the response and/or that there may be a loci where the response originates.

The ability of GABAergic cells to produce depolarizing responses may be important in stabilizing GABAergic networks as well as limiting seizure-like activity. Whether activation of the postsynaptic cell through this mechanism can change the efficacy of synaptic contacts is a possibility, since calcium can enter the cell through these channels. When this occurs intracellular calcium increases, even when not paired with synaptic activation which produces synaptic modifications. As this response is most prominent in neonates, this would be a good mechanism for laying down a framework of GABAergic connections.

486.8

DIFFERENTIAL LAMINAR EFFECTS OF BACLOFEN ON DEVELOPING RAT VISUAL CORTEX.

A.T. Perkins, L.M. Grover & T.J. Teyler*. Neurobiology Dept., Northeastern Ohio Univ. Col. of Med., Rootstown, OH 44272.

Baclofen application has resulted in facilitation, depression and no effect in various CNS structures. These disparate results have led to the speculation that baclofen effects on $GABA_B$ receptors demonstrate regional heterogeneity. We utilized a 16 channel rake electrode with subsequent CSD analysis and intracellular recordings to examine the laminar effects of baclofen following white matter stimulation in 16-22 day old rat visual cortex. Monosynaptic EPSPs in both layers II/III & V were unaffected by low dose (0.5-2.0 μM) baclofen and equally attenuated by high doses (10-40 μM). Polysynaptic EPSPs were selectively attenuated in layer II/III at low doses while layer V EPSPs were facilitated. Low dose baclofen selectively attenuated IPSPs in both layers. We conclude that baclofen, acting at presynaptic terminals, demonstrates differential laminar effects in immature rat visual cortex.

DECREASED NEURONAL INHIBITION IN *IN VITRO* HIPPOCAMPUS AFTER 1 WEEK FLURAZEPAM (FZP) TREATMENT: AN INTRACELLULAR STUDY. X-H. Xie* and E. I. Tietz. Department of Pharmacology, Medical College of Ohio, Toledo, OH 43699

Chronic FZP treatment significantly reduces GABA-mediated hippocampal paired-pulse inhibition (Xie and Tietz, 1991). Orthodromic EPSP-IPSP sequences and action potential (AP) burst frequency and duration, elicited by a 1 sec depolarizing current (0.6 nA) injection, was examined in *in vitro* superfused slices 48 hr after 1 week FZP treatment. Male rats (175-200 gm) were offered FZP in the drinking water (100 mg/kg X 3 dy;150 mg/kg X 4 dy). Selected neurons from treated (8 cells/5 rats) and control (7 cells/4 rats) slices had stable resting membrane potentials (RMP: -64.5±0.8 vs. -63.3±1.3 mV), input resistances > 30 MΩ (78.3±10.6 vs 93.9±10.6) and antidromic APs > 70 mV (82.5±3.9 vs 83.5±1.5 mV). RMP was held at -60 mV throughout the experiment. EPSP-IPSPs elicited by just subthreshold Schaffer-collateral stimulation were recorded (3 M KAc filled glass pipette, 100-170 MΩ) from CA1 pyramidal cells (24°C). There was a significant ($p<.01$) reduction in the amplitude of the *f*IPSP (1.4±0.6 vs 6.3±0.7 mV) and *s*IPSP (3.5±0.4 vs 6.5±0.7 mV) and an increase in EPSP amplitude (10.6±1.3 vs 5.4±0.8 mV). The small increase in burst duration and frequency (265.4±60.4 ms, 34.0±2.4 Hz vs 242.1±50.7 ms, 25.2±4.2) was not significant ($p>.10$). These data provide additional evidence regarding the nature of the impairment in GABA-mediated hippocampal function in chronic benzodiazepine treated rats. Supported by NIDA grant RO1-DA04075.

486.10

FEEDFORWARD INHIBITION IS REDUCED IN HIPPOCAMPUS AFTER CHRONIC BENZODIAZEPINE TREATMENT. X. Zeng and E.I. Tietz* Dept. of Pharmacology., Med. Coll. Ohio, Toledo, OH 43699

Recurrent inhibition was reduced in CA1 region of *in vitro* hippocampal slices of benzodiazepine tolerant rats indicated by a reduction in both orthodromic-orthodromic and antidromic-orthodromic paired-pulse responses (Xie and Tietz, 1991). In this study the magnitude of feedforward inhibition in slices from 1 week chronic flurazepam (FZP) treated rats was evaluated according to Lupica and Dunwiddie (1992). Slices (400 μM) were cut, 48 hr after treatment, from male rats (175-200 gm) offered FZP (100 mg/kg X 3 dy;150 mg/kg X 4 dy) in the drinking water. Control rats received saccharin water. Control and test population spikes evoked by stratum radiatum stimulation (S2) on the subicular side of an extracellular recording electrode (2 M NaCl filled glass pipette, 2-5 Mohm) were compared. The test pulse followed an orthodromic conditioning pulse (S1), subthreshold for a population spike, with interpulse intervals (IPI) of 10-100 ms. A knife cut was made through the alveus between S1 and the recording electrode to block recurrent inhibition. Feedforward inhibition in control slices ranged from 100-55%. Treated slices showed a significant (20-40%, $p<.01$) reduction in feedforward inhibition at all IPI. These data suggest that all levels of GABA-mediated inhibition are impaired in CA1 region of hippocampus of chronic benzodiazepine treated rats. Supported by NIDA grant RO1-DA04075.

486.11

$GABA_A$ RECEPTOR ACTIVATION INDUCES GABA AND GLUTAMATE RELEASE FROM PREOPTIC AREA. A. Fleischmann*[1], M.H. Makman[2], A.M. Etgen[1,3] Depts. of Psychiatry[1], Biochemistry[2], Molecular Pharmacology[2] and Neuroscience[3], Albert Einstein College of Medicine, Bronx, NY 10461.

The effect of γ-aminobutyric acid (GABA) receptor agonists on release *in vitro* of radiolabeled GABA and glutamate was studied using a crude preparation of isolated nerve terminals (neurosomes). GABA agonists were incubated (2 min., 37°C) with neurosomes prepared from hypothalamus (HYP), preoptic area (POA) and cortex (COR) tissues. GABA and the $GABA_A$ receptor agonist muscimol, but not the $GABA_B$ receptor agonist (-)-baclofen, stimulated ^{3}H-GABA and ^{3}H-glutamate release from POA but not HYP or COR neurosomes of male rats. These effects were partially inhibited by the $GABA_A$ receptor antagonists picrotoxin and bicuculline. Muscimol-induced release of ^{3}H-glutamate and ^{3}H-GABA was dependent on extracellular Ca^{2+}. Muscimol failed to release ^{3}H-GABA and ^{3}H-glutamate from POA neurosomes of ovariectomized female rats. However, administration of estradiol and progesterone to ovariectomized females caused the appearance of muscimol induced-release of amino acids comparable to that obtained in male rats. Therefore, $GABA_A$ receptor-induced release of amino acids is brain region-specific and modified by hormonal status.

486.12

EFFECTS OF GABA ON AXONAL CONDUCTION AND EXTRACELLULAR POTASSIUM ACTIVITY IN THE NEONATAL RAT OPTIC NERVE. A. Z.Hassan*[1], K. Sakatani[2] and M. Chesler[1]. [1]Dept. of Neurosurgery, New York University Medical Center, 550 First Avenue, New York, NY 10016 and [2]Dept. of Neurosurgery, Sapporo medical college, South-1st West-16th Chuoku, Sapporo Japan 060.

GABA depolarizes rat optic nerve axons and modulates axonal conduction through the activation of GABA-A receptors. In a number of preparations, application of GABA also causes a rise in $[K^+]_e$. To address whether an increase of $[K^+]_e$ plays a major role in GABA actions on the rat optic nerve, we studied the effects of GABA on axonal conduction and $[K^+]_e$ in the neonatal rat optic nerve *in vitro*. Double-barrelled K^+-sensitive microelectrodes were used to record $[K^+]_e$. The extracellular compound action potential evoked by supramaximal stimuli was recorded from reference barrels of the K^+-sensitive microelectrodes. GABA (10^{-4}-10^{-3} M) increased $[K^+]_e$ in the neonatal optic nerve in a concentration-dependent manner. During prolonged application, the $[K^+]_e$ slowly recovered. Upon washout, a $[K^+]_e$ undershoot was observed, followed by a slow return to baseline. The increase in $[K^+]_e$ induced by GABA was markedly reduced by the GABA-A receptor blocker, bicuculline (10^{-4} M). Isoguvacine (10^{-4} M), a GABA-A agonist, mimicked the effect of GABA but produced larger responses at the same concentration. In contrast, baclofen (10^{-4} M), a GABA-B agonist, had no effect on $[K^+]_e$. The changes in the compound action potential induced by GABA correlated only partially with the $[K^+]_e$ changes; the compound action potential was still depressed when $[K^+]_e$ returned to baseline before the undershoot. Furthermore, the changes in the compound action potential induced by elevation of $[K^+]_e$ were far less than those induced by GABA. These results demonstrate that the GABA-evoked accumulation of $[K^+]_e$ plays a secondary role in GABA actions on the neonatal rat optic nerve. Supported by NINDS Grant NS 1064.

GABA MODULATES CALCIUM AND MEMBRANE POTENTIAL OSCILLATIONS IN IMMORTALIZED HYPOTHALAMIC NEURONS. A.C. Charles* and T.G. Hales. Depts. of Neurology and Anesthesiology, UCLA School of Medicine, Los Angeles CA 90024

Clonal GnRH-secreting hypothalamic neurons (GT1-7) in culture showed spontaneous oscillations in $[Ca^{2+}]_i$ as measured with fluorescence videomicroscopy. Ca^{2+} oscillations had a periodicity of 1-60 seconds and the peak $[Ca^{2+}]_i$ of each oscillation ranged from 100-500 nM. Ca^{2+} oscillations of individual cells were generally asynchronous, although some groups of cells showed synchronous oscillations. Spontaneous Ca^{2+} oscillations were reversibly abolished by 1μM TTX. Bath application of 1 μM GABA evoked an increase in $[Ca^{2+}]_i$ in most cells (100-200 nM), and increased the frequency of Ca^{2+} oscillations; 10 μM GABA evoked a greater increase in $[Ca^{2+}]_i$ (100-500 nM), in some cells further increasing the frequency of Ca^{2+} oscillations. These responses to GABA were inhibited by 10 μM bicuculline. Using the patch-clamp technique under current-clamp conditions, GT1-7 cells showed oscillations of membrane potential between -60 and -40 mV, with a periodicity of 0.5 -30 seconds. Each depolarizing oscillation was preceded by an action potential. Under voltage-clamp conditions, GABA activated Cl^- currents in all cells tested. Depolarizing test pulses activated inward Ca^{2+} currents with high and low threshold components, as well as Na^+ currents which were sensitive to TTX (0.5 μM). Cell-attached patch recordings revealed spontaneous action potentials. Transient application of GABA under these conditions evoked multiple action potentials. These results suggest that GABA has an excitatory action on GT1-7 cells which may be involved in the stimulation of GnRH secretion.

Immortalized Hypothalamic (GT1-7) Neurons Express Functional $GABA_A$ Receptors. R.W. Olsen, H. Kim, B. Longoni, A.J. Tobin and T.G. Hales*. Dept. Pharmacology, Dept. Biology and Dept. Anesthesiology, UCLA, LA, CA 90024.

Neuronal cell-lines provide a source of pure populations of neurons and allow the properties of many neurotransmitter receptors to be studied. None of these cells have been reported to express functional $GABA_A$ receptors. Indeed there have been no reports of cell-lines expressing functional amino acid receptors. Using biochemical and electrophysiological techniques, we have identified a neuronal cell-line expressing functional $GABA_A$ receptors. Membranes from immortalized hypothalamic (GT1-7) neurons bound [^{3}H]muscimol (213 ± 16 fmol/mg protein, 10 nM), but no significant clonazepam-displaceable [^{3}H]flunitrazepam binding was detected. In addition, diazepam (1 - 100 μM) was unable to enhance specific [^{3}H]muscimol binding. Under voltage-clamp conditions, GABA-activated chloride currents, recorded from GT1-7 cells, were blocked by bicuculline (1 μM) and Zn^{2+} (IC_{50} = 2.1 μM), but were insensitive to diazepam (1 - 10 μM). These results suggest that $GABA_A$ receptors on GT1-7 cells lack γ subunits. The neurosteroid 5α-pregnan-3α-ol-20-one (100 nM) and pentobarbital (100 μM) both potentiated GABA responses recorded from GT1-7 cells to 413 ± 89% and 450 ± 61% of control amplitude, respectively. GABA responses were also potentiated by propofol (2 μM). Interestingly neither the anesthetic steroid (1 μM) nor propofol (100 μM) directly activated $GABA_A$ receptors of GT1-7 cells. PCR analysis of the cells revealed the presence of mRNAs encoding α1, β1 and β3 polypeptides but not α2, α4, α6, β2, γ2 or δ. GT1-7 cells may provide a useful model system for studying the regulation of $GABA_A$ receptor polypeptide expression.

PERIPHERAL BENZODIAZEPINE RECEPTOR BINDING IN HYPOTHYROID RAT VENTRICLES

L KRAGIE* & R SMIEHOROWSKI Dept. Biological Sciences, State University of New York at Buffalo, Buffalo, NY 14260

Previously we reported the inhibition of triiodothyronine (T3) uptake into tissue cultured cells, by compounds from the benzodiazepine (BZ) class, but no interaction was seen in competition binding assays for the peripheral BZ receptor in liver preparations (Kragie & Doyle 1992 Endocrinology **130**:1211). Others have demonstrated upregulation of central and peripheral receptors after brief treatment with D-thyroxine (Gavish et al 1986 J Neurochem **47**:1106). We looked at binding of the peripheral receptor ligand, [^{3}H]R05 4864 in cardiac ventricular homogenates from thryroidectomized (TX) and sham-operated Holtzman adult male rats. Thirty days post-operative, TX animals were clinically hypothyroid, as demonstrated by low serum thyroxines and reduced heart / body weight ratios relative to sham controls. Hearts were harvested and flash frozen. Homogenates, 75-150 ug protein in PBS, were incubated with 0.25 to 12 nM [^{3}H]Ro5 4864 at 4°C for 1 hr. Nonspecific binding was determined using 1 uM cold Ro5 4864. Data were analyzed with LIGAND.

	SHAM	significance	TX
Bmax pmol/mg	11.01 +/- 1.16 (8)	p<0.002	6.17 +/- 0.75 (10)
HILL	0.96 +/- 0.02	NS	1.00 +/- 0.02
log Kd	-8.143 +/- 0.07	p<0.001	-8.453 +/- 0.04

The data show increased affinity and decreased receptor density in the TX hearts. Supported by NIH grant to LK: K11 DK01456

ANXIOLYTIC COMPOUNDS HAVE DIFFERENTIAL EFFECTS ON RAT EEG.

K.L. Skinkle and C.M. Sinton*. Neurogen Corp., Branford, CT 06405.

Although currently available antianxiety agents are sedative, it is unlikely that sedation is a necessary property of this class of compound. Here, different anxiolytics were examined with a view to quantifying their effects on central arousal: as an example of a sedating compound, a barbiturate, Sodium Pentobarbital, was compared with a recently developed Type I sedative, Zolpidem, a non-selective benzodiazepine, Diazepam, and a serotonin ($5HT_{1A}$) ligand, Ipsapirone, which has been shown to exhibit little sedation. The electroencephalogram (EEG) was adopted as a sensitive measure of arousal. Rats were chronically implanted with cortical electrodes, and test compounds were administered via a cannulated tail vein. Vigilance was maintained by using a randomized disturbing noise source. The EEG, spectrally analyzed, demonstrated that all compounds except Ipsapirone significantly increased power in the freqency band above 8 Hz. Ipsapirone, in contrast, decreased power at these frequencies. The lowest freqency range (1-4 Hz) was also affected differentially: the barbiturate and Zolpidem increased, but Ipsapirone decreased, power at these frequencies; Diazepam had no effect. These data show that all compounds affected central arousal but there was no common action which might reflect an antianxiety effect. The EEG change produced by the two most sedating drugs indicated that there was increased recruitment of thalamocortical circuits. Such recruitment occurs with reduced vigilance. Diazepam acted similarly but Ipsapirone, under circumstances in which the compound reduces anxiety, increased vigilance. In conclusion these results indicate, firstly, that there is no preclinical EEG signature for anxiolytics because the EEG is a measure of the effect of these compounds on central arousal. And, secondly, that sedation is apparently not required for an anxiolytic action.

[^{123}I]IOMAZENIL SPECT IMAGING DEMONSTRATES SIGNIFICANT BENZODIAZEPINE (BZ) RECEPTOR RESERVE IN HUMAN AND NONHUMAN PRIMATE BRAIN.

E. Sybirska*, J. Seibyl, M. Al-Tikriti, R.M. Baldwin, Y. Zea-Ponce, S.S. Zoghbi, E.O. Smith, P.B. Hoffer, D.S. Charney, R.B. Innis. Yale University /VA Med. Ctr., West Haven, CT 06516.

[^{123}I]Iomazenil has been used as a SPECT (single photon emission computed tomography) probe of the BZ receptor to measure receptor occupancy by agonists and antagonists. The present study involved parallel experiments in humans and monkeys to examine receptor occupancy by a clinically relevant dose of lorazepam.

A total of 36 [^{123}I]iomazenil SPECT scanning studies were performed in 12 humans and 2 monkeys. The effects of lorazepam (0.03 mg/kg i.v.) was assessed by the ratio of the brain washout rate of [^{123}I]iomazenil in the 45 min period after its injection relative to that in the 45 min period prior to injection, and this ratio was compared to that following placebo injection. Although this dose of lorazepam caused moderate sedation of the human subjects, the imaging results in both humans and monkeys could not demonstrate significant enhancement of washout of brain activity. The effects of higher cumulative doses of lorazepam (0.13, 0.25, and 0.5 mg/kg) were examined with a stepwise displacement paradigm and showed an ED50 of 0.17 ± 0.01 mg/kg (mean ± SEM, n=12) to displace specifically bound radioligand in brain. Log-probit plots of these data suggest that the clinically relevant dose of lorazepam (0.03 mg/kg i.v.) is associated with 3.1 ± 0.4% receptor occupancy. To examine whether endogenous GABA might modulates this *in vivo* potency measurement of lorazepam (i.e., ED50 to displace the radioligand), we examined the stepwise displacement with or without the concurrent administration of tiagabine, an inhibitor of the GABA transporter. In a series of 4 experiments, we could not demonstrate a significant *in vivo* GABA shift of lorazepam's potency.

These studies show that clinically relevant doses of lorazepam have low BZ receptor occupancy (< 4%) and suggest the BZ system has significant receptor reserve.

GABA RECEPTORS: FUNCTION V

487.1

PROGESTERONE-INDUCED ELEVATION IN BRAIN 3α-HYDROXY-5α-PREGNANE-20-ONE IS ASSOCIATED WITH ANXIOLYTIC BEHAVIOR AND AN INCREASE IN $GABA_A$ RECEPTOR FUNCTION.

D. Bitran*[1], R.H. Purdy[2], and C.K. Kellogg[3]. [1]Dept. of Psychology, College of the Holy Cross, Worcester, MA, [2]Dept. of Organic Chemistry, Southwest Foundation for Biomedical Research, San Antonio, TX, and [3]Dept. of Psychology, Univ. of Rochester, Rochester, NY.

We have previously reported that intracerebroventricular administration of the progesterone metabolite, 3α-hydroxy-5α-pregnan-20-one (allopregnanolone), elicited significant anxiolytic behavior in a dose-dependent and stereospecific manner (Brain Res, 561: 157, 1991). We have also found that the anxiolytic efficacy of diazepam was enhanced in proestrous female rats, relative to ovariectomized (Ovx) rats, as was the efficacy of GABA-stimulated chloride (Cl-) influx in cortical synaptoneurosomes (Behav Neurosci, 105: 653, 1991). These results are consistent with the well-documented in vitro effects of 3α-hydroxy pregnane steroids as potent positive modulators of the $GABA_A$ receptor.

In the following experiments, the effect of a subcutaneous injection of progesterone (P: 0, 1, or 4 mg) in Ovx rats on exploration of an elevated plusmaze was examined. Blood serum and cortical concentrations of allopregnanolone were assessed. GABA-stimulated $^{36}Cl^-$ influx was determined in cortical synaptoneurosomes from a subgroup of Ovx females treated with vehicle or 4 mg of P. Significant anxiolytic activity was detected 4 hours after the administration of 1 or 4 mg of P; behavioral measures of anxiolytic efficacy were significantly correlated to blood and cortical levels of allopregnanolone. P treatment also increased the sensitivity of cortical synaptoneurosomes to GABA (i.e., decreased the EC_{50}) and increased the maximal efficacy with which GABA stimulated Cl- uptake. Together, these data support the hypothesis that the psychotropic effects of P are mediated by the bioconversion to allopregnanolone, and that allopregnanolone subsequently augments $GABA_A$ receptor-mediated function.

487.2

DEHYDROEPIANDROSTERONE (DHEA) IMPROVES MEMORY IN NORMAL MICE AND MICE WITH AGE-INDUCED MEMORY DEFICITS.

C.L. Melchior*, A. Glasky and R.F. Ritzmann. Olive View Medical Center, Sylmar, CA 91342.

DHEA is a steroid formed in the brain where it is active at the $GABA_A$ receptor complex. DHEA has been shown to enhance memory in avoidance paradigms. The purpose of these studies was to assess the effect of DHEA on working memory in the win-shift foraging paradigm. Briefly, a food deprived mouse is placed in a T-maze with a milk reward in both goal boxes. The mouse traverses the maze and is allowed to consume the milk in one of the goal boxes. On the next trial, if the mouse remembers which way it went on the previous trial, it will go the opposite way. By increasing the delay between trials the length of time a mouse can remember can be determined. Young adult C57BL/6 mice can remember at delays of 120 seconds. DHEA (0.005 mg/kg I.P.) increased the delay at which they could remember to 180 seconds. Young adult Swiss Webster mice are able to perform with delays up to 60 seconds. In 12 month old Swiss Webster mice, 70% had a memory deficit such that they could only remember at delays of 10 seconds. Physostigmine improved performance in these mice to a moderate extent, that is, they could remember with up to a 30 second delay. DHEA not only allowed the animals to perform at the 30 second delay but also, for 50% of these animals, extended the delay at which they could remember to 60 and 90 seconds. Thus, DHEA can improve working memory in young adult mice and improve the memory of mice with age-induced memory impairment to the level of young adults.

PHYSIOLOGICAL VARIATIONS OF GONADAL STEROIDS MAY REGULATE $GABA_b$ SYNAPTIC TRANSMISSION IN THE CEREBRAL CORTEX. M.I. Al-Dahan, M.H. Jalilian-Tehrani and R.H. Thalmann*, Baylor College of Medicine, Houston, TX 77030

These results show that $GABA_b$ agonist binding in the cerebral cortex is consistently affected during normal variations in gonadal steroids that occur during the estrus cycle of the rat. Well-washed synaptic plasma membranes were prepared for filtration assays of the binding of the $GABA_b$ agonist (^{3}H)-baclofen. In addition, we examined the binding of the $GABA_a$ agonist (^{3}H)-muscimol and (^{3}H)-8-OH-DPAT, a 5ht1a agonist that depends upon the same G-proteins as do $GABA_b$ receptors. (^{3}H)-baclofen binding was lowest during estrus (72±10 fmol/mg protein) and then increased over metestrus (145±12) to reach a plateau by diestrus (215±29) and proestrus (237±31). In contrast, (^{3}H)-muscimol binding was at or near its maximum during estrus, and (^{3}H)-8-OH-DPAT binding declined slightly from proestrus to estrus, but then remained constant until the next proestrus. Saturation binding experiments showed that $GABA_b$ receptor density (Bmax) approximately tracked effects upon total specific binding in that Bmax was lowest during estrus. Intracellular recording methods will be used to assess the effects of this variation in $GABA_b$ binding upon receptor-channel coupling in slices harvested from animals in different stages of the estrus cycle. Supported by NIH grant NS-21713.

COMPLEX INTERACTIONS BETWEEN THE STEROID DERIVATIVE RU 5135 AND THE $GABA_A$-RECEPTOR COMPLEX. C Cadoni, LD McCauley and KW Gee*. Dept of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

The diverse pharmacological actions observed *in vivo* following the administration of RU 5135 range from sedation to convulsions. *In vitro* evidence has suggested that these effects may be mediated in part via the $GABA_A$ receptor complex (GRC). The modulation of [^{35}S]t-butylbicyclophosphorothionate (TBPS) binding was used to evaluate the actions of the steroid derivative RU 5135 at the GRC. The inhibition of [^{35}S]TBPS binding by GABA in the presence of various concentrations of RU 5135 was consistent with the hypothesis that RU 5135 is a competitive antagonist at the $GABA_A$ receptor. Schild analysis of 5α-pregnane-3α-ol-20-one (3α,5α-P) modulation of [^{35}S]TBPS binding in the presence of different concentrations of RU 5135 suggested that the action of RU 5135 was not competitive at the putative steroid site on the GRC despite common structural features with the neuroactive steroids (i.e., 3α-OH'ated, 5β-reduced A ring). On the other hand, the reduced potency of 3α,5α-P as an inhibitor of [^{35}S]TBPS binding in the presence of RU 5135, as well as blockade of 5α-pregnane-3α,20α-diol (5α-pregnanediol) inhibition of [^{35}S]TBPS binding by RU 5135 provide further support for the GABA antagonist properties of RU 5135. Moreover, this amidine steroid was able to partially inhibit [^{35}S]TBPS binding independent of GABA with nanomolar potency; yet the mechanism by which this occurs remains to be determined. (Supported by NIH grants NS25986 and NS24645).

487.5

CHRONIC GABA TREATMENT DOWNREGULATES $GABA_A$ RECEPTOR COMPLEX AND α mRNA SUBUNITS IN MAMMALIAN CORTICAL NEURONS. M.K. Ticku, M.C. Mhatre* and A.K. Mehta. Univ. TX Hlth. Sci. Ctr., Dept. of Pharmacology, San Antonio TX 78284-7764

Chronic exposure of GABA was investigated on the binding of ligands to GABA receptor complex, GABA-induced ^{36}Cl-influx and α subunit mRNA levels in cerebral cortical cultured neurons. Chronic GABA (500 μM, 5 days) decreased the specific binding of [^{3}H]flunitrazepam, [^{3}H]Ro15-1788, [^{3}H]Ro15-4513, [^{3}H]GABA and [^{35}S]TBPS by 35-45%. Chronic GABA treatment also decreased the GABA-induced ^{36}Cl-influx by 43% and GABA enhancement of [^{3}H]flunitrazepam binding by 31%. All these effects were blocked by concomitant exposure of the neurons to $GABA_A$ receptor antagonist, R 5135 (1μM). Chronic GABA exposure of cerebral cortical neurons (500 μM for 5 days) also produced 40-50% reduction in the level of $GABA_A$ receptor α_2 subunit mRNAs (6Kb = 54% reduction, 3 Kb = 43% reduction), an effect which was also blocked by R 5135. Chronic GABA treatment did not alter the level of poly A+ RNA. The GABA-induced reduction in $GABA_A$ α_2 subunit mRNA may underlie alteration in $GABA_A$ receptor function, down-regulation and/or uncoupling, observed following chronic GABA exposure of these neurons. Finally, GABA-induced downregulation, uncoupling and a decrease in α_2 mRNA subunit are a $GABA_A$-receptor mediated event. Supported by NINDS grant #NS15339.

487.6

$GABA_A$ RECEPTORS IN MOUSE CORTICAL TISSUE ARE PHOSPHORYLATED IN SITU BY ENDOGENOUS PROTEIN KINASE A. M.H. Jalilian Tehrani* and E.M. Barnes, Jr., Dept. of Biochemistry, Baylor Col. of Med., Houston, TX 77030.

In concordance with the recognition motif for protein kinase A (PKA) identified on all $GABA_A$ receptor (GaR) β subunits, it has been demonstrated that purified bovine GaRs can be phosphorylated by the PKA catalytic subunit. In order to study GaR phosphorylation under more physiological conditions, we have utilized crude membranes from mouse cortex or cortical homogenates eluted from Sephadex G-50. These preparations were incubated with [γ-^{32}P]ATP and 10 μM 8-Br-cAMP or Cl-phenylthio-cAMP. Extracts from these incubations were immunoprecipitated with polyclonal antibodies against affinity-purified GaR and then subjected to SDS-gel electrophoresis and autoradiography. In the absence of cAMP, there was little incorporation of ^{32}P into immunoprecipitates. Addition of cAMP analogs induced phosphorylation of a 57-kD peptide, and to a lesser extent, a 48-kD peptide. Similar results were obtained using purified mouse GaRs which were phosphorylated by the PKA catalytic subunit. The endogenous phosphorylation of native GaR peptides in the ATP-depleted cortical homogenates was markedly higher than that found with crude membranes, presumably due to a higher level of PKA in the former preparation. The in situ phosphorylation of both GaR peptides was time dependent and reached a maximum level in about 30 sec. Addition of PKA inhibitors (Walsh inhibitor peptide or H-89) abolished the cAMP-dependent phosphorylation. The 57-kD peptide is tentatively identified as a β subunit, since 47-kD and 51-kD peptides in cortical membranes were photolabeled using [^{3}H]flunitrazepam.

Effect of Phosphorylation-dependent Rundown on $GABA_A$ Receptor Pharmacology. M. Gyenes, T. T. Gibbs*, & D. H. Farb, Dept. of Pharmacology & Experimental Therapeutics, Boston Univ. School of Medicine, Boston, MA 02118.

Repeated application of 30 μM GABA to cultured chick spinal cord neurons in the whole-cell voltage-clamp configuration resulted in a progressive decline, or "rundown" of currents induced by 30 μM GABA. In contrast, repeated application of 3 μM GABA did not elicit rundown, and responses to 3 μM GABA did not decrease even after induction of rundown by repeated application of 30 μM GABA. Although 3 μM GABA did not normally elicit run-down, run-down of the 3 μM GABA response was observed when the response was potentiated with 5α-pregnan-3α-ol-20-one (5α3α), or when alkaline phosphatase was added to the intracellular buffer. This result is consistent with a model in which $GABA_AR$ activation induces rundown by promoting $GABA_A$ receptor ($GABA_AR$) dephosphorylation. After rundown, there was a decrease in the maximum response to GABA, coupled with a leftward shift of the GABA EC_{50} from 16.7 μM to 6.4 μM. When ATPγS was present in the intracellular solution the decline in the maximum GABA-induced current was prevented and the shift in the EC_{50} was decreased (12.5 μM). Rundown was also associated with a decrease in the maximum percentage enhancement of the GABA response by positive modulators such 5α3α, progesterone, pentopbarbital, and chlordiazepoxide suggesting a decrease in the allosteric coupling of GABA and steroid recognition sites of the $GABA_AR$. In contrast, there was no change in the effects of negative modulators such as pregnenolone sulfate and Zn.

487.8

Protein Kinase C Inhibits Rundown of $GABA_A$ Receptor Currents in Mouse Cortical Neurons and Transfected L_{929} Cells. Y-F. Lin[1], L.J. Greenfield Jr.[2], M.D. Browning[3], and R.L. Macdonald[1,2], Depts of Physiology[1] and Neurology[2], U. of Michigan, Ann Arbor, and Pharmacology[3], U. of Colorado, Denver.

The $GABA_A$ receptor/chloride channel is an oligomeric polypeptide composed of homologous subunits (α,β,γ,δ), each containing four transmembrane segments (M1-M4) and a cytoplasmic loop between M3 and M4. The bovine γ_2 long (γ_{2L}) subunit includes in this loop a consensus sequence for phosphorylation by protein kinase C (PKC) and is phosphorylated by PKC *in vitro*. Phosphorylation by PKC may regulate $GABA_A$ receptor desensitization. During "whole cell patch" intracellular recording, GABA-induced currents gradually decrease in amplitude. This "rundown" is slowed by ATP and enhanced by alkaline phosphatase in the pipette medium, and may result from $GABA_A$ receptor dephosphorylation (Chen et al., J. Physiol. 420:207). We now report that intracellular PKC slows rundown of GABA currents in cultured mouse cortical neurons and L_{929} cells transfected with cDNAs encoding the bovine α_1, β_1 and γ_{2L} subunits. In cortical neurons, peak responses decreased 68% over 20 minutes in control cells, from 853 ± 151nA (mean ± SEM, n=10) to 275 ± 54nA, but only 21% in neurons treated with PKC (940 ± 225nA to 745 ± 209 nA, n=10). For transfected L_{929} cells, the normalized peak current in controls decreased to 56 ± 13% (n=7) at 12 minutes, while cells with PKC showed little decrement (97 ± 23%, n=5). These results suggest that the rate of $GABA_A$ current "rundown" is regulated by PKC, presumably by phosphorylation of the γ_{2L} subunit.

487.9

RAPID DESENSITIZATION OF THE $GABA_A$ RECEPTOR IN OUTSIDE-OUT PATCHES. J.J. Celentano*, and R.K.S. Wong. Dept. of Pharmacology, SUNY Health Science Center, Brooklyn, NY 11203.

Rapid desensitization of the $GABA_A$ receptor has been observed in $^{36}Cl^-$ flux studies ($t_{1/2}$=32 and 533 ms, Cash and Subbarao. Biochem 26:7556, 1987), but not in electrophysiological studies. We examined the effects of rapid GABA application on outside-out patches and found desensitization on the millisecond time scale. Patches were excised from acutely isolated pyramidal neurons of guinea pig hippocampus (Kay and Wong. J Neurosci Meth 16:227, 1986) using standard patch pipets (8-13 MΩ,). Extracellular buffer was (in mM): NaCl 145, $CaCl_2$ 1, $MgCl_2$ 1, glucose 25, Hepes 10, pH 7.4 NaOH, and intracellular buffer was: Tris HCl/ Tris base 130, NaCl 3, $MgCl_2$ 4, Na_2ATP 4, EGTA 10, HEPES 10, pH 7.3 methane sulfonic acid (final Cl^- 11 or 45 mM). Various GABA concentrations (in μM) were applied by means of a 7-barrel flow-tube (200 μm/barrel, 45 cm H_2O) capable of displacing the solution surrounding the patch pipet within 1.5 ms (determined by studying electrode junction potential changes). 1000 GABA typically induced outward currents of 50-150 pA (0 mV) which desensitized with biphasic kinetics (τ=44±5 ms, and 840±130 ms, n=20). 41% of the maximum response desensitized with rapid kinetics, and the total extent of desensitization (%D) was 91%. Over the concentration range of 3-3000 GABA, τ for the slow phase was about 1 sec, while %D increased with concentration from 50 to 95%. The fast phase was not observed at ≤50 GABA, and contributed to 35% of the response to 100 GABA (τ=64±11 ms, n=11). Responses to 300 and 3000 GABA desensitized with kinetics similar to that of 1000 GABA. These results indicate that the $GABA_A$ receptor is capable undergoing rapid desensitization which can result in an underestimation of the maximum GABA response thereby dramatically affecting EC_{50} and Hill slopes determinations. Experiments are currently underway to clarify these issues and to examine the effects of modulators on desensitization parameters.

487.10

$GABA_A$ RECEPTOR DESENSITIZATION: LACK OF MODULATION BY SPECIFIC PROTEIN KINASES AND PHOSPHATASES. D. J. Oh* and M. A. Dichter. Dept. of Neurology, University of Pennsylvania and Graduate Hospital, Philadelphia, PA 19104.

The $GABA_A$ receptor consists of multiple subunits which have consensus sequences for phosphorylation by various kinases, including PKA, PKC, and tyrosine kinase. Based on the structural homology between nACh and $GABA_A$ receptors, phosphorylation may modulate $GABA_A$ receptor desensitization. We studied various activators and inhibitors of protein kinases and phosphatases (listed below) with patch clamp techniques, after intracellular perfusion or extracellular application (DOG and OAG).

	Activators	Inhibitors
PKA (specific)	cAMP+IBMX, PKA	KT5720, PKI 5-24
PKC (specific)	DOG, OAG	Calphostin, PKC19-36
Non Specific Kinases		H7
Tyrosine Kinases		Genistein, Lavendustin A
Phosphatases	Alkaline phosphatase	Okadaic Acid Calyculin A
Tyrosine Phosphatase	EDTA, Spermine Citrate	Heparin Vanadate

These agents had no significant effects on $GABA_A$ receptor desensitization in cultured hippocampal neurons. Our data suggest that either phosphorylation does not regulate desensitization or a $GABA_A$ receptor-specific kinase may exist, analogous to β adrenergic receptor kinase.

PEPTIDES: RECEPTORS IV

488.1

ANGIOTENSIN II (AII) TYPE 2 (AT_2) RECEPTOR-MEDIATED EFFECTS ON POTASSIUM CURRENTS IN CULTURED NEURONS. J. Kang, C. Sumners* and P. Posner. Dept. of Physiology, Univ. of Florida Coll. of Med., Gainesville, FL 32610.

We have shown that AII increases net outward ionic current (I_{no}) in neurons from neonate rat hypothalamus and brainstem. This effect of AII is concentration-dependent, reversible, and mediated by AT_2 receptors. This study analyzed the stimulatory effect of AII on the K^+ component currents of I_{no}. In order to isolate K^+ current from I_{no}, neuronal cultures were superfused with a solution containing TTX (3 μM) and $CdCl_2$ (0.3 mM). The current recorded under this condition consists of I_K and I_A (I_{KTOT}). I_{Na}, $I_{Ca,K}$, and I_{Ca} are blocked. When the external K^+ concentration was changed, the amplitude of I_{KTOT} was changed. A linear relationship between the currents and log $[K^+]_o$ was fitted by the equation $I = g(V_m + 60\log([K^+]_{in}/[K^+]_o))$. ($V_m$ = +10 mV, $[K^+]_{in}$ = 135 mM; g does not change when V_m does not change.) The reversal potential of I_{KTOT} was approximately -90 mV when $[K^+]_o$ = 5.4 mM. The data generated by using pulse protocols to isolate I_K and I_A demonstrate that AII (10 nM) caused an increase in I_A and I_K in cultured neurons. To determine if this stimulatory effect of AII on I_{KTOT} was receptor-mediated, the selective nonpeptide AT_1 receptor blocker Losartan (DuP753) and the selective AT_2 receptor blocker PD123177 were tested. The increase in I_{KTOT} elicited by AII (10 nM) was antagonized by PD123177 (100 nM), but not by DuP753 (100 nM). Further studies of AII effects on I_{Ca} and $I_{Ca,K}$ showed no effects of AII on these currents. Thus, the enhancement of I_{no} by AII is mediated by the AT_2 receptor subtype through enhancement of I_K and I_A. (Supported by NIH Grant NS-19441).

REGULATION OF TYROSINE PHOSPHORYLATION BY ANGIOTENSIN II IN DIFFERENTIATED NG108-15 CELLS. M. D. Carrithers, M. N. Ghoneim, W. Schelman, and J. A. Weyhenmeyer*. Dept. of Cell and Structural Biology, University of Illinois College of Medicine, Urbana, IL 61801.

The neuroblastoma x glioma hybrid cell line, NG108-15, is used as a model system to study neuronal-glial type angiotensin receptors. When differentiated with 1.5% DMSO and low serum, these cells express both AT-1 and AT-2 receptors. Since both receptor types have been hypothesized to regulate cell growth, the present study was performed to determine the effects of angiotensin II (ANG II) on tyrosine phosphorylation in differentiated NG108-15 cells.

To determine regulation of tyrosine phosphorylation, cells were differentiated for four to five days and then incubated in the presence and absence of 10 nM ANG II for five minutes at 37°C. Cells were lysed and immunoprecipitated with a phosphotyrosine Ab (Oncogene Science). Samples were analyzed by SDS-PAGE followed by Western blotting. Blots revealed that ANG II stimulated phosphorylation of tyrosine residues in proteins of $M_r \cong$ 140, 30, and 27 kD. These responses were attenuated by pretreatment of the cells with 1 μM PD 123319, an AT-2 antagonist.

GONADAL STEROIDS ALTER BRAIN ANGIOTENSIN II RECEPTORS IN OVARIECTOMIZED (ovx) RATS. K.L. Grove*, R.C. Speth, P.W. Sylvester, K.P. Briski, Dept. VCAPP, Washington State University, Pullman, WA 99164-6520.

The AT_1 receptor is the subtype expressed in most perihypothalamic nuclei (Rowe *et al., Eur. J. Pharm.* (1990) 186: 339). Previous studies of the effects of gonadal steroids on brain angiotensin II (AII) receptors are limited by the presence of sulfhydryl reducing agents (SHRA), which inhibits the AT_1 receptor subtype (Speth *et al., Brain Res.* (1991) 548:1).

Ovx rats, housed on a 12:12 light:dark cycle were treated with 20 μg of estradiol benzoate (EB) at 0900 h. on Day 1 and Day 4 of steroid treatment and injected with 2.0 mg of progesterone (P) on Day 5 at 1100 h. Animals were sacrificed at 1200, 1400 and 1500 hrs on Day 5. Using *in vitro* receptor autoradiography in the absence of SHRA with 500 pM ^{125}I-sar^1,ile^8 AII (± 3 μM AII) AII receptor expression in several hypothalamic nuclei was quantified. Plasma luteinizing hormone was measured by RIA. AII receptor binding in several perihypothalamic nuclei in the EB+P treated ovx female rat increased over time as follows:

Time(hr)	BSTV	SCh	Arc	ME
1200(n=6)	647±100*	2882±211*	405±43*	745±104
1400(n=6)	1014±72	3668±198	552±43	1084±164
1500(n=4)	1257±107	4184±574	589±89	878±130

Values are fmol/mg tissue ± S.E.M. BSTV-ventral portion of the bed n. of the stria terminalis; SCh-suprachiasmatic n.; Arc-arcuate n.; ME-median eminence. *Significantly different from 1400 and 1500 ($P < 0.05$).

This data suggests that AII receptors in brain areas regulating LHRH release increase prior to the gonadal steroid induced LH surge.

INCORPORATION OF CYTOSOLIC AT_2 ANGII RECEPTORS INTO MEMBRANES OF DIFFERENTIATED N1E-115 NEUROBLASTOMA CELLS. I.R. Siemens*, R. Mir, R.L. Soffer and S.J. Fluharty. Depts. of Animal Biology and Pharmacology, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104 and Cornell University Medical Center New York, NY.

The murine neuroblastoma N1E-115 cell line possesses two subtypes of membranous receptors (AT_1 and AT_2) for the neuroactive peptide angiotensin II (AngII). Upon neuronal differentiation of these cells the density of the AT_2 receptor subtype is substantially increased while the density of the AT_1 receptors remains unchanged. Moreover, only a portion of this increase is prevented by transcriptional blockade suggesting the possible involvement of translational and post-translational processes. In this regard N1E-115 cells also possess a large pool of soluble cytosolic AT_2 binding proteins which require PCMS for binding activity. In the present study we have investigated the possibility that cytosolic AngII binding sites translocate to the membrane and contribute to the large increase of AT_2 receptors observed during cell differentiation. Binding experiments revealed that the increase in AT_2 receptors in differentiated membranes was proportional to the observed decrease in cytosolic binding. Antibodies (Ab_C) directed against cytosolic AngII binding sites immunoprecipitated 80% of cytosolic AngII binding proteins. The same antibody precipitated a small population of AT_2 receptors in crude CHAPS solubilized membranes. Partial purification of AngII receptors from solubilized membranes using heparin sepharose chromatography (HSC) resulted in elution of two major [^{125}I]-AngII binding peaks. The first peak eluted in the absence of any cations and contained approximately 80% of initial [^{125}I]-AngII binding activity. The second binding peak required 1.5 M NaCl for elution and contained 20% of initial [^{125}I]-AngII binding activity. Immunoprecipitation experiments showed that 90% of [^{125}I]-AngII binding activity in peak II could be precipitated with Ab_C, however, no immunoprecipitation was observed in peak I. Despite the high degree of immunoreactivity binding to peaks II was completely independent of PCMS. Collectively these data strongly suggest that cytosolic AngII binding sites can translocate into the cell membrane of differentiated N1E-115 cells by a posttranslational modification that may involve high affinity for HS and altered disulfide bridges. REGULATION OF cGMP AND NITRIC OXIDE PRODUCTION BY ANGII AND CALCIUM IN NEURONAL CELLS. L.P. Reagan*, E.D. Zarahn and S.J. Fluharty. Depts. of Animal Biology and Pharmacology, and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Angiotensin II (Ang II) elicits a rapid and dose-dependent increase in cGMP levels in murine neuroblastoma N1E-115 cells. We have recently demonstrated that this rise in cGMP levels is mediated by AT_1 and AT_2 AngII receptor subtypes. Moreover, the stimulatory effects of Ang II on cGMP formation were attenuated by the nitric oxide synthase (NOS) inhibitor *N*-monomethyl-L-arginine (NMMA). In the present report we have demonstrated that Ang II (100nM) elicits a 2-3 fold increase in the conversion of the NOS substrate [^{3}H]-arginine to [^{3}H]-citrulline, which indirectly demonstrates the production of NO in these cells. This Ang II-induced conversion was blocked by NMMA and also by the Ang II receptor antagonist Sarc^1-Ile^8 (SARILE). Moreover, the calcium ionophore ionomycin (10μM) caused a 10 fold increase in cGMP levels which was blockable by NMMA. On the other hand, sodium nitroprusside (1mM), which spontaneously releases NO and directly stimulates guanylate cyclase, increased cGMP levels, but this response was not blocked by NMMA. Finally, Ang II-induced cGMP production was attenuated by brief exposure to 5 mM EDTA, suggesting a possible role for extracellular Ca^{++} in this response. Collectively these results further demonstrate that the Ang II-induced increase in cGMP levels is mediated by NO, and that this response may require Ca^{++} from both intracellular and extracellular sources. Supported by NS23986 and MH43787.

INTERACTIONS BETWEEN AT_1 AND AT_2 ANGII RECEPTOR SUBTYPES DURING AGONIST-INDUCED DOWNREGULATION IN N1E-115 CELLS. A.K. Butler and S.J. Fluharty*. Departments of Animal Biology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

In many of its target cells, angiotensin II (AngII) is known to regulate the density of its receptor *in vivo*. Recently, we have demonstrated that AngII produces a rapid decrease in AT_1 receptors and a more delayed decline in the AT_2 subtype in murine N1E-115 cells. In the present series of experiments we have examined the relative contribution of each AngII receptor subtype during agonist-induced downregulation. When AngII cells were exposed to AngII (10 nM for 20 min) their was a significant decrease in the density of both AT_1 and AT_2 receptors. Similarly, when cells were concurrently treated with AngII and CGP42112A (0.5 μM), a selective AT_2 receptor antagonist, comparable downregulation of both receptor subtypes was observed. In market contrast, when N1E-115 cells were treated with AngII in the presence of the AT_1 receptor antagonist, DuP753 (2 μM), there was no decline in either receptor subtype. In fact, both AT_1 and AT_2 receptors significantly increased after this combination of agonist and selective antagonist exposure. These results demonstrate that AngII interaction with AT_1 receptors is necessary for downregulation of both subtypes, and that selective stimulation of AT_2 receptors appears to result in an upregulation of AngII receptors. As much, these data suggest that reciprocal interactions between AT_1 and AT_2 receptor subtypes may occur during agonist-induced downregulation in neuron-like cells. Supported by NS23986 and MH43787.

BIOCHEMICAL CHARACTERIZATION OF THE AFFINITY PURIFIED AT_2 ANGIOTENSIN II RECEPTOR FROM MURINE NEUROBLASTOMA N1E-115 CELLS. P. He, I.R. Siemens, M.K. Raizada, M.M. White* and S.J. Fluharty. Depts. of Animal Biology and Pharmacology, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104 and Dept. of Physiology Univ. of Florida, Gainesville, FL.

Differentiated murine neuroblastoma N1E-115 cells posses both subtypes (AT_1 and AT_2) of membrane associated angiotensin II (AngII) receptors, which are similar in specificity, affinity, and molecular weight to those in rat brain. Functional solubilization of N1E-115 cell membranes with the detergent CHAPS exclusively solubilizes AT_2 receptors while AT_1 receptors remain in the 105,000 x g pellet. Covalent cross-linking of [^{125}I]-AngII to solubilized AngII receptors with the homobifunctional cross-linker DSS specifically labeled two proteins, one minor protein of 102 kDa and one major protein of 69 kDa molecular weight. Affinity purification of solubilized AngII receptors with AngII affinity columns resulted in elution of one high molecular weight band (110 kDa) and one low molecular weight band (66 kDa) when excess amounts of agonist were used to elute the proteins from the column. In contrast, when proteins were eluted with an excess amount of an antagonist only one protein band eluted from the column with a molecular weight of 66 kDa. Covalent cross-linking of [^{125}I]-AngII to affinity purified proteins derived from both sets of experiments resulted in specific labeling of one high (102 kDa) and one low molecular weight band (66 kDa) in the presence of an agonist, but only one low molecular weight band (66 kDa) was labeled when an antagonist was used. The single 66 kDa protein was not immunoreactive with antibodies directed against AT_1 receptors. Moreover, proteolytic digestion of the affinity purified protein resulted in peptide fragments whose amino acid sequences were not homologous with cloned AT1 receptors. Supported by NS23986 and MH43787.

CORTICOSTEROID REGULATION OF PLC-α IN RAT BRAIN AND CULTURED NEURONAL CELLS. R. Maki*, P. He, D.M. Zhang, J.R. Williamson and S.J. Fluharty. Depts. of Animal Biology and Biochemistry, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104.

Many of the cellular actions of angiotensin II are mediated by phosphoinositide (PI) hydrolysis and the attendant mobilization of intracellular Ca^{2+}. Recently, we have reported that AngII receptors are coupled to a 60 kDa PI-specific phospholipase C, PLC-α in cultured neuronal cells. In the present study, we have used two-dimensional (2-D) gel electrophoresis to the examine the distribution of immunoreactive PLC-α in rat brain, as well as its regulation by corticosteroids. The PLC-α antibody was raised against a 60 kDa protein purified from rat liver. The N-terminal amino acid sequence of this protein corresponded to the sequence of PLC-α purified from guinea pig uterus. Rats were injected either with aldosterone (ALDO - 250 ug/day) or corticosterone (CORT - 50 ug/day). Control animals were injected with a propylene glycol vehicle. After 3 days, cerebellum, cerebral cortex, hippocampus, amygdala, anteroventral third ventricle (AV3V), and pituitary were dissected and proteins were analyzed by 2-D gel electrophoresis followed by immunoblotting with PLC-α antisera. The results indicated that PLC-α was present in each of the brain regions examined. Moreover, in brain the antisera detected two proteins of 60 and 70 kDa with different pI values, whereas in N1E-115 cells only the 60 kDa species was detected by the antisera. In AV3V, medial amygdala or pituitary, but not other brain regions, ALDO or CORT altered the pI value of both the 60 and 70 kDa protein, and the relative amount of immunoreactivity appeared to change in cultured cells as well. The physiological relevance of steroid regulation of neuronal PLC-α remains to be determined. Supported by NS23986, HD25857 and MH43787.

SOME NEUROPHARMACOLOGICAL PROPERTIES OF PD 123319, A NON-PEPTIDE ANGIOTENSIN II AT_2 RECEPTOR LIGAND. T.A. Pugsley*, S. Whetzel and T. Heffner. Parke-Davis Pharmaceutical Research Div., Warner-Lambert Co., Ann Arbor, MI 48105.

Angiotensin (Ang II) is a peptide hormone that regulates many physiological functions including blood pressure, fluid and electrolyte homeostasis and neuronal activities of various target cells. Two types of receptors for Ang II have been described, AT_1 and AT_2. While both subtypes bind Ang II and its analogs with comparable affinity, AT_1-1 receptors have high affinity for DuP 753, and AT_2 receptors have high affinity for PD 123177, PD 123319 (PD) and CGP 42112A. Ang II has been reported to interact with cholinergic and dopaminergic neurotransmitter systems. We investigated the AT_2 ligand PD for its effects on cholinergic and related indicies in rat brain. PD (1-60 mg/kg, i.p.) given 30 min prior to sacrifice caused a dose dependent decrease of acetylcholine (Ach) content in rat striatum. This effect lasted for up to 6 h after a 30 mg/kg dose of PD. In contrast the AT_1 receptor ligand DuP 753 was inactive in altering Ach levels at 30 mg/kg, in rat striatum. The effect was not selective to striatum as a significant decrease of Ach was observed in hippocampus at 30 mg/kg of the agent. PD in vitro did not alter high affinity choline uptake; thus it is unlikely to be causing the decrease in Ach levels by blocking choline uptake, suggesting that it may be releasing Ach. Basal cerebellar cGMP levels [a well characterized second messenger response modulated by the N-methyl D-aspartate (NMDA) receptor complex] were decreased by PD at 30, but not at 3 and 10 mg/kg. These results suggest that in vivo PD may alter cholingeric function and NMDA receptor complex mediated responses.

INHIBITION OF SODIUM APPETITE BY OXYTOCIN IN FEMALE BUT NOT IN MALE RATS. C. Polidori*, P. Pompei, M. Massi, A.N. Epstein and R.R. Sakai. Department of Biology, University of Pennsylvania, Philadelphia, PA 19104 and Lab. of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

Sodium intake is sexually dimorphic in rats. Female rats drink more than male rats when they are sodium depleted (sodium appetite) and when they are sodium replete (need-free sodium intake)(Chow, et al. 1992). Oxytocin (OT), a peptide hormone secreted by the paraventricular and supraoptic nucleus of the hypothalamus, has been correlated with sodium intake in rats. We first tested OT's effects on furosemide induced sodium depletion (10mg/rat/sc) both in male and female rats and secondly on need-free sodium intake. After sodium depletion a pulse intracerebroventricular (pICV) injection of OT (1μg/μl) reduced the sodium appetite in female rats by 65% and by 20% in male rats. Similarly, female rats reduced their need-free sodium intake by 75% after a pICV injection of OT (1μg/μl). This inhibition of need-free intake was blocked by prior injection of the selective OT antagonist OTA (1μg/μl). In summary, these results suggest that central OT is more effective in female than in male rats and that OT may play a role in the expression of need-free and need-induced sodium intake in female rats. Supported by National Inst. of Neurological Disorders and Stroke NS-03469 and MH 43787.

CHARACTERIZATION OF GUANINE NUCLEOTIDE EFFECTS ON ^{125}I-ENDOTHELIN BINDING IN RAT BRAIN AND HEART. L. Yu, A. Wu, N. Davis, L.C. Wince* and R.A. Colvin. Biological Sci. Dept., Ohio University College of Osteopathic Medicine, Athens, OH 45701

We characterized the binding of ^{125}I-Endothelin (ET-1) to purified plasma membranes from whole rat brain and heart. Binding reactions were done in 5 ml of 137 mM choline Cl, 10 mM HEPES (pH 7.4), 0.1% BSA, and the following protease inhibitors: soybean trypsin inhibitor (50 μg/ml), leupeptin (0.5 μg/ml) and pepstatin (0.7 μg/ml). To distinguish ET receptor subtypes we performed displacement curves using 0.2 nM ^{125}I-ET-1 and increasing concentrations of either ET-1 or ET-3. Rat heart plasma membranes showed high affinity binding for ^{125}I-ET-1 that was only displaced by ET-1 (IC_{50} = 0.15 nM). In contrast, ^{125}I-ET-1 binding in rat brain was equally displaced by either ET-1 or ET-3 (IC_{50} = 0.2 nM). Alamethicin (50 μg/tube) was shown to increase ^{3}H-ouabain binding to rat brain (40%), but had no effect on ^{125}I-ET-1 binding. Alamethicin was included in assays to characterize the effects of added $MgCl_2$ and guanine nucleotides. Scatchard analysis showed no effect of 10 mM $MgCl_2$ on ^{125}I-ET-1 binding Kd and Bmax (0.17 nM, 0.14 nM; 0.19 pmol/mg, 0.18 pmol/mg; with or without $MgCl_2$ respectively). Increasing concentrations of either GTPγS or GDPβS had no effect on ^{125}I-ET-1 binding to rat brain. Similarly, GDPβS (100 μM) had no effect on ^{125}I-ET-1 Kd or Bmax when assayed in either rat brain or rat heart. In conclusion, both ET-A (heart) and ET-B (brain) receptors exist in a high affinity state in purified plasma membranes, which is not affected by the presence of $MgCl_2$ or guanine nucleotides such as GTPγS and GDPβS.

USE OF SELECTIVE ANTAGONISTS TO SUBSTANTIATE THE EXISTENCE OF A B_2-KININ RECEPTOR SUBTYPE IN SPINAL CARDIOVASCULAR CONTROL. P. Lopes[1], D. Regoli[2], M. Thakur[1]* and R. Couture[1]. [1]Dept. Physiology, Faculty of Medicine, Université de Montréal, Montréal, Canada H3C 3J7 and [2]Dept. Pharmacology, Faculty of Medicine, Sherbrooke University, Sherbrooke, Canada J1H 5N4.

A role for kinins has been suggested in spinal cardiovascular regulation and autoradiographic studies have demonstrated the presence of B_2-kinin receptors in the rat spinal cord. In this study, selective antagonists were used to further characterize the receptor subtype involved in the intrathecal (i.t.) action of bradykinin (BK) on mean arterial pressure (MAP) and heart rate (HR) of the conscious rat. The i.t. injection of BK (81 pmol at T-9) elicited a transient increase of MAP and a longer lasting decrease of HR. The cardiovascular response to BK was significantly and dose-dependently inhibited by the prior i.t. injection (717-800 pmol, 3-5 min earlier) of three B_{2B} receptor antagonists (D-Arg[Hyp^3,D-Phe^7,Leu^8]-BK, D-Arg[Tyr^3,D-Phe^7,Leu^8]-BK, Tyr,D-Arg[Hyp^3,D-Phe^7,Leu^8]-BK) but remained unaffected by pretreatment with similar doses of antagonists for the B_{2A} receptor (D-Arg-[Hyp^3,Leu^8]-BK, D-Arg-[Hyp^3,Gly^6,Leu^8]-BK) or the B_1 receptor ([Leu^8]desArg^9-BK). Similarly, D-Arg[Hyp^3,Gly^6,D-Phe^7,Leu^8]-BK, D-Arg[Hyp^2,Thi^{5,8}, D-Phe^7]-BK, two non selective antagonists for B_{2A} and B_{2B} receptors, failed to antagonize the cardiovascular responses to BK and displayed agonistic activities at higher doses. Doses 10-fold higher (7.7 nmol) of Hoe 140, a potent antagonist for peripheral B_2 receptors, were required to inhibit the response to BK. These results suggest that BK may affect the cardiovascular system by acting on a B_{2B} receptor subtype in the rat spinal cord. [Supported by the MRC of Canada].

CHARACTERIZATION OF NON-OPIOID [^{3}H]-DYN A-(1-13) BINDING SITES IN RAT HEART MEMBRANE PREPARATIONS. M. Dumont* and S. Lemaire. Department of Pharmacology, University of Ottawa, Ottawa, Ontario Canada K1H 8M5.

In the brain, Dynorphin A (DYN A) interacts with both opioid and non-opioid receptors, the stimulation of the non-opioid receptor resulting in a loss of tail flick reflex and hindlimb paralysis. In the heart, DYN A also induces non-opioid effects such as a positive inotropic effect and cardiac arrhythmia. Using membrane binding techniques, we have characterized the cardiac non-opioid DYN A receptor using [^{3}H]-DYN A-(1-13). Binding assays were performed with two ml-aliquots of membrane (0.8 mg protein) in 5 mM Tris-HCl (pH 7.4); 0.2% BSA at 4°C for 120 min followed by filtration through polyethylenimine treated glass microfiber filters. [^{3}H]-DYN A-(1-13) binding sites were sensible to trypsin and Scatchard analysis yielded linear plots with a K_d of 56.5 nM and a B_{max} of 1.91 pmol/mg protein. In competition experiments, [^{3}H]-DYN A-(1-13) binding was displaced by DYN A-(1-13), DYN A and DYN A-(2-13) but not by DYN A-(1-8) and levallorphan. [^{3}H]-DYN A-(1-13) binding was insensitive to σ (DTG, (+)-3 PPP, (+)-SKF-10047) and PCP (TCP, MK-801) ligands. These results suggest that [^{3}H]-DYN A-(1-13) labels a non-opioid DYN A receptor in the heart which upon stimulation may lead to cellular damage as seen in myocardial ischemia. Supported by HSFO.

PRESENCE OF FUNCTIONAL CORTICOTROPIN-RELEASING HORMONE RECEPTORS IN HUMAN Y-79 RETINOBLASTOMA CELLS. Maria C. Olianas* and Pierluigi Onali, Department of Neurosciences, University of Cagliari, Cagliari, Italy.

In human Y-79 retinoblastoma cells corticotropin-releasing hormone (CRH) produces a marked (60-fold) and rapid increase of adenylyl cyclase activity. The concentrations of the peptide producing half-maximal (EC50) and maximal stimulations are 60 nM and 1-5 µM, respectively. The effect of CRH is GTP - dependent, being minimal in the absence of added nucleotide and maximal at 10 µM GTP. The specific CRH receptor antagonist α-helical CRH 9-41 competitively counteracts the CRH stimulation with a Ki value of 80 nM. Sauvagine and urotensin I, two peptides displaying sequence homology with CRH and high affinity for CRH receptors, mimick the effect of CRH with EC50 values of 10 and 11 nM, respectively. These results demonstrate the presence of functional CRH receptors in human Y-79 retinoblastoma cells and suggest that this cell line may be a suitable model in which to study the action of CRH on human retinal cell function.

CORTICOTROPIN RELEASING HORMONE (CRH) RECEPTORS INVOLVED IN MEDIATING FEAR IN THE RHESUS MONKEY. N.H. Kalin,[#] D.E. Grigoriadis,[2] E.B. DeSouza,[2] J.E. Turner,[1] G.W. Dent,[2] S.E. Shelton,[1] and H. Uno.[3] [1]Dept. of Psychiatry, Univ. of Wisconsin-Madison, WI; [2]Dupont-Merck, Wilmington, DE; [3]Wis. Regional Primate Center, Madison, WI.

CRH systems are involved in integrating various aspects of the stress response. CRH receptors in the pituitary mediate stress-induced ACTH release, whereas receptors in other brain regions likely mediate fear-related behavioral and autonomic responses. The distribution and density of CRH receptors has been studied extensively in rats, but little work has been done in primates. We examined the regional distribution of CRH receptors in adult rhesus monkeys (Macaca mulatta). Pituitary had the highest receptor density (302 fmol/mg protein). In brain, amygdala and cerebellum had significantly more CRH receptors than cortex, caudate, hippocampus, and hypothalamus. Scatchard analyses revealed similar binding affinities in pituitary, amygdala, and cortex (0.169-0.347 nM). The high density of receptors in pituitary and amygdala is interesting because these sites are major mediators of endocrine and behavioral changes associated with fear. Previously we showed that the pituitary-adrenal response in rhesus monkeys is not mature until animals are 12 weeks old. Quantitative autoradiographic studies were performed in pituitary and discrete brain regions from 2- and 12-week-old monkeys. In pituitary, no significant age-related differences were found. CRH receptors were evident in anterior and intermediate but not posterior lobes, and their density in the intermediate lobe was greater than in the anterior lobe. Binding sites in the anterior lobe had a "cluster-like" distribution similar to that of corticotropes. CRH receptors in the intermediate lobe were more uniformly distributed, reflecting the distribution of opiomelanocortin-producing cells in this region. Data from other brain regions will be presented.

HYPOTHALAMIC LOCALIZATION OF PROLACTIN AND OPIOID BINDING SITES IN A MALE MIGRATORY SONGBIRD. P. Deviche* and J.D. Buntin. Inst. Arctic Biology, Univ. Alaska Fairbanks, Fairbanks, AK 99775 and Dept. Biolog. Sciences, Univ. Wisconsin, Milwaukee, WI 53201.

Studies on several avian species have demonstrated that prolactin (PRL) and opioids (OP) regulate feeding, but neither the mechanisms nor the sites involved are identified. To address this question, we measured the density of specific ^{125}I-ovine PRL and ^{3}H-DPDPE (a delta receptor ligand) binding sites in brain regions of adult male dark-eyed juncos (*Junco hyemalis*) by *in vitro* autoradiography. We found that specific PRL and OP binding sites are present in several hypothalamic regions (PRL: infundibulum (INF) > ventromedial hypothalamus (VMH) > paraventricular nucleus (PVN) > lateral hypothalamus (LHy); OP: PVN > INF > VMH > LHy). Some regions (VMH; LHy) of the avian brain that contain a high density of PRL and OP binding sites control feeding behavior. Thus, these regions may constitute sites of action on this behavior of PRL or of a PRL-like molecule, and also of endogenous OP.

488.17

IMMUNOHISTOCHEMICAL LOCALIZATION OF SP RECEPTOR (SPR) IN RAT BRAIN. C.L. Veenman*, L. Medina, A. Reiner, C. Crankshaw and J.E. Krause. Dept. Anat. & Neurobiol., Univ. TN, Memphis, TN 38163 and Dept. Neurobiol. & Anat., Wash. Univ., St. Louis, MO 63110.

Five antisera against segments of rat SPR (88-T4 against the third cytoplasmic loop; 9323 against the second extracellular loop; and A2P5, 81-7, 80-X against third extracellular loop regions) were used to examine the distribution of SPR in rat brain. The specificity of all antisera was confirmed by solution phase binding, ELISA and/or immunoprecipitation experiments. All antisera extensively labeled the perikaryal and proximal dendritic membranes of a population of neurons in layer 5 of isocortex and in the subiculum. Double-labeling showed that some of these neurons contained parvalbumin, but none contained calbindin or somatostatin. A2P5 and 88-T4 also showed granular labeling on or within neurons in deep cortical layers, pallidum, basal forebrain and substantia nigra pars reticulata (SNr). A2P5 also showed fine granular labeling of structures the apparent size of terminals, particularly in the neuropil of superficial cortical layers, in medial striatum and patches throughout striatum, in globus pallidus, entopeduncular nucleus, thalamic reticular nucleus, superficial layers of the superior colliculus and in SNr. Labeling with A2P5 and 88-T4 could be blocked with synthetic antigen. These results are largely consistent with previous descriptions of SPR distribution based on ligand binding, with the major exception that they do indicate the presence of SPR in SNr. Supported by NS-28721 and NS-19620 (AR), the Spanish Ministry of Education (LM) and NS-21937 (JEK).

PEPTIDES: PHYSIOLOGICAL EFFECTS IV

489.1

MODULATORY ACTIONS OF SEVERAL NEWLY IDENTIFIED LOCUST NEUROPEPTIDES ON LOCUST NEUROMUSCULAR PREPARATION. M. Schiebe* and L. Schoofs. Abt.Angew. Physiol., U of Ulm, D-7900 Ulm, Germany and KU Leuven, B-3000 Leuven, Belgium.

Several modulatory actions of the invertebrate FMRF-NH2 and related peptides on tension generated in the extensor tibiae muscle of the locust hindleg by stimulation of the slow excitatory motor neurone (SETi) are now well established. Here we demonstrate effects of four newly sequenced neuropeptides isolated from the locust which are unrelated to FMRF-NH2. The following parameters were examined: Tension, contraction rate, relaxation rate, E_m and ejp amplitude. The preparations were constantly perfused at 1.4ml/min and kept at 20° C. Peptides were applied as 100 µl aliquots into the superfusion line were they were diluted to a final concentration of $5*10^{-7}$ M. All peptides were isolated from extracts of brain complexes of Locusta migratoria. The following observations were made: 1) Locustatachykinin II (APLSGFYGVR-NH2), increased tension, the relaxation rate, ejp amplitude and could induce a contracture at a stimulation frequency of 0.3 Hz. Effects outlasted the presence of the peptide in the superfusate by several minutes. 2) Locustatachykinin III (APQAGFYGVR-NH2) had identical effects. 3) Locustamyotropin III, a peptide belonging to a separate family of locust peptides which is supposed to stimulate locust oviducts in vitro, had short-lasting, but dramatic inhibiting effects on tension in this preparation, accompanied by a reduction in ejp amplitude and a small depolarisation. 4) Locustamyoinhibiting hormone (AWQDLNAGW-NH2) which suppresses contractions of the hindgut and oviduct of locusts also had inhibiting effects on muscle, similar to Locustamyotropin III but at a higher dose (10^{-6}M). The results of these experiments suggest, that the hindleg of the locust may be subject to complex modulatory actions of different families of peptides. It is as such and as a experimental model particularly useful.

489.2

PEPTIDE IMMUNOREACTIVITY IN THE GENITAL GANGLION OF *APLYSIA*.
S. B. Moffett* Dept. of Zoology, Washington State University, Pullman, WA 99164.

The roles of bag cells and some other CNS neurons in *Aplysia californica* reproduction are well established, but neurons of the genital ganglion, located at the juncture of the genital nerve with the sperm-oviduct, may also play a role. Indirect immunofluorescence in wholemounts of the ganglia of young animals (30-50g) revealed intense immunoreactivity to *Mytilus* inhibitory peptide (MIP) in a quarter of the cells and SCPb-like immunoreactivity in a non-overlapping population. MIP varicosities are densely distributed on the sperm-oviduct and ovotestis as well as in baskets of endings surrounding some non-immunoreactive cells. Antibodies generated against both catch relaxing peptide (CARP) and buccalin reveal several axons which enter the ganglion and project toward the ovotestis. The strategic position of the genital ganglion neurons and the inhibitory role that some of the peptides associated with the ganglion play in muscle contraction in other systems (Kobayashi and Muneoka, 1990, Zool. Sci. 7:801; Kiss, 1991, Comp. Biochem. Physiol. 95C:207) suggest that genital ganglion neurons and bag cells may interact in coordinating egg-laying behavior.

CONANTOKIN GV, THE "SLEEPER" PEPTIDE, PRODUCES HYPERACTIVITY IN ADULT RATS. K.A. Serpa* and L.T. Meltzer. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105

Conantokin GV (C-GV) is a neuropeptide isolated from the marine snail Conus geographus. C-GV was originally isolated on the basis of its ability to induce a sleep-like state in young mice following ICV injection (Olivera et al., Toxicon 23: 277, 1985). In older mice, C-GV produced hyperactivity or "sleepy climber" activity, in which the hyperactivity alternated with periods of behavioral inactivity. We examined the effects of ICV injection of C-GV in adult rats implanted with EEG and EMG electrodes. Animals were placed in an isolation chamber lit with a red light and connected to a swivel to allow free movement. Behavioral effects were visually assessed. C-GV 0.11 nmol/rat had no effect on sleep or behavior. C-GV 1.1 nmol/rat induced hyperactivity as well as ataxia. The EEG during this time appeared to be of greater amplitude than normal awake EEG, with overriding high amplitude waves, and could not be scored for sleep-awake stages. 5 of the 8 rats exhibited seizure-like EEG. The behavioral effects of the high dose appear similar to those seen in adult mice.

489.4

HELODERMIN EVOKED RELEASE OF ENDOGENOUS ACETYLCHOLINE FROM GUINEA PIG LONGITUDINAL MUSCLE-MYENTERIC PLEXUS (LM-MP) PREPARATIONS. P.K. CHIANG*, R.R. GRAY, C.B. REAVES, and R.K. GORDON. WALTER REED ARMY INSTITUTE OF RESEARCH, DIVISION OF BIOCHEMISTRY, WASHINGTON DC 20307-5100.

Vasoactive intestinal peptide (VIP) and related peptides are distributed in the CNS and peripheral nervous systems, and are found in high concentrations in the intestines. We previously showed (Arch. Int. Pharmacodyn. 305:14, 1990) that two VIP analogs induced a concentration-dependent contraction of guinea pig ileum, and that these analogs also induced a concentration-dependent secretion of endogenous acetylcholine (ACh). We now demonstrate that one peptide component of the venom of the Gila monster lizard *Heloderma suspectum*, which has a high homology to VIP, induced the release of [^{3}H]ACh from a LM-MP preparation of guinea pig ileum. The helodermin toxin was approximately equal in potency to the most effective VIP, and the maximum evoked release of [^{3}H]ACh was at 10 µM of each peptide. The evoked [^{3}H]-ACh released was ≈ 0.3% of the total content of tritium in the tissue, which contrasts with 20 µM nicotine inducing ≈ 0.4%, and 25 mM KCl inducing ≈ 5%. These results show that helodermin toxin resembles VIP in specificity and ability to bind to receptors in LM-MP preparations which cause the secretion of endogenous ACh.

ATRIAL NATRIURETIC FACTOR INJECTED INTO RAT SUBFORNICAL ORGAN BLUNTS VASOPRESSIN RELEASE INDUCED BY ANGIOTENSIN II. L. Steardo*, M. Iovino§, J. Perez, N. Brunello and G. Racagni. Center of Neuropharmacology, Institute of Pharmacological Sciences, University of Milan, Via Balzaretti 9, 20133 Milan and §Department of Neurology, 2nd Medical School, University of Naples, Via Pansini 5, 80131 Naples, Italy.

The recently discovered atrial peptides are thought to be importantly involved in controlling body fluid homeostasis, both in animals and in humans. The site and mechanism by which these peptides, collectively indicated as Atrial Natriuretic Factor (ANF), regulate salt–water balance have been the subjects of intensive research over the last few years. ANF has been recognized in the brain. Its receptor sites have been identified in close vicinity to those of angiotensin II in circumventricular organs, such as subfornical organs (SFO) and the organum vasculosum laminae terminalis (OVLT). In the light of this close anatomical association, it has been possible to speculate that both peptides may interact with each other to regulate salt–water balance. Therefore to test this hypothesis, the effect of ANF given into SFO on Ang II induced vasopressin release in rats has been investigated. ANF in dose dependent manner has been able to attenuate the enhancing effect of peripherally injected Ang II (192 μg/Kg/min) on plasma vasopressin levels. These findings support the hypothesis that ANF influences the Ang II effecton fluid balance and they indicate SFO as one of the main sites at which this interaction occurs.

ANGIOTENSIN II_1 RECEPTOR ANTAGONISTS BLOCK ANGIOTENSIN-INDUCED EXCITATION OF HYPOTHALAMIC PARAVENTRICULAR AND SUBFORNICAL ORGAN NEURONS IN RAT BRAIN SLICE. Z. Li and A.V. Ferguson*, *Dept. of Physiology, Queen's University, Kingston, Ont. K7L 3N6*

High densities of angiotensin (ANG) II receptors have been revealed within the hypothalamic paraventricular nucleus (PVN) and the subfornical organ (SFO) of the rat. We have recently shown that intravenous losartan (Dup-753), a nonpeptide antagonist of ANG II_1 (AT_1) receptors attenuates systemic ANG-induced increases in neuronal activity in PVN, and blocks the elevation in blood pressure elicited by electrical stimulation of SFO.

Extracellular single unit recordings were made from 79 PVN and 54 SFO neurons in brain slices (350 μm) of adult male Sprague-Dawley rats (140-220 g). Spontaneous activity of these groups of neurons was 1.72±0.14 Hz (MEAN±SEM) and 3.31± 0.25 Hz, respectively. Bath application of ANG II ($7x10^{-9}$-$7x10^{-8}$ M) for 2-5 min increased firing in 40 (50.6%) PVN neurons, and 29 (53.7%) SFO neurons tested. The mean activity of PVN neurons was increased by 105.2%, while that of SFO neurons was increased by 242.3%. The effects of losartan on ANG II responsiveness of 12 PVN and 14 SFO cells was tested. Bath administration of losartan (10^{-6}-10^{-4}M, 4-5 min) abolished the excitatory effects of ANG II on all PVN (95.6±7.4% reduction in response), and 92.9% (92.9±12.2% reduction in response) of SFO, neurons. Partial recovery of excitatory neuronal responses to ANG II was observed when low concentrations of this antagonist were applied. The ability of PD-123319, an AT_2 antagonist, to block neuronal responses to ANG II was also evaluated and excitatory effects of ANG II were blocked by this drug in one of 5 cells tested. These results demonstrate that losartan can directly block ANG II-induced neuronal excitation on the PVN and the SFO and suggest the predominant existence of AT_1 receptors within these nuclei.

NEUROENDOCRINE, BEHAVIOURAL AND CARDIOVASCULAR RESPONSES TO CORTICOTROPIN-RELEASING HORMONE INTO THE CENTRAL AMYGDALA IN STRESS-FREE AND STRESS SITUATIONS. A. Wiersma, A.D. Baauw, S.F. de Boer*, B. Bohus and J.M. Koolhaas. University of Groningen, Dept. of Animal Physiology, P.O.BOX 14, 9750 AA Haren, The Netherlands.

The central nucleus of the amygdala (CEA) is known to be involved in the regulation of the parasympathetic and passive coping response to conditioned and acute stressors. Neuroanatomical studies revealed that the majority of the corticotropin-releasing hormone (CRH) containing neurons in the CEA have direct connections with autonomic regulatory nuclei in the brainstem. A 7-min infusion of 30 ng CRH (in 1 μl CSF) into the CEA of freely moving male Wistar rats under stress-free conditions, led to an increase in heart rate, without changes in plasma noradrenaline (NA), adrenaline (A), and corticosterone. The CRH-induced tachycardia was effectively blocked by pretreatment with 1 μg α-hCRH, a receptor antagonist of CRH. Both CRH infusion and pretreatment with α-hCRH caused a slight behavioural activation. However, administration of α-hCRH alone did not induce a behavioural activation. The shock-probe defensive burying test was used to examine the conditioned stress response. The results show that CRH infusion in the CEA failed to affect heart rate in a conditioned stress test. The behavioural activity showed a remarkable response towards a more active (sympathetic) behavioural response after CRH infusion, which was blocked by pretreatment of α-hCRH.

The present results suggest that CRH induces a reduction of the parasympathetic output systems and passive coping strategies. As CRH is given at the level of the cell body of the CRH neurons in the CEA, the results can be explained as an autoreceptor mediated inhibition of CRH connections from the CEA with parasympathetic brainstem nuclei.

489.8

BOMBESIN EXCITES NEURONS IN HYPOTHALAMIC ARCUATE AND SUPRACHIASMATIC NUCLEI IN BRAIN SLICES. J.T. Pan*, J.Y. Lin and K.C. Teng. Inst. of Physiology, Natl. Yang-Ming Med. Coll., Taipei, Taiwan 11221, R.O.C.

Both bombesin, a putative peptide neurotransmitter, and its receptors have a wide and extensive distribution in the hypothalamic areas, including the arcuate (ARC) and the suprachiasmatic (SCN) nuclei. A total of 70 ARC and 174 SCN neurons were recorded and tested for bombesin in brain slices. Over 75% of ARC neurons were excited by application of 0.5 nmol of bombesin into the slice chamber. The effects of bombesin on SCN neurons, however, can be differentiated between neurons with different firing patterns, viz. it excited 75% of irregular firing neurons (n=113), while it only excited 17% and inhibited 34% of regular firing neurons (n=61). A dose-dependent effect of bombesin (from 0.005 to 5 nmol) on SCN neurons was also demonstrated. In 25 SCN neurons tested for both bombesin and gastrin-releasing peptide, 24 showed similar responses (67% were excited by both peptides). Pretreatment with Leu^{13}-(CH_2NH)Leu^{14}]-bombesin, a bombesin receptor antagonist, blocked 67% of the bombesin effect in SCN neurons. The data implicate that bombesin may play a significant role in the regulation of selective SCN and ARC neurons.

CRF STIMULATES CATECHOLAMINE RELEASE IN RAT MEDIAL PREFRONTAL CORTEX AND MEDIAL HYPOTHALAMUS, ASSESSED BY MICRODIALYSIS. Jan Lavicky, R. Don Brown*, and Adrian J. Dunn. Department of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130-3932.

In vivo microdialysis was used to measure changes of extracellular concentrations of catecholamines in freely moving rats in response to administration of corticotropin-releasing factor (CRF). With dialysis probes in the medial hypothalamus, intracerebroventricular (icv) administration of CRF (17 or 330 pmoles) dose-dependently increased dialysate concentrations of norepinephrine (NE), dopamine (DA), and all their measurable catabolites except normetanephrine (NM). Dialysate concentrations of serotonin could not be measured reliably, but those of its catabolite, 5-hydroxyindoleacetic acid (5-HIAA) were also elevated. DA and NE increased within the first two 20 min collection periods, and returned to baseline within 3 h. Similar data were obtained with dialysis probes in the medial prefrontal cortex after 17 or 167 pmoles of CRF icv. IP administration of CRF (1 nmole) similarly elevated dialysate concentrations of NE, DA, 5-HIAA, and all catecholamine catabolites except NM in both the medial hypothalamus and the medial prefrontal cortex. These results support earlier neurochemical data suggesting that CRF administered either centrally or peripherally stimulates the release of both DA and NE in the brain.

EFFECT OF GALANIN ON TUBEROINFUNDIBULAR DOPAMINERGIC NEURONAL ACTIVITY AND PROLACTIN SECRETION IN MALE AND FEMALE RATS **C. GOPALAN*, Y. TIAN, K.E. MOORE and K.J. LOOKINGLAND. Dept. of Pharm/Tox., Michigan State Univ., E.Lansing, MI 48824.**

Tuberoinfundibular dopaminergic (TIDA) neurons terminating in the median eminence tonically inhibit the secretion of prolactin from the anterior pituitary. Prolactin, in turn, stimulates the release of dopamine from TIDA neurons and thereby regulates its own secretion. Central administration of the neuropeptide galanin is reported to increase prolactin secretion, but it is not clear if this effect is mediated by changes in the activity of TIDA neurons. In the present study, the effects of galanin on the basal and prolactin-stimulated activity of TIDA neurons were examined by measuring the ratio of 3,4-dihydroxyphenylacetic acid (DOPAC) to dopamine in the median eminence of both male and female rats. Intracerebroventricular (i.c.v.) administration of galanin (2 μg/rat) produced a rapid (by 15 min) increase in plasma prolactin concentrations, but failed to alter the ratio of DOPAC to dopamine in the median eminence of either male or female rats. These results indicate that galanin-induced activation of prolactin release is not mediated by changes in the activity of TIDA neurons. On the other hand, galanin decreased the ratio of DOPAC to dopamine in the median eminence of both male and female rats whose TIDA neuronal activity was stimulated following experimental procedures that increase circulating prolactin concentrations (i.e. administration of the dopamine antagonist haloperidol [1 mg/kg; s.c.; 12 h]. Taken together, these results indicate that the inhibitory effects of galanin on the activity of TIDA neurons is dependent upon the level of activity of these neurons in both male and female rats (supported by ADAMHA grant MH 42802).

489.11

VASOPRESSIN RELEASE FROM AMYGDALA IN VITRO. J. Raber, E. Merlo Pich, G.F. Koob and F.E. Bloom*. Department of Neuropharmacology, Scripps Research Institute, 1006 N. Torey Pines Rd., La Jolla, CA 92037.

Arginine Vasopressin (AVP) containing neurons have been shown to occur in limbic structures, including the hippocampus and amygdala, as well as in the classic magnocellular hypothalamic nuclei. We have investigated the release mechanism of AVP in vitro from dissected rat brain regions. Minced amygdala, hypothalamus and somatosensory cortex were each incubated in balanced Earle's salt solution for a total time of 180 minutes at 37o C. After three 20 minute periods for collecting basal release, depolarization with KCl (60 mM) caused a marked stimulation of AVP release (amygdala; basal level 58 +/- 18 pg/ml, stimulated 90 +/- 23 pg/ml, hypothalamus; basal level 392 +/- 36 pg/ml, stimulated 831 +/- 91 pg/ml). No detectable (stimulated) release was found with slices from the somatosensory cortex. This stimulation effect is calcium dependent and was blocked in the presence of EGTA (10 mM). These results indicate that depolarizing agents induce the release of AVP-like immunoreactivity not only from the hypothalamus but also from limbic structures, such as the amygdala. This system may be suitable for evaluating the effects of other regulatory signals, such as the cytokines, on neuronal neuropeptide release.

489.12

MELATONIN EFFECTS ON TWO ANXIOLYTIC TEST IN RATS. Naranjo-Rodríguez E.B., Vázquez A.M. and C. Reyes-Vázquez*. Sec. Farmacología, Depto. Farmacia, Facultad Química and Depto. Farmacología, Facultad Medicina, UNAM.

Anticonvulsive, hypnotic and sedative effects had been described after melatonin (MEL) systemic administration. The mechanism of action used by MEL to produce such effects are unknown. However, MEL enhances GABA "in vitro" and elicits some biochemical effects resembling those produced by diazepam (DIAZ), chlorodiazepoxide (CDP) and buspirone (BUS). These data suggest that MEL could exert other characteristic effects of these drugs, like anxiolysis. Male Wistar rats (120-230 g) were used in two experiments. Some rats were deprived of food and water for 48 h prior to test on a conflict procedure. Then, after 20 licks from a water bottle with a metal drinking tube, the animal received an electric shock (0.5 mA/2 sec). Also, some rats were tested in a force swimming procedure, in which total immobility during a 5 min period was recorded. The effects of three classical anxiolytic drugs, DIAZ (2 and 5 mg/kg), CDP (5 and 10 mg/kg) and BUS (5 and 10 mg/kg) were compared with those produced by MEL (1 and 2 mg/kg). All drugs were applied 20 min before both tests. Anxiolytic drugs as well as MEL produced a dose-dependent increase in the number of shocks received and in the total immobility time. These results suggest an anxiolytic action of MEL.

CHRONIC PEPTIDE T ADMINISTRATION PREVENTS NEOCORTICAL ATROPHY RESULTING FROM NUCLEUS BASALIS LESIONS IN AGED RATS. D.J. Socci[1], J.M. Hill[2], C.B. Pert[3], M.R. Ruff[3] and G.W. Arendash.*[1] Dept. of Biology[1], Univ. of S Florida, Tampa, FL 33620; NICHD[2], NIH, Bethesda, MD 20892; Center for Molecular & Behav. Neurosci.[3], Rutgers Univ., Newark, NJ 07102.

Vasoactive intestinal peptide (VIP) is co-localized in cholinergic terminals within neocortex. Since VIP has neurotrophic actions *in vitro*, it may be involved with, and/or be capable of preventing, degenerative changes in neocortex resulting long-term after cortical cholinergic denervation induced by nucleus basalis (NB) lesioning (*Science* 238:952, 1987). The two-fold purpose of the present study was: 1) to determine the long-term degenerative effects of NB lesions in the neocortex of aged rats, and 2) to test the ability of "peptide T" (PT), which has a pentapeptide sequence homologous with VIP (7-11), to prevent any observed degenerative changes. Aged (20-21 month old) male Sprague-Dawley rats received NB infusions of ibotenic acid (5 µg/1 ul PBS) bilaterally. Immediately after lesioning, animals began receiving daily i.p. injections of either PT (1 mg) or vehicle solution. After sacrifice 5 months later, brain sections were stained with thionine for analysis of neocortical thickness (Layers II-VI) at the mid-parietal level. Compared to measurements from unoperated controls, NB lesioned animals given vehicle alone exhibited a significant 17.4% decrease in overall cortical thickness ($p<.002$); there was a 13.2% decrease in Layer II ($p<.02$), a 28.6% decrease in Layers III-V ($p<.0001$), and a 15.1% decrease in Layer VI ($p<.02$). Chronic PT treatment completely eliminated the lesion-induced decrease in overall cortical thickness, as well as that within Layers II and VI. Also, the lesion-induced decrease in Layers III-V was significantly attenuated by PT ($p<.03$). PT's action in preventing NB lesion-induced neocortical atrophy may involve a direct or indirect (glial-mediated) neurotrophic mechanism, presumably through VIP receptor activation.

489.14

BLOCKADE OF THE CARDIOVASCULAR AND TOXIC EFFECTS INDUCED BY INTRATHECAL INJECTION OF ENDOTHELIN-1 IN THE CONSCIOUS RAT. P. Poulat[1], P. D'Orléans-Juste[2], M. Yano[3], J. de Champlain[1*] and R. Couture[1]. [1]Dept. Physiology, University of Montreal, Montreal, Qué., Canada H3C 3J7, [2]Dept. Pharmacology, Sherbrooke University, Sherbrooke, Qué., Canada and [3]Banyu Pharmaceuticals Co., Tsukuba, Japan.

Evidence suggests that endothelin-1 (ET-1) acts as a neuropeptide within the CNS by interacting with specific receptors. In the rat spinal cord, the presence of ET_A receptors was demonstrated in binding assay. This study was to determine the intrathecal (i.t.) action of ET-1 and BQ-123 (antagonist of ET_A receptors) on mean arterial pressure (MAP) and heart rate (HR) of the conscious rat. The i.t. injection of ET-1 (6.5 - 650 pmol at T-9) produced dose-dependent increases in MAP and decreases in HR. During the dose-response curve, 40-50% of the rats died while 650 pmol ET-1 caused death of 100% of the animals within 3-5 min after an initial increase of blood pressure. Both the cardiovascular changes and the toxic action of 650 pmol ET-1 were blocked by the prior i.t. injection of 65 nmol BQ-123 (25 min earlier) but were unaffected when the same dose of antagonist was administered i.v. BQ-123 was devoid of intrinsic activity when given either i.t. or i.v. The pressor response to 65 pmol ET-1 was significantly inhibited after i.v. injection of phentolamine while the bradycardia was abolished by either atropine or pentolinium. The latter three treatments failed, however, to prevent the toxic action of i.t. ET-1. These results suggest that the cardiovascular and toxic effects induced by i.t. ET-1 are mediated by ET_A receptors in the spinal cord. The pressor response appears to be due to the activation of the sympathetic nervous system while the bradycardia is ascribed to a vagal reflex. [Supported by the MRC of Canada].

OPIOID RECEPTORS: COUPLING AND BIOCHEMISTRY

490.1

SELECTIVITY PROFILES AND REGULATION BY GUANYL NUCLEOTIDES OF LIGAND BINDING TO μ, δ AND κ OPIOID RECEPTORS IN BRAIN MEMBRANES. M. Williamson and J.M. Herz*. Biochemical Pharmacology Group, Panlabs, Inc., Bothell, WA 98011

We have used specific radioligand binding assays for the μ, δ and κ opioid receptors in whole brain membranes from guinea pig to establish selectivity profiles for various opioids and investigate effects of guanyl nucleotide regulation of agonist binding. [^{3}H]Tyr-D-Ala-Gly-(Me)Phe-Gly-ol (DAMGO), [^{3}H](D-Pen^2,D-Pen^5)-enkephalin (DPDPE), and [^{3}H]U69,593 were used as specific radioligands for the μ, δ and κ receptors, respectively. Assays were carried out in modified Krebs-Hepes buffer containing protease inhibitors. Saturation isotherms revealed a single class of high affinity sites for [^{3}H]DAMGO. Inhibition of [^{3}H]DAMGO binding yielded the following K_is: fentanyl (1.2 nM), naloxone (0.76 nM), DPDPE (370 nM), naltrindole (2.5 nM), and norbinaltorphimine (26 nM). Indirect Hill coefficients for competing ligands were near 1.0. High selectivity of DAMGO for μ-receptors was observed since the ratio of the K_is for δ/μ and κ/μ were 926 and 3,700, respectively. GTP-γ-S completely inhibited [^{3}H]DAMGO binding with an IC_{50} of 0.89 μM. The K_d determined from saturation isotherms for binding of [^{3}H]U-69,593 was found to be 2.2 nM for a single class of sites. U50,488 was found to be highly selective for κ receptors since μ/κ=211 and δ/κ=11,430. Norbinaltorphimine exhibited a K_i of 0.35 nM and a n_H of 0.39, indicating heterogeneity in labeled sites. [^{3}H]DPDPE was found to be highly selective for δ-receptors, with μ/δ=168 and κ/δ=500. Saturating concentrations of GTPγS or GDPβS reduced binding of [^{3}H]U69,593 to 34% and 40% of control with IC_{50}s of 0.70 and 2.0 μM, and reduced the binding of [^{3}H]DPDPE to 12% and 1% of control with IC_{50}s of 0.15 and 0.92 μM. These results establish that guanyl nucleotides act with similar affinity to convert μ, δ and κ receptors to states of reduced affinity for agonists in guinea pig brain membranes

OPIOID RECEPTOR REGULATED SECOND MESSENGER SYSTEMS IN PHEOCHROMOCYTOMA CELLS M.E. Abood* and J.S. Eubanks. Dept. of Pharm., Med. Coll. of Virginia, Virginia Commonwealth Univ. Richmond, VA 23298.

PC12 rat pheochromocytoma cells are useful as a model system for neuronal development. In one subclone of PC12 cells, PC12h, low levels of δ-type opioid receptors markedly increase in response to nerve growth factor (NGF) (Inoue, N. and Hatanaka, H. *J. Biol. Chem.* 257: 9238 1981). We have been investigating the consequences of the appearance of opioid receptors in PC12h cells and examining concurrent changes in the expression of opioid-regulated genes. After 10 days of treatment with NGF, the number of opioid receptors (as measured by ^{3}H-diprenorphine binding), increases from a B_{max} of 40 to 220 fmols/mg protein. We have previously demonstrated that the opioid receptors in this cell line can be down-regulated by etorphine, indicating that they are capable of responding to opioid agonists. In the current study, the question of whether opioid receptors in PC12h cells couple to inhibition of adenylyl cyclase was addressed. Etorphine caused a dose-dependent inhibition of cAMP accumulation. This effect was reversed by naloxone. Furthermore, etorphine inhibition of cAMP accumulation was found in non-NGF as well as NGF-treated PC12h cells. These data indicate that the opioid receptors on PC12h cells are coupled to adenylyl cyclase, similar to δ receptors in other cell lines. (Supported by DA-06867)

EVIDENCE FOR LIGAND BINDING TO TRANSMEMBRANE SEGMENTS OF OPIOID RECEPTORS. J.C. Schaeffer[1], J.A. Bell[2]*, D.K. Arquette[1] and E.T. Consorti[1]. [1]Dept. of Chem. Cal State U., Northridge, CA 91330 and [2]Addiction Research Center, NIDA, Baltimore, MD 21224.

Considerable evidence suggests that opioid receptors are members of the G-protein linked receptor family. For several G-protein coupled receptors, biochemical and genetic analyses have implicated transmembrane segments of the receptor as the sites of ligand binding. The relative potencies of 7α-aminomethyl-6,14,-endo-ethenotetrahydrooripavine(I) (close structural relative of etorphine) and a series of N-acyl derivatives were assessed using a ^{3}H-naloxone/rat brain membrane binding assay. N-acetylation(II) had no effect on potency whereas the introduction of a hydrophobic N-phenylacetyl(III), N-phenylpropionyl (IV), or N-phenylbutyryl(V) substituent increased binding potency 40-fold, and made these compounds as potent as etorphine (IC_{50} = 0.3 nm). The effects of these compounds on an electrically evoked potential from isolated neonatal rat spinal cord showed them to be potent agonists, with III as potent as etorphine and I, II, IV and V being less effective. The electrophysiological effects were reversed by naloxone, but upon naloxone wash-out, effects of the more hydrophobic compounds (III, IV, V) persistently returned. These results suggest that partitioning of these compounds into the hydrophobic core of the neuronal plasma membrane may play a vital role in their duration of action because the μ opioid binding site is located in the transmembrane region of opioid receptors. However, because III is a more potent agonist than IV or V, small structural changes must affect the ligand/receptor complex conformation that transmits binding information to the G-protein involved in the transmembrane signaling process.

490.4

MECHANISMS OF LOW pH PRETREATMENT-MODIFIED G PROTEIN-ADENYLYL CYCLASE INTERACTION IN NG108-15 CELL MEMBRANES. D. E. Selley* and S.R. Childers. Dept. Physiol./Pharmacol., Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27103.

Pretreatment of rat brain or NG108-15 cell membranes at pH 4.5 prior to assay at pH 7.4 produces the following modifications in signal transduction pathways that regulate adenylyl cyclase (AC): 1) decreases stimulation of AC by G_s, 2) increases receptor-mediated inhibition of AC, and 3) increases inhibition by Na^+ and GTP of agonist binding to opioid receptors, with no effect on binding in the absence of Na^+ and GTP. In NG108-15 membranes, low pH pretreatment did not increase opioid stimulation of low K_m GTPase activity, or Gpp(NH)p inhibition of AC, in the presence of 120 mM NaCl. However, studies of the effect of Na^+ concentration on AC and GTPase activity in NG108-15 membranes have revealed that low pH pretreatment: 1) decreased basal AC activity in a manner that was inversely related to Na^+, 2) increased opioid inhibition of AC at Na^+ concentrations below that required to support opioid inhibition of the enzyme in control membranes, and 3) decreased basal low K_m GTPase activity and increased opioid agonist stimulation of low K_m GTPase in a manner that was inversely related to Na^+. The common effect of low pH pretreatment on both AC and GTPase was to increase agonist effects at low Na^+ concentrations. These data suggest that a complex interaction between Na^+, G_s, G_i, and inhibitory receptors is altered by low pH pretreatment.

OPIATE RECEPTOR AGONISTS REGULATE PHOSPHORYLATION OF SYNAPSIN I IN SPINAL CORD-DORSAL ROOT GANGLION COCULTURES. Z. Vogel*, D. Saya, S-Y. Nah. LMB, NINDS, NIH, Bethesda, MD 20892; Dept. Neurobiol., Weizmann Inst. Science, Rehovot, 76100 Israel.

κ-Opiate receptor agonists were shown to inhibit adenylate cyclase activity as well as the voltage-dependent Ca^{2+} channels in spinal cord-dorsal root ganglion (SC-DRG) cocultured neurons (J. Neurochem. *52*, 360, 1989; J. Biol. Chem. *264*,347, 1989). We have, therefore, investigated the effect of κ receptor agonists on the phosphorylation of synapsin I, a synaptic vesicle-associated protein whose phosphorylation was shown to be regulated by cAMP, depolarization, and intracellular Ca^{2+} concentration. Depolarization of SC-DRG cocultures (by high K^+ or veratridine) as well as the addition of forskolin (which activates adenylate cyclase) leads to increased phosphorylation of synapsin I. The addition of κ opiate agonists (such as U50488 and EKC) attenuated both the K^+ depolarization- and forskolin-induced phosphorylation of synapsin I. The EC_{50} obtained for U50488 was ~ 5 and 1 μM, respectively. This attenuation by κ agonists was blocked by the opiate antagonist naloxone. μ and δ opiate receptor agonists had a much weaker effect compared with κ. Similarly, κ opiate agonists attenuated (by 30-50%) the high K^+ or veratridine-induced phosphorylation of synapsin I in synaptosomes prepared from spinal cord. These results show that opiate ligands modulate synapsin I phosphorylation. Moreover, the data could explain the alterations in synaptic efficacy and reduction in neurotransmitter release observed following opiate treatment. *(Supported by the Minerva and Schilling Foundations, the National Institute of Drug Abuse, and the German-Israeli Foundation for Scientific Research and Development.)*

NOVEL OPIOID BINDING SITES ASSOCIATED WITH THE NUCLEI OF NG108-15 NEUROHYBRID CELLS. M.M.Belcheva#, J. Rowinski#, J.Barg#, W.Gregg Clark#, C.Gloeckner#, X.-M.Gao†, D.-M.Chuang† and C.J.Coscia*#.#Dept. of Biochem. and Mol. Biol., St. Louis Univ. Sch. Med. St. Louis, MO 63104 and †Biological Psychiatry Branch, NIMH, Bethesda, MD 20892

Nuclear opioid binding sites have been discovered in NG108-15 cells. Marker enzyme analyses, electron and fluorescence light microscopy studies attested to the purity of nuclear preparations. Immunohistochemical staining of cryostat sections of NG108-15 cells with an anti-opioid receptor antibody corroborated a nuclear localization. ^{3}H-DPDPE, ^{3}H-DADLE and ^{3}H-diprenorphine homologous binding (K_d and B_{max}), ^{3}H-DSLET heterologous competition curves, stereospecificity and kinetic data, satisfied criteria for the presence of δ opioid sites in purified nuclear preparations; neither μ- nor κ- specific binding were detectable. Agonists, ^{3}H-DADLE and ^{3}H-DPDPE, bind with high affinity to nuclear membranes and with lower affinity to chromatin. In contrast, partial agonist ^{3}H-diprenorphine high affinity binding sites were in chromatin, while low affinity binding was found in nuclear membranes. Gpp(NH)p sensitivity of ^{3}H-DADLE binding was detected in nuclear membranes but not chromatin. Opioid binding to nuclear membranes and chromatin was abolished upon cycloheximide treatment of cells. The results suggest that NG108-15 cells contain newly synthesized G protein-coupled δ receptors in nuclear membranes and uncoupled, internalized opioid sites in chromatin.

DOWNREGULATION OF KAPPA OPIOID RECEPTORS IN A MURINE LYMPHOMA CELL LINE. D.B. Joseph* and J.M. Bidlack. Dept. of Pharmacology, Univ. of Rochester Sch. of Med. and Dent., Rochester, NY 14642

Previous studies from this laboratory have demonstrated the presence of κ opioid receptors on membranes from the mouse thymoma cell line, R1.1. Chronic exposure of these cells to the κ agonist U50,488 produced changes in the receptor population, as indicated in ligand binding assays using the κ-selective agonist [^{3}H]U69,593. The binding of 1 nM [^{3}H]U69,593 to membranes from U50,488-treated cells was reduced by as much as 55% in comparison to control cells, which were treated with an equivalent concentration of U50,488 for 15 min. The effect of U50,488 was both concentration- (EC_{50} = 30 nM) and time-dependent, with the maximum decrease in binding observed after 24 hr of exposure. The decrease in [^{3}H]U69,593 binding was due to changes in both receptor density and affinity. Twenty-four hr exposure to 100 nM U50,488, a maximally effective concentration, produced a 50% decrease in the B_{max} value and a 2-3 fold increase in the K_d value. The effects of chronic exposure of the cells to 100 nM U50,488 were completely blocked by 1 μM naloxone. Treatment of R1.1 cells with 10 μM morphine or 100 nM [D-Ala^2, D-Leu^5] enkephalin for 24 hr produced no change in [^{3}H]U69,593 binding to membranes prepared from these cells, suggesting that μ and δ opioids did not produce a change in the number or affinity of κ opioid receptors. The R1.1 cell line will provide a model for characterizing the mechanisms of drug dependence associated with κ opioid receptors. The results from the present studies are the first evidence for the occurrence of opioid receptor downregulation in cells of the immune system. (Supported by USPHS DA04355 and DA07232.)

THE PRESENCE OF δ OPIOID RECEPTORS ON COS-7 CELL MEMBRANES. T. Zalewska, E. Malatynska, H.I. Yamamura*. Department of Pharmacology, College of Medicine, The University of Arizona, Tucson AZ, 85704.

COS-7 cells are very often used in transient gene expression. They might be considered as part of an expression system for opioid receptor cloning. We report the presence on COS-7 cell membranes of high affinity binding sites for [^{3}H]naltrindole (an antagonist of δ opioid receptor). Equilibrium binding studies show that [^{3}H] naltrindole labels a homogenous population of binding sites with a dissociation constant (K_d) of 72.6 pM and Hill value not different from unity. The measured receptor density (B_{max}) is 17 fmol / mg protein. Naltrindole and a ligand selective for δ opioid receptor, p-Cl-DPDPE, displaced [^{3}H]naltrindole from its binding site with high affinity. The K_i value for naltrindole is 200 pM, and for p-Cl-DPDPE is 315 pM. The ligands selective for μ (PL-17) and κ (U69,593) opioid receptors only inhibited [^{3}H]naltrindole binding at micromolar concentrations. This study demonstrates the presence of δ opioid receptor sites on COS-7 cell membranes. It is concluded that these cells should be avoided for the expression of putative δ opioid receptor genes. Supported in part by NIDA grants.

KAPPA-OPIATE RECEPTORS ON ASTROCYTES STIMULATE L-TYPE Ca^{2+} CHANNELS. Peter S. Eriksson[1], Michael Nilsson[1], Maria Wågberg[1], Elisabeth Hansson[1] and Lars Rönnbäck*[1,2] Institute of Neurobiology[1] and Department of Neurology[2] University of Göteborg, Göteborg, Sweden. Cultured astrocytes from the cerebral cortex respond to κ-receptor stimulation with a substantial elevation of the cytoplasmic free calcium, visualized through the use of the fluorescent calcium indicator fura-2. The stimulation of κ-receptors using the agonist U-50,488H increase the level of calcium through a stimulatory effect on the transmembrane calcium influx. The transmembrane influx was dose dependent. Furthermore, it was completely blocked by the selective κ-receptor antagonist *nor*-Binaltorphimine. The presence of L-type channels was verified by the use of Bay K8644. The effect of Bay K8644 was completely blocked by nifedipine, indicating the involvement of L-type channels. L-type channel coupled κ-receptors on astrocytes might represent a novel mechanism contributing to the depressant action of opioids on synaptic transmission via decreasing the availability of extracellular calcium necessary for presynaptic transmitter release.

CHARACTERIZATION OF A PUTATIVE OPIOID RECEPTOR IN THE PROTOZOAN *STENTOR*. M.J. Marino*, T.G. Sherman, and D.C. Wood. *Department of Cellular and Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260*

An understanding of the biochemical events underlying opioid mediated processes has been hindered by the complexity inherent in mammalian systems. Therefore, a simple systems approach may prove beneficial in understanding the biochemistry of opioid-mediated events. The protozoan *Stentor* may express an opioid receptor and this simple organism could provide a useful system for the biochemical study of such receptors. We have previously shown that β-endorphin (β-end) modulates a mechano-sensory conductance in *Stentor* with an EC_{50} of 3.0 μM. The result of this modulation is behaviorally apparent as a marked decrement in the probability that a cell will contract when mechanically stimulated. The effect of β-end appears to be receptor mediated for several reasons. First, the β-end effect is mimicked by morphine and DAGO, but not by dynorphin or the enkephalins indicating a putative μ-like receptor. Second, the actions of β-end, DAGO, and morphine are sensitive to equimolar concentrations of the opiate antagonist naloxone. Third, the effect of β-end is pertussis toxin (PTX) sensitive. *Stentor* incubated for 24 hours in 200 μg/ml of PTX do not exhibit a depression in mechanical stimulus response probability when exposed to 1 μM β-end or 20 μM DAGO. This PTX treatment has no effect on control cells' response probability and does not effect the cells' electrical threshold. This suggests that these opioids act through a G-protein linked opioid receptor. Finally, *Stentor* exhibit tolerance with the continued exposure of β-end. Current work is aimed at identifying any endogenous opioid ligands as well as characterizing this receptor utilizing pharmacological and molecular techniques.

GENETIC CORRELATION BETWEEN THE NUMBER OF MU AND DELTA BINDING SITES IN WHOLE BRAIN PREPARATIONS FROM 8 INBRED MOUSE STRAINS. K. Shimosato*, N. Goodman & R. Marley. NIDA-Addiction Res. Ctr., Box 5180, Baltimore, MD 21224.

To identify animal models differing in opioid receptor binding parameters for use in further examination of opioid-mediated behaviors, we have examined the number (B_{max}) and affinity (K_d) of μ and δ receptor in whole brain preparations from 8 inbred mouse strains. ^{3}H-DAMGO (0.5 - 21 nM) and ^{3}H-pCl-DPDPE (0.04 - 4 nM) were used to characterize μ and δ receptors, respectively. Scatchard analyses revealed that the B_{max} values for μ receptors ranged from 75 to 116 fmol/mg, with a rank order among the strains of BALB, C3H, C57/6J, CBA < C57/6ByJ, DBA, SJL < AKR. No differences in μ receptor affinity were observed among the strains (K_d = 3 - 4 nM). The number of δ receptors among the strains ranged from 55 - 83 fmol/mg, with a rank order (BALB < C3H, C57/6J, C57/6ByJ, CBA < DBA < SJL < AKR) very similar to that observed for μ receptors. There were no differences among the strains in δ receptor affinity (K_d = 0.4 - 0.5 nM). Statistical analyses revealed a significant genetic correlation between the number of μ and δ receptors in whole brain preparations from the 8 inbred strains ($r = 0.88$, $p < 0.01$). The strong genetic correlation between the number of μ and δ opioid receptors suggests that there may be common mechanisms associated with the regulation of the expression of these receptor subtypes.

490.12

INTERACTIONS OF OPIOID PEPTIDES AND OTHER DRUGS WITH MULTIPLE DELTA BINDING SITES IN RAT AND MOUSE BRAIN: FURTHER EVIDENCE FOR SUBTYPES OF THE δ_{ncx} BINDING SITE. H. Xu*[1], J.S. Partilla[2], A.E. Jacobson[1], K.C. Rice[1] and R.B. Rothman[2]. [1]LMC, NIDDK, NIH, Bethesda, MD 20892. [2]NIDA Addiction Research Center, PO Box 5180, Baltimore MD 21224.

These studies tested the hypothesis that there exist subtypes of delta receptors. Rat and mouse brain membranes were depleted of μ binding sites using the irreversible ligand, BIT. δ_{ncx} binding sites were labeled with [^{3}H]DADL (4 - 6 hr at 25° C, in 10 mM TRIS-HCl, pH 7.4, 100 mM choline chloride, 3 mM $MnCl_2$). Initial experiments with rat and mouse brain membranes demonstrated that DPDPE or DPLPE inhibition curves were characterized by low slope factors, both in the absence and presence of 50 μM GppNHp. Binding surface analysis of the interaction of DADL, DPDPE, deltorphin-I and oxymorphindole with [^{3}H]DADL binding sites readily resolved two binding sites in both rat brain membranes. Similar studies with mouse brain membranes also readily resolved two sites, which had a different ligand selectivity profile from the two sites observed using rat brain. Sodium chloride (100 mM) decreased [^{3}H]DADL binding, and increased the Ki values of DPDPE, deltorphin-II and naltrindole for the two sites. These data support the hypothesis of subtypes of the δ_{ncx} binding site, and suggest that there may also be significant difference among species. Additional studies will be needed to test this hypothesis further.

490.13

AUTORADIOGRAPHIC LOCALIZATION OF THE μ AND δ RECEPTORS IN THE BRAIN OF MICE SELECTED FOR THEIR DIFFERENCES IN VOLUNTARY ETHANOL CONSUMPTION. J.-P. DE WAELE* and C. GIANOULAKIS Douglas Hospital Research Center and McGill University, Montréal, Québec, Canada

The implication of the endogenous opioid system in the control of voluntary ethanol consumption is suggested by the observation that the administration of both specific (ICI-174864) or non-specifc (naltrexone) opiate antagonists induces a decrease in voluntary ethanol consumption in rats. Using specific μ (FK-33824) and δ (DPDPE) ligands, we studied the distribution of μ and δ binding sites in the brain of the C57BL/6 (ethanol-preferring) and DBA/2 (ethanol-aversive) mice. It was demonstrated that there is higher release of hypothalamic ß-endorphin and more mRNA coding for POMC in the hypothalamus of the C57BL/6 mice than of the DBA/2 mice. There is a predominance of μ over δ receptors in both strains of mice, with μ receptors present in limbic and thalamic areas, while δ receptors density is low in regions such as the septum or the thalamus. Strain-related differences in μ receptor density may be observed in certain nuclei of the limbic system (n. accumbens, septum, VTA) and of the thalamus. Differences in the opioid receptors distribution between the C57BL/6 and DBA/2 mice may explain in part the differences in their ethanol-drinking behavior.

490.14

EXPRESSION OF OPIOID RECEPTORS IN *XENOPUS* OOCYTES INJECTED WITH RAT BRAIN MESSENGER RNA. S. Kaneko, J. Yuasa, H. Takahashi and M. Satoh*. Dept. Pharmacol., Facl. Pharm. Sci., Kyoto Univ., Kyoto 606-01, Japan.

Voltage-clamp recording was used to detect functional expression of opioid receptors in the *Xenopus* oocyte translation system. By injecting poly(A)$^+$RNA isolated from 3 week-old rat striatum or whole brain, the oocytes often acquired intracellular Ca^{2+}-related oscillatory responsiveness to DAMGO (μ agonist), DADLE (μ+δ agonist), DPDPE (δ agonist) and U-50488H (κ agonist) at a concentration of 1 μM. These responses were very transiently expressed after injection of mRNA, however, water-injected oocytes never responded any of the opioid agonists. After sucrose-density fractionation, RNA size class of about 3 kbase encoded these opioid receptors. In the oocytes injected with striatal mRNA, DADLE and DPDPE evoked the fluctuating current with higher probability and in larger amplitude than other agonists, whereas whole brain mRNA produced DAMGO and U-50488H responses predominantly. The DPDPE response of striatal mRNA-injected oocytes was antagonized by naloxone as well as the δ-specific antagonists ICI 154129 and ICI 174864. DAMGO and U-50488H responses have not been characterized yet because of strong desensitizing property. These observations suggest that putative μ, δ and κ subtypes of opioid receptors mobilizing intracellular Ca^{2+} are expressed in *Xenopus* oocytes by rat brain mRNA.

490.15

IN VIVO IMAGING OF OPIOID RECEPTORS WITH [^{125}I]-IOXY, A NEW IODINATED NALTREXONE DERIVATIVE.

M.J. Iadarola*[1], L.S. Brady[2], M.V. Green[3], K.F. Berman[4], B.R. de Costa[5] and K.C. Rice[5]. [1]NAB, NIDR; [2]CNE, NIMH; [3]DNM, CC; [4]CBDB, NIMH and [5]LMC, NIDDK, NIH, Bethesda, MD 20892.

We have synthesized and radiolabeled Ioxy (de Costa et al., J. Med. Chem. in press) for use in single photon emission computed tomography (SPECT) imaging of endogenous opioid receptors in humans. Ioxy, an iodo-derivative of naltrexone, functions as an antagonist and is an analog of cycloFoxy, a [^{18}F]-labeled compound used in positron emission tomography (PET). Intravenous injection of 20 uCi to rats yielded highest levels of binding in striatum and thalamus, lesser binding in other areas, and the fewest counts in cerebellum. Counts were displaced to levels in cerebellum by pretreatment with (-) but not (+) naloxone. Autoradiography of brain sections after i.v. administration showed dense binding to striatal patches, laminae I-II of spinal cord, medial habenula and interpeduncular nucleus. We used an experimental gamma camera to obtain a brain scan of the distribution of [125I]-Ioxy in a living rat. A planar scan in the vertex projection revealed dense accumulation of radioactivity in the thalamus, midbrain and bilaterally in the caudate nucleus. These studies introduce a new method for imaging receptors in small animals in vivo and suggest that Ioxy will be an effective agent for use as a ligand in SPECT studies of human opioid receptors.

490.16

GLUCOSE METABOLISM AND OPIATE RECEPTOR BINDING IN THE DEAFFERENTED CORTEX IN MONKEY BY PET. D.J. Doudet*, R.E. Carson, M.A. Channing, R. Saunders, M. Der and R.M. Cohen. Clinical Brain Imaging/ NIMH; Nuclear Medicine Dept, NIH, Bethesda, MD.

To examine the role of the cortical opiate system, we studied glucose metabolism and F-18 cyclofoxy (CF) binding in the visual system of rhesus monkeys (N=4). The forebrain commissures and one optic tract were sectioned. CF distribution volume (DV) and glucose metabolic rates (CMRg) were determined for left and right hemispheres. The deafferented occipital and parietal and temporal areas had a significantly increased DV of CF (respectively 33, 18 and 9 %) and a significant decrease in CMRg (12, 8 and 6%) compared to the contralateral side ($p<0.05$). Compared to normal rhesus, CF binding was significantly increased (25%) in the contralateral occipital, parietal and temporal areas and the ipsi and contralateral central and frontal areas, but glucose metabolism was normal. CF binding and CMRg were normal in subcortical areas.

This increase in DV of CF, likely due to an increase in unoccupied opiate receptors, in areas with decreased functional activity suggests that sensory inputs play a role in the modulation of opiate function and that cortico-cortical connections are important in its regulation.

CATECHOLAMINES: RECEPTORS III

491.1

ACTIVATION OF POSTSYNAPTIC BUT NOT PRESYNAPTIC DOPAMINE RECEPTORS BY DIHYDREXIDINE, A POTENT D1 AND D2 RECEPTOR LIGAND. N.F.Nichols,* P.J.K.D.Schreur, M.W.Smith, W.E.Hoffmann, D.E.Nichols and M.F.Piercey, The Upjohn Co., Kalamazoo, MI 49001, Purdue U., W. Lafayette, IN 47906.

Mottola et al. (Neurosci. Abs. 17:818) found that the D1 agonist dihydrexidine (DX) weakly bound to D2 receptors, using radiolabeled spiperone, a D2 antagonist, as a D2 receptor marker. Like D2 agonists, DX depressed tyrosine hydroxylase, but this was not altered by D2 antagonists. In binding tests, we find that DX had higher affinity for D2 receptors (Ki=3.3 nM vs ^{3}H-U-86170, a dopamine [DA] agonist) than for D1 sites (Ki=38.5 nM vs ^{3}H-SCH 23390) and α-2 sites (Ki-62.5 nM vs ^{3}H-clonidine). In reserpinized mice, doses ≥1.0 mg/kg i.p. stimulated locomotor activity similar to other D2 agonists. This effect was blocked by the D2 antagonist raclopride (1 mg/kg s.c.). However, unlike other D2 agonists, DX, 0.1, 1.0, and 10.0 mg/kg i.p. did not block amphetamine-induced locomotor activity in non-reserpinized mice. It did not alter firing rates of DA neurons in substantia nigra pars compacta (SNPC) with doses up to 3 mg/kg i.v. (apomorphine ED50=.009 mg/kg i.v.), nor did it antagonize DA agonists effects in SNPC. In summary, DX behaves like a D2 agonist with some affinity also for D1 receptors, similar to apomorphine. However, it does not stimulate or block the DA autoreceptor, a D2 binding site.

491.2

EFFECTS OF DEPRENYL ON DOPAMINERGIC NEUROTRANSMISSION IN THE RAT MESOSTRIATAL SYSTEM. [1]M. Savasta*, [1]M. Chritin, [2]P. Assouly, [2]H.C. Neuckirch, [2]F. Bougeard, [1]E. Beurriand, [1]M. Manier, [1]P. Pollak and [1]C. Feuerstein. 1. INSERM-LAPSEN U.318, Pavillon de Neurologie, CHU de Grenoble, BP 217, 38043 Grenoble cedex 9, France. 2. SCHERING PLOUGH, 92 Rue Baudin, 92307 Levallois Perret cedex, Fance.

Deprenyl, a monoamine oxidase B inhibitor, has been reported to delay the initiation of levodopa therapy in patients with Parkinson's disease (PD), although the slowing of the progress of PD caused by the drug remains controversial. The present experiments were undertaken in order to examine the influence of this drug on mesostriatal dopaminergic neurotransmission in control and 6-OHDA-denervated rats.

We studied the effect of chronic treatment by deprenyl (0.25mg/Kg, s.c./day) for 15 and 30 days on striatal DA, DOPAC and TH contents, on D_1 and D_2 DA receptor striatal densities and on D_2 mRNA levels in two groups of rats (G_{15} and G_{30}) according to the delay of treatment. Each group was composed of shams (n=8), shams + deprenyl (n=10), 6-OHDA lesioned (n=6) and 6-OHDA lesioned + Deprenyl (n=10). Striatal levels of : DA and the metabolite DOPAC were determined by HPLC-EC ; DA D_1 and D_2 receptors were measured by autoradiography, using [^{3}H]SCH 23390 and [^{3}H]Raclopride respectively as ligands ; D_2 mRNAs were examined by in situ hybridization using a specific oligonucleotide ; TH was studied by radioimmuno-histochemistry. The results obtained showed that :

- striatal DA levels were significantly increased (+70%) in shams+deprenyl animals of G_{30} group. In lesioned animals where more than 90% of DA neurons were destroyed, no consistant effect could be defined ;
- the effects of deprenyl on D_2 receptor expression are clear only after 15 days of treatment. These effects concerned, firstly, shams+deprenyl animals where striatal D_2 receptor densities were significantly increased (18 to 25%, $p<0.001$) as compared to shams ; secondly, lesioned+deprenyl animals where D_2 mRNAs levels were increased by 12 to 17 % ($p<0.01$) as compared to lesioned rats. No effect could be observed for either striatal D_1 receptors and TH levels.

491.3

D_2 DOPAMINE RECEPTOR TURNOVER AND mRNA LEVELS IN THE NEUROLEPTIC-RESPONSIVE (NR) AND NEUROLEPTIC NON-RESPONSIVE (NNR) LINES OF MICE. **Y. Qian*, B. Hitzemann, G. Yount, J. White and R. Hitzemann . Dept.'s of Psychiatry and Neurobiology, Div. of Endocrinology, SUNY at Stony Brook, NY 11794.**

The NR and NNR lines of mice differ >10 fold in their sensitivity (ED_{50s}) to catalepsy induced by neuroleptics with a high D_2/D_1 dopamine receptor activity profile. Recovery of pre- and postsynaptic D_2 receptors was assessed by quantitative receptor autoradiography following *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) blockade. Significant differences in receptor turnover were found between the two lines in the nucleus accumbens (NA) and the caudate putamen (CPu), but not in the substantia nigra zona compacta (SNc) and the ventral tegmental area (VTA). For both lines, receptor production rates in the NA and CPu are higher than those in the SNc and VTA. For the NA and CPu, receptor production rates of the NNR line were lower than those of the NR line. Preliminary nuclease protection data show that such receptor turnover differences are associated with parallel differences in the D_2 receptor mRNA level.

491.4

USE OF BXD RECOMBINANT INBRED MICE TO DETECT GENOMIC MARKERS FOR NEUROLEPTIC SENSITIVITY. S.J. Kanes*, B. Hitzemann, T. Phillips, J. Belknap, J. Crabbe and R. Hitzemann, Departments of Psychiatry and Pharmacology, SUNY at Stony Brook, NY 11794-8101 and VAMC, Portland, OR 97201.

Our laboratory has used selective breeding and standard inbred strains to investigate the biochemical and genetic factors associated with response and non-response to neuroleptic induced catalepsy (see e.g. Kanes et al., Soc. Neurosci. Abst.# 539.6, 1991). The study of recombinant inbred mouse strains provides a mechanism for detecting linkage between the phenotype of interest and specific Quantitative Trait Loci (QTL). The strain distribution pattern (SDP) for the haloperidol ED_{50} in 18 strains of the BXD recombinant inbred series (RI) has been determined. ED_{50}'s in the RI strains are normally distributed confirming that sensitivity to neuroleptic induced catalepsy is a polygenic quantitative trait. This SDP was correlated with the SDP of 360 genomic markers mapped in the BXD's. This analysis indicates 14 markers significantly associated with the catalepsy SDP. Eight markers were found on chromosome 4, six of which were centered on FV-1, which lies 76 cM from the centromere. Correlated responses to neuroleptic-catalepsy include the density of pre and post-synaptic D_2 receptors, the density of midbrain DA neurons and the density of striatal cholinergic neurons. The SDPs for these responses and the associated QTL analysis will be presented.

491.5

CHOLINERGIC AND DOPAMINERGIC REGULATION OF NEUROLEPTIC RESPONSE IN SELECTED AND INBRED STRAINS OF MICE. B. Hitzemann, S. Kanes, Y. Qian and R. Hitzemann* Departments of Psychiatry, Pharmacology and Neurobiology SUNY at Stony Brook, NY 11794-8101 and VAMC, Northport, NY 11768.

The successful selection of the neuroleptic responsive (NR) and neuroleptic non-responsive (NNR) lines of mice (Hitzemann et al. 1991) and the marked variation in neuroleptic sensitivity among inbred strains of mice (Kanes et al. 1991) argues strongly that genetic mechanisms contribute significantly to the variance in neuroleptic-induced catalepsy. The precise nature or extent of these mechanisms remains unclear. Given the well established role of the striatal cholinergic system in regulating extrapyramidal neuroleptic responses, we have investigated striatal cholinergic cell number [choline acetyltransferase (ChAT) positive neurons] in the NR and NNR lines and 8 inbred strains. In comparison to the NNR line, cholinergic cell number is significantly increased 40 to 60% in the rostral but not caudal striatum. Similarly, we have found that among the inbred strains there is a significant correlation ($r = -0.75$ or better, $p < 0.05$) between the ED_{50} for haloperidol-induced catalepsy and cholinergic cell number in both the rostral and caudal striatum. Focusing on the rostral striatum, there is no difference between the NR and NNR lines in D_2 dopamine receptor density; however, for the inbred strains, D_2 receptor density is inversely correlated ($r = -0.72$, $p < 0.05$) to cholinergic cell number. This difference between the selected and inbred lines argues that D_2 receptor and cholinergic cell number can have independent genetic regulation within the striatum.

491.6

PHARMACOLOGICAL CHARACTERIZATION OF HUMAN DOPAMINE D_{2A}, D_{2B} AND D_3 RECEPTORS. Å.H. Malmberg[1], D.M. Jackson*[1], U. Hacksell[1,2], A.M. Johansson[2], A-M. Eriksson[1], N.A. Mohell[1] Astra Arcus AB, S-151 85 SÖDERTÄLJE, Sweden[1] and Department of Organic Pharmaceutical Chemistry, Uppsala Biomedical Center, Uppsala University, S-751 23 UPPSALA, Sweden[2].

The genes coding for six subtypes of dopamine (DA) receptors have recently been characterized and expressed in various cell lines. In this study we have compared the pharmacological properties of the human D_3 receptor with the two alternatively spliced forms of the human D_2 receptor, D_{2A} (long) and D_{2B} (short). The D_3 receptor was expressed in hamster ovary cells and the D_2 receptors in mouse fibroblasts. In vitro radioligand binding studies demonstrated that the benzamide radioligands [^{3}H]raclopride and [^{125}I]NCQ298 bound with high affinity, saturability and low non-specific binding to the three DA receptor subtypes. The K_d (dissociation constant) values of [^{3}H]raclopride for D_{2A}, D_{2B} and D_3 were 1.41, 0.77 and 1.58 nM, and the K_d values of [^{125}I]NCQ298 for D_{2A} and D_3 were 31 and 17 pM, respectively. As expected the binding of the benzamide radioligands was regulated by sodium ions. In competition studies most of the antagonists tested showed about equal affinities for the three DA receptor subtypes. However, remoxipride and spiperone had ten fold lower affinity, and some 2-aminotetralin derivates twenty fold higher affinity for D_3 than D_2 receptors. Among agonists DA, quinpirole and several 2-aminotetralin derivates displayed up to fifty fold higher potencies at D_3 receptors. Two affinity states for DA and quinpirole were observed in all three subtypes. It is concluded that in spite of the high level of homology in transmembrane (ligang binding) domains it is possible to obtain D_2/D_3 selective drugs that migth prove useful for development of antipsychotics.

EFFECTS OF D2 AND D3 RECEPTOR ACTIVATION MEASURED BY MICROPHYSIOMETRY. M.P. Rosser,*M.R. Kozlowski, R.L. Neve, and K.A. Neve. Screening and Biochemical Research, Bristol-Myers Squibb, Wallingford, CT 06492; Molecular Neurogenetics Laboratory, McLean Hospital, Belmont, MA 02178; Research Service, VA Medical Center, Portland, OR 97207.

The dopamine (DA) D3 receptor is a novel binding site for DA, first identified by cloning and expression of a novel cDNA from rat brain. The D3 receptor has been classified as a subtype of the D2 receptor based on its D2-like pharmacological profile and its sequence homology to D2 receptors. C_6 glioma cells transfected with the rat cDNA for the D3 receptor expressed, at a density of 200-300fmol/mg protein, a binding site with high affinity for ^{125}I-epidepride and low affinity for D2 antagonists. These characteristics are consistent with the expression of a D3 receptor. A silicon microphysiometer (Molecular Devices) was used to compare second messenger responses to stimulation of D2 and D3 receptors. The DA agonist, quinpirole, causes an increase in the rate of acid extrusion in cell lines expressing recombinant D2 receptor. The response is inhibited by amiloride and amiloride analogs selective for the Na^+/H^+ antiporter, but not affected by pertussis toxin. D2 receptor stimulation, therefore, appears to accelerate Na^+/H^+ exchange via a pathway that does not involve inhibition of adenylyl cyclase or pertussis toxin sensitive G proteins. In the presence of quinpirole, C_6 cells expressing recombinant D3 receptors also increased their rate of acid extrusion. As with D2-expressing cells, this increase was inhibited by amiloride and its analogs, suggesting that D3 receptor stimulation also activates a Na^+/H^+ antiporter. This is the first report of a functional response to stimulation of D3 receptors.

INTERNAL ACCEPTOR SITE DIRECTS ALTERNATIVE SPLICING IN THE MOUSE D_3 DOPAMINE RECEPTOR. Fishburn C.S., David C., Carmon S. and Fuchs S*. Dept. of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel.

Dopamine receptors have been implicated in several neuropathological conditions. A number of receptor subtypes are recognised, and their respective roles in normal brain function and in neurological disorders may be advanced by the availability of cloned receptor cDNA forms. We have cloned the mouse D3 dopamine receptor from olfactory tubercle cDNA using PCR, and have found it to exist in two alternatively spliced forms. These two mRNA isoforms differ by the presence of 63bp, which encode 21 amino acids in the putative third cytoplasmic loop of the receptor. The longer form bears sequence homology of 94% to the rat D_3 dopamine receptor. We have also found alternative splicing to occur in the rat D_3 receptor. Using PCR analysis on different mouse brain regions, we have shown the long and short D_3 receptors to be present in the same tissues, the longer form invariably being the predominant one. Analysis of the gene for the mouse D3 dopamine receptor revealed an acceptor site at the 3' end of the 63bp stretch. This suggests that the alternatively spliced shorter D_3 mRNA isoform may be the result of splicing at this alternative acceptor site. It therefore appears that the D 3 receptor undergoes alternative splicing in the third cytoplasmic loop, in a region similar to the location of the splicing reported to occur for the D_2 dopamine receptor.

CHARACTERIZATION OF THE HUMAN D3 DOPAMINE RECEPTOR EXPRESSED IN TRANSFECTED MAMMALIAN CELL LINES. **R.G. MacKenzie*, D. VanLeeuwen, T.A. Pugsley, P. Boxer, L. Tang++, R.D. Todd+ and K.L. O'Malley++, Dept. Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48106, +Dept. Psychiatry, ++Dept. Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.**

CHO-K1, human neuroblastoma SK-N-MC and SK-N-Be(2), mouse fibroblast CCL1.3 and rat glioma/mouse hybrid NG108-15 cells were transfected with a pcDNAI/neo vector containing the cDNA of the human D3 dopamine receptor. Transfection of the CHO-K1 and SK-N-MC cells resulted in high expression of the D3 receptor (>1 pmol receptor/mg membrane protein) as evidenced by radioligand binding assays. In the CHO-K1-D3 cells, a small guanine nucleotide shift was noted for dopamine binding but all other tests for D3 function were negative, including inhibition of forskolin-stimulated cAMP generation, [3H]thymidine uptake as a measure of mitogenesis and Ca2+ flux in single cells containing the Ca2+-sensitive dye, FURA-2. Stable transfectants of CCL1.3 (≈500 fmoles/mg membrane protein) exhibited the expected D3 pharmacological profile. However, there was no guanine nucleotide-induced shift of dopamine binding, no effect of receptor activation on adenylyl cyclase activity and no inositol phosphate responses. In contrast, D2 receptors expressed in CCL1.3 cells inhibited adenylyl cyclase and increased inositol phosphate metabolism. Therefore, D3 receptors do not appear to couple to the same G-protein(s) as do D2 receptors. Experiments testing the function of the D3 receptor in other cell lines are in progress.

491.10

CHARACTERIZATION AND REGULATION OF DOPAMINE D3 RECEPTORS. B.A. Cox*, R.A. Henningsen, K. Duwe, R.L.Neve, and K.A. Neve, VA Medical Center and Oregon Health Sciences University, Portland, OR 97213, and McLean Hospital, Belmont, MA.

The dopamine (DA) D3 receptor is a novel D2-like receptor whose pharmacological profile differs from that of DA D2 receptors. We have stably expressed D3 receptors in C6 glioma cells (C6-D3) and have characterized their binding using the radioligand [^{125}I]epidepride, which has high affinity (60-100 pM) for D3 receptors. Drug potencies in rat basal forebrain minus neostriatum (BF) were compared to those using tissue from rat neostriatum (NS), and recombinant D3 (C6-D3) and D2 (C6-D2) receptors. Two site analysis of the data indicated that a small population (11-20%) of binding sites in rat BF a pharmacological profile similar to that of C6-D3 receptors. For neostriatum, however, curves are best fit to only one site.

	IC_{50}, in nM (n=3-4)				
Drug	C6-D3	BF-D3	BF-D2	NS	C6-D2
quinpirole	198	59	11700	10700	11000
spiperone	6	3.5	0.16	0.17	0.32
domperidone	117	125	2.5	3.4	3.4

Treating C6-D3 cells with agonists caused a concentration-dependent increase in the density of D3 receptors. Maximal increases observed, as determined by saturation analysis using [^{125}I]epidepride, were over 500% for DA and NPA and 373% for quinpirole. Increases were not prevented by treatment with pertussis toxin. (MH45372)

491.11

THE D_3 ANTAGONIST, AJ76, INCREASES ACCUMBENS DOPAMINE AND SEROTONIN RELEASE: SIMULTANEOUS DETECTION *ON LINE* WITH BEHAVIOR. F. Eng*, F.T. Phelan, R.T. Wechsler, M.F. Piercey[1] and P.A. Broderick. Dept. Pharmacol., CUNY Med. Sch., Convent Ave. & W. 138th St., NY, NY 10031, USA, CNS Res., The Upjohn Co.[1], Kalamazoo, MI 49007, USA.

AJ76 is a dopaminergic (DA-ergic), antagonist with a higher affinity for the D_3 than the D_2 receptor (Sokoloff *et al., Nature* 347:146; 1990). AJ76 is a weak stimulant due to DA autoreceptor antagonism (Svensson, *et al., J. Neural Transm.* 65:1; 1986), with preferential activity at the nerve terminal (Piercey and Lum, *Eur. J. Pharmacol.* 282: 219; 1990). AJ76 increases Ca^{++} dependent DA release (Waters *et al., Eur. J. Pharmacol.* 187:425; 1990). We now study the effects of AJ76 on concurrent accumbens (NAcc) release of DA and serotonin (5-HT) with *in vivo* electrochemistry. Simultaneously, activity patterns were studied by infrared photocell beam detection. Stearate working microelectrodes (Broderick, P.A., *Brain Res.* 495:115,1989) were implanted in NAcc, under Na pentobarbital anesthesia; 9-15 recovery days were allowed. The results show that AJ76 increased both DA and 5-HT release, while concomitantly increasing locomotor activity, rearing behavior, stereotypy and agoraphobic inhibitory behavior (central ambulations). While DA release remained above baseline in the second hour, 5-HT release in concert with behaviors, decreased to baseline values or below. Thus, AJ76 maintains an upregulated DA release while 5-HT and behavioral stimulant components subside, without sedation. Consistent with electrophysiological data (Piercey *et al., Neurosci. Abstr.* 15:1234; 1989), the data demonstrate that AJ76 may have an autoreceptor antagonist mechanism for 5-HT. [Supp: in part Upjohn Co. RF #7-76207].

491.12

MICRODIALYSIS STUDIES OF DOPAMINE (DA) SYNTHESIS IN VIVO: EFFECTS OF D_2/D_3 PREFERRING AGONISTS AND ANTAGONISTS

S. Benloucif* and M.P. Galloway. Cell. and Clin. Neurobiol. Program, Dept. Psychiatry, Wayne State Univ. Sch. of Med., Lafayette Clinic, Detroit, MI 48207.

To investigate the regulation of DA synthesis in vivo, we used microdialysis to measure striatal DOPA accumulation after perfusion with the aromatic amino acid decarboxylase inhibitor NSD-1015 (m-hydroxybenzylamine)[1]. D_2 and D_3 receptor preferring agonists and antagonists were perfused through concentric type microdialysis probes located in the anterior lateral striata of chloral hydrate anesthetized rats beginning 40 min. before perfusion of NSD. For each subject, probes were inserted bilaterally and levels of Dopa were compared with control responses from the contralateral striatum. Data are presented as the ratio of Dopa levels in drug-treated fractions over Dopa levels in the control striatum. Perfusion with NSD-1015 (100 μM) increased levels of Dopa to 24 ± 2.8 pg/μl in dialysate from control striata at 2 hr. (n = 12). Agonists and antagonists were chosen for their relative D_3 and D_2 receptor selectivity, based on K_i values reported by Sokaloff et al.[2] Perfusion with the DA agonist quinpirole (10 μM) (K_{iD2}/K_{iD3} = 113) resulted in a treated/untreated ratio of 0.63 ± 0.04. Perfusion with the non-selective DA agonist apomorphine (10 μM) (K_{iD2}/K_{iD3} = 1.2) resulted in a ratio of 0.70 ± 0.03. Co-perfusion of the D_2 preferring antagonist haloperidol (30 μM) (K_{iD2}/K_{iD3} = 0.046) with apomorphine resulted in a ratio of 1.04 ± 0.17. Co-perfusion of the D_3 preferring antagonist (+)UH232 (K_{iD2}/K_{iD3} = 4.4) with apomorphine resulted in a ratio of 1.21 ± 0.47. Thus, administration of either D_2 or D_3 preferring agonists decreases DA synthesis in a DA antagonist sensitive manner. These preliminary results (n = 3/group) suggest that microdialysis can be used to determine the relative influence of D_2 and D_3 receptor stimulation on both DA synthesis and release in vivo. [1]Westerink et al., J. Neurochem., (1990) 54:381; [2]Sokoloff et al., Nature, (1990) 347:146. (Supported by DA-04120, and the Mich. Dept. of Mental Health).

COMPARISON OF DOPAMINE- D2 AND D3 AGONISTS AND ANTAGONISTS [(+)UH-232] AT SYNTHESIS MODULATING DA AUTORECEPTORS in vitro. M.P. Galloway*, M.J. Keegan, and S. Benloucif, Cellular & Clinical Neurobiology, Wayne State Univ Sch Med, Detroit, MI 48207 USA

The recent discovery that mRNA levels for the dopamine (DA)-D3 receptor subtype are sensitive to 6-OHDA lesions suggests that expressed D3 receptors may function as DA autoreceptors. Since DA autoreceptors are defined functionally according to the function they regulate (i.e., DA synthesis, release, and cell firing), we have investigated the effects of D3-preferring agonists (7-OHDPAT) and antagonists [(+)UH232, (+)AJ76] at the DA synthesis modulating autoreceptor. Using the accumulation of DOPA in the presence of the decarboxylase inhibitor NSD1015 as a measure of tyrosine hydroxylation in K^+-stimulated (30mM) striatal slices, we found potent and efficacious agonist activity of monohydroxylated aminotetralins such as 7-OHDPAT and 5-OHDPAT. The DA agonist effects (0.3 μM) were fully reversed by (+)UH232, (+)AJ76, sulpiride, clozapine, haloperidol, and eticlopride. The calculated (Gaddum equation) equilibrium dissociation constant (K_B) for the antagonists at the DA autoreceptor were determined in the presence of 7-OHDPAT: HAL = 3nM, ETIC = 19nM, (-)SULP = 81nM, (+)UH232 = 112nM, clozapine = 427nM, and AJ76 = 1.8μM. In the presence of either 5 mM K^+ or forskolin (10μM), K_B values for (+)UH232 or SULP increased approximately 10 fold suggesting that anatagonist potency in vitro is enhanced by elevated levels of extracellular DA. Comparison of these data with kinetic parameters (K_i) derived from ligand binding studies may elucidate a functional role for D3-DA receptors. Supported by MI Dept of Mental Health and NIDA R01-04120 (MPG).

IODINATED 7-OH-DPAT: A POTENTIAL LIGAND FOR THE D3 DOPAMINE RECEPTORS. C. Foulon, M-P Kung, J. Billings, V.A. Boundy, P.B. Molinoff, and H.F. Kung*. Depts. of Radiology, Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104

Recent success in cloning the D3 dopamine receptors and defining its properties has generated significant interest in developing new ligands for *in vivo* and *in vitro* studies of this receptor subtype. D3 selective ligands could be useful as pharmacological tools and therapeutic agents. Quinpirole, AJ76, UH232 and 7-OH-DPAT have been reported to be D3 selective. Among them, 7-OH-DPAT appears to show highest affinity (Kd=0.7nM) and selectivity (ratio for Ki of D2/D3>100). 7-OH-DPAT was synthesized according to the published method, and iodination produced the corresponding 6-iodo-7-OH-DPAT(racemic). Spectra, HPLC and elemental analysis are consistent with the expected chemical structure. In *in vitro* binding assays using [^{125}I]NCQ 298 showed similar affinity for D2 (rat striatal membrane) and D3 (membranes are from Sf9 cells infected with a recombinant baculovirus containing the rat D3 gene) The Ki values for D3 receptors were 0.7±0.18 and 12±1.8 nM for 7-OH-DPAT and 6-I-7-OH-DPAT, respectively; while the Ki values for D2 were 156±17 and 264±33 nM, respectively. Adding the iodine atom clearly decreases the D3 affinity of 7-OH-DPAT by 17-fold. Nonetheless, the 6-I-7-OH-DPAT retained D3 selectivity. Radioiodination was accomplished by reacting sodium [^{125}I]iodide in the presence of peracetic acid as the oxidant. *In vivo* biodistribution studies in rats indicated that the 6-[^{125}I]I-7-OH-DPAT crosses the blood-brain barrier easily. Further studies are needed to validate the nature of brain localization. It appears that the 6-[^{125}I]I-7-OH-DPAT may be a useful agent and warrants further evaluation. CLONING OF THE HUMAN DOPAMINE D3 RECEPTOR AND ITS EXPRESSION AND PHARMACOLOGICAL CHARACTERIZATION IN A VARIETY OF MAMMALIAN CELL LINES. R.A. Horlick, D.S. Conklin, D.G. Grigoriadis, G.M. Cooke, K.D. Cornwell, S. Hutton, E.B. DeSouza and B.G. Sahagan*. CNS Research and Biotechnology Dept., The DuPont Merck Pharmaceuticals Co., Wilmington, DE. 19880-0400

Dopamine receptors are thought to play a key role in the clinical manifestations and treatment of psychoses including schizophrenia. The discovery of multiple dopamine receptors offers new tools for the development of receptor subtype-specific ligands that will effectively ameliorate psychotic symptoms without unwanted extrapyramidal or neuroendocrine side-effects. The dopamine D3 receptor, identified by molecular cloning (*Nature* **347**:146,1990), has an unique localization in the brain. Its presence in areas of the brain linked to the limbic regions and its absence from the pituitary make it a likely target for antipsychotic drug activity without the generation of undesirable side-effects. Here we describe the cloning of the human dopamine D3 receptor from human nucleus accumbens cDNA using PCR. The receptor was introduced into a panel of mammalian cell lines: CHO (Chinese Hamster ovary epithelial cells), 293 (Human embryonic kidney cells), Ltk- (murine fibroblast cells), and GH4C1 (rat pituitary lactotroph cell). The relative levels of expression of the D3 receptor in CHO, 293 and Ltk- cells are as follows: 12,500, 625, and 250 fmol/mg of protein. In all four backgrounds, the receptor exhibited [3H]spiperone binding which was saturable, membrane concentration dependent, temperature dependent, stereoselective and of high affinity. These four dopamine D3 receptor lines exhibit dopaminergic pharmacology with the appropriate rank-order profile for dopamine receptors.

ACUTE AUTONOMIC EFFECTS OF D,L-HOMOCYSTEIC ACID LESIONS OF THE INSULAR CORTEX IN SPONTANEOUSLY HYPERTENSIVE AND WISTAR RATS. K.S. Butcher*, V.C. Hachinski and D.F. Cechetto. Robarts Research Institute, University of Western Ontario, London, Ontario, Canada N6A 5K8.

Middle cerebral artery occlusion (MCAO) results in an acute increase in sympathetic activity in Wistar rats, and a decrease in spontaneously hypertensive rats (SHR). There is evidence to suggest that these autonomic changes are due to damage of the insular cortex (IC). The IC was selectively lesioned, using D,L homocysteic acid (DLH; 1 M), in urethane-anesthetized Wistar and SHR rats. Arterial pressure (AP), heart rate (HR), renal sympathetic nerve discharge (SND), and ECG were measured in male SHR (12) and Wistar (12) rats, following a 500 nL injection of DLH or saline control into the IC. Initial AP and SND were not significantly different in SHR (85 ± 3 mmHg; 27 ± 9 $\mu v \cdot s$) and Wistar rats (78 ± 3 mmHg; 26 ± 9 $\mu v \cdot s$). Wistar HR (375 ± 11) was initially higher than that of SHR (319 ± 10; $p<0.05$). In the SHR, AP rose continuously in control animals, and was significantly greater than initial, as well as IC lesioned rats, by 3 hr after injection. SND did not change in SHR control animals, but declined significantly in IC lesioned rats, by 3 hr after DLH injection. HR increased in both groups of SHR. The pattern of changes was different in Wistar rats. IC lesion, in Wistar, resulted in a significant increase in AP by 4 hr after DLH injection. There was no change in the AP or SND of Wistar controls. HR increased in both Wistar groups. IC lesion appears to result in a fall in sympathetic activity in the SHR and a pressor response in the Wistar rat. This suggests that the IC is at least partially mediating the autonomic responses to MCAO. (Supported by HSFC and HSFO)

CARDIOVASCULAR RESPONSES TO NEURONAL ACTIVATION OF THE EXTENDED AMYGDALA IN ANESTHETIZED AND CONSCIOUS RATS. A.J. Gelsema*, N.E. Copeland, G. Drolet and H. Bachelard. Hypertension Unit, University of Ottawa Heart Institute, Ottawa, and Unité d'Hypertension du CHUL, Université Laval, Québec, CANADA.

The bed nucleus of the stria terminalis (BNST) and sublenticular substantia innominata (SLSI) are considered rostral extensions of the amygdaloid nuclei, but their involvement in cardiovascular control has not been studied. We explored these areas systematically in 27 spontaneously breathing, urethan-anesthetized Wistar rats for sites from where changes in arterial pressure (AP) and heart rate (HR) could be obtained by injection of 20 nL glutamate (Glu, 0.5M). Injections into 84 of the 130 histologically verified sites in the BNST and SLSI were followed after a 8.0 ± 0.7 s. latency by depressor responses ranging from -4 to -33 (mean -13.3 ± 0.8) mmHg, accompanied by variable changes in HR. Pressor responses (4.5 ± 1.3 mmHg) were found after stimulation of only three sites; 43 sites were not responsive. Depressor responses evoked by stimulation in 17 sites in 6 rats before and during paralysis and artificial ventilation were not significantly different ($p>.05$).

A different group of 10 rats was instrumented for bilateral Glu injections (200 nL, 0.1M) into the lateral BNST and for the recording of AP, HR and regional blood flow (using pulsed Doppler flow probes) in the conscious state. Decreases in AP (-10.2 ± 1.6 mmHg) were elicited exclusively, accompanied by small (9.8 ± 4.4 bpm) increases in HR and renal conductance ($11.1 \pm 2.2\%$) and larger ($32.2 \pm 11.3\%$) increases in hindquarter conductance, while mesenteric conductance decreased by $7.9 \pm 3.7\%$.

These results suggest that the BNST and SLSI may participate in the cardiovascular correlates of the defense reaction.

CHANGES IN THE NEUROCHEMICAL ORGANIZATION OF FOREBRAIN AUTONOMIC SITES FOLLOWING FOCAL CEREBRAL ISCHEMIA. G.V. Allen*, M.A. DiCarlo and D.F. Cechetto. Robarts Research Institute, University of Western Ontario, London, Ontario, Canada, N6A 5K8.

Occlusion of the middle cerebral artery (MCAO) at the level of the rhinal fissure in anesthetized rats mimics the cardiovascular abnormalities that are observed in patients following focal cerebral ischemia. The stroke-induced autonomic symptoms may be due to pathophysiological changes that occur centrally following brain ischemia. MCAO or sham MCAO was done in pentobarbital-anesthetized male, Wistar rats. Five days after MCAO, the animals were perfused and reacted for the immunohistochemical demonstration of neuropeptide-Y (NPY), leu-enkephalin (leu-ENK) and neurotensin (NT) using the diaminobenzidine reaction. A computerized-microscopic imagine system was used to quantify differences in staining between the two sides of the MCAO brains and between the MCAO rats and sham animals. A three-fold increase in the density of NPY labeled fibers and terminals was observed in the insular cortex and basolateral amygdala ipsilateral to the MCAO compared to that of the contralateral side and sham-operated controls. In the central nucleus of the amygdala, two to three-fold increases in NT and leu-ENK labeled fibers and terminals were also observed ipsilateral to the MCAO. The marked changes in the neurochemical organization of the insular cortex and amygdala following MCAO may underly the autonomic changes that occur following MCAO in the rat and the similar effects observed clinically. (Supported by HSFC and MRC).

492.4

Fos IMMUNOREACTIVITY IN RAT BRAIN ELICITED BY ELECTRICAL STIMULATION OF THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS. K.H. Harris*, J.H. Jhamandas, and T.L. Krukoff. Depts. of Medicine (Neurology) and Anatomy & Cell Biology, Univ. of Alberta, Edmonton, Canada T6G 2E1.

To further study the role of the paraventricular nucleus (PVN) in autonomic regulation, Fos-immunoreactivity (Fos-ir) was examined as a marker of neuronal activiation after electrical stimulation of the PVN. In urethane-anesthetized rats, the PVN was unilaterally stimulated (25-40 V, 10 sec pulsed trains, 20 Hz, 100 μsec duration) for 1-2 h so that arterial pressure (AP) was elevated 10-25 mm Hg. In control rats, the electrode was placed in the PVN, current was passed briefly to verify placement with AP changes, and current then discontinued. PVN stimulation led to ipsilateral induction of Fos-ir in piriform cortex, insular cortex, medial amygdala, lateral septum, and several hypothalamic nuclei (medial preoptic area, anterior, arcuate, posterior, dorsomedial, ventromedial). In control rats, increases in Fos-ir were found in the ipsilateral piriform cortex and insular cortex. To assess whether increases in Fos-ir were due to ortho- or antidromic stimulation of neurons, PVN magnocellular neurosecretory cells (MNCs) were antidromically activated following pulsed electrical stimulation of their terminals within the neurohypophysis. Preliminary data indicate that there are no differences in Fos-ir within MNCs between stimulated and control animals.

Our results suggest that electrical stimulation of the PVN leads to increases in Fos-ir in many forebrain areas known to receive projections from the PVN. Our data from anesthetized rats also suggest that changes are due to orthodromic stimulation of target neurons and not to antidromic stimulation of inputs to PVN.

ELECTROPHYSIOLOGICAL AND ANATOMICAL CHARACTERIZATION OF A PROJECTION FROM THE PARABRACHIAL NUCLEUS TO THE DIAGONAL BAND OF BROCA IN THE RAT. J.C. Easaw*, T. Petrov, and J.H. Jhamandas. Depts. of Medicine (Neurology) and Anatomy and Cell Biology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E1.

The brainstem parabrachial nucleus (PBN) is viewed as an important site for the transfer of cardiovascular-related information from peripheral receptors to the forebrain. Anatomical and electrophysiological methods were utilized in this study to characterize the projection from the PBN to the diagonal band of Broca (DB) a forebrain nucleus implicated in central autonomic regulation.

Rats received iontophoretic injections of the anterograde tracer phaseolus vulgaris leucoagglutinin (PHA-L) in the PBN region. After 14-17 days, the DB from perfused brains was immunocytochemically processed for detection of PHA-L fibers and choline acetyltransferase (ChAT), a synthesizing enzyme for cholinergic neurons. PHA-L fibers with axonal varicosities and boutons were observed to course over ChAT-positive neurons in both the horizontal and vertical limbs of the DB. Extracellular recordings from 348 DB cells revealed both excitatory and inhibitory responses following electrical stimulation in the PBN. 25% (93/348) of DB neurons displayed an increase in excitability (latency 38.81 ± -2.67 ms; duration 47.98 ± 2.97 ms), whereas, 6% (23/348) exhibited a depressant response (latency 28.39 ± 3.69 ms; duration 70.59 ± 13.59 ms) consequent to the PBN stimulus.

These data provide evidence for a predominantly excitatory projection from the PBN to the DB and a portion of this input appears directed towards cholinergic neurons.

PARABRACHIAL NUCLEUS PROJECTION TO THE AMYGDALA IN THE RAT: ELECTROPHYSIOLOGICAL AND ANATOMICAL OBSERVATIONS. J.H. Jhamandas*, K.H. Harris, T. Petrov, T. Vu and T.L. Krukoff. Depts. of Medicine (Neurology) and Anatomy & Cell Biology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E1.

The pontine parabrachial nucleus (PBN) is a major relay for the transmission of autonomic inputs to the forebrain. This study describes the synaptic responses evoked within the amygdala (AMYG) following activation of PBN efferents and the chemical identity of AMYG target neurons that receive PBN projections.

Extracellular recordings from 152 AMYG neurons in anaesthetized rats revealed a set of complex synaptic responses following electrical stimulation in the PBN. 47 cells displayed a short duration (34.4 ± 2.0 ms) excitatory response while 30 cells demonstrated a long duration (158.1 ± 15.1 ms) excitation. Inhibitory responses were observed in 17 AMYG neurons. In 6 rats, iontophoretic injections of the anterograde tracer PHA-L were made in the PBN and after 14-18 days, the forebrains of perfused animals were processed immunocytochemically for visualization of PBN projections to AMYG neurons. PHA-L labelled fibers were found throughout the amygdaloid complex; within the lateral and medial subdivisions of the central nucleus of AMYG, fibers with axonal varicosities and boutons were observed coursing over galanin and neurotensin immunopositive neurons.

These results indicate that the PBN input to the AMYG is predominantly excitatory with a less frequently observed inhibitory component. Furthermore these projections are, in part, directed at identified peptidergic neurons.

NEUROCHEMICAL CHARACTERIZATION OF PONTINE NEURONS WITH COLLATERALS TO THE CENTRAL NUCLEUS OF THE AMYGDALA (CNA) AND THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS (PVN) IN THE RAT. T. Petrov*, J.H. Jhamandas, and T.L. Krukoff. Depts. of Anatomy and Cell Biology and Medicine (Neurology), Univ. of Alberta, Edmonton, Alberta, Canada T6G 2H7.

It is becoming increasingly clear that brainstem neurons have the potential to simultaneously innervate distant forebrain areas via branching collaterals. Within the nucleus of the solitary tract and the ventrolateral medulla catecholamines have been implicated in such pathways; in the dorsal raphe nucleus,serotonin (5-HT) neurons provide collateral inputs to various targets.

In the present study we examined transmitter- and peptide-containing pontine neurons that innervate, via branching collaterals, the CNA and PVN. Rats were stereotaxically injected with fluorescent labelled retrogradely transported latex microspheres (LLM). Rhodamine-LLM (R-LLM) and fluorescein-LLM (F-LLM) were injected in the CNA and in the PVN respectively. After 4-5 days a third fluorophore (AMCA-conjugated to anti-rabbit IgG) was used to detect substance P (SP), galanin (GAL), choline acetyltransferase (ChAT), tyrosine hydroxylase (TH) or 5-HT immunoreactivity in 40 μm thick pontine coronal sections.

Triple-labelled neuronal profiles containing both R-LLM and F-LLM that were immunopositive for TH or GAL were located in the locus coeruleus; ChAT or SP- in the laterodorsal tegmental nucleus; and 5-HT- in the dorsal raphe nucleus. These results suggest that there exist distinct pathways, originating in the pons that utilize neurotransmitters and neuropeptides to innervate simultaneously the CNA and the PVN. Such chemically specific circuits may selectively transmit and modulate autonomic- and pain-related information within the neuraxis. Supported by MRC and AHFMR.

DIRECT INNERVATION OF CIRCUMVENTRICULAR ORGANS BY ARCUATE NUCLEUS NEURONS. M.P. Rosas-Arellano* and J. Ciriello. Dept. of Physiology, Univ. of Western Ontario. London, Canada, N6A 5C1.

The arcuate nucleus (ARC) has been suggested to be involved in the regulation of the neuroendocrine and cardiovascular systems, and in body fluid balance. This study was done to investigate the innervation of the circumventricular organs (CVO's) by neurons in ARC using the anterograde tract-tracer Phaseolus vulgaris leuccoagglutinin (PHA-L; 2.5%) in combination with the immunocytochemical localization of atrial natriuretic peptide (ANP) in the rat. PHA-L was iontophoresed into either the dorsomedial (dm), ventromedial (vm) or ventrolateral Arc. After 9-14 days the rats were perfused transcardially and brain sections were processed using the double labelling immunofluorescence technique for identification of PHA-L and ANP. Projections from the dmARC and vmARC were observed to the subfornical organ (SFO), the organum vasculosum lamina terminalis (OVLT), the median eminence (ME), and the area postrema (AP). As the CVO's are midline structures, PHA-L labelled fibers and their presumptive terminals were found throughout these areas. A moderate number of these PHA-L fibers were also labelled for ANP in SFO, OVLT and ME. These data suggest that ARC neurons may be involved in modulating the function of CVO's with regards to drinking behavior, sodium excretion and release of vasopressin to systemic changes in circulating levels of Angiotensin II and plasma osmolality. THE EFFECTS OF CARDIOVASCULAR PERTURBATIONS ON NEURONS OF THE BED NUCLEUS OF THE STRIA TERMINALIS (BST). M.F.Wilkinson and Q.J.Pittman. K.E.Cooper*. Dept. of Med. Physiology, Univ. of Calgary, Calgary, Alberta, CANADA T2N 4N1.

Control of febrile body temperature and blood pressure homeostasis are two autonomic functions thought to involve the BST. Via the ventral septal area (VSA), BST neurons affect body temperature during febrile episodes. This pathway may be responsible for the antipyretic effect observed following hemorrhage. We investigated, using in vivo electrophysiology, the effects of blood pressure changes on BST neurons with projections to the VSA. In addition, BST projections to other limbic areas, namely the paraventricular nucleus (PVN) and the lateral habenula (HAB) were also investigated following blood pressure (bp) alterations. Single unit extracellular voltage recordings were made in the BST of urethane-anesthetized (1.5g/kg, ip) S-D rats. Cannulation of the femoral artery and veins were performed for the monitoring arterial bp and iv administration (or hemorrhage, 3mL) of pressor (angiotensin II, 100ng or methoxamine, 40ng) or depressor drugs (nitroprusside, 0.2mg), respectively. Bipolar stimulating electrodes were placed into the VSA, PVN and HAB to evoke antidromic or orthodromic potentials in BST neurons. 50 BST units were antidromically invaded following stimulation of the VSA (n=33), HAB (n=12) or PVN (n=5). No PVN projecting BST neurons responded to changes in bp. However, of the VSA projecting neurons, activity was altered in 19% following increases in bp and 24% following decreases in bp. 25% of HAB projecting BST neurons changed their firing rate following increases in bp and 11% responded to decreases in bp. We also observed bp sensitive BST units with orthodromic connectivity (approx. 20%) in all areas examined. These studies show that neurons of the BST are sensitive to changes in bp and that BST to VSA pathways may play a role in hemorrhage-induced antipyresis. It is also apparent that bp-sensitive BST units are modulated by input from a variety of limbic sources.

ELECTROPHYSIOLIGICAL AND MORPHOLOGICAL PROPERTIES OF CAUDAL HYPOTHALAMIC HYPOXIC- AND HYPERCAPNIC-SENSITIVE NEURONS *IN VITRO*. G.H. Dillon* and T.G. Waldrop. Dept. of Physiology and Biophysics, Neuroscience Program, and College of Medicine, University of Illinois, Urbana, IL 61801

We have reported previously that hypoxia and hypercapnia stimulate separate populations of caudal hypothalamic neurons in a brain slice preparation. The purpose of the present study was to examine the electrophysiological and morphological properties of these groups of neurons, as well as those neurons unexcited by either stimulus. 400-500 µm coronal slices were taken from Sprague-Dawley rats. Slices were placed in an interface chamber and perfused with nutrient media equilibrated with 95% O_2/5% CO_2. Whole-cell patch recordings were obtained during hypoxic (10% O_2/5% CO_2/85% N_2 or 5% CO_2/95% N_2) and hypercapnic (7% CO_2/93% O_2 or 10% CO_2/90% N_2) bouts. The fluorescent dye lucifer yellow was included in the tips of several electrodes for subsequent morphological analysis. Neurons activated by hypoxia (77% of cells studied) had a resting membrane potential (V_m) of 52.6±1.6 mV; peak input resistance (R_n) was 429.0±72.6 MΩ. Hypoxia elicited a significant depolarization (8.3±1.7 mV) with an accompanying decrease in R_n (to 84.0±5.4% of control) in excited neurons. Hypercapnia-stimulated neurons (35% of cells studied) tended to have a lower resting V_m (48.4±1.7 mV) and a lower R_n (353.1±60.4 MΩ) than those stimulated by hypoxia. CO_2 elicited a depolarization of 2.9±0.6 mV in stimulated cells. Neurons unexcited by either stimulus were electrophysiologically similar to hypoxia-stimulated neurons (V_m = 51.9±2.9 mV, R_n = 442.5±61.9 MΩ). Post-inhibitory rebound and inward rectification were present in all cell types. Hypoxia-stimulated neurons had typically 3-4 main projections, many with subsequent branching, from the cell body. Projections toward the third ventricle and/or ventral surface were common. We suggest electrophysiological, and possibly morphological, properties may underlie the different responses to hypoxia and hypercapnia seen in these cell populations. AFFERENT PROJECTIONS TO THE DORSOMEDIAL HYPOTHALAMIC AREA MEDIATING STRESS-INDUCED CARDIOVASCULAR CHANGES. T.J. Cavanagh* and J.A. DiMicco. R&D Division, Boehringer Mannheim Corp., and Prog. in Med. Neurobiol., Ind. Univ. Sch. of Med., Indianapolis IN 46202.

Previous studies suggest that neurons in the dorsomedial hypothalamus mediate stress-induced cardiovascular changes in rats. Blockade of inhibitory $GABA_A$ or stimulation of excitatory amino acid receptors in this region elicits cardiovascular effects resembling those caused by experimental stress. Conversely, stimulation of $GABA_A$ or blockade of excitatory amino acid receptors at the same sites abolishes or attenuates the increases in heart rate and blood pressure seen in a paradigm for emotional stress. In order to identify afferents to this region, WGA-HRP (1 or 2%) was coinjected with kainate (5 pmol) in 5 nL. Retrograde transport was assessed after 48 hrs only in those experiments where heart rate increased by >80 beats/min with onset <20 sec. In all experiments where the cardiovascular response met these criteria, injection sites were clearly located in the hypothalamic dorsomedial nucleus (DMH). Most areas previously shown to project to the DMH were labelled, but no labelling was present in the hippocampus. Some of the previously described afferents were more precisely defined in light of new cytoarchitectonic descriptions. Also, labelling was noted in regions not previously described as projecting to the DMH, including the anterior parvicellular paraventricular nucleus (APVHp), and cells within the posterior intralaminar complex of the thalamus (subparafascicular and lateral parafascicular nuclei, retroethmoid nucleus, posterior intralaminar nucleus). Although neuropeptide content of APVHp has been characterized immunohistochemically, its afferent and efferent connections are largely unknown. The posterior intralaminar complex, noted for its dense distribution of CGRP-immunoreactive cells, is thought to relay visceral sensory information to insular cortex and to project to amygdala and medial preoptic nucleus, regions implicated in central cardiovascular control. These findings (1) support previous suggestions of a key role for the DMH in the integration of the cardiovascular response to emotional stress, and (2) provide novel evidence for afferent projections to the DMH from the APVHp and the posterior intralaminar complex of the thalamus. (Supported in part by USPHS Grant NS 19883)

492.12

SYMPATHOADRENAL AND VASOPRESSIN (AVP) INVOLVEMENT IN THE PRESSOR RESPONSE TO ADMINISTRATION OF CARBACHOL (CCh) INTO THE POSTERIOR HYPOTHALAMIC NUCLEUS (PHN). J. R. Martin*, Dept. of Pharmacol., KCOM, Kirksville, MO 63501.

Injection of CCh into the PHN of conscious rats evokes a dose-dependent rise in mean arterial pressure (MAP). To define the mechanisms involved in this increase, antagonists were administered intravenously to Sprague-Dawley rats instrumented for MAP measurement and injection of CCh (50 nl of 5.5 or 3.3 nmol) into the left PHN. Pretreatment with prazosin (PRAZ; 0.2 mg/kg) or yohimbine (YOH; 0.3 mg/kg) attenuated the CCh-induced increase in MAP. Pretreatment with an AVP V_1 receptor antagonist (AVPX; 20 µg/kg) attenuated the pressor response to 5.5 but not 3.3 nmol of CCh. Combining YOH or AVPX with PRAZ further attenuated the pressor response. Combining PRAZ, YOH and AVPX resulted in an initial decrease in MAP which was reversed by addition of propranolol (PRO; 1 mg/kg) thereby revealing an underlying increase in MAP. Pretreatment with PRO alone enhanced the increase in MAP evoked by 5.5 but not 3.3 nmol of CCh. Only the combination of pentolinium (10 mg/kg), methyl-atropine (2 mg/kg) and AVPX completely blocked the CCh-evoked increase in MAP. These results suggest that AVP, epinephrine, norepinephrine, and a fourth unidentified substance are involved in the pressor response evoked by injection of CCh into the PHN. (Supported by AHA MO Affiliate and HL-44531.)

INTERACTION BETWEEN THE LATERAL HYPOTHALAMUS AND THE MEDIAL SEPTAL AREA IN THE CONTROL OF CARDIOVASCULAR, FLUID AND ELECTROLYTIC RESPONSES INDUCED BY CENTRAL CHOLINERGIC ACTIVATION IN RATS. A.S. Haibara, L.A. De Luca Jr.*, W.A. Saad, L.A.A. Camargo, A. Renzi and J.V. Menani. Dept. of Physiology, School of Dentistry, UNESP, Araraquara, SP 14800, Brazil.

In the present study we investigated the effect of bilateral electrolytic lesions of the lateral hypothalamus (LH) on the pressor, dipsogenic, natriuretic and kaliuretic responses induced by cholinergic activation (carbachol injection) of the medial septal area (MSA). In addition, the effect of opiate agonist (FK 33824) injection into the LH on the same responses was also studied. Male Holtzman rats were used. The bilateral lesion of the LH (1 and 18 days) or the injection of FK 33824 (100 ng) into the LH impaired the pressor, dipsogenic, natriuretic and kaliuretic responses induced by the injection of carbachol (2 nmol) into the MSA. The results show that pathways dependent on the LH integrity are involved in the cardiovascular, fluid and electrolytic responses to a cholinergic activation of the MSA. They also suggest that opiate pathways of the LH have an inhibitory action on the effects produced by cholinergic activation of the MSA.

CARDIOVASCULAR RESPONSES TO PARAVENTRICULAR (PVN) INJECTIONS OF OPIOID AGONISTS IN CONSCIOUS RATS. Hélène Bachelard* and Guy Drolet. Unité de Recherche sur l'Hypertension, Centre de Recherche du CHUL, Université Laval Québec (Qc), G1V 4G2.

The present study was designed to investigate the regional haemodynamic effects of some opioid agonists injected bilaterally into the PVN of conscious Wistar Kyoto rats. The rats were chronically instrumented with intracerebral cannulae, intravascular catheters and pulsed Doppler flow probes in a three step surgery. PVN microinjection of artificial CSF had no consistent effects whereas the μ-opioid agonist, DAGO (D-Ala^5, MePhe^4-Gly^5-ol-enkephalin) produced dose-related cardiovascular effects. DAGO (1.0 nmol) produced a significant ($P<0.05$, ANOVA followed by a Dunnett test) increase in mean arterial blood pressure (maximum, +17 $\pm$ 3 mm Hg, mean + s.e.m.), a fall in both renal (-27 $\pm$ 7%) and mesenteric (-45 $\pm$ 4%) vascular conductances and an increase in hindquarter (+79 $\pm$ 22%) vascular conductance. There was no significant change in heart rate. Moreover, PVN microinjections of increasing doses (0.01-5.0 nmol) of a δ-opioid agonist, DPDPE (D-Phe^{2,5}-enkephalin) and a κ-opioid agonist, U50488H, had no cardiovascular effects. Together these results suggest that PVN μ-opioid receptors might be important in cardiovascular regulation.

INTRACELLULAR RECORDINGS FROM RAT DIAGONAL BAND OF BROCA (DBB) NEURONS AND RESPONSES TO NOREPINEPHRINE (NE) IN BASAL FOREBRAIN-HYPOTHALAMIC EXPLANTS J.T. Cunningham*, C.R. Jarvis, R. Nissen, B. Hu & L.P. Renaud, Neuroscience Unit, Loeb Res. Inst., Ottawa Civic Hospital, Ottawa, Ontario K1Y 4E9.

Electrophysiological studies in the rat have demonstrated that the noradrenergic innervation of the DBB mediates the baroreceptor-induced inhibition of vasopressin-secreting (Vp) neurons in the hypothalamic supraoptic nucleus. Moreover, NE injections in the DBB selectively arrest the spontaneous firing of supraoptic Vp neurons. In the present study, we utilized intracellular recordings in basal forebrain explants to define the effects of NE on DBB neurons whose axons project towards the supraoptic region. Virtually all DBB neurons antidromically activated from the supraoptic region have action potentials ranging 0.9 to 1.45 ms and afterhyperpolarizations greater than 100 ms. Similar features have been ascribed to cholinergic neurons in the DBB. Both antidromic and non-antidromic DBB neurons displaying these features were consistently depolarized by bath application of NE (100-120 uM) from membrane potentials of -60 to -70 mV. The results indicate that putative-cholinergic neurons in the DBB are sensitive to NE and may participate in the baroreceptor-induced inhibition of supraoptic Vp neurons. (Supported by Heart & Stroke Foundation of Ontario and the MRC).

INFLUENCE OF INTRAVENTRICULAR PRETREATMENT WITH α-AGONISTS AND THAT OF HYPOTHALAMIC STIMULATION ON THE PRESSOR ACTION INDUCED BY VASOPRESSIN IN RATS. N. Ono*, T. Furukawa and H. Kamiya, Dept. of Pharmacol., Fac. of Pharmaceut. Sci., Fukuoka Univ., Fukuoka, 814-01, Japan.

Influences of α-agonists on the central regulation of blood pressure induced by vasopressin were investigated using urethane-anesthetized rats. Vasopressin (1-10 nmol) administered intracerebroventricularly (i.c.v.) elicited dose-relatedly the pressor and positive chronotropic effects restored about 1-2 hr after administration. The pressor action of vasopressin were inhibited by the intravenous pretreatment with pentolinium and phentolamine, the i.c.v. pretreatment with α-agonists, norepinephrine, phenylephrine, methoxamine and V1-antagonist, d(CH2)5OMe(Tyr)-AVP, but not the i.c.v. pretreatment with clonidine and β-blocker. While the pressor action was augmented by the i.c.v. pretreatment with prazosin. In the experiment of electric stimulation to the hypothalamic nucli, the pressor action of vasoressin was supressed significantly by the continuous stimulation (for 15 min, 200 μA, 2 msec) of anterior hypothalamic area. The supression was frequence-dependently (10 and 12.5 Hz). These results suggest that vasopressin may be affected by α-1 subsystem of the CNS in cardiovascular regulation through the activation of sympathetic nervous system, all involving in the CNS.

492.17

ROLE OF CORTICOTROPIN-RELEASING FACTOR IN MEDIATING CARDIOVASCULAR RESPONSES TO SEROTONIN AND A SEROTONIN$_{1A}$ RECEPTOR AGONIST. A. Dedeoğlu and L.A. Fisher*. Department of Pharmacology, College of Medicine, University of Arizona Health Sciences Center, Tucson, AZ 85724.

Corticotropin-releasing factor (CRF), by virtue of its central nervous system (CNS) distribution and actions, is hypothesized to be a neurotransmitter in brain pathways mediating the endocrine, autonomic and cardiovascular responses to stressful stimuli. Hypophysiotropic CRF neurons (i.e., those regulating pituitary ACTH secretion) are stimulated by serotonin (5-HT) and several 5-HT receptor subtype-selective agonists. The purpose of the present study was to test the hypothesis that 5-HT and related agonists likewise produce excitatory effects on CRF-containing neurons governing cardiovascular function. This hypothesis was based on previous studies demonstrating that low doses (< 10 nmol) of 5-HT and the 5-HT$_{1A}$ receptor agonist, 8-hydroxy-2-(di-n-propylamino)-tetralin (8-OH-DPAT), act within the CNS to elevate arterial pressure (AP) and heart rate (HR), effects similar to those produced by CRF administration. All experiments were performed in conscious, unrestrained male Sprague-Dawley rats (220-250 g) previously instrumented with lateral cerebroventricular (icv) guide cannulas and iliac arterial catheters. Icv administration of CRF (0.15 nmol), 5-HT (1 nmol), and 8-OH-DPAT (3 nmol) produced concurrent increases in AP (12-15 mm Hg) and HR (45-75 beats/min). Icv administration of the CRF receptor antagonist, α-helical CRF$_{9-41}$ (9 nmol), did not alter AP or HR when given alone. Co-administration of α-helical CRF$_{9-41}$ significantly attenuated (by 50-100%) the pressor and tachycardic responses to injections of CRF, 5-HT, and 8-OH-DPAT. It is concluded that the cardiovascular actions of low icv doses of 5-HT and 8-OH-DPAT are in part mediated by the release of CRF within the CNS.

SELECTIVE ELIMINATION OF HYPOTHALAMIC NEURONS BY GRAFTED HYPERTENSION-INDUCING NEURAL TISSUE R.Eilam, R. Malach, L. Sklair*, M. Segal, Dept. Neurobiology, Brain Research, The Weizmann Institute, Rehovot 76100, Israel.

Embryonic hypothalamic tissue originating from spontaneously hypertensive rats (SHR) was implanted in young normotensive (Wistar Kyoto; WKY) rats in an attempt to localize brain regions directly responsible for the induction of hypertension. A 30% elevation in host systolic blood pressure was noted 3 months after implantation in animals grafted with rostral hypothalamic tissue (R-SHR), while that of the group receiving caudal tissue did not change. The hypertension in the R-SHR group was accompanied by hypertrophy of the heart and kidneys. A 77% reduction of vasopressin immunoreactive (VP+) of parvocellular cells was noted in the paraventricular nucleus (PVN) of the R-SHR group. In the C-SHR animals, on the other hand, the parvocellular VP+ remained unaltered but the magnocellular VP+ was reduced by 53%. TH immunoreactivity did not show difference in PVN cells number between experimental and control groups, suggests a possible specificity of disappearance of VP+ cells. While we do not know why these cells degenerate, the disappearance of VP+ PVN parvocellular cells in the R-SHR's indicates that they may contribute to the development of hypertension.

C-FOS EXPRESSION IN HYPOTHALAMIC NEURONS OF HEMORRHAGIC AND HYPOTENSIVE RATS. E. Shen*, S. L. Dun, T. H. Chiu and N. J. Dun. Dept. of Anatomy & Dept. of Pharmacol., Medical College of Ohio, Toledo, OH 43699

One hour after lowering the arterial blood pressure of adult Sprague Dawley rats to 60-70 mm Hg by either withdrawing 5-6 ml of blood from the femoral artery or infusion of nitroprusside (2 mg/ml,total volume injected 60-120 μl/hr), Fos-immunoreactivity (Fos-IR) was detected in neurons of the supraoptic (SON) and paraventricular (PVN) nuclei. Double staining with antibodies to vasopressin (AVP) and oxytocin (OXY) showed that 70% and 20% of Fos-IR neurons in the SON and PVN were AVP-positive; whereas, 5% and < 1% Fos-IR cells in SON and PVN were OXY-positive. Sectioning of the carotid sinus nerve reduced the number of Fos-IR neurons in the epsilateral hypothalamus. An increase of Fos-IR neurons could be detected as early as 15 min and reached the plateau one hour after hemorrhage or hypotension; the number remained elevated in 3 hr. Northern blot analysis of c-fos mRNA from the hypothalami showed a consistent increase, reaching the peak between 30-60 min. The results show that lowering of blood pressure effectively induces c-fos mRNA and Fos-IR in hypothalamic neurons known to be associated with cardiovascular regulation. (Supported by NS 18710 & NS24226).

PROJECTIONS FROM THE PARAVENTRICULAR NUCLEUS TO THE CAUDAL VENTROLATERAL MEDULLA. S.L. Cravo, L.R.G. Britto*, L.V.Bonaldi. Dept. of Physiology, São Paulo Medical Sch.; Dept. of Physiol. Biophysics, Univ. of São Paulo, Brazil.

The paraventricular nucleus of hypothalamus (PVH) plays a major role in the regulation of body fluid homeostasis. Besides acting through the secretion of arginine-vasopressin (AVP), the PVH can also modulate the activity of other brain autonomic nuclei. We sought to determine the relationship between PVH and the vasomotor centers of the ventrolateral medulla (VLM). In anesthetized rats, the anterograde tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L) was iontophoresed into PVH. After 7-14 days, animals were reanesthetized, perfused and tissue was processed immunocytochemically for PHA-L. Our results showed that: i) PHA-L-immunostained fibers were found in the ipsilateral n. of tractus solitarius (NTS), and rostral (RVL) and caudal (CVL) nuclei of VLM; ii) RVL fibers were distributed over the region of C1 adrenergic neurons; iii) PVH projections to VLM were particularly dense at the CVL level. A dense network of fibers and terminals was observed extending from the parambigual region to the ventral surface between the lateral reticular and the V nerve spinal nuclei. Double label experiments combining retrograde transport of fluorescein- labeled microspheres with AVP immunocytochemistry demonstrated double-labeled cells in the PVH after injections into CVL. We conclude: a) PVH projects to both vasomotor center of ventrolateral medulla, particularly to CVL; b) PVH vasopressinergic cells are part of this projection. (Supported by FAPESP, Brazil).

CARDIOVASCULAR REGULATION: UPPER BRAINSTEM MECHANISMS

493.1

CHARACTERISTICS OF CENTRAL SEROTONIN (5-HT) UPTAKE SITES IN HYPERTENSIVE RATS: INTERACTION WITH CLONIDINE AND CENTHAQUIN Anil Gulati, Ramesh C. Arora and John W. Crayton*, Dept. of Pharmacodynamics, Univ. of Illinois, Chicago, and Section Biol. Psychiat., VA Hospital and Depts. Pharmacol. & Psychiat., Loyola Univ., Hines IL.

The binding of a highly specific ligand for 5-HT uptake sites, [^{3}H] paroxetine, was studied in brain regions of normotensive Wistar Kyoto (WKY) and spontaneous hypertensive (SHR) rats. [^{3}H] paroxetine bound to a single, high affinity binding site in the brain. The affinity (K_d) and density (B_{max}) of [^{3}H] paroxetine binding were found to be similar in spinal cord, pons and medulla and cerebral cortex of WKY and SHR rats. However, in midbrain the B_{max} values of [^{3}H] paroxetine binding were significantly reduced (27.16 %) in SHR as compared to WKY rats. The K_d values were found to be similar in SHR and WKY rats. The effects of clonidine and centhaquin, centrally acting hypotensive agents, on [^{3}H] paroxetine binding were also determined and compared with imipramine, a known 5-HT uptake inhibitor. Clonidine did not displace [^{3}H] paroxetine binding at any concentration (1 X 10^{-4} to 1 X 10^{-7} M). On the other hand, centhaquin, which produces hypotension similar to clonidine, could displace [^{3}H] paroxetine binding in a concentration dependent manner. In cerebral cortex and brain stem the IC_{50} values of imipramine and centhaquin for [^{3}H] paroxetine binding were found to be similar in WKY and SHR rats. The affinity (K_i) of centhaquin to displace paroxetine from 5-HT uptake sites was 10 times lower than imipramine, while clonidine had no effect on 5-HT uptake sites. The results indicate that (1) the density of 5-HT uptake sites is reduced in the midbrain of hypertensive rats, and (2) centhaquin, a centrally acting hypotensive agent, acts on 5-HT uptakes sites. This study suggests the possiblity that 5-HT uptake mechanisms play a role in hypertension.

493.2

MESENCEPHALIC CUNEIFORM NUCLEUS PATHWAYS SERVING CARDIOVASCULAR RESPONSES DURING ADAPTATION TO STRESS. S.M. Korte*, D. Jaarsma, P.G.M. Luiten, and B. Bohus. Dept. of Animal Physiol., University of Groningen, P.O. Box 14, 9750 AA HAREN, The Netherlands.

The aim of the present study was to explore the neuroanatomic network that underlies the cardiovascular responses of reticular formation origin in the region of the cuneiform nucleus. The left iliac artery was supplied with a catheter for the measurement of systolic blood pressure. Low intensity electrical stimulation if the mesencephalic reticular formation (MRF) in the vicinity of the cuneiform nucleus (CNF) always resulted in pressor and bradycardiac responses, whereas stimulation in the parabrachial nucleus (PB) and Kölliker-Fuse nucleus (KF) led to a pressor response and a small tachycardiac response. The efferent connections of the effective stimulation sites in the CNF area, were investigated by anterograde tracing with the lectin Phaseolus vulgaris leucoagglutine (PHA-L). The CNF sends descending fibers to the gigantocellular reticular nuclei (GI), the motor nucleus of the vagus (DMNV) and nucleus tractus solitarious (NTS). These projections are probably involved in the bradycardiac response to stimulation. The descending pathway to the NTS/DMNV and GI may therefore be the parasympathetic limb of the circuit. Furthermore, the CNF sends ascending fibers to limbic forebrain areas and descending fibers to the PB-KF complex. The KF in its turn projects to the rostroventrolateral medullary nucleus (RVLM) and the intermediolateral cell column (IML). These latter projections are partly involved in producing the pressor response and thereby represent the sympathetic limb of the circuit. The widespread connections of the CNF correspond with the possible role of this area in the integration and production of fear-related immobility (orientation and freezing) accompanied by anticipatory/expectancy-related bradycardia.

493.3

EFFECT OF NEUROTRANSMITTER ANTAGONISTS IN THE PARABRACHIAL NUCLEUS ON VISCERAL INPUT TO THE THALAMUS. T.M. Saleh* and D.F. Cechetto, Robarts Research Inst./University of Western Ontario, London, Canada, N6A 5K8.

The putatative neurotransmitter(s) in ascending visceral sensory pathways was investigated by recording the changes in the response of thalamic neuronal activity evoked by vagal stimulation before and after neurotransmitter antagonist injection into the parabrachial nucleus (PB). Synaptic blockade with cobalt (10 mM) injections into the PB resulted in inhibition of both the evoked thalamic response to vagal stimulation (100%) and the spontaneous firing of thalamic neurons (86%). Injections of kynurenate (0.25 μM) or the NMDA antagonist AP5 (200 μM) effectively blocked the evoked thalamic response to vagal stimulation (94% and 100% respectively), but did not significantly change spontaneous activity. In contrast, injections of phentolamine (α-agonist; 0.1 μM) or yohimbine (α-2 antagonist; 200 μM) into the PB inhibited the spontaneous firing of thalamic units (56% and 77% respectively) but had no effect on the evoked response to vagal stimulation. Prazosin and propranolol (α-1 and β antagonists respectively) were ineffective. Bicuculine significantly enhanced spontaneous thalamic unit activity (76%) without affecting the evoked response to vagal stimulation. Atropine (0.1 μM) had no significant effects. These results indicate that an excitatory amino acid NMDA receptor is necessary for transmission of visceral input through the PB and that neurons in the PB with α-2 receptors contribute to the tonic, spontaneous firing activity of ventral basal thalamic neurons. EFFECTS OF PEPTIDES IN THE PARABRACHIAL NUCLEUS ON VISCERAL INPUT TO THE THALAMUS. D.F.Cechetto* and T.M.Saleh. Robarts Research Inst./ University of Western Ontario, London, Ont., Canada. N6A 5K8

The role of neuropeptides in ascending visceral pathways was investigated by recording the changes in the response of thalamic neuronal activity evoked by vagal stimulation before and after peptide injection in the parabrachial nucleus (PB) in anaesthetized rats. Injection of calcitonin gene-related peptide (CGRP, 5 mM), substance P (SP, 2 mM) or cholecystokinin (CCK) into the PB significantly attenuated the vagal evoked response of thalamic neuronal activity. In contrast, vagal evoked responses were significantly enhanced (508%) by injection of neurotensin (NT, 1 mM) into the PB. Spontaneous activity of thalamic neurons was inhibited by CGRP and SP and excited by NT injections into the PB. Cholecystokinin (CCK) at low doses (0.0002 - 0.2 mM) attenuated (up to 78%), while the highest dose, 2 mM, briefly enhanced (189%) the spontaneous activity of thalamic units before inhibiting their activity. Injections of somatostatin (SOM; 1 mM) did not significantly alter the response evoked by vagal stimulation, but significantly inhibited the spontaneous firing of thalamic units resulting in a ten-fold increase in the response to background ratio. The results indicate that these peptides play a significant and specific role in the PB in modulating visceral sensory input to the ventral basal thalamus. Their function may be to relay specific visceral modalities or specific patterns of visceral sensory information to the forebrain.

SYNAPTIC BLOCKADE OF LATERAL TEGMENTAL FIELD NEURONS DOES NOT ALTER THE CARDIOVASCULAR RESPONSES TO MUSCULAR CONTRACTION OR HYPOTHALAMIC STIMULATION. G.A. Iwamoto* and T.G. Waldrop. Depts. of Physiology & Biophysics and Veterinary Biosciences, Univ. of Illinois, Urbana, IL 61801.

Prior results have indicated that neurons in the lateral tegmental field (LTF) are involved in the generation of sympathetic drive. Our previous studies have shown that contraction of hindlimb muscles increases the discharge rate of LTF neurons and elevates mean arterial pressure (MAP) and heart rate (HR). The purpose of the present study was to determine if blockade of synaptic transmission in the LTF alters the pressor response to muscular contraction. MAP and HR responses to muscular contraction (evoked by stimulation of the L_7 and S_1 ventral roots) and caudal hypothalamic stimulation (hypo stim) were recorded before and after microinjections (100 nl) of $CoCl_2$ into the LTF in anesthetized cats. Both muscular contraction and hypo stim elicited increases in MAP and HR during control conditions. Bilateral $CoCl_2$ (100 mM) microinjections into the LTF did not alter these cardiovascular responses. Moreover, LTF microinjections of lidocaine (1%) did not have any effects upon the responses to muscular contraction and hypothalamic stimulation. Thus, synaptic transmission through the lateral tegmental fields is not required for full expression of the cardiovascular responses to muscular contraction or caudal hypothalamic stimulation. ***IN VIVO* NORADRENERGIC NEURAL ACTIVITIES IN LOCUS COERULEUS OF WISTAR KYOTO RATS AND SPONTANEOUSLY HYPERTENSIVE RATS.** K.H. Ko*, Y.T. Kim, M.J. Jo and E.K. Lee. Department of Pharmacology, College of Pharmacy, Seoul National University, Seoul 151, Korea.

Purpose of the present study was to adress the question whether *in vivo* noradrenergic neural activity in locus coeruleus is coupled to the manifestation of hypertension. Two groups of animals were prepared, 1) normotensive wistar kyoto rats (WKY) and 2) spontaneously hypertensive rats (SHR). At 16 weeks of age, blood pressure (BP) and release of norepinephrine (NE) and 3,4-dihydroxyphenylglycol (DOPEG) from locus coeruleus of WKY and SHR were measured by microdialysis technique at three conditions; 1) normal; 2) α_1-agonist (phenylephrine) systemically treated; 3) α_1-, α_2-, β-receptor agonist or antagonist (phenylephrine, phentolamine, clonidine, yohimbin, isoproterenol, propranolol) treated into locus coeruleus through microdialysis probe. At normal condition, BP of WKY was 106.46 ± 2.87 mmHg and BP of SHR 180.42 ± 2.57 mmHg. Basal outputs of NE and DOPEG were 0.539 ± 0.050 pg/20min, 1.896 ± 0.050 pg/20min in WKY and 0.897 ± 0.278 pg/20min, 3.568 ± 0.500 pg/20min in SHR respectively. Following systemic application of phenylephrine, BP was increased but the release of NE was decreased in both WKY and SHR, while the level of DOPEG was decreased only in SHR. However, activation of α_1-, α_2-, β-receptor increased the level of DOPEG in WKY whereas the blockade of those receptors did not. Stimulation as well as blockade of α_1- and β-receptor consistently increased the level of DOPEG while those of α_2-receptor did not. BP and the release of NE did not change significantly in any condition of those. The result from the present study suggests that noradrenergic neural activity in locus coeruleus may not be strongly coupled to regulatory mechanism of hypertension in adult WKY and SHR.

493.7

THE ORIGINS OF NON-CATECHOLAMINERGIC VASOPRESSOR AREAS IN THE GIGANTOCELLULAR TEGMENTAL FIELD OF THE ROSTRAL PONS IN CATS. S.D. Wang*, H.T. Horng. J.C. Liu, J.S. Kuo and C.Y. Chai. Dept. of Biol. and Anat., Natl. Defen. Med. Ctr., Dept. Med. Res Taichung Veterans Gen. Hosp., and Inst. of Biomed Sci., Academia Sinica, Taiwan, Republic of China.

The present study used retrograde technique to examine the origins of the gigantocellular tegmental field (FTG) of the rostral pons, in which vasopressor responses could be induced by rectangular pulses and/or sodium glutamate. Different from other vasopressor areas in the pons and medulla, regions of FTG did not contain cells immunoreactive to catecholamines. After vasopressor response was induced at FTG, HRP was injected to the same region. After two days of survive, the animals were sacrificed to process for HRP histochemical reaction from upper thoracic spinal cord to diencephalon. HRP-labeled cells were observed at dorsomedial and ventrolateral regions of the medulla and pons. Besides, numberous HRP-labeled cells were evident at the periaqueductal gray of the midbrain. These results suggest that vasopressor neurons in the non-catecholaminergic FTG regions may work with the vasopressor neurons in other catecholaminergic areas to integrate cardiovascular functions.

493.8

BARORECEPTOR INHIBITION OF SUPRAOPTIC VASOPRESSIN CELLS: NO ROLE FOR LOCUS COERULEUS. T. A. Day* and J. R. Sibbald, Dept. of Physiology and Pharmacology, University of Queensland, Qld 4072, AUSTRALIA.

Activation of arterial baroreceptors inhibits neurosecretory vasopressin (AVP) cells but the central pathways mediating this effect remain open to dispute. We have now investigated the proposal (Banks and Harris, J. Physiol., 1984) that inhibition of supraoptic nucleus (SON) AVP cells following carotid sinus baroreceptor activation is mediated via noradrenergic neurons of the ipsilateral locus coeruleus (A6 group).

Extracellular recordings were obtained from SON AVP cells in pentobarbital anaesthetized male rats in which all baroreceptor afferents except those arising from the carotid sinus had been sectioned. Electrolytic lesions which destroyed the ipsilateral locus coeruleus and immediately surrounding tissue reduced the frequency of AVP cell inhibition following baroreceptor activation (2-10 µg metaraminol i.v.) from 93% (14/15 cells) to 35% (9/26 cells). However, this effect was not duplicated by inhibition of local neurons: injection of gamma aminobutyric acid (100 mM, 100-150 nl, i.e. 10-15 nmol) into the ipsilateral locus coeruleus had no effect on AVP cell activity or responses to baroreceptor activation, even when the contralateral locus coeruleus had been destroyed by electrolytic lesion (6/6 cells). Finally, the effects of ipsilateral locus coeruleus stimulation on AVP cell activity was tested. Electrical stimulation (100-200 µA) altered the activity of 6/30 AVP cells, inhibiting 1 and exciting 5, but chemical stimulation (200 µM glutamate, 100 nl) was without effect (8/8 cells).

These data suggest that changes in AVP cell responses to baroreceptor activation after dorsolateral pons manipulations are attributable to effects on axons of passage rather than neurons of the locus coeruleus or the adjacent area.

FASTIGIAL STIMULATION INCREASES C-FOS EXPRESSION IN SELECTED BRAINSTEM AUTONOMIC NUCLEI. X. Xu* F. Zhang and C. Iadecola, Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Electrical stimulation of the cerebellar fastigial nucleus (FN) elicits profound cardiovascular, cerebrovascular and behavioral changes. These responses are initiated not from local FN neurons but from passing fibers that may originate in the dorsal parabrachial n. (PBd)(Brain Res 473:352, 1988). We used c-fos expression as a marker of neural activity to determine whether FN stimulation activates neurons in PBd. Rats were anesthetized (halothane 1-3%), paralyzed and ventilated. Arterial pressure and blood gases were controlled. The FN or cerebellar white matter (CWM) was stimulated for 1 hr (50-100 µA; 50 Hz; 1 sec on/1 sec off) through microelectrodes. Fos, the gene product of c-fos, was detected immunocytochemically. Fos+ cells were counted in several brainstem regions. In rats that were surgically prepared for brain stimulation but not stimulated (n=7), numerous Fos+ cells were seen in the nucleus tractus solitarii (NTS; 52±13), PBd (74±20), paraventricular hypothalamus (PVH; 192±31) and periventricular thalamus (84±25; Th-PV). In rats anesthetized and sacrificed without surgery (n=5) there were few or no Fos+ cells in these regions. Stimulation of the FN (n=5), but not CWM (n=5), increased the number of Fos+ cells ($p<0.05$) in vestibular complex (VC; +179%), PBd (+181%), intralaminar thalamus (Th-IL; +282%), Th-PV (+131%), and medial amygdala (+214%). FN or CWM stimulation did not affect the number of Fos+ cells ($p>0.05$) in parvocellular reticular n., NTS, ventral parabrachial, PVH, lateral and medial habenula. We conclude that: (1) Surgery, anesthesia and ventilation may induce c-fos expression in brainstem nuclei involved in autonomic regulation and, (2) FN stimulation increases c-fos expression in some regions receiving monosynaptic projections from FN neurons (VC, Th-IL) as well as regions that do not, most notably PBd. The increase in c-fos expression in PBd supports the hypothesis that FN stimulation activates reciprocal projections between parabrachial nuclei as they cross the midline via the subfastigial bundle. Thus, PBd may participate in the responses elicited by FN stimulation. (Supported by the American Heart Association of Minnesota)

RESPONSES OF NEURONS IN THE SUBRETROFACIAL ROSTRAL VENTROLATERAL MEDULLA (RVLM) OF THE CAT TO NATURAL VESTIBULAR STIMULATION. B.J. Yates*, T. Goto & P.S. Bolton. Lab. of Neurophysiology, Rockefeller Univ., New York, NY 10021.

There is considerable evidence suggesting the existence of vestibulosympathetic reflexes (VSR) which may be important in counteracting posturally-related changes in blood pressure (Yates, Brain Res. Rev. 1992). We previously showed that over 2/3 of the neurons in the RVLM with slowly-conducting projections to the thoracic spinal cord responded to vestibular nerve stimulation (Yates et al., Brain Res. 1991), and hypothesized that these cells are likely to mediate VSR. In the present study we determine the nature of vestibular inputs to this region by analyzing the responses of RVLM neurons to sinusoidal whole body tilts in vertical planes and to horizontal rotations.

Experiments were conducted on decerebrate cats that were baroreceptor-denervated, vagotomized and had a cervical spinal transection. Of the 38 neurons whose type of vertical vestibular inputs could be classified, the majority (27) received signals mainly from otolith organs, 4 had inputs predominantly from semicircular canals, and 7 were categorized as receiving convergent inputs from otoliths and canals. In addition, only 2 of 68 neurons responded to horizontal rotations. The presence of otolith-dominant labyrinthine inputs to the RVLM is consistent with the hypothesis that this area mediates VSR which participate in correcting orthostatic hypotension.

HYPOVOLEMIC HYPOTENSION PRODUCES LOCALIZED GLUTAMATE INCREASES WITHIN THE CARDIOVASCULAR PRESSOR REGION OF THE CEREBELLAR FASTIGIAL NUCLEUS

T. J. Parry* and J. G. McElligott. Dept. of Pharmacology, Temple University School. of Medicine, Philadelphia, PA 19140.

The cerebellar pressor region located in the rostro-medial fastigial nucleus has been shown to be important for the regulation of blood pressure. Our previous work demonstrated that microdialysis administration of kainic acid into this area produced a dose dependent increase in blood pressure and an elevation of extracellular levels of several amino acid neurotransmitters, namely, glutamate, taurine, aspartate, glycine, and GABA. In order to determine if any of these transmitters plays a functional role in blood pressure regulation, we examined the relationship between a natural perturbation to the cardiovascular system (hypovolemic hypotension) and transmitter levels within the pressor region of the fastigial nucleus. Experiments were conducted on unanesthetized rats implanted with bilateral femoral catheters. Thus, blood pressure was monitored while being reduced from 111 ± 6 to 50 mm Hg within 5 minutes by controlled hemorrhage. Six rats that had been previously adapted to head restraint were implanted with microdialysis probes (dia. = 250 μM; tip length 1 mm) within the pressor region of the fastigial nucleus. Microdialysis samples were taken every 10 minutes before, during, and after experimentally induced hypovolemic hypotension. In these animals, there was a significant increase (42% above baseline; $p \leq 0.05$) in extracellular glutamate during this hypotension which returned to baseline following reflex recovery from hypotension. There was also a delayed increase in GABA levels (38%; $p \leq 0.05$) which reached significance when reflex recovery was complete. These GABA levels then remained elevated for the duration of the experiment. No changes were detected in the levels of the other amino acid neurotransmitters. Futhermore, reinfusion of the blood did not produce any change. In addition, no changes in amino acid neurotransmitter levels during the experimentally induced hypotension were measured in the cerebellar dentate nucleus, an area unrelated to cardiovascular control. CAROTID SINUS NERVE STIMULATION INDUCES FOS-LIKE IMMUNOREACTIVITY WITHIN ADRENERGIC, NORADRENERGIC AND SEROTONERGIC NEURONS OF THE RAT BRAINSTEM.

J.T. Erickson* and D.E. Millhorn. University of North Carolina, Chapel Hill, NC)

Stimulation of the rat carotid sinus nerve (CSN) induces a discrete distribution of Fos-like immunoreactivity (Fos-LI) within the medulla oblongata (Erickson and Millhorn, Brain Res. 567:11;1991). In this study, we extend these observations to the pons and midbrain and demonstrate, using immunohistochemical double labeling techniques, that many of these functionally activated neurons are adrenergic, noradrenergic or serotonergic. After electrical or hypoxic stimulation of CSN afferent fibers, Fos colocalization was observed with phenylethanolamine-N-methyltransferase (PNMT), or tyrosine hydroxylase (TH) in the A1/C1 cell groups in the ventrolateral medulla and to a lesser degree within the A2/C2 cell groups in the dorsal vagal complex (DVC). Fos was also observed within serotonergic cells of raphe pallidus, raphe magnus, in the "parapyramidal region" just lateral to the pyramids, and along the ventral medullary surface. Within pons, prominent Fos-LI was observed in the lateral parabrachial complex, the Kolliker-Fuse nucleus, and within the dorsal tegmental region in and around nucleus raphe dorsalis. In addition, Fos colocalization was observed with TH in the A5 cell group and within locus coeruleus. Fos colocalization with serotonin in nucleus raphe dorsalis was relatively rare. Within the midbrain, Fos immunoreactivity was consistently observed along the midline, ventral to the cerebral aqueduct, intermixed but rarely colocalized with TH-positive cells, and within the inferior colliculus.

494.2

HEMORRHAGE INDUCES FOS-IMMUNOREACTIVITY IN AMINERGIC AND SEROTONINERGIC NEURONS IN THE RAT MEDULLA.

S. L. Dun and N. J. Dun.* Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

In anesthetized rats 1 hr after lowering the arterial blood pressure to 60-70 mm Hg by removing 4-5 ml of blood,numerous cells containing nuclear Fos-immunoreactivity (Fos-IR) were detected in the nucleus of the solitary tract (NTS) and ventrolateral medulla (VLM). A number of Fos-IR neurons were also noted in the inferior olive, nucleus raphe obscurus and raphe pallidus. In sham-operated rats only a few Fos-IR neurons were scattered in the NTS, VLM and other nuclei. Double labeling techniques with antisera to tyrosine hydroxylase (TH), phenylethanolamine-N-methyltransferase (PNMT) and 5-HT showed that nearly all TH-positive cells in the NTS and VLM were Fos-IR. Fos-IR neurons in the rostral VLM were both TH- and PNMT-positive, whereas they were TH- but not PNMT-positive in the caudal VLM. Only a few TH-or PNMT-positive cells were Fos-IR in the C3 area. Most of the 5-HT positive neurons in the raphe obscurus and raphe pallidus were Fos-negative. The results indicate that during hemorrhage, noradrenergic neurons in the caudal VLM and caudal NTS, and adrenergic neurons in the rostral VLM, and to a lesser extent the C3 adrenergic cells and 5-HT neurons, are activated insofar as c-fos expression is concerned.

494.3

FOS EXPRESSION IN NEURAL CIRCUITS SERVING CARDIOVASCULAR AND BODY FLUID REGULATION.

Z. Ying *, A. Singha, J. M. Ding, and J. Buggy. Depts. of Physiology and Psychology, University of South Carolina, Columbia, SC 29208.

The *c-fos* immediate early gene is acutely induced in many brain regions by relevant stimuli; Fos immunoreactivity (Fos-IR) presents a useful mapping technique to identify activated neuronal systems. After presentation of various body fluid and cardiovascular stimuli, Fos-IR was observed in rat brainstem regions: nucleus of the solitary tract (NTS), area postrema (AP), ventrolateral medulla (VLM), and parabrachial nucleus (PBN); and in hypothalamic regions: organum vasculosum of the lamina terminalis (OVLT), preoptic nucleus medianus (NM), bed nucleus of the stria terminalis (BNST), subfornical organ (SFO), paraventricular nucleus (PVN), and supraoptic nucleus (SON). Hypertonic NaCl did not induce Fos in SFO and only weakly in the brainstem. Ang icvt induced Fos poorly in brainstem whereas hemorrhage or iv Ang induced Fos throughout the circuit. Hypertonic NaCl activated Fos in both dorsal and ventral SON whereas induction by hemorrhage was more focused in the ventral SON where vasopressin predominates over oxytocin. Blockade of glutamate NMDA receptors with MK-801 failed to prevent Fos-IR for any of the stimuli in any of the regions. Histochemical mapping of nitric oxide synthase with NADPH-diaphorase showed a striking overlap with Fos-IR in hypothalamus but not brainstem.

494.4

IDENTIFICATION OF DEPRESSOR NEURONS IN RABBIT VENTROLATERAL MEDULLA MEDIATING THE BARORECEPTOR VASOMOTOR REFLEX: A PHYSIOLOGICAL AND C-FOS IMMUNOHISTOCHEMICAL STUDY.

Yu-Wen Li* and R. A. L. Dampney. Department of Physiology, University of Sydney, NSW, 2006, AUSTRALIA.

Three series of experiments were carried out to identify depressor cells in the rabbit ventrolateral medulla (VLM) that mediate the baro-vasomotor reflex. In the first series, rabbits were anesthetised with urethane, paralysed and ventilated, and arterial pressure (AP) was recorded. The depressor area in the VLM was mapped by glutamate microinjection (0.02M, 20nl) in the same rabbits before and after baro-denervation. Before denervation depressor responses were only evoked from sites in the VLM caudal to the obex. After denervation, the depressor area extended more rostrally to the level just caudal to the rostral pressor area. In the second series, the effect of baroreceptor stimulation on c-fos expression in VLM neurons was studied in conscious rabbits. Raising AP 20 mmHg for 60 min greatly increased, compared to control cases, the number of c-fos immunoreactive neurons in the VLM (c-fos antibody, OA-11-823, CRB). The location of these c-fos positive neurons in the VLM corresponded closely to the depressor area mapped in baro-denervated rabbits. In the third series, rabbits were prepared as in the first series, and AP and renal sympathetic nerve activity (rSNA) were recorded. Bilateral microinjections of muscimol (5 nmol in 50 nl) into the rostral part of the VLM depressor area, but not the caudal part, virtually abolished the reflex rSNA response to AP alterations. These results suggest that (1) the VLM depressor area in the rabbit extends more rostrally after baro-denervation; (2) baroreceptor activation induces neuronal c-fos expression throughout this depressor area; (3) neurons in the rostral part of the depressor area are critical for the expression of the baro-vasomotor reflex.

494.5

MECHANISMS MEDIATING VASOPRESSIN RESPONSES TO SIMULATED HAEMORRHAGE: ELECTROPHYSIOLOGICAL AND C-FOS STUDIES. D.W. Smith*, J.R. Sibbald and T.A. Day, Dept. of Physiology and Pharmacology, University of Queensland, Qld 4072, AUSTRALIA.

Central and peripheral mechanisms mediating vasopressin (AVP) responses to hypotensive haemorrhage are not fully understood. We have now used short duration caval occlusion as a model to investigate potential mechanisms underlying haemorrhage-induced activation of rat supraoptic nucleus (SON) AVP cells.

Extracellular recordings in pentobarbital anaesthetised rats showed that intra-thoracic inferior vena cava occlusion excited most SON AVP cells within 5-15 sec. This was unaltered by sectioning of cardiac buffer nerves or cervical spinal cord, suggesting central receptor involvement.

Central mechanisms mediating the AVP response were further investigated by examining caval occlusion-induced expression of the immediate early gene c-Fos. Animals were perfused 60-90 mins after caval occlusion and tissue processed for Fos plus AVP, oxytocin (OT) or tyrosine hydroxylase (TH) immunocytochemistry using a two colour immunoperoxidase technique. SON cells showed a significant increase in Fos-like immunoreactivity (FLI), predominantly in AVP cells. The A1 cell group of caudal medulla and the central nucleus of amygdala showed mild increases in FLI but the strongest correlations with SON FLI were apparent in the lateral bed nucleus stria terminalis (BST) and at the ventral surface of the rostral medulla.

These data suggest possible involvement of BST and ventral medulla chemosensitive cells in AVP responses to haemorrhage.

TIME COURSE OF HEMORRHAGE EFFECTS ON TYROSINE HYDROXYLASE mRNA IN MEDULLARY CATECHOLAMINE NEURONS MANIFESTING FOS INDUCTION. R.K.W. Chan* and P.E. Sawchenko, The Salk Institute, La Jolla, CA 92037.

Medullary catecholamine cell groups are involved in multiple modes of cardiovascular regulation and display various indices of functional activation, including widespread *c-fos* expression, in response to hypotensive hemorrhage. Assessments of the impact of such challenges on transmitter-related gene expression are complicated by the varying degrees of biochemical and connectional heterogeneity that characterize these cell groups. We used quantitative hybridization histochemical methods to follow the effects of 15% hemorrhage on levels of mRNA encoding tyrosine hydroxylase (TH), the rate-limiting enzyme in catecholamine biosynthesis; concurrent staining for nuclear Fos-immunoreactivity (Fos-ir) permitted comparisons between cells that ostensibly were and were not targeted by the challenge. Increased levels of TH mRNA were detected in Fos-ir neurons in all cell groups examined. Mean maximal increases ranged between 133 and 168% of control values, and were attained within 0.5-1 hr post-hemorrhage in noradrenergic (A1 and A2) cell groups, and at 2 hr in adrenergic ones (C1, C2, dorsal strip). By 4 hr after the challenge, TH mRNA levels in Fos-ir neurons in all cell groups had returned to control values. By contrast, TH mRNA in *non*-Fos-ir cells either did not change significantly over the course of the experiment (C2 and dorsal strip), or showed a very rapid and transient increase, whose magnitude was less than that seen in Fos-ir cells (A1, A2, C1 cell groups). The extent to which this early response might precede the capacity of neurons to manifest detectable Fos-ir is not clear. These findings indicate that hemorrhage up-regulates TH mRNA levels in medullary catecholaminergic cell groups which have access to adaptive neuroendocrine and/or autonomic control mechanisms. The paradigm employed here may prove of value in assessing the impact of environmental events on gene expression at a cellular level in any complex or heterogeneous cell group.

Fos IMMUNOREACTIVITY IS INDUCED IN RAT SPINAL CORD AUTONOMIC AREAS FOLLOWING LIPOPOLYSACCHARIDE (LPS) INJECTION. N.C.Tkacs* AND A.M.Strack. UCSF Dept. of Physiology, San Francisco, CA 94143-0444.

We have investigated LPS treatment as a model of increased drive to the sympathetic nervous system as indicated by Fos expression in spinal cord loci of sympathetic preganglionic neurons. Male Sprague-Dawley rats were surgically instrumented with intravenous and intraarterial lines and allowed to recover for 4-6 days. On experimental days, saline or LPS (0.2 mg/kg or 1.0 mg/kg) was administered intravenously. After three hours the animals were deeply anesthetized, then perfused with saline and paraformaldehyde; brains and spinal cords were removed and processed for Fos immunocytochemistry (sheep anti-Fos, Serotec). LPS administration resulted in a dose-related appearance of Fos-positive nuclei in spinal segments T4-T13 in the intermediolateral, intercalated, and central autonomic nuclei and the lateral funiculus. LPS also induced Fos in a few cells in the T3 spinal segment. Several stress- and autonomic-related hypothalamic and brainstem nuclei showed Fos (+) cells including SON, PVN (magnocellular and parvocellular), circumventricular organs, amygdala, locus coeruleus, parabrachial region, NTS, and cells within the rostral and caudal ventrolateral medulla. These results demonstrate activation of central autonomic regions and sympathetic preganglionic neurons by LPS treatment.

CENTRAL STRUCTURES RELATED TO RENAL NERVES IDENTIFIED BY TETANUS TOXIN C-FRAGMENT. L.P. Solano-Flores*, M.P. Rosas-Arellano* and J. Ciriello. Dept. of Physiology, Univ. of Western Ontario, London, Canada, N6A 5C1.

The afferent and efferent information conveyed by renal nerves (RN) to and from the central nervous system is thought to be an important component of mechanims involved in cardiovascular and body fluid homeostasis. The present study was done to identify the central structures that integrate RN information using the anterogradely and retrogradely trans-synaptically transported tracer, the C-fragment of tetanus toxin (TTC). The central stump of the cut left RN of anesthetized adult Wistar rats was covered by a TTC (3-5 ul; 30 mg/ml)-soaked piece of gelatin foam and enclosed with vinyl plastic. The animals were allowed to survive for 7-14 days and then perfused transcardially. Transverse or horizontal sections of the forebrain; brainstem and spinal cord were processed immunohistochemically for the visualization of TTC. Neurons and neuropil containing TTC immunoreactivity were observed in the spinal cord, commissural aspect of the nucleus of the solitary tract, area postrema, the region of the A5 cell group, arcuate nucleus, median eminence, subfornical organ, and organum vasculosum laminae terminalis. The celiac and nodose ganglia were also densely labelled. These data suggest that RN may be functionally linked to several central sites via both spinal cord pathways and the vagus nerve. (* postdoctoral fellows from Universidad Nacional Autónoma de México; support by MCR and ICCS of Canada).

HEMODYNAMIC ANALYSIS OF THE CENTRALLY EVOKED CARDIOVASCULAR RESPONSES OF ENDOTHELIN-1 (ET). M.A. Hashim* and A.S. Tadepalli, Division of Pharmacology, Burroughs Wellcome Company, Research Triangle Park, NC 27709.

Previously, we reported that central ET produces profound decreases in blood pressure (*Am. J. Physiol* 262: H1-H9, 1992). The hemodynamic effects of central ET were elaborated in this study. In anesthetized, ventilated rats, cardiac output (CO) and renal blood flow were monitored by ultrasound Doppler and skin blood flow (SBF) in the hindpaw by laser Doppler flowmetry. ET (10 pmol) applied to the IV cerebral ventricle decreased mean arterial blood pressure (40 ± 5%; peak response, mean ± SE) for up to 60 min. Cardiac output increased initially (64 ± 30%) for up to 15 min and subsequently returned to baseline level. Total peripheral vascular resistance (TPR) decreased (53 ± 12%) while SBF increased (71 ± 17%) for up to 60 min. Changes in heart rate were small and variable. These data suggest that: i) central ET-induced hypotension is due to peripheral vasodilation and ii) initial increase in cardiac output may be due to decreased output impedance. RBF decreased (33 ± 6%) concomitant with the blood pressure, but did not recover for up to 90 min; renal vascular resistance remained unchanged for up to 60 min. These observations suggest that the fall in RBF is secondary to the hypotension, probably because the blood pressure is below the autoregulatory limits of the kidney. Thus, the primary cardiovascular response of centrally administered ET appears to be a reduction in TPR, probably via withdrawal of sympathetic vascular tone. Peripherally administered ET increases blood pressure and decreases RBF; these effects are due, primarily, to the vasoconstrictor actions of ET. In contrast, this study suggests that central ET-induced hypotension is due to peripheral vasodilation; the fall in RBF is secondary to the hypotension and occurs in the absence of renal vasoconstriction.

494.10

SYMPATHOADRENAL NEURONS RECEIVE MORE TYROSINE HYDROXYLASE SYNAPSES THAN SYMPATHETIC PRE-GANGLIONIC NEURONS PROJECTING TO THE SUPERIOR CERVICAL GANGLION. I.J. Llewellyn-Smith*, J.B. Minson, P.M. Pilowsky and J.P. Chalmers, Dept of Medicine and Centre for Neuroscience, Flinders University, Bedford Park SA 5042 AUSTRALIA

Sympathetic preganglionic neurons (SPN) receive synapses from nerve fibres that contain a variety of neurotransmitters. However, it is not known if the density of synapses from different types of nerve fibres varies depending upon the target of the SPN. In this study, varicosities that directly contacted or synapsed on rat SPN projecting to the adrenal medulla or superior cervical ganglion (SCG) were evaluated for the presence of tyrosine hydroxylase (TH) immunoreactivity. Cholera toxin B subunit (CTB) was injected into either the SCG or the adrenal medulla and the rats were perfused after 2-3 days. Parasagittal sections through the lateral horn were stained simultaneously for CTB and TH. Immunoreactivity was localized with avidin-biotin-peroxidase and a nickel-DAB reaction. TH-immunoreactivity was present in 25.9% of terminals that contacted or synapsed on sympathoadrenal neurons (305/1178; range in 4 rats, 24.8%-28.1%) whereas only 11.2% of terminals on SPN projecting to the SCG contained TH-immunoreactivity (120/1073; range in 4 rats, 10.3%-12.8%). These ultrastructural findings support the physiological evidence that there is regional specificity in the control of sympathetic outflow.

BIOCYTIN-FILLED SYMPATHETIC PREGANGLIONIC NEURONS IN THE CAT LUMBAR AND THORACIC SPINAL CORD LACK AXON COLLATERALS. P.M. Pilowsky*, I.J. Llewellyn-Smith, L.F. Arnolda, J.B. Minson and J.P. Chalmers. Dept of Medicine and Centre for Neuroscience, Flinders Univ., Bedford Pk 5042, AUSTRALIA.

A few recent studies have used the technique of intracellular recording and dye-filling to assess the detailed morphology of electrophysiologically identified sympathetic preganglionic neurons (SPN). These studies have revealed that in the cat thoracic spinal cord, SPN have extensive dendritic arborisations that are mostly restricted to the nucleus intermediolateralis pars principalis (IMLp), and that their axons arise either directly from the soma, or from a primary dendrite-like process. No examples of axon collaterals have been reported. We report here results from a survey of 26 SPN from the T3 (n=13) or L3 (n=13) spinal segments that had been identified by stimulation of the appropriate white ramus, and then filled intracellularly with biocytin. Biocytin is a recently introduced marker that is particularly effective in demonstrating axon collaterals. Most of the somata were found in the IMLp. The soma of one neuron in the L3 segment was found 100μm lateral to the IMLp. There was a positive correlation between conduction velocity and soma area ($r=0.46$; $P<0.05$). The majority of SPN dendrites were found in the IMLp, although several had dendrites that projected dorsolaterally, or medially as far as the central canal. No examples of axon bifurcation or collateralization were found. These results confirm the findings of others with regard to the dendritic morphology of SPN, and demonstrate a lack of axon collaterals from SPN in the cat lumbar and thoracic spinal cord.

DISTRIBUTION OF PEPTIDES IN AUTONOMIC NUCLEI OF SPINAL CORD IN THE RAT. Y.Hong* and L.C.Weaver. John P.Robarts Res. Inst. and Dept. of Physiology, Univ. Western Ontario, London, Canada N6A 5K8

The distribution of substance-P (SP), enkephalin (Enk) and VIP in fibers and cells was examined in the lower thoracic (T) and lumbar (L) segments of the rat spinal cord. Attention was focused on the relationship between the location of the peptides and sympathetic preganglionic neurons (SPNs) contributing to the greater and lesser splanchnic nerves. To identify splanchnic preganglionic neurons, Fluorogold was applied to the left splanchnic nerve in anaesthetized rats and some of these animals received intrathecal administration of colchicine (10-15 μg each at T6, T9 and T12) 24-48 hrs before perfusion with fixative. The spinal cords (T6-L2) were sectioned at 40 μm and SP-, Enk- and VIP-like immunoreactivity (Li) in fibers and cells was detected with fluorescent immunocytochemical techniques. Most retrogradely labelled cells (90%) were located in the nucleus intermediolateralis (IML) and the rest were situated in the nucleus intercalatus spinalis (IC) and the central autonomic (CA) region of the gray matter. Terminals of fibers containing immunoreactivity to all three peptides were found in all autonomic regions. Fibers containing SP- and Enk-Li were seen projecting in the white matter to the region of the IML and extending from the IML to CA. Putative terminals containing each of the three peptides were further found surrounding the retrogradely labelled cells in the IML. Approximately 2 cells containing VIP-Li were found per section and 80% were located in the autonomic regions. Fewer cells with SP- and Enk-Li were observed (approximately 1 per section) and 70% were outside Laminae VII and X. Although SP-, Enk- and VIP-Li cells were located in all autonomic regions of the spinal cord, very few cells were doubly labelled with retrograde dye and with the antisera to either of the peptides. The data suggest that 1) SP, Enk and VIP are contained in fibers of neurons regulating preganglionic sympathetic control of the abdominal viscera and its vasculature; 2) these peptides may not be major transmitters within splanchnic SPNs. IDENTIFICATION OF RENAL PREGANGLIONIC NEURONS USING HERPES SIMPLEX 1 IN HAMSTERS. N.S. Dehal, G.Dekaban, A. Krassioukov, F. Picard and L.C. Weaver*. J.P. Robarts Research Institute, London, Ont., Canada.

Members of the family of Herpes viruses have been used in various animals to trace pathways from target tissues to the CNS. We used Herpes Simplex 1 (HSV1) to trace the sympathetic pathway from the kidney to the spinal cord. Initially we determined that rats (n=20) and guinea pigs (n=9) were not susceptible to infection with neurotropic strains of HSV1 after injections into visceral organs or ganglia. Hamsters were susceptible to infection with the McIntyre strain of HSV1. To verify that control of renal sympathetic nerves in hamsters is similar to that in rats, electrophysiological studies were done using anesthetized hamsters. Accordingly, blockade of firing of rostral ventrolateral medullary neurons with microinjections of glycine decreased discharge of hamster renal sympathetic nerves by 41±3% and this nerve activity was reduced by only 11±5% after cervical spinal cord transection. To identify renal neurons 5µl of HSV1 ($1x10^9$ pfu/ml) was injected into one kidney of hamsters. After 3-7 days they were perfused and ganglia, spinal cords and brains were removed. Immunohistochemistry was used to visualize the virus-infected neurons. Sympathetic preganglionic neuron (SPN) labelling was found in the ipsilateral intermediolateral cell column of the spinal cord as well as the lateral funiculus in 13 of 28 hamsters. Most infected SPNs were located in thoracic segments 7-9 (T7-9) but the virus labelled SPNs as high as T3 in hamsters with longer survival times. Infected neurons were not found caudal to T11 and rarely were found in the medulla. SPN morphology was usually normal, showing detailed dendritic arborizations, and lysis was not prevalent. Small infected cells were sometimes observed close to SPNs. Because HSV1 was not found in ganglionic neurons in these same hamsters, the polymerase chain reaction was used in different hamsters and detected viral DNA in the paravertebral ganglia ipsilateral to the kidney injected with HSV1. In conclusion, because HSV1 infects a limited number of neurons and appears to cross only one or two synapses it cannot identify all neurons in a pathway. However, the absence of lysis and lack of cellular reaction to the infection permit neurons in a select population to be studied in detail. Support:MRC Canada

CARDIOVASCULAR REGULATION: CARDIAC CONTROL AND SYMPATHETIC RHYTHMS

495.1

DIRECT VISUALIZATION OF OPIOID RECEPTORS ON PREGANGLIONIC PARASYMPATHETIC CARDIAC NEURONS IN THE NUCLEUS AMBIGUUS. D. Mendelowitz* and D.L. Kunze. Department of Molecular Physiology and Biophysics, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030.

It is well known that administration of opiates evoke pronounced cardiorespiratory depression. However, the neurons that possess opioid receptors and are responsible for these responses are unknown. In this study we examined whether preganglionic parasympathetic cardiac neurons in the nucleus ambiguus possess opioid receptors and, therefore, could be responsible for the increased parasympathetic activity and bradycardia.

Preganglionic parasympathetic neurons were identified as described previously (*Neurosci. Lett.* 132:217-221, 1991). Rats were anesthetized with pentobarbital, respirated, and a right thoracotomy was performed to expose the heart. To label cardiac motorneurons the retrograde fluorescent rhodamine tracer (XRITC) was applied to the epicardial surface of cardiac tissue that contain parasympathetic ganglia. The incision sites were closed and the animals recovered for 3 days.

The animals were then sacrificed and the medulla was cut in sections 200 microns thick using a vibratome. Tissue that contained cardiac neurons was incubated in a solution containing 10 microM of the opioid antagonist naloxone labeled with a fluorescent fluorescein tag for 2 hours.

Parasympathetic cardiac neurons and opioid receptors were visualized simultaneously using a laser confocal scanning microscope. Opioid receptors were densely localized to the soma of cardiac neurons, as well as other unidentified neurons, within the nucleus ambiguus. Electrophysiological studies will be needed to identify the potency of different opioid agonists, and the role of opiates in mediating parasympathetic cardiac activity.

495.2

HETEROGENEOUS DISTRIBUTION OF NEUROTRANSMITTER EXPRESSING NEURONS IN THE CANINE PARASYMPATHETIC CARDIAC GANGLIA. M. Mostafa, E.J. Neafsey, R.D. Wurster and T.S. Gray*. Neuroscience Program, Loyola University Stritch Sch. of Med, Maywood, Il. 60153

The distribution of choline acetyltransferase (ChAT), dopamine beta hydroxylase (DBH), substance P, vasoactive intestinal polypeptide (VIP), neuropeptide Y and serotonin in the dog cardiac ganglia was examined using immunohistochemistry. The cardiac ganglia were immersion fixed in 4.0% paraformaldehyde in borate buffer. Frozen sections were cut and processed using the nickle-intensified DAB immunoperoxidase technique.

All large cells were intensely immunoreactive for ChAT and lightly positive for DBH. Fewer large cells contained substance P and VIP immunoreactivity and were distributed evenly throughout the various ganglia. Distinct clumps of large cells were stained positive for neuropeptide Y. Smaller neurons that resembled intensely fluorescent cells stained positively for serotonin and DBH. Many densely staining neuropeptide Y fibers and terminals were observed throughout the ganglia. The terminals appeared to contact large neurons in the ganglia. Fewer fibers stained positive for VIP and substance P. DBH immunostained fibers usually were observed outside the ganglia, but on occasion entered the ganglia.

The results demonstrate that there is heterogeneous distribution of neurotransmitter phenotypes in the parasympathetic cardiac ganglia of the dog. (Support: NIH HL 27595)

POTASSIUM (K^+) CURRENTS IN ADULT RAT INTRACARDIAC NEURONS *IN SITU*. S.X.Xi-Moy*, N.J.Dun. Dept. of Anat., Med. Col. of Ohio, Toledo, OH 43699.

Potassium currents of *in situ* parasympathetic, intracardiac ganglion neurons of 5-wk-old rats were studied using single-electrode voltage-clamp techniques. Ganglia were dissected from small fat pads on dorsal atrial wall. Intracellular Lucifer Yellow iontophoresis verified that intracardiac ganglion neurons are unipolar cells with few dendrites. Resting potentials ranged from -40 to -79 mV. Prolonged intracellular current pulse evoked either single or multiple (30-35%) spike(s). Spontaneous EPSPs (with or without spikes) or pacemaker-like action potentials were observed in approximately 40% of the neurons. An inwardly rectifying current was slowly activated by step hyperpolarization and was blocked by cesium (1 mM). This current showed a steady-state amplitude of 200-400 pA and threshold of -80 to -90 mV. Background currents evoked in a Ca^{2+}-free solution containing cesium (1 mM), TEA (10 mM) and 4-AP (1 mM) showed the characteristics of "leak" K^+ conductance. The time- and voltage-dependent outward currents activated by step depolarization in the presence of TTX (3 μM) showed reversal potentials as predicted by the Nernst equation. The depolarization-activated K^+ currents were reduced by TEA (10 mM) or Ca^{2+}-free solution, suggesting the presence of both delayed rectifying K^+ current and Ca^{2+}-activated K^+ current. Inhibition of K^+ currents increased membrane excitability and evoked spontaneous spikes, and may also increase the presynaptic release of ACh. These results underscore the important role of K^+ currents in vagal control of cardiac functions. (Supported by AHA Ohio Affiliate)

DOES SMOKING IMPAIR VAGAL CONTROL OF HEART RATE? B. Bishop*, J. A. Hirsch, and J. L. York. Dept. Physiology, SUNY/Buffalo; and Research Institute on Alcoholism, Buffalo, NY 14214.

Respiratory sinus arrhythmia amplitude (RSA) is the difference between maximum and minimum instantaneous HRs following inspiratory onset, and is accepted as an index of vagal cardiac control. We studied 33 smokers (S) and 33 non-smokers (NS), who were matched for age, race, gender, height, and blood pressure, in supine and seated positions. Mean resting HR, obtained over 30 seconds, was higher in S than NS suggesting that chronic tobacco use alters the relative sympathetic and parasympathetic contributions to cardiac control. RSAs, determined for 10 consecutive deep (>50% VC) and slow (5-7/min) breaths, were not different in S and NS in either position, but RSA was higher in the seated than in the supine position, suggesting that smoking blunts neither respiratory nor baroreflex modulation of vagal cardiac control. We concluded the higher HRs in smokers is likely the result of the sympathomimetic effects of nicotine rather than an impaired vagal control. (Supported by NIAAA RO1-AA06867)

CHOLINERGIC INFLUENCES ON BEHAVIORAL AND CARDIAC RESPONSES TO ACUTE UMBILICAL CORD COMPRESSION IN THE RAT FETUS. S. M. Umphress*, S. R. Robinson and W. P. Smotherman. Laboratory of Perinatal Neuroethology, Center for Developmental Psychobiology, SUNY-Binghamton, Binghamton, NY 13902-6000.

On day 20 of gestation, fetal rats exhibit a stereotypic bradycardia and transient increase in motor activity following experimental compression of the umbilical cord. Previous research has identified a role for cholinergic mediation of fetal cardiac responses, but not motor responses, to other forms of sensory stimulation. In this experiment, pregnant rats were prepared by chemical transection of the spinal cord to permit direct observation of fetal rats in vivo. Fetuses were fitted with paired cardiac leads for measurement of heart rate (HR) and received an ip injection of atropine (1.0 mg/kg) or the isotonic saline vehicle 9 min before testing. Real-time recordings of fetal motor behavior and HR were collected during a 1-min period prior to placement of a microvascular clamp on the umbilical cord, a 2-min period of umbilical cord compression, and a 3-min period following removal of the clamp and restoration of umbilical circulation. Saline-injected fetuses showed the typical, brief period of increased motor activity, which was predominated by lateral flexions of the body trunk, and a pronounced HR deceleration, which gradually returned to pre-clamp baseline levels after removal of the clamp. Atropine-injected fetuses exhibited a slower onset of bradycardia and more rapid return to baseline HR after removal of the clamp. Further, atropine-injected subjects showed a reduced behavioral response during the period of cord compression and exhibited a secondary increase in trunk movements during recovery. These findings suggest a role for parasympathetic mediation of the magnitude and patterning of both cardiac and motor responses to cord compression.

NORCOCAINE AND COCAETHYLENE SHARE DELETERIOUS CARDIO-ELECTROPHYSIOLOGICAL EFFECTS WITH COCAINE. H. K. Erzouki, S. R. Tella, S. R. Goldberg* and C. W. Schindler. Behav. Pharmacol. and Genetics Lab., NIDA Addiction Research Center, Baltimore, MD 21224.

To compare the electrophysiological effects of cocaine with its metabolites, three different groups of pentobarbital anesthetized, artificially ventilated rats were infused with cocaine (COC), norcocaine (NC), and cocaethylene (CE) at a rate of 1.5 mg/kg/min (n = 5-6). CE is formed when cocaine and alcohol are used in combination. If remarkable changes in cardiac electrical function were observed, $NaHCO_3$ (4 mEq/kg) was given to attempt reversal of the observed effect. Mean blood pressure (BP), sinus cyclic length (CL), PR interval, QRS duration, QT interval and blood pH were measured throughout the experiments.

	CL (ms)	PR (ms)	QRS (ms)	QT (ms)	PH
Pre-COC	202±25	50±5	20±1	75±11	7.441
COC	304±42	76±11	59±8*	147±15*	7.380
COC +$NaHCO_3$	502±83†	50±7	27±3†	91±11†	7.826†
Pre-NC	208±15	63±9	22±3	86±13	7.424
NC	299±37	104±15	53±8*	151±20*	7.300
NC +$NaHCO_3$	340±53	80±9	26±3†	152±22	7.693†
Pre-CE	165±9	52±5	18±1	58±1	7.443
CE	283±9*	97±10*	57±5*	152±15*	7.383
CE +$NaHCO_3$	305±21	69±5†	27±2†	144±11	7.813†

$p < .05$ *Pre versus Drug, †$NaHCO_3$ vs Drug Values are mean ± S.E.M.

Ventricular tachycardia was noted in all groups, but was inconsistent across animals. COC, NC and CE all prolonged CL, PR, QRS, and QT. All three agents exhibited a local anesthetic effect on the myocardium and were potent arrhythmogenic agents. $NaHCO_3$ reversed the QRS prolongation and converted the ventricular tachycardia to a regular sinus rhythm.

NEUROPEPTIDE Y PRODUCTION IN RAT MYOCYTE CULTURE IS REGULATED BY SYMPATHETIC NEURONS . K.L.Marek* and T.Niven-Fairchild, Dept. of Neurology, Yale Univ. School of Medicine, New Haven CT 06510

Sympathetic innervation of heart dramatically alters cardiac peptide production. The neural regulation of Neuropeptide Y (NPY) production and secretion has been examined in cardiac myocyte culture and in cardiac myocyte-sympathetic neuron (superior cervical ganglion) co-culture. NPY mRNA levels were quantitated by Northern analysis. NPY content was measured by radioimmunoassay and NPY processing was further analyzed by gel filtration. NPY was stable in spent medium for at least 48 hours. Cultures were maintained in complete serum free medium for up to 21 days.

NPY production and secretion was increased (by 1.5-2 fold) in atrial and ventricular cultures treated with neuron conditioned medium, but was reduced (by 2-4 fold) in SCG-atrial cultures and SCG-ventricular cultures. The changes in myocyte NPY expression were dependent on the age of the cardiac cells in culture and on the duration of treatment with neuron conditioned medium or neurons. Changes in atrium and ventricle were tissue specific.

NPY production in myocytes is regulated by SCG neurons and by SCG culture conditioned medium as myocytes develop in culture. Experiments are underway to further elucidate the mechanisms of this neuronal-target interaction and to identify the developmental significance of cardiac NPY expression. NSO1168, AHA900834.

SYMPATHETIC NERVE RESPONSE TO ACUTE AND CHRONIC MORPHINE ADMINISTRATION IN THE RAT. S.C. Baraban* and P.G. Guyenet. Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

This study investigates the effects of acute and chronic administration of morphine sulfate (MS) on the discharge of the lumbar sympathetic nerve (SND) and phrenic nerve (PND) in urethane-anesthetized, paralyzed, vagotomized 300-350g Sprague-Dawley rats. Acute MS (5 mg/kg i.v., N=5) reduced i) resting MAP (-27mmHg, $p<0.05$) ii) resting PND amplitude (-90%, $p<0.05$) iii) the central respiratory modulation of SND and iv) the effect of carotid chemoreceptor stimulation (10% O_2, 10-15 seconds) on PND amplitude (-55%, $p<0.05$) and SND (-45%, $p<0.05$). MS also attenuated the sympathetic baroreflex and raised the resting SND (+34%, $p<0.05$). The opiate antagonist naloxone (Nal, 1 mg/kg i.v., 45-60 min. after MS) reversed the effects of MS on resting MAP, resting SND, the sympathetic chemo- and baroreflexes. Interestingly, Nal increased significantly above pre-MS control level i) the resting PND amplitude at constant 5% expired pCO_2 (+146%, $p<0.05$) and ii) the central respiratory modulation of SND.

Rats chronically treated with MS (one 75 mg pellet day 1, 1 p. day 2, 2 p. day 3 2 p. day 4, and 3 p. day 5, N=5) were compared on day 6 with controls implanted with inert pellets (same schedule). MS-treated rats had i) a higher threshold for apnea (3.8% expired CO_2) and ii) attenuated sympathetic baroreflexes. Nal (1 mg/kg i.v.) given to MS treated rats increased resting MAP (+25mmHg, $p<0.05$), PND amplitude (+344%, $p<0.05$) and the central respiratory modulation of SND, but reduced PND rate and resting SND (-45%, $p<0.05$). Nal also restored baroreflex function to normal. Nal exerted no effect in control rats. In summary, the major effects of acute and chronic MS administration on SND include perturbations of the baroreflex and changes in the respiration dependant portion of central sympathetic tone generation. NALTREXONE PRECIPITATED MORPHINE WITHDRAWAL STIMULATES C-FOS PRODUCTION IN AUTONOMIC AREAS OF RAT BRAINSTEM AND FOREBRAIN. R.L. Stornetta*, R. Norton and P.G. Guyenet. Dept. of Pharmacology, Univ. Va. Health Sci. Center, Charlottesville, VA 22908. Autonomic activity is greatly increased during morphine withdrawal. We sought to determine the specific autonomic areas that might be responsible for this increased activity by using an antibody against the nuclear protein *c-fos* in brain tissues from rats withdrawn from morphine. Five groups of 4 male, Sprague-Dawley 250-300g rats were implanted with morphine pellets (75 mg, NIDA) or placebo pellets over a 5 day regimen and injected on day 6 with either saline or naltrexone (100 mg/kg) (Rasmussen et al, 1990). Two and one half hours after injection, rats were quickly anesthetized with pentobarbital, i.p., and perfused transcardially with 4% paraformaldehyde. Coronal brain sections (40 μm) were cut on a vibratome and reacted with an antibody against *c-fos* protein kindly provided by T. Curran. After a standard PAP protocol, *c-fos*-like immunoreactivity was observed in several autonomic areas of the medulla including the nucleus of the solitary tract (NTS), caudal (CVL) and rostral ventrolateral medulla (RVL). Although some *c-fos*-like reactivity was seen in these areas in control rats (either morphine-implanted, saline injected (n = 5), or placebo-implanted, saline (n = 5) or naltrexone injected (n = 5)), a significantly higher number of *c-fos* positive cells in NTS, CVL and RVL were seen in the naltrexone injected morphine-implanted rats (n = 5). Large numbers of *c-fos*-like immunoreactive cells were also seen in locus coeruleus (LC), central gray adjacent to LC, A5 pontine noradrenergic nucleus, pontine parabrachial nucleus and paraventricular nucleus of the hypothalamus from morphine withdrawn rats. (NIDA R29 DA07353-01)

CLINICAL EVALUATION OF SYMPATHETIC ACTIVITY WITH CARDIOVASCULAR REFLEX TESTS AND SPECTRAL ANALYSIS OF HEART RATE VARIABILITY. S. Šega and T. Kiauta*. Dept. of Neurology, University Medical Centre, SLO-61105 Ljubljana, Slovenia.

Orthostatic test, handgrip test and spectral analysis of heart rate variability were performed on 70 healthy volunteers of both sexes, aged 21 to 60 years. Arterial blood pressure changes during orthostatic test, diastolic blood pressure increase during handgrip and integrals of the low- and medium-frequency bands of amplitude spectra in the standing posture were evaluated.

Blood pressure changes during orthostatic and handgrip tests did not correlate with age, whereas integrals of amplitude spectra did. Blood pressure changes during handgrip and orthostatic test did not correlate with each other or with integrals in the standing posture.

A possible explanation of these results could be that tests involving non-invasively measured ABP changes are less sensitive than amplitude spectra in the standing posture for the evaluation of sympathetic activity.

495.11

INTERACTION BETWEEN SYMPATHETIC NERVE ACTIVITY AND ARTERIAL PRESSURE IN CONSCIOUS AND ANESTHETIZED RAT. D.R. Brown, L.V. Brown, A. Patwardhan and D.C. Randall*. Ctr. Biomed. Engin. and Dept. Physiol. & Biophys., Univ. Kentucky, Lexington, KY, 40536.

Sympathetic nerve activity (SNA) and blood pressure (BP) were sampled for 9.56 min. $\geq$ 2 days after implantation of renal nerve electrodes and arterial catheters in rat (n=3) to test the premise that low frequency BP oscillations are generated by the baroreflex. The measurements were repeated after anesthetizing the animals (pentobarbital, 30 mg/kg). SNA and BP autospectra and coherence were computed. In the low frequency range the maximum coherence (0.90 ± .002, mean ± SD) and maximum SNA power occurred at 0.40 ± .0004 Hz. In contrast, the coherence computed at the frequency (0.17 Hz) for maximum BP spectral power was only 0.40 ± 0.21. After anesthesia the frequency (0.40 ± .003 Hz) at maximum coherence and coherence (0.88 ± .004) were essentially unchanged although SNA and BP spectral power decreased by 78.5 and 70.2 percent, respectively. These data suggest that BP spectral power at a frequency of approximately 0.4 Hz may be due to a SNA-baroreflex interaction and that anesthesia does not abolish this interaction. However, anesthesia apparently profoundly reduces both the SNA and BP responses at this frequency. (Supported by KY Affiliate, AHA and KY Tobacco Health Res. Inst.)

COMPARISON OF VAGAL POWER DURING PACED BREATHING AND TREADMILL EXERCISE TESTING IN CHRONIC FATIGUE SYNDROME. **W.L. Boda, S.A. Sisto, P.Z. Zhang, T.W. Findley, and W.N. Tapp, B.H. Natelson*. Kessler Institute for Rehabilitation, West Orange, NJ, New Jersey Medical School, Newark, NJ, VA Medical Center, East Orange, NJ, 07019**

Currently the etiology of Chronic Fatigue Syndrome (CFS) is unknown. It is characterized by many neuropsychological, infectious, and immunological symptoms. The most debilitating feature of CFS is fatigue that is severe enough to reduce activity by greater than 50 % for longer than 6 months. Since there is no diagnostic test for CFS, arguments exist as to whether it is medical or functional in etiology. To evaluate this problem, a static paced breathing protocol of 8, 12, and 18 breaths/min both in sitting and standing was used to compare vagal power in CFS patients and normals. Vagal power was derived through the application of heart rate spectrum analysis on the ECG and respiration signals. Paced breathing was lower in sitting for CFS patients vs. normals. Vagal power did not fall in the standing posture as compared to controls. Progressive exercise tests on a treadmill showed an increased vagal response to exercise as compared to normals. It is not clear at this point how to reconcile these differences between these two studies. Measurement of fatigue was also analyzed using biomechanical parameters through video analysis to determine if there is a correlation between physiological and functional fatigue of CFS patients and normals at similar work levels.

These results preliminarily indicate that CFS patients may exhibit a consistent organic component to their illness, that is, inappropriate vagal firing in different postures and during exercise. Comparisons of the extent to which this vagal firing affects exercise, may aid in the diagnosis of CFS or perhaps in the classification of severity of CFS.

AGE-RELATED COHERENCE OF EFFERENT SYMPATHETIC (SYMP) ACTIVITY IN NEONATAL SWINE. B. W. Hundley, P. M. Gootman*, G. Condemi, J. M. Sierra, H. L. Cohen, L. P. Eberle and A. P. Rudell. Dept. of Physiology, SUNY- Hlth. Sci. Ctr., Brooklyn, NY 11203.

Simultaneous recordings of cervical SYMP, splanchnic and efferent phrenic (PHR) activity were obtained in Saffan-anesthetized, paralyzed and artificially ventilated piglets (1-38 days of age) along with aortic pressure, EKG and end-tidal CO_2. Power spectra and coherence functions of SYMP discharge were obtained by a fast Fourier transform routine. PHR discharge defined the separate inspiratory (I) and expiratory (E) epochs used for gating spectral estimates. Peaks were revealed in four frequency ranges (3-7 Hz, 10-15 Hz, 18-24 Hz, 30-38 Hz). Coherence varied from insignificant values (< 0.1) in swine < 2 wks old to significant coherence values (> 0.3) in animals 19 days or older. Peak coherence values were obtained for 15 swine, separated into three age groups, for analysis of variance. The linear component of the age-coherence relationship for the 3 - 7 and 18 - 24 Hz peaks was significant for both I and E epochs ($p < .05$). The quadratic component was not significant. For the 10 - 15 Hz peak both the linear and quadratic components were significant ($p < .05$). For the 30 - 38 Hz peak, neither linear nor quadratic components were significant ($p > .05$). Correlation of age with E to I power ratios of the SYMP was only significant in the cervical SYMP (rho = 0.52). Results suggest that coherence is a good indicator of postnatal maturation occurring within the SYMP rhythm generating system(s). (Supported by NIH grants HL-20864 and HD-28931.)

HEART RATE DYNAMICS DURING SLEEP-WAKING STATES IN NORMAL INFANTS. R.K. Harper*, V.L. Schechtman and R.M. Harper. Brain Research Institute and the Dept. of Anatomy & Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024.

Extent and pattern of heart rate variation, assessed by summary procedures, undergo marked developmental changes over the early postnatal period. Summary measures of heart rate variation, however, fail to demonstrate the beat-by-beat dynamics of heart rate. We examined the development of moment-to-moment changes in cardiac interbeat intervals in normal infants over the first 6 months of life.

Twelve-hour physiological recordings were obtained from 24 normal infants at 1 week and 1,2,3,4, and 6 months of age. For each recording, plots were made of each cardiac R-R interval as a function of the previous interval (Poincaré Plots) during all periods of quiet sleep, REM sleep, and waking. In each plot, the extent of dispersion of points about the line of identity was quantified at a relatively high and a relatively low heart rate. The dispersion of points at both low and high heart rates showed significant age and state effects. Analysis of covariance indicated that all state and age related changes paralleled changes in basal heart rate; only the effect of dynamic rate (heart rate during the previous beat) remained significant after controlling for differences in basal heart rate. Thus, the relationship of one cardiac R-R interval with its predecessor changes significantly with age over this period, paralleling short and long term changes in heart rate.

Supported by HD22695. Data acquisition and sleep state classification were performed under the direction of Drs. J. Hodgman and T. Hoppenbrouwers under NICHD contract HD22777.

DYNAMIC ANALYSIS OF BEAT-TO-BEAT HEART RATE CHANGES IN DEVELOPING INFANTS. V.L. Schechtman*, R.K. Harper and R.M. Harper. Brain Research Inst. and Dept. of Anatomy & Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024.

Poincaré Plots demonstrate particular aspects of heart rate dynamics. However, the strong positive correlation between one **interval** and the next obscures the immediate relationship between a **change** in heart rate and the next change. The nature of this relationship was examined in 24 infants recorded at 1 week and at 1,2,3,4, and 6 months of age. In each sleep-waking state, the number of ΔRRs (the difference between two successive RR intervals) larger than 4 msec was determined as a percentage of the total number of heart beats, and each pair of successive changes was categorized based on the directions of the two changes. Analysis of variance was used to identify differences in the proportion of large ΔRRs and their temporal patterns over ages and sleep states. During all states, the proportion of large ΔRRs decreased over the first month of life and increased from 1 to 3 months of age. The reduction over the first month depended on the increase in heart rate over that period, but some subsequent changes were heart rate independent. Furthermore, during the first month of life, infants showed significantly more sustained increases in heart rate than sustained decreases, while the opposite pattern was seen in infants from 3 to 6 months of age. We speculate that the profound and enduring changes in cardiac rate dynamics occurring between 1 and 3 months of age may reflect the emergence of cardiosympathetic reflexes.

Supported by HD22695. Data collection and state classification performed under direction of Drs. J. Hodgman and T. Hoppenbrouwers under contract HD22777.

CARDIOVASCULAR REGULATION: HYPERTENSION, REFLEXES AND PERIPHERAL AUTONOMICS

496.1

HYPERTENSION INDUCED BY RANDOM AIR-JET STRESS IN THE BORDERLINE HYPERTENSIVE RATS (BHR). Guy Drolet*, Sylvie Laforest and Hélène Bachelard. Unité d'Hypertension, Centre de Recherche du CHUL, Université Laval, Québec (Qc), G1V 4G2.

The relationship between psychological stress and hypertension is regarded to be circumstantial. However, it has been suggested that a genetic predisposition for the development of hypertension might be necessary for the expression of this relationship. The present study investigated the existence of such relationship in the F1 offspring of female genetically predisposed to hypertension (SHR) and normotensive male Wistar Kyoto (WKY) rats. Five weeks old male BHR were randomly assigned to an experimental and a control group. Rats in the experimental group were placed 5 days/week for 30 minutes in a restrainer while receiving randomly-timed (interval 10-60 sec.) compressed air puffs of random duration (0.5 to 10 sec.) directed toward the snout. This treatment lasted 8 weeks. Maturational control BHR remained in their home cage and were handled daily. Weekly blood pressure measurements were made in all rats using tail plethysmography. Exposure to air puff stress for 8 weeks induced an increase of ~ 20 mmHg in mean arterial pressure as compared to the control rats. However, there were no differences neither in resting heart rate nor in basal plasma catecholamines concentrations suggesting that the activity of the autonomic nervous system was not different between stressed and control BHR, at least in resting conditions. These results suggest that randomly delivered air puff stress induced-hypertension in BHR is independent of an increase in sympathetic nervous system activity in resting conditions.(Supported by MRC, HSFQ and FRSQ)

ALCOHOL-INDUCED SECRETION OF ATRIAL NATRIURETIC FACTOR (ANF) IN RATS:POSSIBLE IMPLICATION OF ß-ENDORPHIN P. Guillaume*, C. Gianoulakis, Dept. Physiology, Douglas Hospital Research Centre, McGill University, Verdun, Québec.

It has been previously reported and confirmed by us that small quantities of ethanol decrease the age-dependent development of hypertension in rats. The objective of the present studies was to test the hypothesis that ethanol stimulates the release of Atrial Natriuretic Factor (ANF), which in turn could mediate its antihypertensive effects. Male Long-Evans rats having a catheter in the jugular vein were used. The animals were injected i.p. with various concentrations of ethanol or saline. Blood samples were withdrawn at 0, 15, 30, 60 and 120 minutes post-injection for estimation of plasma ANF, corticosterone and ß-endorphin (ß-EP). Results indicated that ethanol increased the plasma concentration of ANF, ß-EP and corticosterone. The increased plasma content of ANF could be due to a direct effect of ethanol on the heart atria, or mediated by a number of hormones the release of which is enhanced by ethanol. Since it was previously shown that opioids modulate the secretion of ANF from heart atria, ß-EP could be partially responsible for the increased ANF release following ethanol administration. Further studies using appropriate opiate antagonists could confirm this hypothesis.

496.3

THE IMMEDIATELY RELEASABLE STORE OF TRANSMITTER IN SYMPATHETIC NEURONS FROM SHR. *J.C. Magee and G.G. Schofield. Dept. Physiology, Tulane Medical School. New Orleans, LA 70112.*

A greater amplification of preganglionic nerve activity (at physiological frequencies) occurs at sympathetic ganglia of spontaneously hypertensive rats (SHR), compared with normotensive controls. However, transmission of high frequency (70-100 Hz) nerve activity is depressed in these ganglia. This relative depression could result from a greater depletion of the presynaptic transmitter store by an elevated quantal content observed in SHR. Or, less transmitter could be available for release from SHR preganglionic nerve terminals. To test this, trains of 30 supramaximal orthodromic stimuli were delivered to superior cervical ganglia (SCG) isolated from SHR and WKY rats and the resulting EPSCs were recorded from postganglionic neurons. The neurons were voltage clamped, at 31 - 33° C, using conventional electrodes and the discontinuous SEVC. The resulting trains of synaptic currents from both groups initially increased in size and then rapidly decreased to a new steady-state amplitude by the 20-25th stimulation. Plots of EPSC amplitude versus time for each neuron could be fit by a single exponential plus a constant function. The mean time constants of these fits were 5.8±0.8 ms and 5.2±0.8 ms, for SHR and WKY, respectively. The steady-state amplitudes reached were 136±10 nS for SHR and 150±26 nS for WKY. The number of quanta residing in the immediately releasable store, as calculated from these plots, was found to be 4700±200 and 4500±600 for SHR and WKY, respectively. These results demonstrate that the amount of transmitter immediately available for release is the same in SHR and WKY. An enhanced removal of transmitter from a similarly sized store by the increased quantal content of SHR preganglionic neurons could lead to a pronounced depletion of transmitter stores, reducing the ability of SHR SCG to transmit high frequency impulse activity. *Work supported by PHS Grant HL43656.*

496.4

EFFECTS OF CALCIUM AND POTASSIUM ON HYPERTENSION IN RATS. A.D.Dalhouse,* M.Moitzheim, C.Cannon, V.Streich, J.Byrne, J.Tjaden, and J.Kozel. Dept. Psyc., Moorhead State Univ. Moorhead, MN 56563

In a series of experiments to investigate the effects of diatery electrolytes on blood pressure (BP) 20 SHR and 20 WKY male rats were placed on combination diets of high and low calcium (HCa, LCa) and potassium (HK, LK) for 7 weeks after 7 days of base rate data. Pulse, BP, and urine were collected daily during base rate and once weekly during the 7 weeks on the diets. Blood was collected via heart puncture for plasma electrolytes analysis. No pre-post diet related BP differences were observed for WKYs however, SHR HCaHKs showed significant ($p<.01$) BP elevation from base rate. The HCaHK and LCaHK SHRs also showed higher BP than the WKYs ($p<.05$). The HCaHK WKYs showed lower post diet pulse than the HCaHK and LCaHK SHRs but did not differ significantly from the LCa WKYs. All groups showed post diet urine reduction ($p<.01$) in calcium, potassium and sodium with the HCaLK and LCaLK WKYs, and the LCaLK SHRs showing greatest change in urine K. The HCaHK SHRs showed significantly lower plasma Ca than the WKYs, but no other plasma differences were observed. High potassium appears to be associated with elevated BP and pulse in hypertensive rats but with lower BP and pulse in the normotensive rats.

496.5

CALCIUM DEFICIENCY INCREASES RENAL VASCULAR REACTIVITY IN SHRs BUT DOES NOT ALTER TUBULAR RESPONSES TO NERVE STIMULATION. D.C. Hatton*, Y. Qi, and D.A. McCarron. Oregon Health Sciences University, Portland, OR 97201.

SHRs fed high Ca^{2+} diets have lower BP, less BP reactivity to NE, smaller BP responses to α-1 adrenergic blockade and fewer α-1 receptor binding sites in whole kidneys than SHRs fed low Ca^{2+} diets. To determine the functional correlates of the difference in renal α-1 binding sites, tubular and vascular responses were assessed in the current study. SHRs fed either high (2.0%) or low (0.1%) Ca^{2+} diets for 8 weeks were used. While anesthetized with inactin (100mg/kg) intrarenal injections of norepinephrine (NE) were made at 10, 20, 40 or 80 ng/kg. In other animals, a bipolar Ag-AgCl electrode was placed around the renal nerve. The nerve was stimulated at a level just below that required to change blood flow. Urine was collected for 20 min before, during and after stimulation. BP was significantly higher in animals on low Ca^{2+} diets (140 vs 122 mmHg, $p<.01$) as was blood flow (7.9 ml/min/gkw vs 5.6 ml/min/gkw). Animals on low Ca^{2+} diets had greater reductions in renal blood flow at all doses of NE ($p<.005$). Nerve stimulation caused a significant antidiuresis and antinatriuresis but the change was not different between diet groups. The results suggest vascular but not tubular responses may be altered in animals on different Ca^{2+} diets.

496.6

MECHANISM OF PRESSOR RESPONSE TO RAT JOINING PEPTIDE. M. Yoshida, T. Hamakubo F. Sulser* and T. Inagami. Depts. of Biochemistry and Psychiatry, Vanderbilt Univ. Sch. of Med., Nashville, TN 37232.

Intracisternal administration of rat joining peptide (rJP), generated from the pro-opiomelanocortin, has a pressor effect especially in spontaneously hypertensive rats (SHR). To characterize this pressor response, we investigated the effect of angiotensin or adrenergic receptor blockers in conscious SHR. The pressor response to 10 nmol of rJP was abolished by intracisternal pre-administration of 5 μg of losartan (DuP 753) (34 ± 5 vs. 4 ± 1 mmHg). Similar blocking effect was observed by [Sar^1 , Ile^8] angiotensin II. The concentration of angiotensin II in CSF was increased 2.0- and 4.4-fold by 10 and 30 nmol of rJP, respectively. Pre-administration of yohimbine or propranolol did not prevent the pressor response to rJP. These results suggest the brain renin-angiotensin system may participate in the pressor response to rJP.

496.7

POTENTIAL ADVERSE EFFECTS OF LOW DIETARY COPPER AND RANDOM LIGHT/DARK CYCLES ON BLOOD PRESSURE IN NORMOTENSIVE RATS. E.S. Halas* and L.M. Klevay. Department of Psychology, University of North Dakota and USDA, ARS, Grand Forks Human Nutrition Research Center, Grand Forks, ND 58202.

Humans who work a night shift have a significantly higher rate of heart disease than people who work a day shift. A disruption in the circadian rhythms may be a major cause of the increased heart disease among shift workers. However, other factors such as disrupted family life, an inadequate diet, lack of recreational opportunities, and reduced social activities may also contribute to the elevated heart disease. Rats were subjected to random light/dark cycles (Halas and Klevay, *Soc. Neurosci. Abstr.* 17: 1000, 1991). The 8-hour light cycle was initiated at one of three starting periods: 12:00 a.m., 8:00 a.m. or 4:00 p.m. A given cycle would last from 2 to 4 days and then it would be changed. Half of the rats were exposed to the random light/dark cycle while the other half received the standard 12-hour light/dark cycle. Half of the animals in each group were fed a purified diet (Klevay, *Am. J. Clin. Nutr.* 26: 1060, 1973) with 2.00 ppm Cu diet while the others were fed the diet with 5.00 ppm Cu. There were 15 normotensive, Sprague-Dawley male weanling rats in each of the four groups. The experiment lasted nine weeks. Significant elevation of blood pressure occurred in the 2.00 ppm Cu groups ($p<0.01$) whereas the random light/dark cycle groups did not exhibit any increase in blood pressure. These results are in contrast with a prior experiment (loc. cit.) which found that both the 2.00 ppm Cu diet and random light/dark cycle significantly increased plasma cholesterol. These results suggest that the environmental factors that control blood pressure and cholesterol may be different.

496.8

NPY IMMUNOREACTIVITY IS DECREASED IN SYMPATHETIC GANGLIA OF HYPERTENSIVE, BUT NOT HYPERACTIVE RATS. X-M. Fan, K. M. Braas, V. May, E. D. Hendley and C.J. Forehand*. Depts. of Physiology & Biophysics and Anatomy & Neurobiology, Univ. of Vermont, Sch. of Med., Burlington, VT 05405.

Four inbred rat strains (WKY, SHR, WKHT and WKHA) were used to examine whether neuropeptide Y (NPY) levels are specifically altered in sympathetic ganglia of hypertensive animals. SHRs are both hypertensive and hyperactive; WKYs are neither. WKHTs are hypertensive, but not hyperactive; WKHAs are hyperactive, but not hypertensive (Hendley & Ohlsson, Am. J. Physiol 261:H584, '91).

Immunocytochemistry was combined with computerized densitometry to quantitate relative intracytoplasmic NPY in individual sympathetic ganglion cells. Total NPY immunoreactivity was reduced in superior cervical ganglia of both SHR and WKHT rats (75% and 66%, respectively, relative to WKY). A similar reduction in NPY immunoreactivity was observed in stellate ganglia. Inferior mesenteric ganglia in the hypertensive strains showed an even greater reduction in NPY immunoreactivity (to 45% in SHR and 37% in WKHT, relative to WKY). Although both fewer NPY-immunoreactive cells/ganglion and lower NPY/cell contributed to the reduction of ganglionic NPY in hypertensive animals, a decreased level of NPY immunoreactivity in individual cells accounted for the majority of the reduction. Significant differences were not observed between WKY and WKHA rats. These studies suggest that a reduction of NPY levels in sympathetic ganglia is specifically associated with the hypertensive trait.

NOVELTY-INDUCED GROOMING BEHAVIOUR AND DOPAMINE RECEPTORS IN THE SPONTANEOUSLY HYPERTENSIVE RAT. A.C.E. Linthorst, P.L.M. Van Giersbergen*, Th. De Boer, Tj.B. Van Wimersma Greidanus, W. De Jong and D.H.G. Versteeg. Rudolf Magnus Institute, Medical Faculty, State University of Utrecht, Utrecht, The Netherlands.

Recent work from our lab has provided further evidence for a role of the nigrostriatal dopamine (DA) system in the development of hypertension in the spontaneously hypertensive rat (SHR). It was shown that the release of DA in the caudate nucleus of SHR is lower than in that of normotensive Wistar-Kyoto rats (WKY). In addition, in the caudate nucleus of SHR a super-sensitivity of presynaptic DA D_2 autoreceptors was found. To further characterize the nigrostriatal DA system of SHR and WKY novel environment-induced grooming behaviour, regulated extensively by central DA systems, was studied. Moreover, receptor binding studies were performed to establish affinity and concentrations of DA D_1 and D_2 receptors in the caudate nucleus of both rat strains. Novelty-induced grooming behaviour scores were lower in SHR than in WKY. A dose-dependent suppression of grooming behaviour was induced by the DA D_1 antagonist SCH 23390 and by the DA D_2 agonist quin-pirole. The SCH 23390-induced suppression was less, whereas that by quinpirole was more pronounced in SHR than in WKY. No differences between SHR and WKY were found in binding characteristics of DA receptors. The results suggest that differences between SHR and WKY as found in the grooming paradigm are not related to changes in binding characteristics of caudate DA receptors. However, the stronger quinpirole-induced inhibition of grooming behaviour may correspond to the previously reported super-sensitivity of presynaptic DA D_2 receptors in the caudate nucleus of SHR.

496.10

HYPOVOLEMIA-INDUCED VASOPRESSIN SECRETION IN CHRONIC BARORECEPTOR DENERVATED RATS. A.M. Schreihofer*, E.M. Stricker, and A.F. Sved. Department of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA, 15260.

We previously demonstrated that in chronic sino-aortic denervated (SAD) rats, bilateral nucleus tractus solitarius (NTS) lesions had no effect on plasma vasopressin (VP) levels (McDonald and Sved, Neurosci. Abstr. 1991). Since these results are inconsistent with the notion that cardiopulmonary (CP) baroreceptor vagal afferents provide a tonic inhibitory influence on VP secretion, the present study sought to further examine the role of CP baroreceptor afferents in the regulation of VP secretion in chronic SAD rats. In chloralose-anesthetized, ventilated chronic SAD rats (n=4) plasma VP levels remained low following bilateral vagotomy (7±2 pg/ml), consistent with our previous results indicating a lack of tonic inhibition of VP secretion mediated via the NTS. To examine the VP response to hypovolemia, chronic SAD rats were subjected to serial hemorrhage (4 samples of 2 ml/300 g at 10-min intervals); plasma VP levels were increased similarly to control rats (SAD=148±56 pg/ml, n=5; control=146±34 pg/ml, n=6). However, rats with chronic NTS lesions (arterial and CP baroreceptor reflexes were abolished) also responded to hemorrhage with increases in plasma VP levels not significantly different from control or chronic SAD rats, indicating that hemorrhage is not specific enough to evaluate CP baroreceptor function. To elicit a more specific hypovolemic stimulus, rats were injected with a 30% polyethylene glycol solution (5 ml, sc.); the colloid was allowed to draw protein-free plasma out of the vasculature for 6 hrs, creating a 25-40% decrease in plasma volume (plasma protein concentration increased from 5.4±0.1 g/dl to 7.0-8.8 g/dl). Colloid treatment increased plasma VP levels in chronic SAD rats (n=7) similarly to control rats (n=6). However, the VP response to colloid was substantially attenuated in chronic NTS lesioned rats (n=6), suggesting that this hypovolemic stimulus acted through remaining vagal afferents in chronic SAD rats. These results suggest that although remaining CP baroreceptor afferents do not provide tonic inhibition of VP secretion in chronic SAD rats, hypovolemia is still capable of increasing VP secretion through a non-tonic excitatory mechanism mediated through the NTS.

EFFECTS OF CHEMORECEPTOR STIMULATION ON REGIONAL HEMODYNAMICS IN RATS. A.M. Hoque, R.A. Shaffer and S.J. Lewis,* Dept. of Pharmacology and Cardiovascular Center, Univ. of Iowa, Iowa City, IA 52242.

Chemoreceptor (CR) reflexes are critical in the regulation of cardiovascular function. In this study the effects of CR stimulation by sodium cyanide (NaCN 50 - 200 μg/kg, i.v.) on regional hemodynamics were examined before and after bilateral transection of the carotid sinus nerves (CSNX) in urethane-anesthetized rats. The injection of NaCN produced a fall in arterial pressure (AP), an increase in cardiac output (CO) and a reduction in total peripheral resistance (TPR). NaCN also increased hindquarter (HQF), renal (RF) and mesenteric (MF) blood flows and consequently reduced the resistances in these beds. Bilateral CSNX produced marked increases in TPR, hindquarter (HQR), renal (RR) and mesenteric (MR) resistances, a decrease in CO and no change in AP. Bilateral CSNX did not modify the hemodynamic effects of NaCN. These results suggest that stimulation of chemoreflexes produces marked cardiovascular changes and that the CSNs also provide tonic regulation of regional hemodynamics. The present study also suggests that i.v. NaCN stimulates chemoafferents other than those in the CSN. (Supported by HL14388 and HL44546)

FUROSEMIDE IMPAIRS CENTRAL AND PERIPHERALLY-INDUCED PRESSOR RESPONSES. D.S.A. Colombari; E. Colombari; W.A. Saad*; L.A.A. Camargo; A. Renzi; L.A. De Luca Jr. and J.V. Menani, Dept. of Physiology, School of Dentistry, UNESP, Araraquara, SP 14800, Brazil.

In the present work we investigated the effect of previous treatment with furosemide on the pressor responses to intracerebroventricular (ICV) angiotensin II (AII), carbachol (CARB), norepinephrine (NOR) and 2 M NaCl (HS) as well as intravenous (IV) AII, NOR and vasopressin (AVP). Normotensive rats received two injections of furosemide (Lasix, Hoechst, 30 mg/kg b.w., 12 and 1 h before the experiment). The pressor responses to ICV AII (25 ng), CARB (7.5 nmol) and NOR (80 nmol) and to IV AII (50 ng) and NOR (0.3 ug) were reduced after the treatment with furosemide. The pressor response to ICV HS and to IV AVP was not changed after furosemide. The unchanged pressor response to central HS could be more related to AVP release since the effect of IV AVP was also not changed after furosemide. The results are in accordance with the idea that furosemide impairs sympathetic-induced vasoconstriction. It is also possible that the impairment in pressor responses is a result of changes in fluid-electrolyte balance.

INFLUENCE OF ESTROUS CYCLE ON CONTRACTILE RESPONSES TO SENSORY AND ADRENERGIC NERVE STIMULATION IN FEMALE RAT BLOOD VESSELS. Z. Li and S.P. Duckles*, Dept. of Pharmacology, University of California, Irvine, CA 92717

To study whether the estrous cycle has a significant effect on vascular reactivity to nerve stimulation, 3 month old F-344 rats in medestrous and proestrous stages (characterized by vaginal smear) were used. In the isolated Krebs' perfused mesenteric vascular bed with guanethidine present to block adrenergic nerves and methoxamine to maintain smooth muscle tone, sensory nerve activation caused by nicotine (Nic) exposure or transmural nerve stimulation (TNS) was not significantly different between medestrous and proestrous groups. In isolated tail artery ring segments which are rich in

	Perfused Mesentery Relax. (%)		Tail Artery Contraction (g)	
	Nic (3×10^{-4} M)	TNS (4 Hz)	NE (3×10^{-6} M)	TNS (4 Hz)
Med-E	49.1 ± 12.6	48.1 ± 17.5	0.28 ± 0.05	0.35 ± 0.04
Pro-E	60.4 ± 6.0	41.5 ± 3.3	0.28 ± 0.07	0.47 ± 0.15

adrenergic but lack sensory innervation, increasing frequencies of TNS caused an increase in developed force in both medestrous and proestrous groups; no significant difference was seen. Furthermore concentration response curves to norepinephrine (NE) were superimposed. In addition, there was no significant difference in the non-specific relaxation produced by higher concentrations of nicotine. We conclude that different estrous stages do not significantly influence vascular responses to sensory or adrenergic nerve stimulation.

ROLE OF NITRIC OXIDE (NO) IN THE CARDIOVASCULAR EFFECTS OF ACETYLCHOLINE (Ach). J.S. Simon*, R.A. Shaffer, A.M. Hoque, and S.J. Lewis. Depts. Pharmacol., Internal Medicine & Cardiovasc. Ctr., Univ. of Iowa, Iowa City, IA 52242.

It is well established that Ach releases NO from the vascular endothelium. This study examined the possibility that the effects of Ach on regional hemodynamics in urethane-anesthetized rats involves NO. Ach (0.1 - 5 μg/kg, i.v.) produced a fall in mean arterial (MAP) and pulse pressure (PP) and heart rate, an increase in cardiac output (CO) and decreases in total peripheral resistance (TPR), hindquarter (HQR) and mesenteric (MR) but no change in renal (RR) resistance. Following injection of the NO-synthesis inhibitor L-NAME (25 μmole/kg, i.v.), Ach produced exaggerated falls in MAP, no bradycardia, an exaggerated increase in CO, similar changes in TPR and HQR but larger reductions in RR and MR. However, the duration of the Ach effects were markedly reduced following L-NAME. L-NAME also abolished the Ach-induced reduction in PP. These results suggest that a) NO is involved in the Ach-induced bradycardia and the maintenance but not the initiation of the hemodynamic effects of Ach, b) Ach reduces PP (probably via a decrease in vascular compliance) by a NO-dependent mechanism. (Supported by HL14388 and HL44546.)

496.15

EVIDENCE THAT NITROSYL FACTORS (NOFS) ARE RELEASED FROM SYMPATHETIC NERVES. R.L. Davisson*, A.K. Johnson, and S.J. Lewis. Depts. Psychology, Pharmacology, & Cardiovasc. Ctr., Univ. of Iowa, Iowa City, IA 52242.

Bretylium (BRE) selectively depolarizes sympathetic nerve terminals leading to a release of neurotransmitter stores. This study examined the effects of BRE on vascular hemodynamics in conscious rats. BRE (5 mg/kg, iv) caused an increase in arterial pressure (AP), a sustained decrease in hindquarter resistance (HQR), and a gradual increase in renal (RR) and mesenteric (MR) resistances in saline-treated rats. After the α1-adrenoceptor antagonist prazosin (100 μg/kg iv), BRE produced hypotension and exaggerated decreases in HQR, RR, and MR. The NO synthase inhibitor L-NAME (25 μmol/kg iv) abolished the BRE-induced decrease in HQR in saline-treated rats and the decreases in HQR, RR, and MR in prazosin-treated rats. This suggests that BRE causes the co-release of pre-formed stores of norepinephrine and vasodilator NOFs from sympathetic nerves. This raises the possibility that NOFs are neurotransmitters in sympathetic vasodilator neurons and neuromodulators in sympathetic vasoconstrictor neurons. (Support by HLB 14388 & 44546)

IMMUNOCYTOCHEMICAL CHARACTERISTICS OF DORSAL FACIAL AREA OF THE MEDULLA IN CATS. J.S. Kuo[1], T. Chyi[2], V. Cheng[2], J.Y. Wang*. [1]Dept. Med. Res., Taichung Veterans General Hosp., Taichung, [2]Inst. Biol., Tunghai Univ., Taichung; *Dept. Physiol. and Biophysics, Natl. Def. Med. Cent., Taipei, Taiwan, Republic of China.

The so called dorsal facial area (DFA) is located at levels from 5 mm to 7 mm rostral to the obex and dorsal to the facial nucleus in the medulla in cats. Either electrical or glutamate stimulation of the DFA in the anesthetized cats induced predominantly an increase of blood flow of the ipsilateral common carotid artery, accompanied with neither change in blood flows of other vascular beds nor changes in the heart rate and blood pressure. The DFA response were mediated via the 7th and 9th cranial nerves. By measuring tissue blood flows (TQ) with radioisotope-labeled microspheres reference flow technique, we found both the intra- and extra-cranial TQ were all increased in the DFA response. In addition, the DFA vasodilation involved atropine sensitive and insensitive mechanisms. Results of immunohistochemical studies showed that 10±3 ChAT and 7±2 DBH immunoreactive soma in the DFA. The substance P and serotonin immunoreactive fibers also presented in the DFA.

497.2

INCREASES IN INTRA- AND EXTRA-CRANIAL TISSUE BLOOD FLOWS IN RESPONSE TO STIMULATION OF DORSAL FACIAL AREA OF THE MEDULLA IN CATS. T. Chyi[1], E.H.Y. Lee*, and J.S. Kuo[2]. [1]Inst. Biol., Tunghai Univ., Taichung; *Inst. Biomed. Sci., Academia Sinica, Taipei; [2]Dept. Med. Res., Taichung Veterans General Hosp., Taichung, Taiwan, Republic of China.

Microspheres reference flow techniques was used to measure regional blood flows (RBFs) of the intra- and extra-cranial tissues. Electrical or glutamate stimulation of the dorsal facial area (DFA) generally increased the intracranial RBFs of both cerebral hemispheres. Intracranial blood flow increases were enhanced after i.v. administration of atropine but reduced after physostigmine. In contrast, extracranial blood flow increases responded to both drugs in the opposite direction. Thus, DFA stimulation may cause acetylcholine release to promote extracranial RBFs increase, but to restrict intracranial RBFs increase.

497.3

CARDIOVASCULAR RESPONSE TO TREADMILL EXERCISE IS SUPPORTED BY THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) IN THE CONSCIOUS DOG. K.J. Dormer* and S.R. Ashlock. Physiology Dept., Univ. Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK 73190.

Questions remain as to the physiological role of C1 adrenergic cells within the RVLM in the maintenance of arterial pressure (AP) at rest and during daily stressors. The instrumented dog has been our model for recording cardiorespiratory responses before and after incomplete lesions are made in pressor regions of RVLM by microinjection of kainic acid. Understanding the central command component of cardiorespiratory control during dynamic treadmill exercise tolerance testing (ETT) is the purpose of this study. Mongrels (n=15) were conditioned to run a modified Bruce protocol up to 4 mph, 16 % grade during which heart rate (HR), AP, aortic blood flow and cardiac output (CO), internal thoracic arterial flow (IT) and total peripheral resistance (TPR) were monitored. Instrumentation included solid state pressure transducers (Konigsberg) and pulse-transit time flowmeter (Transonic) and 20 MHz Doppler probes. With a unilateral lesion (100 nl, 100mM), in the transition region between the compact division of n. ambiguus and retrofacial n. the cardiovascular pattern response to exercise was unchanged. AP was significantly decreased ($P < 0.01$) and did not even attain pre-lesion resting values during the ETT. TPR was significantly lower at all workloads except 3/0. The CO, peak systolic aortic flow, and IT were consistently lower than pre-lesion values but not significantly. When observing behavioral and motor control there was no discernable difference in the pre- to post-lesion treadmill performance. Lesions causing these results were relatively small, approximately 1mm diameter, and within the rostral portions of the C1 cell column as revealed by immunocytochemical staining for PNMT. We conclude: portions of the C1 area are universally important in the maintenance of AP during rest and exercise. (Supported by NIH grant HL 39105)

ANATOMICAL RELATIONSHIPS AMONG THREE POPULATIONS OF MEDULLARY EFFERENTS: RETICULOHYPOTHALAMIC, RETICULOVAGAL, AND RETICULOSPINAL NEURONS. S.G.P. Hardy*. Departments of Physical Therapy and Anatomy, University of Mississippi Medical Center, Jackson, MS 39216.

Within the medulla are neurons that project to the hypothalamus, the vagus nerve, and the spinal cord. The primary purpose of the present study was to identify those regions which contain representatives from each of these neuronal populations. (The long term hypothesis being that these areas, containing a diversity of efferents, may serve to integrate medullary control over vital functions.) For this purpose, a variety of retrogradely-transported tracers were made into either the postero-lateral hypothalamus, vagus nerve or thoracic spinal cord, in a series of anesthetized rats. Subsequently, the locations of labeled medullary neurons were plotted.

The three neuronal populations, mentioned above, were observed in close apposition within the ventrolateral (CVL) and dorsomedial (CDM) aspects of the caudal medulla. In the CVL, the three populations of neurons were observed in the vicinity of the nucleus ambiguus (NA). Vagal projections originated from the dorsomedial aspect of NA, whereas spinal projections originated from the ventrolateral aspect of NA. Hypothalamic projections did not originate from the NA, but rather from an area immediately ventral to it. In the CDM, the three neuronal populations were observed in the vagal-solitary complex.

NUCLEUS TRACTUS SOLITARIUS (NTS) HYPERTENSION IN GUANETHIDINE-SYMPATHECTOMIZED RATS. E. E. Benarroch*, J. D. Schmelzer, K. K. Nickander and P. A. Low. Neurophysiology Laboratory, Dept. of Neurology, Mayo Clinic, Rochester, MN 55905

Guanethidine (GU) produces chronic postganglionic sympathectomy (GUSX) in adult rats. We sought to determine the effects of chronic sympathectomy on the development of hypertension induced by kainic acid (KA) injection into the nucleus of the tractus solitarius (NTS). Guanethidine (40 mg/kg i.p.) was administered daily for 5 weeks. Controls received saline. Six to eight weeks after treatment, rats were anesthetized (urethane), cannulated and ventilated. Arterial pressure (AP) and heart rate (HR) were continuously monitored. Plasma norepinephrine (NE) and epinephrine (E) were measured by HPLC and vasopressin (AVP) by radioimmunoassay. KA (1 nmol) was injected bilaterally into the NTS. Basal AP, HR, and plasma NE and E were slightly but not significantly lower in GUSX. KA injection into the NTS produced hypertension in both controls and GUSX rats, but increase of AP was higher in controls (ΔAP: 94±5 vs. 40±9 mm Hg, $p<0.01$). In control, but not GUSX rats, NTS hypertension was associated with significant elevation of NE (from 1.8±0.3 to 15±4 ng/ml, $p<0.05$) and E (from 2.5±0.3 to 7.6±1.5 ng/ml, $p<0.05$). Plasma AVP was similar between groups. GUSX attenuates, but does not prevent, NTS hypertension. Expression of NTS hypertension may reflect denervation supersensitivity of vascular targets and sparing of prevertebral ganglion neurons, as well as pressor effects of circulating AVP.

BRAINSTEM PROJECTIONS OF Na^+ SENSITIVE SITES IN THE PARAHYPOGLOSSAL AREA. S. L. Hochstenbach* and J. Ciriello. Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

We have previously shown that microinjections of hypertonic phosphate buffered saline (PBS) solutions into the dorsal vagal complex and the region immediately ventral to it elicits changes in both arterial pressure and heart rate in the rat. In this study, the efferent pathways that may be involved in mediating the pressor responses from Na^+ sensitive sites in the parahypoglossal area (PHA) were investigated using the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L) combined with either tyrosine hydroxylase (TH) or phenylethanolamine-N-methyltransferase (PNMT) immunohistochemistry. In male Wistar rats under equithesin anesthesia PHA-L (2.5%) was iontophoresed at sodium sensitive sites in the PHA that were identified with microinjections of 150 mM NaCl in a PBS solution. After a survival period of 7-12 days the rats were perfused transcardially and transverse sections of the brainstem were processed using the double labelling immunofluorescense technique for the identification of PHA-L, TH and PNMT. PHA-L labelled fibers and presumptive nerve terminals were observed bilaterally within the nucleus of the solitary tract, area postrema, the rostral and caudal ventrolateral medulla in association with catecholaminergic neurons, nucleus ambiguus, in the region of the A5 noradrenergic cell group, locus coeruleus, inferior olive, lateral paragigantocellular nucleus and parabrachial nucleus. These data provide the neuroanatomical substrate by which sodium sensitive pressor sites in the PHA can alter the regulation of the cardiovascular system. AREA POSTREMA STIMULATION EXCITES THEN INHIBITS MEDULLARY NEURONS IN THE BAROREFLEX PATHWAY. A.C. Bonham*, M-A. Obaidi, K. Ravi and J.A. Stewart. University of California, Davis, Davis, CA 95616.

Neurons in the area postrema augment baroreflex-mediated sympathoinhibition. We have shown previously that this augmentation may occur in the nucleus tractus solitarius (Soc Neurosci 16:220, 1990). The current study was aimed to determine if area postrema neurons also modulate the activity of neurons in the rostral ventrolateral medulla (RVLM) in the baroreflex pathway. We performed experiments in α-chloralose-anesthetized, paralyzed and ventilated rabbits in which renal sympathetic nerve activity (RSNA), arterial pressure, ECG and tracheal pressure were recorded. Extracellular single unit activity was recorded in the RVLM and tested for discharge patterns locked to RSNA; for baroreceptor input by injecting iv phenylephrine (6 - 20μg/kg) and nitroprusside (6 - 20μg/kg); and for responsiveness to single electrical pulses delivered to the area postrema (25 - 50μA, 1Hz, 0.3 - 0.7ms). Six of seven cells which discharged in phase with RSNA, were inhibited by increases in arterial pressure (4 - 41mmHg), and were excited by decreases in arterial pressure (5 - 19mmHg), also received a biphasic excitatory/inhibitory input from the area postrema. The early excitatory phase had a mean peak latency of 31.7 ± 4.0ms ($\bar{x}$±SD)(range = 24.9 - 36.9ms); the subsequent inhibitory phase had a mean onset latency of 60.8 ± 17.7ms (range = 41.6 - 91.2ms) and a duration of 99.4 ± 51.4ms (range = 40.0 - 168.0ms). The remaining cell was excited (peak latency of 30.7ms) but not inhibited by area postrema stimulation. These findings suggest that area postrema neurons may modulate in a complex manner the activity of medullary sympathetic neurons in the baroreflex pathway. Supported by AHA 9-138.

A1 AREA NEURONS WITH PROJECTION TO THE SUPRAOPTIC NUCLEUS ARE EXCITED BY ELECTRICAL STIMULATION OF THE ABDOMINAL VAGUS NERVE. Z.J. Gieroba* and W.W. Blessing. Centre for Neuroscience, Flinders University, Bedford Park, SA 5042, Australia.

Neurons in the A1 area of the medulla oblongata excite vasopressin-secreting cells in the hypothalamic magnocellular nuclei. Vasopressin neurons in the hypothalamus are affected by stimulation of the abdominal vagus. We have now tested, in urethane-anesthetized rabbits (1.5 g/kg, i.v.), whether the discharge rate of A1 area neurons, identified with extracellular tungsten electrodes and antidromic activation from the supraoptic nucleus, meeting collision criteria, is affected by electrical stimulation of the abdominal vagus (cuff electrode at the level of the diaphragm, 0.5 ms, 200 Hz, 1-3 cathodal pulses). Peristimulus time histograms were constructed using an ITC16 interface and a Macintosh IIfx computer programmed with IGOR. Of 58 neurons identified, 42 (72%) were excited by stimulation of the vagus. No neurons were inhibited. The latency to maximum excitation was 251 ± 11 ms (conduction velocity 0.52 m/s). Excitation of neurons was followed by inhibition lasting approximately 50 ms. Of the 30 neurons excited by the vagus, 26 were inhibited by activation of baroreceptors using intravenous phenylephrine. We have searched for a physiological stimulus which might activate these neurons. Infusion of hypertonic saline into the portal vein did not affect the discharge of the A1 cells. Nor did distension of the stomach with a balloon. Nor did stimulation of the central end of all nerves entering the hilus of the kidney. These results provide evidence, that nearly all neurons in the A1 area with projections to the supraoptic nucleus are excited by electrical stimulation of the abdominal vagus. The relevant physiological stimuli activating the cells via abdominal vagal afferents are not yet identified.

Cardiovascular effects of oxytocin injections into areas of the medulla oblongata receiving oxytocinergic innervation.
R.E.Gomez, M.A.Cannata, M.Anwar* and D.Ruggiero. ININCA,UBA,Bs.As. and Div. of Neurobiol., CUMC,NY

We examined the distribution of oxytocinergic terminals and the effect on arterial pressure (AP) of oxytocin microinjections into the nucleus tractus solitarii (NTS) and the reticular formation of the caudal (CVL) and rostral (RVL) ventrolateral medulla. Immuno-cytochemical labeling with an antiserum against a synthetic oxytocin conjugate revealed axons and punctata with oxytocin-like immunoreactivity in NTS and RVL. In combined retrograde transport immunofluorescence studies deposits of Fluoro-Gold into NTS labeled larger numbers of neuro-peptidergic neurons in the parvicellular paraventricular hypothalamic nucleus than RVL deposits. Changes in AP (mmHg) after bilateral microinjections in anesthetized rats occured within the first minute after injection:

Oxytocin	NTS	CVL	RVL
10 pmol	3±1	-3±7	6±1
20 pmol	2±2	-0.3±3	15±0.5

A similar dose of oxytocin injected intravenously produced no change in AP. The data suggest that oxytocin may modulate AP via receptors in the medullary reticular formation.

497.10

TRACING OF SINGLE FIBERS DEMONSTRATES THAT MIDBRAIN PERIAQUEDUCTAL GRAY NEURONS HAVE COLLATERALIZED PROJECTIONS TO SOMATIC AND CARDIOVASCULAR RELATED REGIONS IN THE MEDULLA.
P. Carrive, R. Bandler and M. Christie* Departments of Anatomy and Pharmacology, University of Sydney, NSW 2006, Australia.

The midbrain periaqueductal gray (PAG) plays a crucial role in the integration of somatic and autonomic components characteristic of different patterns of defensive reactions. These components are mediated by descending projections to autonomic and somatic regions of the lower brainstem, but the extent of collateralization within these projections is not known. We report here the existence of collateralized projections to distinct somatic and autonomic regions of the medulla and cervical cord.

Biocytin was used as an anterograde tracer. It was applied iontophoretically at sites located in the intermediate third of the lateral PAG of 3 rats and 2 cats. Ten fibers labelled with biocytin were followed from section to section and reconstructed along their entire medullary course.

The results show that 6 of 8 fibers terminating in the vasopressor region of the rostral ventrolateral medulla also have collaterals terminating (i) in the dorsomedial part of the facial nucleus (control of ear musculature; 3 fibers), (ii) in the nucleus retroambigualis (control of expiratory musculature; 3 fibers), and (iii) in the ventral horn of the upper cervical spinal cord (control of neck muscles; 2 fibers). Each region mediates a characteristic component of the defensive reaction evoked from the intermediate third of the lateral PAG. Such collateralized projections may well play a significant role in the integration of the autonomic and somatic functions characteristic of this region of the PAG.

497.11

MODULATION OF THE CARDIOVASCULAR DEFENCE RESPONSE BY THE MEDULLARY RAPHE NUCLEI. T.A. Lovick. (SPON: Brain Research Association). Dept. of Physiology, University of Birmingham, Birmingham B15 2TT, U.K.

Electrical stimulation (10sec, 80Hz, 30-100μA) in the lateral area of the anterior hypothalamus (LAAH) or dorsal periaqueductal grey matter (PAG) evoked a pressor response with tachycardia and vasodilatation in hindlimb muscle in rats anaesthetised with Saffan. Activation of perikarya in nucleus raphe magnus (NRM) and nucleus raphe obscurus (NRO), by microinjection of 10-15nmol D,L-homocysteic acid (DLH) attenuated all components of the PAG-evoked cardiovascular defence response whereas individual components of the LAAH-evoked response were modified selectively. Stimulation in NRM reduced the LAAH-evoked vasodilatation by 64%, converted the tachycardia to a bradycardia and had no significant effect on the pressor response. Activation of cells in NRO also produced a reduction (38%) in the LAAH-evoked vasodilation but potentiated the tachycardia and pressor response by 110% and 35% respectively.

The results suggest 1) that the medullary raphe may differentially modulate activity in the descending pathways from the hypothalamic and midbrain defence areas and 2) that functional differences exist between NRM and NRO with respect to control of the LAAH-evoked response.

LONGITUDINAL COLUMN OF CARDIOVASCULAR SYMPATHOINHIBITORY CELLS IN CAT MEDULLA EXTENDS MEDIALLY INTO LATERAL TEGMENTAL FIELD. C. W. Dempesy*, D. E. Richardson, and C. J. Fontana. Lab. of Neurosurgery, Tulane University School of Medicine, New Orleans, LA 70112.

We have previously shown (Neurosci. Abst. 17: 994, 1991) that cardiovascular sympathoinhibitory cells in cat medulla are distributed in a longitudinal column running parallel and lateral to the longitudinal array of cells comprising the ambiguus nucleus. The column extends 4.5 mm from its posterior end in the caudal ventrolateral medulla (CVLM) to its anterior end above the rostral ventrolateral medulla (RVLM). In contrast, Gebber and Barman have reported in cat a similar columnar distribution of cells displaying cardiovascular sympathoinhibitory activity, but lying entirely medial to the ambiguus nucleus in the lateral tegmental field (J. Neurophysiol. 54: 1498, 1985). We now report that a survey of the medullary region lying medial to our lateral column, using microinjection of excitatory amino acids, verifies the existence of a continuum of cardiovascular sympathoinhibitory cells distributed from 2 to 4 mm laterally and encompassing the region of the ambiguus nucleus. Chemical inhibition of small areas of this continuum yields hypertension, tachycardia, and partial loss of baroreflex, with these effects weakening in the more medial and caudal aspects of the array.

497.13

MODULATION OF THE NEURONAL FIRING IN THE NUCLEUS TRACTUS SOLITARIUS BY ELECTRICAL STIMULATION OF THE HYPOTHALAMIC DEFENSE AND VIGILANCE AREAS IN RABBITS. Y-F. Duan*, R.W. Winters, P.M. McCabe, E.J. Green, Y. Huang, and N. Schneiderman, Neuroscience Program and Department of Psychology, University of Miami, Coral Gables, FL, 33124.

Stimulation of the hypothalamic defense area (HDA) elicits a cardiorespiratory response that is thought to prepare the animal for "fight or flight". This response is characterized by increases in cardiac output, blood pressure (BP), heart rate (HR), hindlimb blood flow and hyperventilation. The cardiorespiratory response elicited by stimulation of the hypothalamic vigilance area (HVA) is associated with the inhibition of movement and is characterized by a BP increase, HR decrease and brief inspiratory apnea or a shallow tachypnoea. The present study was conducted to determine if HDA and HVA make functional connections with NTS in rabbits.

Adult New Zealand albino rabbits were anesthetized with isoflurane. The HDA and HVA stimulation was delivered to the posterior dorsomedial hypothalamus via a bipolar stainless electrode (200-300 uA,100 Hz, 0.5 ms duration, 0.1-5 sec train). Extracellular unit recordings were made in NTS with stereotrode electrodes during the hypothalamic stimulation.

Most of the NTS neurons affected by electrical stimulation of the HVA showed a decrease in firing rate. Approximately half of the NTS neurons that responded to the HDA stimulation showed an increase in firing rate. Many of these NTS neurons were found to receive barosensory information as well. A small number of the NTS neurons recorded did not respond to either the HVA or HDA stimulation. These findings suggest that both HVA and HDA make functional connections with the NTS. (Supported by NIH HL 36588 and HL 07426).

USE OF PSEUDORABIES VIRUS IN DEFINING THE CONNECTIONAL CIRCUIT OF THE MEDULLARY BARORECEPTOR VAGAL REFLEX IN THE RAT *J.A. Escardo, L. Enquist, M. Whealy and J.S. Schwaber*, DuPont Co & Dupont-Merck, Wilm., DE 19880.*

Experiments using Cholera Toxin-Horseradish Peroxidase (CT-HRP) as a tracer have delineated the region of baroreceptor and cardiac afferent input as well as the distribution of vagal preganglionic cardiomotor neurons (Escardo et al., 1991). However, the location, extent and number of interneuronal groups subserving the medullary component of the baroreceptor vagal reflex is unknown. In order to address these questions, in the present study we have used the attenuated Bartha strain of the pseudorabies virus (PRV) as a retrograde trans-neuronal (putatively trans-synaptic) tracer. PRV was injected into two distinct cardiac sites shown by injections of CT-HRP to receive vagal preganglionic innervation: between the superior vena cava and the aorta and at the crossing of the jugular vein, left ventricle and pulmonary artery. The earliest labeling of neurons in the medulla was present at 48 hours and was confined to members of the rostral and caudal nucleus ambiguus (NA) vagal cardiac efferent populations, as defined by location and morphology seen earlier in the CT-HRP studies. With longer survival times the picture became much more complicated, but we will focus here on just a few relevant cell groups. At 68-72 hours survival time numerous non-vagal motor neurons were labeled with PRV in the vicinity of the caudal NA group, basically in the area of the caudal ventro-lateral medulla or A1 catecholaminergic population. Labeled neurons were scattered along an arc through the dorsal medullary reticular field and a few scattered neurons were labeled in the nucleus tractus Solitarii (NTS), particularly in its ventral subdivisions. At 94 hours+ this later labeling became more abundant, but in addition a new, densely packed group appeared in the dorsal NTS within the regions receiving baroreceptor and cardiac afferents. We interpret these results to suggest that the simplest baroreceptor vagal reflex involves at least two interneurons.

497.15

PHYSIOLOGICAL CHARACTERIZATION OF RHYTHMICALLY BEATING NEURONS IN THE CARDIORESPIRATORY NUCLEUS OF THE SOLITARY TRACT (crNTS) IN THE RAT. *J.F.R. Paton* & J. S. Schwaber,* Neural Computation Group, E.I. DuPont Co., Wilmington, DE 19880-0323.

We previously characterized two groups of rhythmically beating cells at 5Hz (autoactive & synaptically driven) in the crNTS *in vitro* (Paton et al. *J.Neurophysiol.* **66**: 824-838, 1991). The present study sought to determine whether such neuronal activity existed *in vivo* and, if so, to physiologically characterize cells based on the visceral origin of synaptic input(s). Extracellular recordings were made from 28 rhythmically discharging single units in the crNTS in anesthetized rats (chloral hydrate: 375 mg/kg & pentobarbital: 75 mg/kg; i.p.). All cells fired a single spike regularly (mean 6.5 Hz) and were divided into two groups based on their firing relationship with the R wave of the ECG. One group of neurons (n=10) discharged with a relatively constant phase angle to the R wave whereas the second group was less tightly coupled to the cardiac cycle but fired at a similar frequency as heart rate. Both groups of cells showed a peak in the R wave triggered histogram (mean latency: 18ms). Of 18 cells tested, 16 received an excitatory synaptic input following electrical stimulation of the ipsilateral vagus nerve (mean latency 20 ms) and 3 neurons were also excited by aortic nerve stimulation (latency range: 15-18ms). Brief periods of cardiac arrest, produced by electrically stimulating the peripheral end of the cut vagus nerve, decreased the firing frequency and, following recovery of heart rate, disrupted the phase relationship with the R wave of the ECG. Veratridine (5-20 μg; i.v. bolus) strongly excited all 4 rhythmically firing cells tested. These data indicate the presence of neurons beating rhythmically at the cardiac rate in the crNTS that receive cardiac afferent synaptic inputs.

497.16

ENCODING OF ARTERIAL BLOOD PRESSURE CHANGES BY PUTATIVE SECOND ORDER BARORECEPTIVE NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT IN THE RAT. *R.F. Rogers, J.F.R. Paton, W.F. Herblin,* & J. S. Schwaber,* Neural Computation Group, E.I. DuPont Co., Wilmington, DE 19880-0323.

There is a paucity of information concerning the response patterns of second order NTS neurons to graded arterial pressure changes. Thus, the present study examined the firing response characteristics of putative second order baroreceptive neurons during increases in arterial pressure following i.v. administration of phenylephrine (PE; 5-20 μg). Anesthesia was induced in rats using halothane followed by an infusion of Saffan (12 mg/kg/hr i.v.). Extracellular recordings were made from 19 single NTS neurons receiving a short and invariant excitatory synaptic input following ipsilateral aortic nerve stimulation (range of latency to spike: 1.8-4.0 ms). From a total of 19 cells tested 10 were silent at baseline mean arterial pressure of 90-120 mmHg. The response of these neurons to PE injection was characterized by either a single action potential or a transient burst of activity (2-7 spikes) at a specific level during the rising phase of the blood pressure response. As blood pressure continued to rise past this point firing ceased until the same blood pressure level was reached during the falling phase, at which time a similar pattern of discharge occurred. The remaining 9 cells showed ongoing activity (mean pressure range 90-120 mmHg) which increased and decreased proportionally during the rising and falling phases of the blood pressure response to PE injection respectively. These results show a heterogeneous population of putative second order baroreceptive NTS neurons. It is suggested that while some NTS neurons reflect mean arterial pressure in their individual firing frequencies, other neuron types may contribute to population encoding of mean arterial pressure and changes in blood pressure.

497.17

IONIC CURRENT MODEL OF DELAYED EXCITATION IN NEURONS OF RAT MEDIAL NUCLEUS TRACTUS SOLITARIUS (mNTS). M.C. Andresen*, S. Khushalani, J.H. Schild, M. Yang, D.L. Kunze, and J.W. Clark. Oregon Health Sciences Univ., Portland, OR 97201, Rice Univ. and Baylor College of Medicine, Houston, TX 77251.

Anatomical studies suggest that aortic arch baroreceptors synapse within a limited area of mNTS. Our studies focused on intracellular recordings from medullary slices including this area and on patch clamp work with cells acutely dispersed from mNTS. In slices, depolarizing current injection resulted in a rapid increase in spike rate followed by spike frequency adaptation (SFA). Pre-hyperpolarization induced a prolonged delay (DE) before resuming spiking and eliminated SFA in all neurons. In isolated mNTS neurons, two hyperpolarization-activated, transient-outward potassium currents were found with time constants matching the DE time course. We developed a comprehensive ionic current model with thirteen coupled, first-order, non-linear differential equations (Hodgkin-Huxley) to represent 8 ionic conductances, two ATPase pumps (Na-K and Ca), a Na/Ca exchanger, and calcium balance within the neurons. With a single fixed set of fit parameters, the model effectively predicted neuronal responses to a wide range of multi-step current injection protocols over tens of seconds. The voltage dependence of DE, SFA, and changes in action potential shape were successfully reproduced. The model demonstrates the dynamic interaction of a family of voltage dependent conductances, emphasizes the pivotal role of transient potassium currents in shaping neuronal responses and suggests a valuable tool for integrating information from isolated cells with more intact preparations.

497.18

THE INTERRELATIONSHIP OF RENIN-ANGIOTENSIN SYSTEM AND ADENOSINE IN THE BRAINSTEM NUCLEI OF RATS. H.C. Lin, C.S. Tung, C.T. Yen*, C.J. Tseng, Depts. of Pharmacology, Physiology, and Zoology, National Defense Medical Center and National Taiwan University, Taipei, Taiwan, R.O.C.

The purpose of this study is to determine the possible interaction of adenosine and renin-angiotensin system in the brainstem nuclei of the rat. Male Sprague-Dawley rats were anesthetized with urethane. Adenosine, angiotensin (ANG) II, ANG III, and their antagonist 1,3-Dipropyl-8-p-sulfophenylxanthine (DPSPX) and Sar^1,Ile^7 ANG III were microinjected into the nucleus tractus solitarii (NTS) and area postrema (AP) of rats. Our results demonstrated that microinjection of DPSPX significantly attenuated the depressor and bradycardia effect at low dose (9.6 pmol) of ANG II and ANG III. Whereas, the same dose of DPSPX significantly potentiated the pressor effect at high dose (480 pmol) of ANG II and ANG III in the NTS and AP. The depressor and bradycardia induced by high dose ANG II and ANG III were slightly inhibited by DPSPX. On the other hand, when ANG antagonist were microinjected 10 minutes prior to the injection of adenosine, we found that the Sar^1,Ile^7 ANG III can affect the depressor and bradycardia effects of adenosine in the AP, not in the NTS. In conclusion, the endogenous adenosine may influence the renin-angiotensin system in the brainstem nuclei of rats. Precisely modulatory mechanisms remain to be clarified.

497.19

REGULATION OF ANGIOTENSINOGEN mRNA EXPRESSION IN THE MEDULLA OBLONGATA IN HYPERTENSIVE AND NORMOTENSIVE RATS. A. Milsted*, C.H. Block, K.B. Brosnihan, Z.R. Rodriguez and C.M. Ferrario. Cleveland Clinic Fndn, Research Institute, Cleveland, OH 44195.

A critical role for the dorsal and ventral medulla oblongata in cardiovascular regulation is well established. Further, angiotensin (Ang) peptides and receptors have been demonstrated in these cardiovascular regions. We showed an increase in expression of angiotensinogen (Aogen) mRNA in aortic-ligated hypertensive rats, compared to sham-operated controls (Nishimura et al., Hypertension, 1992). To further define more discrete changes in Aogen mRNA expression in these medullary areas, we carried out *in situ* hybridization histochemistry to both localize and quantitate changes in Aogen mRNA. Aogen-specific probe was a 30-base long synthetic oligodeoxynucleotide, 3'-labeled with ^{35}S-ATP, complementary to the nucleotides encoding Ang I [anti-sense]. Non-specific [sense] probe was its reverse complement. Following autoradiography, signals were quantitated by microdensitometry to measure relative film density in the area postrema, nucleus tractus solitarius, dorsal motor nucleus of the vagus (DMNX), hypoglossal nucleus, reticular formation, and inferior olive. Expression of Aogen mRNA was increased by approximately 50% in the DMNX and the hypoglossal nucleus six days after aortic ligation, at a time when circulating and central renin-angiotensin systems are activated and plasma renin activity and Ang II levels are elevated. Twenty-four days after aortic ligation, no apparent changes in Aogen mRNA expression were found in the regions examined, suggesting homeostasis in Aogen mRNA expression. This return to normal levels of Aogen mRNA expression in the medulla parallels changes in plasma renin activity and Ang II levels which have returned to near normal levels, despite persistently elevated blood pressure. Results of these studies confirm a role for the DMNX during the development of hypertension, and further indicate that compensatory homeostatic systems are likely to assume a more prominent role in regulating expression of Aogen mRNA in the medulla oblongata during the chronic stages of hypertension. (Supported in part by NIH HL-6835).

497.20

MICROINJECTION OF AN ENDOTHELIN ANTAGONIST INTO THE NUCLEUS TRACTUS SOLITARII FACILITATES BAROREFLEX ACTIVATION. R. Mosqueda-Garcia*, T. Inagami, M. Appalsamy and R.M. Robertson. Departments of Medicine and Biochemistry, Vanderbilt University, Nashville, TN 37232.

Previous reports have documented that central administration of endothelin-1 (ET-1) affects BP, HR and baroreflex sensitivity. Interpretation of these effects, however, has been complicated by the potential non-specific effects of this peptide. We have sought to circumvent this limitation with the use of a specific ET-receptor antagonist.

Glass micropipettes were placed in the nucleus tractus solitarii (NTS) of urethane anesthetized Sprague-Dawley rats. Baroreflex function was evaluated with bolus administration of phenylephrine. After control baroreflex slopes were obtained, the animals were divided into groups that received saline or different doses of the specific receptor ET_A-antagonist BQ-123 (1,4,8 nmols/60 nl). Ten minutes after intra-NTS administration of the drugs, baroreflex slopes were again evaluated. Bilateral microinjection of BQ-123 into the NTS decreased BP and HR in a dose-dependent manner (8 nmols, -30±4 mmHg and -80±21 bpm) and increased baroreflex slope.

DRUG	n	CONTROL SLOPE	DRUG SLOPE
SALINE (60 nl)	4	2.6 ± 0.4 mmHg/sec	2.2 ± 0.3 mmHg/sec
BQ-123 (1 nmol)	6	1.3 ± 0.2	2.3 ± 0.5*
BQ-123 (4 nmol)	12	2.0 ± 0.2	3.5 ± 0.8*
BQ-123 (8 nmol)	16	2.0 ± 0.2	2.5 ± 0.4*

Values are mean ± sem; * indicates significant difference from control ($p<0.5$).

These results suggest that ET-1 has an important modulatory effect on baroreflex activation which are mediated by specific receptor subtype.

QUANTITATIVE STUDY OF THE PATTERN OF REINNERVATION OF VIBRISSAL FOLLICLES AFTER PARTIAL DENERVATION OF THE WHISKERPAD OF ADULT MICE.

M-E.Corthésy, E.Welker, H.Van der Loos, B.M.Riederer*.
Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

Partial denervation of skin in adult animals leads to changes in the central representations of neighboring skin areas. We have quantified the peripheral innervation of the caudalmost whisker follicles of rows B, C & D at varying intervals after denervation (double ligation followed by transection of the nerve) of follicles of row C in 9 adult mice. Controls show a caudo-rostral (c→r) gradient of innervation (figure). Numbers are medians based on counts in 3 mice per group. At five days *post lesionem* (*p.l.*) Wallerian degeneration is complete: there are no fibers in the follicles of row C. At 15 days *p.l.* reinnervation appears, and from about 60 days *p.l.* onwards the number of nerve fibers reaches a plateau. The c→r gradient of innervation is restored, although fiber numbers are smaller than in controls. There were no changes in the innervation of the neighboring, intact follicles. These observations provide evidence of a numeral regulation of the reinnervation of vibrissal follicles and will be used in elucidating the mechanisms underlying adult plasticity in the somatosensory pathway. Support: Swiss NSF 31-30932.

TIME COURSE OF SEROTONERGIC AFFERENT PLASTICITY IN RAT SPINAL TRIGEMINAL NUCLEUS AFTER INFRAORBITAL NERVE CUT. B.G. Klein*, W.D. Blaker, C.F. White and B.R. Misra. Dept. of Biomedical Sciences, College of Veterinary Medicine, VA Tech, Blacksburg, VA 24061, Dept. of Biology, Furman University, Greenville, SC 29613.

Non-peripheral serotonergic afferents to rat spinal trigeminal subnucleus interpolaris (SpVi) exhibit an increased concentration of serotonin (5-HT) and an increased density of 5-HT immunoreactive (5-HTIR) varicosities >76 days following infraorbital nerve (ION) transection in adults (Klein & Blaker, 1990, Brain Res., 536:309-314). To delineate the time course of this change, high performance liquid chromatography with electrochemical detection (HPLC-ED) and immunocytochemistry were used to examine serotonergic afferent plasticity within SpVi between 3 and 79 days following ION transection. For HPLC-ED, samples from the infraorbital (IO) region of SpVi on the lesioned side were compared to similar samples on the intact side and to samples in normal rats. For post-lesion survival times from 3-49 days, no change in 5-HT concentration was observed on the lesioned side. Also, at 49 days after ION cut, no change in density of 5-HTIR varicosities was seen in the IO region on the lesioned side. In rats surviving 76-79 days post-lesion, we replicated our previous finding of a significant increase (38%) in 5-HT concentration on the lesioned side. It appears that the anatomical and biochemical changes in 5-HT afferents to SpVi following ION transection exhibit a slow or delayed development, that does not reach detectable proportions until >7 wks following the cut. Such data will help to interpret the role of 5-HT afferent plasticity in the somatosensory sequelae observed following ION damage. Support: NIDR DE08966 to BGK.

CENTRAL EFFECT OF DECIDUOUS TOOTH PULPECTOMIES. [1,3]M.A. Henry* and [1,2,3]L.E. Westrum. Depts. [1]Neurol. Surg., [2]Biol. Struct., and [3]Restor. Dent., University of Washington, Seattle, WA 98195.

We are studying the response of the trigeminal nuclei (TN) to injury. Previous studies have shown argyrophilia and degenerative alterations of axons and terminals within the TN following tooth pulp lesions performed in the adult cat. The effect of similar lesions performed on deciduous teeth in kittens has not previously been reported. Pulpectomies and gutta percha obturation of the canals were performed on the left maxillary and mandibular deciduous cuspids of 8-10 week old kittens (8 subjects) with survival periods ranging from 1 day to 3 weeks. Tissue from throughout the TN was reacted with the Fink-Heimer stain and in addition laminae I and II of pars caudalis/medullary dorsal horn was examined with the electron microscope (EM) in regions where dental afferents are known to terminate. Examination of the Fink-Heimer preparations showed a lack of argyrophilia. Sections examined with the EM revealed axonal and terminal alterations suggestive of degeneration and less commonly of regeneration or recovery and the latter were characterized by the presence of agranular reticulum. Most of the terminal alterations were electron lucent and included flocculent forms with reduced synaptic vesicles often surrounded by enlarged glial profiles or terminals with inclusions including glycogen particles. The lack of argyrophilia and the presence of fibers with agranular reticulum suggest a greater potential for recovery in the immature feline trigeminal system following injury. NERVE GROWTH FACTOR RECEPTOR (NGFR) PATTERNS IN NORMAL SPINAL TRIGEMINAL NUCLEUS AND AFTER DEAFFERENTATION: LIGHT AND ELECTRON MICROSCOPY. [1,2,4]L.E. Westrum*, [1,4]M.A. Henry, and [3]M.A. Bothwell. Depts. of [1]Neurol. Surg., [2]Biol. Struct, [3]Physiol. & Biophys. and [4]Restorative Dentistry, University of Washington, Seattle, WA 98195.

Light and electron microscopy (LM, EM) are being used to study localization of immunoreactivity (IR) to NGFR in the brainstem spinal trigeminal (V) nucleus of normal adult felines and after retrogasserian rhizotomy (10 and 30 days). The antibody was raised against human NGFR and presumably recognizes both high and low affinity sites. The LM-IR occurs as either dense pockets of label or as a more homogeneous label, greater than background, that outlines the nuclei. Lamina II in pars caudalis shows dense NGFR-IR. EM of this region shows NGFR-IR in small unmyelinated or medium-sized myelinated axons and in terminals that form asymmetric synaptic contacts, some of which are a part of a glomerulus. Trigeminal rhizotomy results in a complete loss of NGFR-IR (both types) throughout the nuclei, but spares a few dense pockets of IR compatible with inputs from VII, IX and X. The findings show that NGFR-IR clearly delineates the boundaries of the V nucleus, represents primary afferents, some of which are associated with nociception (dense pockets) and that spared non-V input may represent nociceptive input from VII, IX and X. (Supported by NIH Grants DE00219, DE04942 and NS23343. L.E.W. is a research affiliate of CDMRC).

RESPONSES AND THALAMIC PROJECTIONS OF THERMORECEPTIVE NEURONS IN RAT SUPERFICIAL MEDULLARY DORSAL HORN (MDH). W.D. Hutchison* and J.O. Dostrovsky, Dept. Physiology, Univ. of Toronto, Toronto, Canada M5S 1A8

Little is known concerning central processing of innocuous temperature inputs in the rat. The aim of the present study was to determine the characteristics and projection targets in thalamus of neurons in rat MDH that respond to innocuous thermal stimuli applied to the orofacial region.

Recordings were made from 58 cold cells in the superficial MDH of chloralose/urethane-anesthetized rats. Cells were identified by responses to cold probes and radiant warmth and their responses further quantified with a Peltier thermode. The receptive fields of most of the neurons were on the upper lip (54%) or tongue (27%). Many (45%) of the neurons responded only to innocuous cooling, whereas the remainder could also be activated by mechanical stimulation although these responses were small compared to those produced by a rapid thermal change. Of these mechanically sensitive neurons, 57% responded to touch, 25% only to noxious pinch and 17% to both touch and pinch stimuli. Many (56%) of the 27 neurons tested responded also to noxious thermal stimuli. Cooling steps (5°C) produced mostly tonic responses in 40% of the 15 cells tested, mostly phasic responses in 27% and both types in the remaining 33%.

Antidromic mapping was performed for six MDH cold cells. Stimulation was delivered at 250μm steps as the bipolar electrode was driven through thalamus. Multiple tracks at mediolateral intervals of 0.5 mm were made. The neurons were antidromically activated from thalamus with currents of 9-50 μA (0.2ms, 1Hz) at latencies of 2.0-2.4 ms (mean conduction velocity 6.6 m/s +/- 0.9 S.D.). All 6 neurons were activated from the ventrobasal complex; 2 of the neurons were also activated from sites that were in medial thalamus, one within Sm. (supported by NIH DE05404)

DISTRIBUTION OF TRIGEMINAL NEURONS PROJECTING TO SPECIFIC CEREBELLAR CORTICAL REGIONS IN THE RAT. J.J.A. Arends*, T.J.H. Ruigrok & M.F. Jacquin, Dept. of Anatomy & Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104; Dept. of Anatomy, Erasmus University, 3000 DR Rotterdam, The Netherlands.

Single and multiple retrograde tracing studies using WGA-HRP, Fluorogold, Diamidino-yellow, and FITC- and TRITC-labeled latex bead injections into different "orofacial" areas of the cerebellar cortex were used to study the distribution of trigeminal neurons that project to specific or widespread cerebellar regions. Injection targets included the vermis/paravermis (uvula and lateral lobules II-V) and the hemispheres (paramedian lobule, Crus I and II, simple lobule). In 22 rats, labeled cells were seen in trigeminal subnuclei principalis, oralis and/or interpolaris, as well as the trigeminal ganglion. There was a clear relationship between the dominant receptive field type within the cerebellar injection site (vibrissa vs. non-vibrissa; from Welker, '87) and the numbers and distribution of retrogradely labeled trigeminal neurons. For example, injections in regions with predominant vibrissa representations (Crus I, uvula) produced the largest numbers of labeled cells in vibrissa regions of ventral principalis and interpolaris, with moderate numbers in dorsal oralis following uvula injections. Tracer deposits in other non-vibrissa cortical regions produced labeled cells primarily in non-vibrissa regions of dorsal principalis, oralis and interpolaris. Similarly, contralateral and bilateral projections were primarily to non-vibrissa cerebellar areas and originated in rostral interpolaris, caudal oralis and rostral principalis. Labeled ganglion cells were seen in all cases except those involving the paramedian lobule. Only a small % of the trigeminal mossy fibers branched to terminate in more than one cerebellar region. DIFFERENTIAL FOCI OF TRIGEMINAL PRINCIPALIS AND INTERPOLARIS PROJECTIONS TO THALAMUS. M.N. Williams* & M.F. Jacquin, Anat/Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

The thalamic VPM nucleus receives inputs from all 4 trigeminal brainstem subnuclei. We (Williams et al., Neurosci. Abstr. 17, '91) have reported that principalis (PrV) terminals are more likely to synapse on more proximal portions of VPM dendrites than terminals from interpolaris (SpVi). To further assess the extent to which PrV and SpVi inputs to thalamus are complementary or overlapping, adult rats each received HRP injections in PrV and rhodamine- or fluorescein-dextran deposits in ipsilateral SpVi. Only those 8 cases where HRP-TMB reaction product spanned all of PrV and revealed a complete whisker-like projection pattern in VPM were considered. PrV's most robust projection was to the barreloid region of VPM. SpVi's most robust projections were to non-barreloid regions of thalamus, including the VPM "shell" that encapsulates the barreloid area, posterior thalamus, and nucleus submedius. In the barreloid region, SpVi projections were relatively sparse and terminal swellings occurred most frequently in the peripheral fringes of individual, HRP-labeled, whisker-related patches. In nucleus submedius, SpVi inputs were dense and patchy. A dense SpVi projection was also revealed within ventral and caudal VPM that intrudes in a "finger-like" manner into the barreloid region. We therefore conclude that PrV and SpVi have, for the most part, complementary projection foci in thalamus. In conjunction with our prior indications of a differential synaptic organization of PrV and SpVi inputs to VPM dendrites, the present results suggest additional anatomical bases for the relative efficacies of these 2 parallel pathways in dictating thalamic responses to trigeminal stimuli.

RECEPTIVE FIELD SYNTHESIS IN RAT NUCLEUS PRINCIPALIS: SPINAL TRIGEMINAL CONTRIBUTIONS. D.W. Doherty*, H.P. Killackey & M.F. Jacquin, Psychobiology, Univ. Calif., Irvine, CA 92717; Anatomy & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

Most cells in trigeminal nucleus principalis (PrV) have single whisker receptive fields (RFs) with phasic responses lacking direction sensitivity. As a first step in assessing how spinal V inputs impact on PrV RFs, 79 PrV cells (66 thalamic-projecting, 13 local circuit) were recorded in 11 barbiturate anesthetized rats before and after infusions (0.037 - 0.53 μl) of glutamate (0.5 M) or lidocaine (2%) into most of subnuclei caudalis and interpolaris. The projection status of PrV cells was determined with antidromic and intracellular labeling methods. Glutamate-induced changes in PrV RFs were seen in 19 of 43 thalamic-projecting cells, where 13 exhibited smaller RFs or became less responsive to peripheral stimuli and 6 displayed larger RFs or more spikes per whisker deflection. Glutamate-induced changes were seen in 5 of 6 local circuit neurons, all of which became less responsive to peripheral stimuli. In 3 projection neurons with phasic responses to sustained whisker deflection, glutamate infusion induced tonic responses.

Lidocaine-induced changes were seen in 12 of 23 thalamic-projecting cells, where 3 exhibited smaller RFs or fewer spikes per stimulus, 7 displayed larger RFs or more spikes per stimulus, and 2 shifted their RF to another whisker(s). Lidocaine-induced changes in local circuit neurons were only seen in 2 of 7 cells, where 1 expressed a RF shift and the other showed a larger RF. Lidocaine infusion also affected directional sensitivity in 3 projection neurons and altered adaptation properties in 4 others. Thus, it would appear that spinal V neurons have robust influences on the RFs of many PrV cells. DE07662, DE07734, BNS87-19311.

IS AVIAN BASILAR MEMBRANE TRULY LINEAR? A.N. Temchin and G. Moushegian*. Callier Center, University of Texas at Dallas, Dallas, TX 75235.

The only available measures of avian basilar membrane (BM) intensity functions indicate that its behavior is linear in pigeon (Gummer et. al., Hear. Res., 29:63-92, 1987), implying passive cochlear mechanics. Evidence is presented of the existence of three main types of rate-versus-level functions (saturating, slope-saturating, and linear) at the characteristic frequency (CF) of pigeon primary auditory fibers. These functions were obtained with 2dB steps between 0 and 90 dB SPL. Saturating fibers have had broad dynamic ranges (up to 40-45 dB) and sometimes were hardly distinguished from slope-saturating. Unlike mammals, type of function does not depend on the spontaneous rate or threshold at CF. Correlation between CF-threshold and spontaneous rate was small (r=-0.06) and statistically insignificant. Clear break points of sloping-saturated fibers within narrow CF region in the same animal occur over a narrow range of intensities and may be found between 35-45 dB SPL in different animals. The results, along with the earlier described phenomenon of single-tone suppression, which could occur at SPLs even slightly below the CF-threshold may be explained by the nonlinearities of BM and active mechanics in avian cochlea.

CHARACTERIZATION OF MINERALOCORTICOID (TYPE I) RECEPTORS IN THE INNER EAR BY COMPETITION STUDIES WITH SPIRONOLACTONE. D.Z. Pitovski[1]*, E.C. Burton[1], and D.G. Drescher[1,2], [1]Department of Otolaryngology, [2]Laboratory of Bio-otology, Wayne State University School of Medicine, Detroit, MI 48201.

Spironolactone, a clinically important anti-mineralocorticoid, is thought to compete with aldosterone at mineralocorticoid (Type I) receptor sites in target tissues. Since Type I receptors are present in the inner ear (Pitovski et al., Soc. Neurosci. Abstr. 17: 1107, 1991), it was of interest to investigate the antagonistic action of spironolactone in auditory and vestibular fractions. Microdissected inner ear tissues of male Hartley guinea pigs were incubated with various concentrations of spironolactone (4×10^{-7} to 4×10^{-5} M) in the presence of 4×10^{-9} M ^{3}H-aldosterone. A 500-fold excess of RU 28362 (a highly specific glucocorticoid agonist) was included to minimize binding to glucocorticoid (Type II) receptors. Paired control incubations were performed with ^{3}H-aldosterone, RU 28362, and a 2,000-fold excess of unlabeled aldosterone to determine non-specific binding. Specific binding was calculated from the difference between total binding in the presence of spironolactone (experimental) minus non-specific binding (control, opposite ear). Binding values were also corrected for ^{3}H-aldosterone present intercellularly, monitored with ^{14}C-sucrose and normalized to tissue dry weight. The IC_{50} values for spironolactone in the lateral wall of the basal cochlear turn and the ampulla of the semicircular canal were 4.1×10^{-6} and 4.6×10^{-6} M, respectively, while the corresponding values of K_i were 2.0×10^{-6} and 1.9×10^{-6} M.

Inhibition studies performed with spironolactone showed a dose response reduction of ^{3}H-aldosterone binding, implying that in inner ear tissues this compound behaves as an aldosterone antagonist. DEVELOPMENTAL CHANGES IN THE RESPONSE OF THE PERIPHERAL AUDITORY SYSTEM TO TWO-TONE STIMULI. J.L. Fitzakerley*, J. McGee and E.J. Walsh. Boys Town National Research Hospital and Creighton University, Omaha, NE 68131.

Auditory nerve rate suppression studies have been used to characterize the mature cochlear transduction process, which is nonlinear in nature. In contrast to the adult, some immature peripheral auditory neurons exhibit facilitation, rather than suppression (Fitzakerley et al., ARO 14:422, 1991). This study was designed to investigate several of the stimulus parameters and neural factors influencing the expression of facilitation and suppression during postnatal development. Single unit responses of peripheral auditory neurons were examined using standard extracellular recording techniques. Rate differences were evaluated for test tones placed both above and below characteristic frequency (CF), with probe tones placed at CF. Facilitation was observed throughout the first postnatal month, although its incidence declined with increasing age, while suppression was observed as early as 7 postnatal days. Although all test/probe tone ratios tested were capable of producing facilitation in the youngest animals, above-CF test tones produced facilitation in a higher percentage of units than below-CF test tones. Magnitude of suppression was directly correlated to the degree of frequency selectivity, and facilitation was less likely to be expressed in units showing mature tuning characteristics. The ability of the system to produce action potentials appeared be one of the factors limiting the magnitude of facilitation, while suppression seemed to be more dependent upon probe tone rate than facilitation. (Supported by NIDCD #DC1007).

ORGAN OF CORTI PROTEIN II SEQUENCE. K. E. Isenberg*, P. K. Robeff, I. Thalmann, and R. Thalmann. Departments of Psychiatry and Otolaryngology, Washington University, St. Louis, MO 63110.

The distinctive structure and function of the organ of Corti probably requires the expression of unique proteins. Two such proteins, designated OCPI and OCPII, have been isolated (Thalmann et al., Laryngoscope 100:99-105, 1990). OCPII was purified by separation of 2-dimensional polyacrylamide gel electrophoresis, electroblotted to PVDF membranes, and subjected to amino acid sequencing. The determination of internal sequence was performed by subjecting OCPII to limited proteolysis with chymotrypsin, papain, subtilisin, or V8 protease, separation of the peptide fragments by one-dimensional polyacrylamide electrophoresis and sequencing the resulting bands. The sequence of OCPII, although incomplete, does not resemble the sequence of any previously described protein. A synthetic peptide corresponding to OCPII residues 3 to 16 was used to raise polyclonal antisera; the polyclonal antisera recognizes OCPII on Western blots. An oligonucleotide was designed to correspond to OCPII sequence and found to detect unique genomic fragments on Southern blotting. The oligonucleotide was used to screen a cochlear cDNA library (provided by Dr. A. F. Ryan); positive clones are being tested with the polyclonal sera against OCPII. The molecular characterization of OCPII will permit the elucidation of the role this protein plays in organ of Corti function.

INFORMATION RATES AND CODING EFFICIENCIES OF AUDITORY NERVE FIBERS. DA Bodnar*, FM Rieke, RR Capranica, and W Bialek, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853, and NEC Research Institute, 4 Independence Way, Princeton, NJ, 08540

Changes in either the amplitude or phase spectrum of a complex sound produce changes in both the spike rates and the synchronization characteristics of auditory nerve fibers in the bullfrog. Because of the simultaneous variation in these two coding parameters it is difficult to assess how complex sound stimuli are represented based on solely on spike rate and synchronization patterns. Therefore, we have applied a new decoding analysis method [Bialek et al.(1991), *Science*, 252:1854], to examine additional coding properties of peripheral auditory units. With this method, an estimate of the stimulus waveform can be made from the spike train response of a neuron. In addition, this method provides measures of the information rate and coding efficiency of a fiber's spike output. Thus, although a unit may have the same average spike rate in response to two different sound stimuli, the information rate and coding efficiency of its spike output may differ – in particular, "naturalistic" stimuli may be coded with higher information rates and efficiencies than white noise stimuli. In this study, we have examined how changes in the amplitude and phase spectra of an acoustic signal affect the information rate and coding efficiency of the spike outputs of auditory nerve fibers in response to complex sound stimuli. This research is supported by NIH Grant #NS-09244 to RRC and NEC Research Institiute.

EFFECTS OF CHANGES IN THE AMPLITUDE AND PHASE SPECTRA OF COMPLEX SOUND STIMULI ON THE PHASE SENSITIVITY OF AUDITORY NERVE FIBERS. RR Capranica* and DA Bodnar, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In a recent study, we have demonstrated that auditory nerve fibers in the bullfrog (*Rana catesbeiana*) exhibit changes in their spike outputs in response to changes in the relative phase angle of a single excitatory harmonic component in a multi-harmonic stimulus [Bodnar and Capranica (1991), *Soc Neurosci Abstr* 17: 1107]. In the present study, we have examined the effects of changes in the relative amplitudes or phase angles of components in a multi-harmonic stimulus on the phase sensitivity of peripheral auditory units. For studies of changes in relative amplitudes we have compared cases in which the stimulus components have equal amplitudes or relative amplitudes comparable to the power spectrum of the bullfrog advertisement call. For studies of changes in the phase spectrum we have compared the cases when all the harmonic components have either a relative starting phase of 0°, 180°, or random. Results from these experiments indicate that the phase sensitivity of a unit can be influenced by the relative amplitudes and phase angles of the other components in a stimulus. In addition, we have found that units which exhibit two-tone suppression are sensitive to changes in the relative phase angle of the suppressor component and this phase sensitivity is also affected by changes in the relative amplitudes and phase angles ofother stimulus components. This research is supported by NIH Grant #NS-09244 to RRC.

EXPRESSION OF mRNAs ENCODING FOR ALTERNATELY SPLICED SEGMENTS OF FIBRONECTIN IN THE DEVELOPING RAT COCHLEA. N.K. Woolf*, D.V. Jacquish, F.J. Koehrn and V.L. Woods. Depts. of Otolaryngology and Medicine, UCSD Medical Center and Veterans Administration Medical Center, La Jolla, CA 92093-9112.

Previously we demonstrated the distribution of fibronectin-like protein within the developing inner ear of rats. From embryonic day 18 through day 1 postpartum, intense, discrete immunoreactivity was observed in the cochlea immediately beneath the inner and outer hair cells, sites of auditory nerve fiber growth and nerve-cell synaptogenesis. Fibronectin was also found to be a major structural component within the basilar membrane throughout development. In order to define the cellular site(s) of fibronectin synthesis and the role of functionally distinct forms of fibronectin, we are performing in situ hybridizations on rat cochlear tissue with segment-specific mRNA probes (kindly provided by Dr. R.O. Hynes, MIT), which distinguish three alternately spliced segments of fibronectin. Data will be presented demonstrating ontogenetic changes in cochlear fibronectin mRNA expression.

SIMULTANEOUS MEASUREMENTS OF TUNING IN THE ANTEROVENTRAL COCHLEAR NUCLEUS AND DISTORTION PRODUCT OTOACOUSTIC EMISSIONS: EFFECTS OF ENDOCOCHLEAR POTENTIAL VARIATION. R. Rübsamen, D.M. Mills*, E.W. Rubel Hearing Development Lab., Dept. of Otolaryngology - Head & Neck Surgery, Univ. of Washington, Seattle, WA 98195.

The objective of this study was to precisely evaluate the relationship between tuning characteristics and the thresholds of cochlear afferents and the properties of distortion product otoacoustic emissions (DPOE). Response areas of multiunit clusters in the anteroventral cochlear nucleus and DPOEs at a range of input stimulus levels were simultaneously measured in the adult gerbil during furosemide-induced changes of the endocochlear potential. Intraperitoneal injection of 75 mg/kg furosemide has only a minor effect on the high level DPOEs (stimulus intensity 75-80 dB SPL), but the low level DPOEs (stimulus intensity 50 dB SPL) are reduced from approximately +20 to -10 dB SPL within 15 min. Emissions fully recover after about 60 min. Characteristics of the frequency threshold curves (FTC) after furosemide injection were: (1) threshold at the best frequency (BF) increased by about 30-40 dB, (2) threshold of the FTC-tail (one octave below BF) was elevated by 10-20 dB, and (3) the FTC-bandwidth 10 dB above threshold *widened from 0.2-0.4 octaves to 0.6-0.8 octaves. The dynamics of FTC deterioration and recovery are the same as for the DPOE* reduction and recovery. This congruence indicates that tuning characteristics of cochlear afferents are dynamically regulated by the same biological mechanism that regulates otoacoustic emissions.

DISTRIBUTION OF OLIVOCOCHLEAR NEURONS IN THE CHINCHILLA. J.M. Weekly, W.B. Warr* and B.J. Morley. Boys Town National Research Hospital, Omaha, NE 68131

Although the chinchilla is a commonly used animal in auditory research, very little work has been done on the origins and distribution of its cochlear efferents. The purpose of this study was to define and quantify these distributions using retrograde fluorescent tracer techniques. Four adult chinchillas were anesthetized and 10 µl of 4% w/v FluoroGold (Fluorochrome Inc.) was infused into one cochlea. After a survival time of 6-10 days, the animal was fixed by intracardiac perfusion of 4% paraformaldehyde, the brain removed and sectioned at 35 µm in the coronal plane (N=3) or in the horizontal plane (N=1) and studied under fluorescence microscopy. We could readily classify labeled OCN into two groups: lateral (LOC) and medial (MOC) olivocochlear neurons, as is the case in most mammals studied. Labeled OCN averaged a total of 1268 (s.d.=143) and were located mainly in the neuropil of the lateral superior olivary nucleus (LSO) ipsilaterally (mean=965:76% of total, s.d.=118) and in the contralateral dorsomedial periolivary region (DMPO) (mean=231:18% of total, s.d.=68). OCN were present in fewer numbers in the ipsilateral DMPO (mean=50:3.9% of total, s.d.=25) and contralateral LSO (mean=22:1.7% of total, s.d.=14). Although the general distribution of OCN in the chinchilla is similar to that known in other rodents, the restriction of MOC neurons to the DMPO is unique among rodent species so far studied. [Supported in part by NIH-NINDC/P60 DC00982]

499.10

EXPRESSION OF NMDA-RECEPTOR mRNA IN THE RAT AUDITORY SYSTEM. H. Kuriyama[1], R. Albin[2], S. Shiosaka[3] and R.A. Altschuler[1]*. Kresge Hearing Research Institute[1], Dept. Neuroscience[2], Univ. of Michigan, Ann Arbor MI, 48109 and Dept. Neuroanatomy, Osaka Univ.[3], Japan

There is now considerable evidence suggesting that glutamate or a related excitatory amino acid is the transmitter of auditory pathways and that it acts on an excitatory amino acid receptor. The NMDA receptor has been known to play a key role in many excitatory amino acid CNS synapses, however its role in the cochlea and auditory brainstem has not been well established. Recently two sequences for the NMDA-receptor have been reported (Moriyoshi et al., 1991 and Kumar et al.,1991), each with different properties. Expression of NMDA receptor mRNA in the rat auditory system was examined using *in situ* hybridization histochemical techniques. For *in situ* hybridization studies one oligoprobe was made of antisense codons (2225-2269) of Moriyoshi's sequence (NMDAR-1) and another one was made of the antisense codon (1107-1151) of Kumar's sequence (NMDAR-2). These probes were end labeled with α-^{35}S dATP (NEN) and applied to cryostat sections of rat brainstem and decalcified cochlea. Sections were hybridized overnight followed by rinse and dip in emulsion. Slides were then exposed for 1-3 weeks and developed. A density of silver grain considerably over background level was seen over spiral ganglion cells in the cochlea, and over neurons in cochlear nuclei and superior olivary complex in the brainstem with both NMDAR-1 and NMDAR-2 probes. This pattern of staining represents expression of NMDA receptor mRNA in these neurons. In spiral ganglion cells, the signal seen for NMDAR-1 was much stronger than for NMDAR-2. The specificity of the hybridization signal was confirmed by using sense probe and RNAase as a control. In all control specimen, the hybridization signals were virtually absent. These results suggest that NMDA-receptor is a component of excitatory amino acid synapses in the cochlea and auditory brainstem. Immunohistochemical studies will be necessary to determine the specific synaptic localizations of these receptors in the cochlea and brainstem auditory nuclei.

HSP 72 INDUCTION WITH ACOUSTIC OVERSTIMULATION IN THE RAT COCHLEA AND AUDITORY BRAINSTEM. H.H. Lim, O.H. Jenkins, J.M. Miller*, M. Myers and R.A. Altschuler. Kresge Hearing Research Institute, Department of Otolaryngology, University of Michigan, Ann Arbor, MI, 48109.

Heat shock proteins (HSPs) are induced after the exposure of cells to various metabolic and environmental stresses. In the auditory system, induction of the 72 kD HSP has been shown with heat in the rat (Kim et al., 1991) and guinea pig (Thompson et al., 1992) cochlea , as well as with hypoxia in the rat cochlea (Myers et al., 1992). The purpose of this study was to determine if high intensity acoustic stimulation would induce HSP 72 in the rat cochlea and auditory brainstem. Sprague-Dawley rats were exposed to 110 dB SPL broad band noise for 1.5 hours and sacrificed 4, 6 and 8 hours after stimulation. Control animals did not receive any stimulation. Immunocytochemical and western blot analysis were performed using monoclonal antibodies against HSP 72 (Amersham, StressGen). Tissue for western blot analysis came from unfixed dissected cochlea, cochlear nucleus and inferior colliculus. Immunoperoxidase immunocytochemistry was performed on vibratome sections of the rat brainstem, cryostat sections of cochlea and cochlea with the bony shell removed, the latter yielding surface preparations.

Western blots showed an intense 72 kD band in the noise exposed animals compared to a very light band in control animals. Immunocytochemical results in the cochlea revealed noise induced HSP 72 immunoreactive (IR) staining of outer hair cells. The maximal IR staining was observed 6 hours after noise exposure. Only a few IR stained inner hair cells were seen and spiral ganglion cells were not stained. In the brainstem, noise induced HSP 72 IR labeling of neurons was observed in cochlear nucleus, medial nucleus of the trapezoid body, lateral superior olive, but not in inferior colliculus.

These results indicate that acoustic overstimulation can induce the expression of HSP 72 in the rat cochlea and auditory brainstem nuclei. HSP 72 immunolabeling may serve as a marker for cellular stress and potential damage. Further studies may also help to determine a protective function for HSP 72 in the auditory system.

CONTRALATERAL SOUND SUPPRESSES DISTORTION PRODUCT OTOACOUSTIC EMISSIONS VIA CHOLINERGIC MECHANISMS. S.G. Kujawa, T.J. Glattke, M. Fallon and R.P. Bobbin*, Dept. of Speech & Hearing Sciences, Univ. of Arizona, Tucson, AZ 85721 and Kresge Hear. Lab., LSUMC, New Orleans, LA 70112.

Contralateral sound suppression (CSS) of distortion product otoacoustic emissions (DPOAEs) involves the activation of olivocochlear efferent fibers which synapse on outer hair cells (OHCs) (Puel & Rebillard, JASA, 76:1713, 1990). One neurotransmitter of these fibers is acetylcholine (ACh). We studied the effects of ACh antagonists on CSS of DPOAEs to determine if ACh is involved and the receptor type. Urethane anesthetized guinea pigs with sectioned middle ear muscles were used. Perilymph spaces of cochleae were perfused with artificial perilymph (AP) and drugs at 2.5 µl/min for 10 min. After each period of perfusion the $2f_1$-f_2 DPOAE at 5 kHz (f_1 = 6.25 kHz; f_2 = 7.5 kHz; 60 dB SPL) was measured before, during and after a contralateral wideband noise (70 dB SPL). CSS of DPOAEs was 1.59 ± 0.15 dB. AP did not alter CSS of DPOAEs. Strychnine (10 µM), curare (10 µM) and atropine (10 µM) reversably blocked CSS of DPOAEs. Results support the involvement of both nicotinic and muscarinic receptors in CSS of DPOAEs. (Supported by NIH grant DC-00722).

MIDDLE EAR TRANSFERFUNCTION AND DIRECTIONAL CHARACTERISTIC IN CLAWED FROG AND ZEBRA FINCH.

H.-P. Rangol[1)], J. Golden jr.[1)], H.-J. Bischoff[2)], K. Brändle[1)], A. Elepfandt[3)], W. Plassmann[1)]* 1) Zoologisches Institut J. W. Goethe-Universität, Frankfurt/Main, FRG; 2) Fakultät für Biologie, Universität Bielefeld, Bielefeld FRG; 3) Fakultät für Biologie, Universität Konstanz, Konstamz FRG

Acoustic properties of the middle ear were studied in the clawed frog *Xenopus laevis* and in the zebra finch *Taeniopygia guttata*. During the experiments the frog was positioned 10 cm below the water surface on a small turntable in the center of a circular 4m pond. A probe microphone was inserted into each middle ear. Reference hydrophones were placed on both sides of the frog's head. The zebra finch was positioned inside a sound proof-chamber, on a turntable, with similar positioning of middle ear and reference microphones. In both cases acoustic stimulation consisted of continuous white noise delivered at every 10° rotation angle, up to 360° azimuth. Sound pressures received by all the microphones were processed by means of a special program for signal analysis. Transfer functions between freefield and middle ear and between the middle ears of both sides were established for the two species. These experiments were performed under experimental conditions of intact ear and various systematic manipulations of ear structures.

Morphological analysis of the internal connection between both ears consisted of three-dimensional computer reconstructions on the basis of serial sections of the head regions involved. Shapes and dimensions of the cavities between both ears were also made visible by filling with plastic material. While the interaural-pathway of the clawed frog consists of only one direct connecting with an opening to the mouth cavity the zebra finch possesses a more diverse internal connection that has no orifice. The eustachian tube of the frog opens in the medial corner of the roof of the mouth; the larynx lies just beneath this opening. Acoustic measurements revealed a certain frequency range around 5 kHz in the zebra finch and 3 kHz in the clawed toad without an acoustic crosstalk. These are also the frequency ranges, where sound pressure differences between the two ears occur, which are large enough for directional hearing. On the basis of the morphological and experimental results a theoretical model was designed for the description of a bird's and a frog's ear.

GROWTH PHASES OF THE COCHLEAR DUCT IN THE OPOSSUM, *MONODELPHIS DOMESTICA*. F.H. Willard*, Department of Anatomy, University of New England, Biddeford, ME 04005.

Two distinct growth phases were observed in the mammalian cochlear duct using quantitative light microscopy and image analysis (Sigma-Scan) of Nissl-stained sections. The ***first phase*** featured the linear growth of the cochlear duct but with no concomitant increase in its absolute volume. From birth (13 days after conception) the cochlear duct, a cul-de-sac whose spiral has only 3/4s of a turn, expands over the next 8-10 days to reach one and 3/4s turns without a detectable increase in absolute volume. From birth to postnatal day (PND) 6, numerous mitotic figures (MFs) were seen in the epithelium along the full length of the duct (2-6 MFs per cross-sectional profile of the duct). By PND-8 the mitotic figures, although plentiful (2-4 MFs per profile), were confined to a bud in the apex of the duct. The ***second phase*** of growth was initiated between PND 8-10 when the linear growth and cell division in the cochlear epithelium diminished (less than one MF per profile) and volumetric expansion of the duct began. The growth curve for the volume of the duct is sigmoidal, reaching its asymatote by PND-20. During this time the cross-sectional profiles of the duct increased in size, however, there are very few mitotic figures present in the cochlear epithelium. Hypertrophy of the cartilaginous posterior wall of the duct begins around PND-13 and ossification follows around PND-15. The zone of ossification sweeps rostrally (from base to apex) finally ossifying the anterior wall of the duct around PND-20. Thus two phases of growth are present in the mammalian cochlear duct, the first phase involves linear growth with cell division present in the cochlear epithelium. The second phase involves volumetric expansion with little evidence of cell division. The second phase may be limited in duration by ossification of the duct walls.

EFFERENT TERMINATIONS IN THE NEONATAL HAMSTER COCHLEA. N.B. Mansdorf, D.D. Simmons*, and K. Bell. Dept. of Biology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1606.

In adults, lateral olivocochlear (OC) neurons terminate below inner hair cells (IHCs) while the medial OC neurons terminate only on outer hair cells (OHCs). Although both lateral and medial OC neurons are presumably present in the cochlea at birth it is unclear which system matures first, innervates hair cells first and whether they maintain separate innervations of IHCs and OHCs. Our investigations have attempted to characterize the development of OC terminations using light- and electron-microscopic techniques in the postnatal hamster. Biocytin was injected into the crossed OC bundle using an *in vitro* brainstem preparation. At postnatal day (P) 6, efferent fibers gave rise to at least two types of endings: large diameter swellings that terminated directly on IHCs, and smaller diameter varicose swellings that terminated below the IHCs. The majority of efferent endings were found on the modiolar side of the IHC. No terminal endings were observed on or below the OHCs. The developmental expression of calcitonin gene-related peptide (CGRP), a marker specific for lateral OC neurons, was also immunocytochemically characterized. Immunoreactivity could not be detected on or before P 6 but was readily observable at P 9 as a dense plexus of CGRP-positive terminals only under IHCs. Our data are consistent with the hypothesis that the medial OC efferents terminate on IHCs before OHCs.

DEVELOPMENT OF THE TUNNEL OF CORTI IN THE RAT.
L.P. Rybak*, C. Whitworth. Department of Surgery, SIU School of Medicine, Springfield, IL 62794-9230.

The rat is an altricial animal which has proven to be a useful model for the study of auditory development. The purpose of the present study was to study the surface development of the organ of Corti using scanning electron microscopy (SEM). Rat pups from 1-30 postnatal days of age were anesthetized with pentobarbital and the cochleas were removed and processed for SEM using a modification of the TOTO procedure (Davis and Forge, J Microsc 1987; 147:89-101). The specimens were viewed with a Hitachi S500 Scanning Electron Microscope. The tunnel of Corti was found to undergo dramatic changes between 9 and 11 days after birth. The tunnel of Corti was extremely narrow prior to 9 days of age. A base to apex gradient of development of the tunnel width was observed. At 9 and 10 days of age the tunnel width increased in the lower middle turn and the hook region. By 11 days of age the tunnel of Corti was well developed throughout the cochlea. These morphological findings correlated with the onset of CAP response which was first detected at 13 days of age. It appears that opening of the tunnel of Corti coincides with a series of developmental phenomena which must occur prior to onset of sound-evoked responses in the cochlea.

INPUTS TO THE SUPERIOR PARAOLIVARY NUCLEUS. N. Kuwabara* and J.M. Zook. *Dept. of Biological Sciences and OUCOM, Ohio University, Athens, OH 45701.*

Projections to the superior paraolivary nucleus (SPN) were studied at the single cell level in the gerbil, mouse and big brown bat, *Eptesicus fuscus*, using intracellular labeling in a brainstem tissue slice preparation.

An unexpected major source of SPN input was traced from principal cells (PC) of the adjacent medial nucleus of the trapezoid body (MNTB). This input was in the form of collateral projections off of the main PC axon as it travels to the lateral superior olive (LSO). MNTB projections generally ramified across the entire dorsoventral extent of the SPN and the terminal arborizations formed bands as extensive or more extensive than those seen in the MNTB projections to the LSO. Most of the fine *en passant* and terminal boutons characteristic of this projection may be associated with dendrites of SPN cells, but this has not been established conclusively. The MNTB projection to SPN is topographically organized. Principal cells located in the medial MNTB projected to the medial SPN, while those located in the lateral MNTB projected to the lateral SPN.

Other sources of input to the SPN were also labeled. Trapezoid fibers, presumably from the ipsilateral cochlear nucleus, sent branches to SPN which terminated in thin sheets parallel to the MNTB projection. The extent and pattern of these projections may distinguish the SPN from the dorsomedial periolivary nucleus (DMPO) which is recognized in the cat and mustache bat. The DMPO, but not the SPN, is a major target of collateral branches of the calyciferous axon projection to the MNTB (Morest '68; Kuwabara et al., '91). (Supported by NIDC01303 and OUCOM)

A CONNECTIONIST MODEL OF THE OWL'S SOUND LOCALIZATION SYSTEM. D.J. Rosen, D.E. Rumelhart, E.I. Knudsen and T. Masino*. Depts. of Psychology and Neurobiology, Stanford University, Stanford, CA 94305.

We describe a connectionist model of the barn owl's auditory localization system. Simulated sound is fed into an inner ear model whose output is used to generate spike activity in frequency tuned units (auditory fibers). These units feed into paired models of the nucleus magnocellularis, containing units sensitive to input phase, and the nucleus angularis, containing units sensitive to input level. Output from the magnocellular nuclei feeds into a cross-correlation model of the nucleus laminaris whose units are therefore tuned to interaural phase differences (IPD). Time averaged samples of laminaris activity, representing a range of interaural time differences, are fed into a model of the inferior colliculus (IC) core. In parallel, outputs from the angular nuclei feed into a subtraction model of the VLVp whose units are sensitive to interaural level differences (ILD). The network integrates signals from the IC core and the VLVp in its model of the IC lateral shell, which in turn feeds into the external nucleus of the IC (ICx).

Before training, VLVp units were fully interconnected to lateral shell units of similar frequency tuning. Lateral shell and ICx units were fully interconnected. Only these two sets of connections were modifiable. The network was trained by backpropagation to create ICx units with discrete auditory spatial fields as well as lateral shell units with realistic tuning properties.

By manipulating learning algorithms, sites of plasticity and training procedures we can use the network to explore details of the structure and development of the owl's localization system.

MULTIPLE AUDITORY PATHWAYS INTO HVc.
E.S.Fortune*and D.Margoliash. Dept. of Org. Bio. and Anat, Univ. of Chicago, Chicago, IL, 60637

We examined the organization of auditory inputs to the caudal nucleus of the ventral hyperstriatum (HVc), a neostriatal site of sensory-motor interaction in the pathway for song learning and production.

Neurons in the field L complex, a thalamorecipient group of cytoarchitectonically distinct auditory nuclei, project to HVc, the 'shelf' ventral to HVc, and surrounding caudal neostriatum (NC). Injections of biotinylated dextrans into these areas retrogradely label cells throughout L1 and L3 of the field L complex. These two nuclei form the major pathways for auditory input to HVc. Cells in L1 and L3 have morphologies similar to types 1 and 2 cells seen in Golgi preparations. Occassionally type 3 oriented cells were labelled within L2a. Injections into HVc which did not invade the shelf appear to label more cells in L1 than in L3 whereas injections into NC ventral to HVc label more cells in L3. Injections that included the shelf appear to label a greater number of cells in field L than those that did not.

The majority of NIf cells that were labelled by injections into HVc have dendritic arbors which are within the borders of the nucleus. Some cells, however, have denritic arbors that extend into adjacent L1 and thus may have access to auditory information.

Some HVc cells have dendrites in the shelf. These include cells that have large somata with thick, spiny dendrites and elongate dendritic arbors, which were labelled by injections into the field L complex and presumably project to area X. Small cells with thin, short, sparsely spined dendrites and large cells with thick, densely spined dendrites that were labelled by injections into the dorsal archistriatal tract and presumably project to RA, also have dendrites which invade the shelf.

Most injections into HVc labelled nearly all of the cells in NIf whereas the numbers of cells labelled in the field L complex appears to be dependent on the size of the injection site. We are investigating the axonal organization of these projections. Supported by NIH grant NS25677 to DM.

ON THE ROLE OF THE DORSAL NUCLEUS OF THE LATERAL LEMNISCUS IN ACOUSTICALLY-EVOKED INHIBITION IN INFERIOR COLLICULUS NEURONS C.L. Faingold*, C.A. Boersma Anderson and M.E. Randall. Dept. Pharmacol., So. IL Univ. Sch. Medicine, Springfield, IL 62794.

Acoustically-evoked GABA-mediated inhibition is observed in neurons in the central nucleus of inferior colliculus (ICc). The dorsal nucleus of the lateral lemniscus (DNLL) is a GABAergic nucleus that projects to ICc. The present study examined the effects of stimulation and/or blockade of the DNLL on ICc neuronal firing. Rats were anesthetized (pentobarbital, 40mg/kg ip). A cannula or bipolar concentric electrode was placed into the DNLL, and the effects of stimulation and/or microinjection on contralateral ICc neuronal firing were evaluated. Microinjection of a local anesthetic, lidocaine (2%), or a GABA-A agonist, THIP, (10 nMol, 0.5 µl) into DNLL blocked acoustically-evoked binaural or intensity-induced inhibition in most ICc neurons. The spontaneous activity of ICc neurons exhibited a dramatic reversible increase following DNLL blockade. Trains of electrical stimulation of DNLL resulted in reduced acoustically evoked firing in most ICc neurons, which mimicked binaural or intensity-induced inhibition. The degree of firing reduction was dependent on the intratrain frequency. Effects of DNLL stimulation were blocked by microinjection of THIP into the site of stimulation, suggesting mediation of the effects of stimulation by direct actions on DNLL cell bodies. These data support the idea that contralateral GABAergic input from the DNLL is inhibitory to ICc neurons. Thus, binaural, intensity-induced and tonic inhibition in ICc neurons may be mediated, in part, by the GABAergic projection from the contralateral DNLL. (Support NIH NS 21281).

TOPOGRAPHICAL ORGANIZATION OF THE MOTONEURON POOLS INNERVATING THE MUSCLES OF THE PINNA IN THE FACIAL NUCLEUS OF THE CAT. Luis C. Populin* and Tom C. T. Yin. Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

The external ear of the cat filters the acoustic signal in a manner dependent upon the location of the sound source, and thus may play an important role in sound localization. Unlike humans, cats can move and change the shape of their pinnae extensively, thus they are able to control the filtering properties of the pinna.

As an initial step in a study of the role of the pinna in sound localization, we have characterized the topographical organization of the motoneuron pools innervating pinna muscles in the cat's Facial Nucleus (FN). Individual muscles were dissected, isolated from neighboring tissue, and injected (30-65 μL) with horseradish peroxidase conjugated to the B subunit of cholera toxin (CTB-HRP; List Laboratories, 0.1%). After survival times of 48 to 72 hours, brainstems were cut into 70 μm frozen sections, treated with tetramethyl benzidine, and counterstained with cresyl violet. Using camera lucida the contour of the nuclei and the positions of the labeled motoneurons of most pinna muscles have been reconstructed.

Retrograde labeling indicates that each muscle is innervated by a column of motoneurons extending along the rostrocaudal axis of the nucleus. These vary in the number of cells and in their length along this axis. In the coronal plane, each motoneuron pool occupies a discrete position in the medial division of the nucleus. There is little overlap among motoneurons that innervate large muscles, but the pattern is not as sharply defined for those innervating smaller muscles. Motoneurons innervating muscles that pull the pinna rostrodorsally (e.g., the Adductor Auris Inferior m.) are located dorsolaterally, and those that move the pinna caudally (e.g., the Levator Auris Longus m.) are located ventromedially in the medial division of the FN.

STRUCURAL BASIS OF BINAURAL PHASE PROCESSING IN N. LAMINARIS: POSSIBLE FUNCTION OF BIPOLAR DENDRITES. W. E. Sullivan *, Dept. of Ecology and Evolutionary Biology, Princeton Univ., Princeton, N.J. 08544

For horizontal sound localization, binaural synaptic inputs time locked to the sound wavefronts at each ear activate neurons sensitive to time differences between these inputs. Maximum firing occurs for coherent bilateral inputs, suggesting that these cells are "coincidence detectors". These neurons in chicken nuc. laminaris have long bipolar dendrites. Their homologues in barn owls, which respond to higher frequencies, do not have dendrites (Carr and Konishi 1990).

Possible functions for dendrites in phase comparison were explored using compartmental modeling. The results suggest that dendrites can enable selectivity for synchronous bilateral inputs in the face of large variations in synaptic input, due to fluctuations in spike rate or to changes in sound level. The mechanism requires electrical isolation between bilateral inputs and makes use of the fact that post-synaptic voltage can approach but not exceed the synapse's equilibrium potential. If synaptic conductances are large, a single input will locally depolarize the dendrite near to saturation. Thus, another input at that location will be less effective at the soma than a separate input on another dendrite. This can produce a virtually all-or-none selectivity for bilateral coincidences over unilateral ones. This function cannot be achieved in an iso-potential, soma-only model. The model's properties can be used to predict several features of laminaris cells such as dendrite length, branching pattern and number (Smith and Rubel, 1979). Cells tuned to higher frequencies have shorter, more numerous dendrites which can be related in the model to constraints of pre- and post-synaptic processing at different frequencies.

THREE DIMENSIONAL ATLAS OF THE LATERAL NUCLEUS OF THE TRAPEZOID BODY IN GUINEA PIG. R. Bawa and G.A. Spirou*, Department of Otolaryngology, West Virginia University School of Medicine, Morgantown, WV 26506.

The lateral nucleus of the trapezoid body (LNTB) is the lateral most of a group of nuclei surrounding the major cell groups of the superior olivary complex (SOC). The proximity of the LNTB to the cochlear nucleus (CN) indicates that LNTB neurons could rapidly exert significant effects on signal processing in the CN. Topographical relationships between LNTB and CN neurons may be a function of cell position in the LNTB and morphological characteristics of LNTB neurons. We have constructed an atlas of Nissl stained LNTB neurons using transverse sections from two animals. Cells were projected at 560X and drawn using camera lucida. LNTB boundaries extend from the caudal pole of the superior olive to the rostral LSO, encompassing the caudal 50% of the SOC. The total number of LNTB neurons in each animal was 638 and 603. The greatest number of cells per 50μm section, as many as 43 cells, were found caudal to the LSO; the least number of cells per section, as few as 7 cells, were found through the middle region of the LSO. The distribution of cell areas was unimodal with a peak between 50-150μm^2 and included cells as large as 600μm^2. Neuron size was similarly distributed in each section in one animal; the largest neurons were clustered rostrally in the other animal. Over half of the LNTB neurons are caudal to a plane passing through the caudal auditory nerve root region of the CN and are positioned to exert effects in the posterior CN if interactions are largely confined to the transverse plane. Supported by NIDCD grant DC01387.

SENSORY PROPERTIES OF NEURONS IN THE ACOUSTIC THALAMUS THAT PROJECT TO THE AMYGDALA. F. Bordi*, and J.E. LeDoux. Center for Neural Science, New York Univ., NY, NY 10003.

Cells in the medial division (MGm) of the medial geniculate body (MGB) and adjacent areas of the posterior thalamus are known to respond to both auditory and somatosensory stimuli. Cells in this region also project to the amygdala. In the present study we investigated the sensory properties of single cells in the MGm nucleus and underlying posterior intralaminar nucleus (PIN). Antidromic stimulation of lateral amygdala (AL) was also carried out in some experiments to characterize the sensory properties of the neurons that project to amygdala. Rats were anesthetized and single units were recorded in the posterior thalamus during stimulation with white noise (80dB), isointensity tones (1-30 kHz, 0-90 dB), or footshock (0.3 mA). Cells responded to white noise with initial onset latencies of 7-8 ms. These units showed either phasic or sustained responses. Some cells had clear frequency preferences but even these tended to be more broadly tuned than units in the nearby pars ovoidea of the ventral division (MGv) of MGB, where narrow tuning and a tonotopic organization was found. The tonotopic organization was preserved in MGm but with broader tuning characteristics. Unlike cells in MGv, some cells in MGm and PIN responded to both auditory and somatosensory stimulation. Some multimodal cells showed frequency preferences. Cells identified by antidromic stimulation of AL were localized in MGm and PIN, but never in MGv. These cells exhibited similar response to those described. Thus, thalamo-amygdala projection neurons respond to auditory and somatosensory stimulation and some are relatively tuned with respect to frequency. Supported by MH38774 and MH46516.

OPTICAL IMAGING OF FUNCTIONAL ARCHITECTURE OF THE GUINEA PIG AUDITORY CORTEX. **I. Taniguchi*, J. Horikawa, T. Moriyama and M. Nasu. Dept. of Neurophysiology, Med. Res. Inst., Tokyo Med. and Dent. Univ., Tokyo 101, Japan.**

Three tonotopically organized auditory cortical fields (field A, DC and S) have been identified in the guinea pig with a microelectrode technique. Fields A and S have within them a rostral-to-caudal, low-to-high-frequency gradient, while field DC has a mirror-image relationship to field A with respect to the frequency gradient. Functional difference between fields A and DC has not yet been clarified. We studied functional organization in fields A and DC with an optical method using a 144-channel photodiode array and the potential sensitive dye (RH795). Guinea pigs were anesthetized with Nembutal (30 mg/kg) and the temporal brain field was exposed. Tone-bursts were delivered as stimuli from the contralateral ear with a closed system. The 12x12 channel optical responses were recorded for different frequencies and sound pressure levels. To obtain the spatio-temporal pattern of neural activity, the potentials of topological responses were color-coded and transformed to sequential images. Our results showed the tonotopical organization in field A, but not clearly in the smaller field DC. On stimulation, enhanced activity was found first in field A and propagated towards field DC. This suggests functional difference between fields A and DC in sound information processing.

PNA BINDING PATTERNS IN THE DEVELOPING DORSAL COCHLEAR NUCLEUS. G. H. Riggs and L. Schweitzer*. Dept. of Anatomical Sciences and Neurobiology, Univ. of Louisville Sch. of Med., Louisville, KY 40292.

Various studies have suggested that glycoconjugates may influence connectivity and lamination in the developing CNS. This project used peanut agglutinin (PNA) to investigate glycoconjugate distribution in the dorsal cochlear nucleus (DCN) of the developing hamster, a nucleus whose development is well characterized. Laminar differences were found, and within laminae a dorsomedial to ventrolateral gradient was observed. Specifically, PNA is most dense in the DCN's molecular layer, with label evident on PND 3, beginning to recede on PND 13 and virtually disappearing by PND 23. PNA did not differentially label the fusiform and deep cell layers at any age. Within the deep and fusiform cell layers, a pattern of trabeculation was observed beginning dorsomedially on PND 3 and extending ventrolaterally with development. By PND 14, trabeculation was less distinct dorsomedially, giving way to a more homogenous distribution of label. This homogenous pattern of labeling progressed ventrolaterally with age. The last evidence of trabeculae appeared at the ventrolateral-most limit of the DCN on about PND 23. These patterns of PNA binding parallel other events in normal development. Ingrowth of primary cochlear afferents, for example, follows the same spatiotemporal gradient as the initiation of trabeculation, occurring during PND 3-10 and following a dorsomedial to ventrolateral pattern of development. Descending inputs also grow into the deep DCN at this time. PNA label in the molecular layer diminishes concurrently with the maturation of granule cell axons, GAD-positive inputs and apical dendritic processes of fusiform cells in that layer. Unlike laminar patterns of PNA observed in other systems, the distribution of label in the DCN does not delineate all three cell layers. Therefore, changing PNA patterns are not simply a function of cell sorting in the DCN, but rather may reflect afferent ingrowth.

PARALLEL PATHWAYS FOR SOUND LOCALIZATION IN THE FOREBRAIN AND MIDBRAIN OF THE BARN OWL. E.I. Knudsen* and P.F. Knudsen. Dept.Neurobiology, Stanford University, Stanford, CA 94305.

We tested the hypothesis that the forebrain and the optic tectum (superior colliculus) are each capable of mediating sound localization independently of the other. The species studied was the barn owl, a species with highly developed sound localization abilities rivaling those of humans. The behavioral assay for sound localization was orientation of gaze. (Lesions can cause the expression of more complex behaviors, such as moving to a source, to be lost even when accurate localization persists, as revealed by simpler behaviors.) Moreover, both the optic tectum and the forebrain have direct access to the premotor circuitry that controls gaze.

The strategy was to interrupt the tectal pathway at the level of the optic tectum and interrupt the forebrain pathway at the level of the auditory thalamus, a nucleus called ovoidalis in birds (medial geniculate in mammals). The ability of 5 trained owls to orient gaze toward sound sources was assessed with one or both structures either lesioned or inactivated with muscimol (0.12-0.25 µg in ovoidalis; 1.0 µg in tectum). Localization responses to sources located in the contralateral (affected side) hemifield were compared with those to sources in the ipsilateral hemifield. Unilateral inactivation of the tectum caused a decrease in the probability of response, a decrease in accuracy and precision and in some owls an increase in latency. Unilateral inactivation of ovoidalis alone had little effect and, if anything, caused a slight increase in accuracy. However, unilateral inactivation of both structures left the animal unresponsive to sound sources located contralaterally. Thus, information essential for sound localization is processed in parallel in the tectum and forebrain. The pattern of deficits is remarkably similar to the deficits in gaze responses to visual stimuli observed in primates following tectal and/or forebrain lesions.

This work was supported by a grant from the NIH (DC 00155-12).

SPATIO-TEMPORAL IMAGING OF AUDITORY CORTEX OF GUINEA PIG HEARING SOUND WITH VOLTAGE-SENSITIVE-DYE. K.Fukunishi,N.Murai,H.Uno,H.Kawaguchi*. Advanced Research Laboratory,Hitachi Ltd.,Hatoyama,Saitama 350-03,JAPAN.

The neural evoked responses which are the outputs of dynamical brain system working for each specific purpose maintain useful information utilized for the brain system identification. Optical recording seems to be an important measurement method of the neural responses which could lead to identify the brain system. A 128-channel optical recording system was developed to measure the neural responses of a animal brain for hearing sounds. The voltage sensitive dye (RH795) was applied for the probe. The temporal fields of anesthetized guinea pigs (male) were observed after click and tone burst stimuli respectively. A boomerang-shaped spatial pattern due to the movement of the response parts on the auditory field was observed for the click. This kind of movement pattern was invisible for the tone bursts. The direction of the movement of the response parts for the click crossed the response parts for the tone burst. The frequency selectivity of the cortical neuron was observed but depending on the latency. This characteristics was also clarified by focusing to the strong response parts for each tone burst. The cross-correlation among the responses of each observed section revealed the existence of the modular unit of the neural information processing on the cortical field for the complex sound as the click.

CHANGES IN HEARING AND SOUND-INDUCED 2DG-PATTERN IN THE AUDITORY SYSTEM OF DEVELOPING TREE SHREWS. E. Zimmermann*, H. Binz, H. Rahmann. Deutsches Primatenzentrum, 3400 Göttingen and Institute of Zoology, University Stuttgart-Hohenheim, 7000 Stuttgart 70, FRG.

The development of hearing and sound perception in mammals has received increasing interest due to the scarce knowledge we have about the influence of epigenetic factors on differentiation.

Our present study was designed to map and compare the representation of physically defined sounds with different biological significance in the auditory system of tree shrews by means of the 2DG-method, to analyze if and at which age these sounds induce an altered metabolic response, if the evoked patterns are immutable or variable, at which age they become stimulus-specific and at which age they correspond to the pattern of adults. Besides, the development of auditory thresholds from birth to nutritional weaning was determined by psychophysical methods.

Tree shrews are born deaf, their hearing capability develops postnatally and their hearing and sound communication range is quite similar to those of higher primates (Binz et al. Behav. 109, 1989; Zimmermann, Cambr. Enc. Hum. Evol. 1992). Discrete stimulus - specific 2DG-patterns were discerned in the core area of the auditory cortex, the central nucleus of the inferior colliculus and the dorsal and ventral part of the cochlear nucleus in adult tree shrews. They imply a tonotopic organization. First sound-induced patterns of 2DG-uptake - were visualized at the time the external meatus opens and sound-induced behaviors could be evoked. However, it was not before weaning that auditory sensitivity and sound representation correspond to those of adults. These findings suggest that experience may be involved in shaping sound perception in tree shrews. Supported by the DFG (Zi 345/1-3).

FUNCTIONAL REORGANIZATION IN THE INFERIOR COLLICULUS FOLLOWING ACUTE COCHLEAR TRAUMA. R.J. Salvi* and S. Saunders Hearing Research Lab, SUNY at Buffalo, Buffalo, NY 14214.

The tonotopic organization and response properties of neurons in the auditory cortex can be dramatically altered when a segment of the cochlea is damaged. However, it is unclear how neurons distal to the cortex contribute to this reorganization. In order to explore this issue, we recorded from neurons in the inferior colliculus (IC) immediately after damaging a region of the cochlea with acoustic overstimulation. The frequency of the traumatizing tone was located above the unit's excitatory response area in order to selectively eliminate inhibitory inputs originating above CF. Units with monotonic rate-level functions were unaffected by this type of exposure; however, the response properties of units with non-monotonic discharge rate-level functions were dramatically altered. Non-monotonic units responded to a broader range of low-frequency stimuli and thresholds in the tail of the tuning curve sometimes improved by more than 30 dB after the exposure. Saturation discharge rates also increased significantly (100-200%). These results suggest that the traumatizing tone can selective inactivate regions of the cochlea which drive the inhibitory inputs to these cells and significantly alter the unit's excitatory response area and level of excitability.

LOCATION OF AUDITORY CORTEX IN THE RAT AND FERRET: A DOUBLE-LABELING STUDY USING ^{18}F- AND ^{14}C-2-DEOXYGLUCOSE. M.N. Wallace* and D. Roeda *Dept of Biomedical Sciences, AB9 1AS and Dept of Bio-medical Physics, AB9 2ZD, University of Aberdeen, Scotland, UK.

The number and location of auditory areas in the rat and ferret neocortex is uncertain. We used the deoxyglucose method to study the cortex of control and deafened animals. Commercial ^{14}C-2-deoxyglucose was injected (i.p.) (555 kBq/100g rat or 370 kBq/100g ferret) and the animals exposed to normal laboratory sounds for 45 min.. Some were then deafened under ether(rat) or ketamine(ferret) anaesthesia by bi- or unilateral desruction of the tympanic membrane. Two hours later ^{18}F-2-deoxyglucose produced with the University cyclotron was injected (i.p.) (37 MBq/100g). The brains were sectioned at 50 µm in a cryostat and exposed using Kodak X-Omat-L film for 8 hours (^{18}F) and then after 2 days for a further 16 days (^{14}C). Two areas of high deoxyglucose uptake were found in the rat auditory region (area 41) and three areas on the ferret ectosylvian gyrus. This activity was not altered by bilateral ablation but was reduced contralateral to a unilateral ablation.

THE FUNCTIONAL ANATOMY OF MIDDLE LATENCY AUDITORY EVOKED POTENTIALS: THALAMOCORTICAL CONNECTIONS S. DI* and D. S. BARTH *Department of Psychology, University of Colorado, Boulder, Colorado 80309 USA*

Recent studies in our laboratory have demonstrated that by using high resolution epicortical potential mapping in combination with numerical methods of spatiotemporal analysis, it is possible to identify and separate putative neural generators of the middle latency auditory evoked potentials (MAEP) complex in the region of auditory cortex. The object of the present study was to compare the click evoked epicortical MAEP complex with potentials evoked by direct electrical stimulation of the ventral and dorsal divisions of the medial geniculate body (MGV and MGD). Epicortical responses to click stimuli replicated earlier findings. The responses consisted of a positive-negative biphasic waveform (P1a and N1) in the region of primary auditory cortex and a positive monophasic waveform (P1b) in the region of secondary auditory cortex. A linear combination of these patterns was sufficient to explain from 90-94% of the variance of the evoked potential complex at all latencies. In the same animals, epicortical responses to electrical stimulation of the MGV and MGD were also localized to areas 41 and 36, respectively. A linear combination of potential patterns from these separate stimulation conditions was sufficient to explain from 80-93% of the variance of the original click evoked potential complex at all latencies. These data provide functional evidence for anatomically defined topographical thalamocortical projections to primary and secondary auditory cortex. They suggest that short latency cortical evoked potentials (10 - 60 msec post-stimulus) are dominated by parallel thalamocortical activation of areas 41 and 36.

SELECTIVE STAINING OF OLFACTORY AFFERENT FIBRES IN FISHES USING ANTIBODIES RAISED AGAINST APGW-NH_2.

R.Y.S. Lo and R.P. Croll*, Department of Physiology & Biophysics, Dalhousie University, Halifax, Nova Scotia Canada B3H 4J7.

APGW-NH_2 (Ala-Pro-Gly-Trp-NH_2) has recently been suggested as an important neuropeptide with roles involved in, but probably not restricted to, reproduction in molluscs (Kuroki et al, 1990, *Biochem. Biophys. Res. Comm.* 167:273; Smit et al, in press, *J. Neurosci.*). The AKH and RPCH peptides found in arthropods have common C-termini (X-PGW-NH_2 and X-GW-NH_2, respectively), thus suggesting a family of related peptides which spans phyla. In the present study, we found that polyclonal antibodies (Croll & Van Minnen, in press, *J. Comp. Neurol.*) raised against APGW-NH_2 selectively label the afferent fibres entering the olfactory bulbs of the guppy, damselfish and zebrafish. These fibres appear to be homogenously distributed in the olfactory nerve. In the olfactory bulb, they form glomeruli located in the entire lateral half and the rostral part of the medial half of the olfactory bulb. In some cases, diffused fibers are also found converging toward the anterior commissural area in the forebrain. While the projection patterns and immunoreactivity are reliably reproduced in the guppy and damselfish, immunoreactivity varies in the zebrafish and appears to be absent in the goldfish. Preliminary studies also suggest the absence of immunoreactivity in the olfactory bulb of the rat. Current studies in progress attempt: i) to double label receptor somata in the olfactory epithileum using antibodies and retrograde tracers, ii) to determine the specificity of the antibodies and characterize the immunoreactive substance(s), and iii) to screen for immunoreactivity in other classes of vertebrates.

A NEW STRUCTURE, THE "PIT ORGAN", IN HUMAN AND MONKEY OLFACTORY MUCOSA.

W.H. Feng, I.S. Kauer, M. Stockmayer, and B.R. Talamo*. Neuroscience Labs, Tufts Med. Sch.. Boston, MA

A new whole mount immunocytochemical method (Feng et al. 1991) was used to study the olfactory receptor neurons (ORNs) on the surface of the olfactory mucosal sheet. Studies with neuron-specific tubulin antibody, J1, of 26 specimens of human olfactory mucosa taken at autopsy from patients ranging in age from 2d to 83 yrs revealed a structure not previously described, an olfactory pit organ. In 2 infants (2d and 2mo of age), the olfactory pits appeared in 2 groups of 8-12 openings (diameter ≅ 50-70 μM) within the olfactory epithelium (oe) located on the anterior lateral and septal walls of the nasal cavity. The openings of the pits can be oriented in different directions. In mature specimens, most of the pits were distributed near the roof of the nasal cavity. However, the number, morphology and distribution of these pit organs varied among different individuals. A detailed analysis of the structure of the pit organ was carried out by rehydrating and sectioning the whole mount specimens. The pit organ is a blind pouch lined with ORNs which appears as an invagination of oe into the connective tissue (depth of the invagination ≅ 150-200 μM). In some sections, a thick axon bundle emerging from the bottom of the pouch was observed. The extension and termination of this axon bundle in the CNS has not been explored. In specimens from aged and Alzheimer's patients, degenerative changes were found both in the oe lining the surface of nasal cavity and in the pit organs. ORNs may be sparse and the oe is often replaced by respiratory epithelium or squamous epithelium. Some pit organs have been found in monkey olfactory mucosa, but have not been observed in rodents. The function of the pit organ is unclear. The blind pouch may prolong odorant association with the ORNs, or it may contain specialized neurons that cannot yet be distinguished morphologically or immunocytochemically. OLFACTORY MUCOSA DEGENERATION FOLLOWING TREATMENT BY THE CHELATING AGENT DIETHYLDITHIOCARBAMATE (DDTC).

R. Ravi, L. P. Rybak, R. G. Struble*. Depts. of Pharmacology and Pathology So. Ill. Sch. of Med., Springfield, IL 62794

DDTC is a potent chelating agent proposed as a rescue agent in chemotherapy with cisplatin. It is hypothesized to bind excess cisplatin and facilitate its removal from tissue. As part of a study of neurotoxicity of cisplatin, we examined the effects of DDTC on olfactory mucosa.

To date, five adult wistar rats have received a single 600mg/kg dose of DDTC (s.c.). Within three days, substantial sloughing of olfactory mucosa was observed with relative preservation of the respiratory mucosa. In addition, glial response in glomeruli was substantial.

These observations suggest that DDTC is toxic to olfactory receptor neurons. However, the mechanism of this toxicity is unknown but may be related to carnosine. Carnosine, a di-peptide chelating agent, is greatly enriched in olfactory receptor neurons, although its function is unclear. Carnosine has been suggested to play a role in membrane stabilization and free radical scavenging. Perhaps DDTC disrupts functioning of carnosine resulting in olfactory mucosal degeneration.

501.4

TWO TRANSDUCTION MECHANISMS IN OLFACTORY NEURONS

T. Ivanova and J. Caprio*. Dept. of Zoology & Physiology, Louisiana State University, Baton Rouge, LA. 70803-1725.

Olfactory receptor neurons in channel catfish, Ictalurus punctatus, were investigated with the whole-cell patch-clamp method. L-alanine, L-norvaline, L-arginine and L-glutamic acid were used as odorants, since these stimuli predominantly bind to different receptor sites. Two major types of odorant responses occurred. Inward currents were evoked by application of amino acids in 10 of 50 olfactory neurons tested. Receptors for different amino acids were colocalized in the membrane of these neurons. A fundamentally different way of odorant detection was found in 12 of the remaining cells. Arginine and glutamic acid acted on membrane receptors to trigger events which did not result in conductance increase, but led to modulation of voltage-gated potassium channels. In the absence of odorants, depolarization elicited potassium current which contained an inactivating component. After exposure to arginine or glutamic acid, the potassium current was enhanced and did not inactivate. Thus, olfactory neurons use at least two different transduction mechanisms: a depolarization that is attributed to odorant-dependent opening of transduction channels, and a hyperpolarization due to modulation of potassium channels.

MICROSCALE MEASUREMENT OF ODOR PLUMES WITH ELECTROCHEMICAL MICROELECTRODES: CONSEQUENCES FOR THE CODING OF SIGNALS FOR RECEPTOR ORGANS.

P.A. Moore*, R.K. Zimmer-Faust, M.J. Weissburg, S. BeMent, J.M. Parrish and G.A. Gerhardt, Depts of Pharmacology and Psychiatry, UCHSC, Denver, CO; Dept of Biology, USC, Columbia, SC; Dept of EE., UM, Ann Arbor, MI.

The dispersal of chemicals (and hence stimulus structure) is due to the fluid dynamics of a particular marine environment. To quantify the smallest spatial scales associated with chemical patches, we measured the structure of chemical signals under turbulent flow simultaneously with carbon-based and a novel semiconductor-based, multisite, microelectrochemical electrode.. Simultaneous recordings showed that patch sizes may be as small as 200 microns. Plume parameters such as pulse height and pulse slope had spatial distributions that could provide directional or distance information about the odor source to an orienting animal. Such differences in chemical signal structure over small spatial scales might be important to animals that use olfactory orientation. We propose two alternate ways in which organisms might deal with these fine scale differences in odor concentration. Animals much larger than the microscale patches may have evolved elongated olfactory organs to smooth variations in sensory input, whereas smaller animals may be able to capitalize on microscale variation to extract directional information from turbulent odor plumes.

MOLECULAR CLONING OF PUTATIVE OLFACTORY SPECIFIC GENES FROM CATFISH.

E. Bettini, N. Dahmen, H.L. Wang, F. Margolis*, Department of Neurosciences, Roche Institute of Molecular Biology, Nutley, NJ 07110.

To identify genes selectively transcribed in olfactory tissue we have used multiple strategies including differential library screening. Most recently we have reported on the use of functional expression of transcribed RNA in *Xenopus* oocytes in a search for olfactory receptor cDNAs (Dahmen; Wang Soc. Neurosci. 1991). Recent advances in automated DNA sequencing coupled with computerized access to data bases facilitate the direct use of DNA sequencing for this purpose.

Plasmid DNA was isolated from 162 clones selected from a subpool of a directional cDNA library prepared from catfish olfactory mRNA. The inserts were sequenced from both the 5' and 3' directions using fluorescent tagged dideoxy nucleotides and an ABI automatic DNA sequencer. The obtained sequence data were analyzed and compared to Genbank, EMBL and Swissprot data bases.

Thirty independent sequences were present in the pool whose abundance varied from 1-28 copies. The three most abundant sequences were apparently novel and not similar to any previously reported sequence. An additional 14 were highly homologous to cloned sequences from other species. Among these were a homologue of a β-subunit of a G-protein and a human tag sequence. In addition, we have identified a clone coding for a novel protein with putative EF-hand calcium binding domains and one with a basic-HLH (helix loop helix) domain suggesting it may be a novel gene transcription factor. Experiments are underway to determine the tissue specificity and functional significance of these various clones.

CELL DYNAMICS OF OLFACTORY BASAL CELLS. J.M.T. Huard* and J.E. Schwob. Dept of Anatomy and Cell Biology, SUNY Health Sci Ctr, Syracuse, NY 13210

In adult rats, the olfactory epithelium has the capacity to generate new sensory neurons during normal life and after experimental injury as a consequence of the division of olfactory basal cells and the differentiation of their daughters into replacement neurons. However, the basal cell population is poorly characterized with regard to the regulation and maintenance of the neurogenic process. As a first step, we are investigating the kinetics of the mitotic cycle of basal cells and the fraction of the basal cell population that retains the capacity to re-enter the mitotic cycle. The duration of the S-phase was determined in normal adult rats (n=3) using sequential pulse-labeling with iododeoxyuridine (IdU) followed by bromo-deoxyuridine (BrdU) and was found to be 5.9 hours. Using this new information, animals were labeled with a pulse injection of ^{3}H-thymidine and subsequently by a 12 hour infusion of BrdU that began 12 hrs after the administration of the thymidine. In both normal and methyl bromide-lesioned adult animals (4 days post exposure), basal cells labeled with both thymidine and BrdU were found, indicating that some daughter cells generated by the division of olfactory basal cells can re-enter the mitotic cycle. Experiments are underway to further characterize the dynamics of the stem cell and neuronal progenitor populations. Supported by NIH R29 DC00467.

HSP 70 EXPRESSION IN RAT OLFACTORY RECEPTOR NEURONS. V.McM.Carr* and A.I.Farbman. Dept. of Neurobiol. & Physiol., Northwestern Univ., Evanston, IL 60208.

In a study of stress protein expression in rat olfactory epithelium (OE) we have observed olfactory receptor neurons (ORNs) immunoreactive for the 70kDa heat shock protein family (hsp 70). IR ONRs are widely and predictably scattered in the OE, occurring most densely in posterior and ventral septum and turbinates. More anterior regions of rostral turbinates show them also, but they are virtually nonexistent in the dorsal half of the septum. While total numbers vary among animals, IR ORNs occur in approximately equal numbers on both sides of the OE.

Following olfactory bulbectomy (OB-X) these hsp70 IR ORNs persist in equal numbers in ipsi- and contralateral OE through 7 days post-op, even though most other ipsilateral ONRs die several days earlier. Subsequently, ipsilateral IR ORN numbers also decline dramatically.

These IR ORNs may be responding to some as yet unknown physiological stress. Their disappearance after OB-X indicates a certain degree of maturity is required for hsp70 expression. Autoradiographic birthdating studies show this maturity is achieved as early as 2 wks after neuronal 'birth'. Supported by NIH grants DC 00347 and DC 01593.

TRANSFER OF MOLECULAR INFORMATION FROM OLFACTORY RECEPTORS TO MITRAL CELLS: ANALYSIS BY A COMPUTATIONAL MODEL. David A. Berkowicz*# and Gordon M. Shepherd (Section of Neurobiology and #Interdisciplinary Neuroscience Program, Yale University School of Medicine, New Haven, CT 06510)

Mitral cells in the olfactory bulb show differential responses to related members of a homologous series of fatty acid molecules (Mori et al., 1992). The fatty acid sensitive cells are concentrated in one region of the olfactory bulb, implying that olfactory receptor neurons bearing receptors preferentially tuned to these molecules converge their axons onto glomeruli in this region. In order to analyze these complex relations we constructed computational models of olfactory neurons and connected them to a model mitral cell via multiple synapses. The model olfactory neurons contain an odor ligand-gated conductance sited in the cilia and voltage-gated Na+ and K+ conductances in the soma. The ligand-gated conductance displays a differential response to stimuli based upon the number of C-atoms in the fatty acid side chain. Each olfactory neuron thus responds independently in a manner reflecting the affinity of its receptor for structurally related odor molecules. One hundred olfactory neurons send axons which converge on the glomerular tuft of a single mitral cell. The mitral cell has compartments for synaptic inputs and outputs and for voltage-gated conductances. The temporal aspects of the afferent input to the glomerular dendrites can be precisely controlled, as can the time course of the synaptic current. We have tested two models: either the receptor neurons express one type of receptor, or the receptor neurons are divided into 3 unequal populations, each expressing receptors with different affinities for members of the fatty acid series. With the homogeneous receptor neuron population, the receptor neuron responses map relatively directly onto the mitral cell responses. By contrast, the mitral cell responses to the mixed sensory neuron population show complex patterns of spike discharge to related molecules, similar to the physiological recordings. The results are a first step toward constructing more realistic models of the initial processing of molecular information in the peripheral olfactory pathway.

SEXUALLY DIMORPHIC OLFACTORY SENSITIVITY TO THE BOAR PHEROMONE, ANDROSTENONE, IN PIGS. K.M. Dorries[1], M.J. Thomas[2], B.P. Halpern[1] and E. Adkins-Regan[1]* Depts. of Psychology[1] & Animal Science[2], Cornell Univ., Ithaca, NY 14853.

Adult domestic pigs (Sus scrofa) show sexually dimorphic behavioral responses to the steroidal pheromone 5α-androst-16-en-3-one (androstenone). Androstenone is attractive to, and facilitates expression of a standing mating posture in estrous females. Adult males show neither response to the steroid. Olfactory sensitivity to androstenone is sexually dimorphic in humans: Adult females have lower androstenone detection thresholds, and adult males are more likely to be specifically anosmic to the odor. We measured androstenone detection thresholds in adult pigs to determine whether olfactory sensitivity to androstenone is also dimorphic in this species. To measure detection thresholds, we trained pigs to perform a modified go/no-go operant task. Data from 3 females and 3 males indicated that adult female pigs' detection thresholds in our apparatus are a five-fold dilution lower than adult males' (1.47×10^{-3} M in mineral oil vs. 2.93×10^{-4} M). In a second experiment (N=4) that included a control odorant, geraniol, these results were confirmed, and it was found that geraniol detection thresholds for males and females do not appear to differ. The finding of a sex difference in sensitivity to this specific stimulus in pigs may prove invaluable in understanding the neural bases of odor quality coding in mammals.

NITRIC OXIDE AND OXYGEN CHEMORECEPTION OF THE CAROTID BODY. N. R. Prabhakar*, M. Haxhiu and H. Cao. Department of Medicine; Case Western Reserve University, Cleveland, Ohio 44106, USA.

Recent evidence suggests that Nitric Oxide (NO) can be synthesized in mammalian cells and that it acts as an intracellular messenger in a number of neuronal and non-neuronal tissues. NO is synthesized from Arginine by the enzyme NO synthase. Carotid bodies are sensory organs that detect the changes in arterial oxygen. Hypoxia stimulates the sensory discharge of the carotid body. The purpose of the present study is to investigate whether NO synthase is present in the chemoreceptor tissue, and if so, whether alterations in endogenous NO influence carotid body responses to hypoxia. Experiments were performed on anaesthetized adult cats. In the first group of experiments, carotid bodies were fixed in 4% paraformaldehyde and sectioned for histological examination of NO-synthase using NADPH-Diaphorase method. Many nerve fibers enveloping the glomus cells were found to be positive for NO-synthase. In addition, some glomus cells also display positive reaction for NO-synthase. The effects of blockade of NO-synthase activity on chemoreceptor responses to hypoxia was examined on isolated perfused, superfused carotid bodies (n =6). NO-synthase inhibitor, (L-NNA; 100-300 μM) enhanced the hypoxic response by 54 ± 12% of controls. L-Arginine (500 μM) reversed L-NNA -induced potentiation of the hypoxic response. In fact, in 4 of the 6 experiments, L-Arginine attenuated the hypoxic excitation by 63 ± 7% of the controls. These results demonstrate that (1) the carotid body can synthesize NO and (2) NO is inhibitory modulator of the chemosensory response to hypoxia.
Supported by grants NIH HL-38986, HL-45780 and HL-02599.

501.12

NITRIC OXIDE SYNTHASE IN THE CAROTID BODY. Z.-Z. Wang*, D.S. Bredt, S.H. Snyder, S.J. Fidone and L.J. Stensaas. Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, UT 84108; and Dept. Neuroscience, Johns Hopkins Univ., Baltimore, MD 21205

Nitric oxide (NO) has recently been identified as a novel neurotransmitter involved in glutamate toxicity and long-term potentiation. Our previous studies demonstrated that a NO-producing agent, sodium nitroprusside, stimulated cGMP production in the carotid body (Histochemistry 96: 523-539, 1991). However, the role of NO in chemoreception is unknown. The present immunocytochemical study utilized an antibody to nitric oxide synthase (NOS) to determine whether an endogenous source of NO exists in the rat carotid body. NOS immunoreactivity was found to occur in an extensive plexus of nerve fibers innervating parenchymal cells and blood vessels. These immunoreactive axons disappeared following transection of the carotid sinus nerve (CSN), but were unchanged following removal of either the superior cervical or nodose ganglia. NOS was also present in the somata of petrosal ganglion neurons whose axons could be shown to project to the carotid body by retrograde tracers. The results indicate that the carotid body is innervated by a large contingent of NOS positive nerve fibers derived from the petrosal ganglion and that NO may play a role in modulating the functional activity of carotid body chemoreceptors. Supported by NIH grant 12636 and 07938.

EFFECTS OF HYPOXIA INDUCED BY $Na_2S_2O_4$ ON K^+ AND Ca^{2+} ACTIVITIES OF CULTURED CAROTID BODY GLOMUS CELLS. X.-Q. Zhang, L. Pang and C. Eyzaguirre.* Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108

Carotid bodies were removed from anesthetized rats or mice for mechanical dissociation and glomus cell culture. After 2-7 days, cells were superfused with oxygenated physiological saline (pH 7.43 at 30-36°C) and viewed with phase-contrast. Rat glomus cells appeared either clustered or isolated, whereas all mouse cells appeared isolated. All cells were impaled with two microelectrodes (tip <1 μM) for recording E_m (filled with 3 M KCl) and V_{ion} (K^+ or Ca^{2+}, filled with an exchanger or ionophore). Clustered rat cells had a mean a_iK^+ of 73 mM (a_oK^+, 6 mM; E_K, -62 mV). In isolated cells, the mean a_iK^+ was about 32 mM (a_oK^+, 3-5 mM; E_K, -41 to -61 mV). The mean a_iCa^{2+}, measured only in 16 mouse cells, was 83 nM (a_oCa^{2+}, 0.3 mM; E_{Ca}, 211 mV). After the controls, 1-1.25 mM $Na_2S_2O_4$ was applied to reduce saline PO_2 to 30-5 Torr. Hypoxia depolarized most clustered rat cells and all mouse glomus cells. Most isolated rat cells hyperpolarized. When cells were depolarized, a_iK^+ decreased by 31 mM in the clusters and by 27 mM in isolated cells. During hyperpolarization, $[K^+]_i$ increased by a mean of 6 mM. Hypoxia had biphasic effects on $[Ca^{2+}]_i$. As PO_2 fell, the mean $[Ca^{2+}]_i$ decreased to 41 nM, followed by an increase to 254 nM. Changes in a_i were accompanied by shifts in E_{ion}. When cells depolarized, the mean E_K shifted positively by 16 mV in the clusters and by 42 mV in isolated cells. When cells hyperpolarized, the mean E_K shifted negatively by 3 mV. E_{Ca} became less positive (188 mV) when mouse cells depolarized. Supported by NS grants 05666 and 07938.

FURTHER STUDY ON ELECTROTONIC COUPLING BETWEEN GLOMUS CELLS OF RAT CAROTID BODY. L. Monti-Bloch* V. Abudara and C. Eyzaguirre, Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, UT

Many carotid body glomus cells are electrotonically, and bi-directionally, coupled at rest. This report describes the effects of dopamine, lactic acid, hypoxia (induced by N_2 or $Na_2S_2O_4$), hypercapnia, temperature and cholinergic agents on intercellular coupling. Carotid bodies were excised from 50 g anesthetized rats and superfused with oxygenated physiological saline, pH 7.4 at 30°C. Seventy-one adjacent pairs of glomus cells were simultaneously impaled with 3 M KCl-filled micropipettes. The mean resting potential (E_m) was -25.2 ± 0.8 (SE) mV. Current pulses of either polarity (0.1-1.0 nA), alternatively delivered through both electrodes, measured the input resistance (R_o = 68.3 ± 6.6 MΩ), the coupling coefficients (K_c = 0.3 ± 0.2) and coupling resistance (R_c = 833.6 ± 371 MΩ). Applications of the different agents most commonly (55-65%) depolarized both cells in the couplets, reduced their R_o, uncoupled them and their R_c increased. Fewer cells (15-25%) showed dual hyperpolarization, increased R_o and K_c, and reduced R_c. A similar low proportion of pairs showed opposite effects, namely, depolarization of one cell and hyperpolarization of the other, uncoupling of one cell and increased coupling of the other. There was a significant ($p=0.001$) and negative correlation between ΔR_c and ΔK_c. Results suggest that intercellular coupling of glomus cells is not always symmetrical. Coupling may be accomplished by different types of connexons in the unions, or the same connexons may occasionally react differently when acted upon by the chemosensory stimuli. Supported by NS grant 07938.

FACTORS INFLUENCING CYCLIC GMP FORMATION AND CHEMOSENSORY INHIBITION IN THE RABBIT CAROTID BODY. B. Dinger*, L. He, J. Chen and S. Fidone. Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, UT 84108

Recent studies in our laboratory have shown that atrial natriuretic peptide and its analog, atriopeptin III (APIII), increase cyclic GMP (cGMP) formation in chemosensory type I cells in the carotid body. Furthermore, APIII and cell permeant forms of cGMP inhibit carotid sinus nerve (CSN) activity evoked by hypoxia. Earlier studies established that hypoxia depresses basal cGMP levels in the chemosensory tissue while increasing the content of cAMP; low pH, another natural stimulus for the carotid body, likewise elevates cAMP content. The association between cAMP and carotid body excitation was further suggested by the finding that the adenylate cyclase activator, forskolin, potentiates CSN activity evoked by hypoxia. In the present study, we have examined the influence of hypoxia, low pH and cAMP on the elevated cGMP content and CSN inhibition produced by APIII.

Rabbit carotid bodies superfused *in vitro* in physiological media equilibrated with 100% O_2 (pH 7.4) contained 69.7 ± 4.3 ($\bar{X}$ ± SEM) pmol cGMP/g tissue. Incubation for 10 min in 100 nM APIII (100% O_2-media) elevated the cGMP content 41-fold. In media equilibrated with 10% O_2, basal levels of cGMP were reduced by 19% and the response to APIII was decreased by 48% ($p<0.005$). Basal levels of cGMP were unaffected at pH 6.8 (100% O_2-media), but the APIII response was again diminished by 44%. The combination of pH 6.8 in 10% O_2-media resulted in a total 67% decrease in the effect of APIII. In contrast, forskolin (10 μM) potentiated the APIII induced generation of cGMP by 2-fold. Nevertheless, recordings of CSN activity *in vitro* showed that forskolin (10 μM) completely reverses APIII related inhibition. Our data suggest interactive influences between cAMP and cGMP, and that chemoreceptor activity is a consequence of their combined actions. Supported by USPHS grants NS12636 and NS07938.

501.16

THE EFFECT OF HYPOXIA ON TYROSINE HYDROXYLASE GENE EXPRESSION IN THE *IN VITRO* RAT CAROTID BODY. J. Chen*, B. Dinger and S. Fidone. Dept Physiol, Univ Utah Sch Med, Salt Lake City, UT 84108

Previous neurochemical and immunocytochemical studies established that tyrosine hydroxylase (TH) activity in the carotid body is elevated 24-48 hr after breathing hypoxic gas mixtures. However, evidence for the induction of TH-mRNA in the carotid body has only recently been obtained using *in situ* hybridization techniques, and little is known regarding the cellular mechanisms which regulate TH expression in the chemosensory tissue. In the present study, we have exposed carotid bodies *in vitro* to chemoreceptor stimuli in an effort to identify the experimental conditions which are responsible for TH induction.

Carotid bodies and superior cervical ganglia (SCG) exposed for 3 hr to superfusion media equilibrated with either 10% O_2 (hypoxia) or 100% O_2 (normoxia) were rapidly frozen on dry ice and processed for reverse transcriptase-polymerase chain reaction (RT-PCR) in accord with the method of Singer-Sam et al. (Nuc. Acids Res. 18: 1255, 1990) which is designed to measure the relative accumulation of specific transcripts. The size and amount of a putative 234 bp TH-DNA product was evaluated using HPLC and agarose gel electrophoresis, and the results expressed per mg protein. Hypoxia elevated the total RNA in the carotid body 2.49 ± 0.50-fold ($\bar{X}$ ± SEM), while the TH mRNA increased 3.63 ± 0.84-fold. In contrast, these parameters were unchanged in SCG similarly exposed to hypoxic media. Incubation of carotid bodies in zero Ca^{++} superfusates greatly attenuated the increase in TH mRNA evoked by hypoxia (1.39 ± 0.34-fold increase; $p<0.025$ compared to normal Ca^{++} group). Our results suggest a direct role for hypoxia in TH mRNA induction in the carotid body, and that Ca^{++} is an important component of the signal transduction pathway. Supported by USPHS grants NS123636 and NS07938.

NON-RADIOACTIVE *IN SITU* HYBRIDIZATION ANALYSIS OF TYROSINE HYDROXYLASE GENE EXPRESSION IN THE CAROTID BODY. L. Zhang and L.J. Stensaas*, Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108

Tyrosine hydroxylase (TH) is the rate-limiting enzyme in the synthesis of dopamine, an important carotid body neurotransmitter. We have shown that exposure to hypoxia leads to a rapid increase in the level of TH in the carotid body. In the present study, *in situ* hybridization with a digoxigenin nonradiolabeled oligonucleotide probe was employed to determine the effect of hypoxia on TH gene expression at the single cell level. Chronic hypoxia experiments involved the maintenance of rats in a hypobaric chamber at half atmosphere. In normoxic animals, and following 3 hr of chronic hypoxia, TH is expressed at uniformly low levels throughout the CB. After exposure to hypoxia for 6 hr and 2 days, TH mRNA levels progressively increased in type I cells near the periphery of the CB. Intensely labeled cells were scattered throughout the CB at 7 days; high levels of TH mRNA were expressed in most type I cells at 2 weeks. In studies involving acute hypoxia, rats were exposed to a gas mixture of 5% O_2, 95% N_2 for three 30 min periods followed by 20 min of room air. High TH mRNA levels occurred in most type I cells of the CB. These observations indicate a different mode of response in TH mRNA levels to chronic and acute hypoxia.

FREQUENCY-RESPONSE CHARACTERISTICS OF CO_2 SENSITIVE PRIMARY AFFERENTS IN THE REPTILIAN LUNG. Richard. D. Tallman, Jr.*[1], and Michael C.K. Khoo[2] [1]Allied Medical Professions, Ohio State University, Columbus, OH and [2]Dept. of Biomedical Engineering, Univ. of So. Calif, Los Angeles, CA.

Receptors have been identified within the gas exchange regions of the lungs of various reptiles and birds which are inversely sensitive to airway CO_2. These intrapulmonary CO_2 receptors (IPC), send their afferent fibers via the vagus nerve. The purpose of the present study was to characterize the dynamic response characteristics of IPC in the bull snake (*Pituophis melanoleucus*). To accomplish this, we utilized a binary random function known as a pseudo-random binary sequence (PRBS) as the input signal. CO_2 was randomly switched between two levels during unidirectional ventilation while IPC activity arising from a single unit was recorded. IPC responses to three CO_2 step responses were measured, (3-1%, 2-1% and 1-0%). The receptor transfer functions were derived from the frequency-domain characteristics of the best-fit ARX (auto regressive with exogenous input) model to the data. The results indicated the presence of significant rate-sensitivity in receptor dynamics. However, the linear ARX model accounted for only 40-60% of the actual nerve responses. Further analysis suggested that unidirectionality in rate-sensitivity and half-wave rectification are important nonlinearities that account for the remainder of the observed dynamics. (Supported in part by NIH grants HL-02536 and RR-01861).

BETA-ADRENERGIC RECEPTOR KINASE-2 AND BETA-ARRESTIN-2: LOCALIZATION TO OLFACTORY RECEPTOR NEURONAL CILIA. *G.V. Ronnett[1]*, T.M. Dawson[1], J.L. Arriza[2] and R.J. Lefkowitz[2]. [1]Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205, [2]Howard Hughes Med. Inst., Duke Univ. Med. Center, Durham, NC 27710.*

Desensitization of receptor systems, notably G-protein-linked receptors, is regulated by receptor phosphorylation. The β-adrenergic receptor kinase (βARK) phosphorylates the agonist-occupied β-adrenergic receptor (βARK) to promote rapid ($t_{\frac{1}{2}}$=15 sec) receptor uncoupling from G_s. More recently, a novel protein, β-arrestin (βARR) has been shown to quench phosphorylated β_2AR-coupling to G_s.

Olfactory signal transduction likewise proceeds via interaction of odorants with G-protein-coupled receptors and is capable of rapid (5-10 sec) desensitization. Using affinity-purified antibodies we have localized by immunocytochemistry βARK2 and βARR2, two isozymes of each protein to olfactory receptor neuronal cilia and dendritic knobs (the site of the initial steps of olfactory signal transduction). Immunoreactivity for βARK2 and βARR2 is depleted upon bulbectomy, which results in olfactory receptor neuronal (ORN) degeneration. Primary cultures of ORN's demonstrate immunoreactivity for βARK2 and βARR2. The presence of these two specific isoforms of βARK and βARR suggests that olfactory signal desensitization may involve ligand-mediated phosphorylation of olfactory receptors.

PERIPHERAL DENERVATION INDUCES SELECTIVE CHANGES IN THE RAT OLFACTORY BULB. S.R. King* and J.H. McLean. Div. Basic Med. Sci., Memorial Univ. of Nfld., St. John's, NF, Canada A1B 3V6.

Lesion-induced plasticity of neurotransmitter systems is observed in many regions of the CNS. However, the response of different neurotransmitter systems to lesions may not be identical. The olfactory bulb (OB) receives direct inputs from the periphery. In addition, the connections and neurotransmitter content of the OB has been well characterized. Thus, the OB may provide a useful cortical model of lesion-induced plasticity. In this study, dopamine beta-hydroxylase, serotonin (5-HT), glial fibrillary acidic protein and S-100 immunocytochemisty was performed to elucidate the response of different transmitter systems and non-neuronal elements to peripheral denervation of the OB.

Deafferentation of the right OB was achieved by application of $ZnSO_4$ to the olfactory epithelium (OE) of young adult male rats. Following survival of at least 3 weeks, the rats were sacrificed by perfusion. The effectiveness of the lesion was determined by the degree of the loss of tyrosine hydroxylase (TH) immunoreactivity in the periglomerular cells which require the presence of the OE in order to express the TH phenotype (Baker *et al.*, 1983). The deafferentation resulted in a decrease in the density of 5-HT fibres in the OB but had no significant effect upon the noradrenergic innervation. The density of the glial cells did not appear to be affected by the lesion. However, there was an increase in the number of astrocytes that express S-100, a 5-HT growth factor. These results suggest that the lesion did not induce sprouting in the 3 week time period. In contrast, 5-HT fibres were selectively decreased for an unknown reason, perhaps due to selective neurotoxicity of zinc to 5-HT. Supported by the MRC of Canada.

TOPOGRAPHIC COURSES OF INDIVIDUAL AXONS WITHIN THE OLFACTORY NERVE. Charles A. Greer* and Christine Kaliszewski. Sections of Neurosurgery and Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

The topography of olfactory receptor cell axons originating in the olfactory epithelium (OE) and terminating in the glomeruli of the olfactory bulb (OB) is not well understood. Though the rules that govern the distribution of axons to their glomerular targets remain uncertain, it is evident that a significant rearrangement occurs between the OE and OB. That is, axons from adjacent receptor cells in the OE do not necessarily maintain a neighborly topography in the OB. In this vein, Daston et al. (Brain Res. 537: 69) reported that axons maintained neighbors over long distances in the olfactory nerve (ON) until they reach the OB. To investigate further the rearrangement of the ON we followed the courses of small populations of axons in mesaxons using electron microscopy of serially sectioned ON.

Turtles (*Pseudemys scripta*) were prepared for routine thin section electron microscopy. Segments of the ON, approximately 4-5 mm in length, were blocked into sections proximal to either the OB or OE. Serial sections (10-50) were collected on slot grids, photographed with a JEOL 1200 and printed at a magnification of 37,500X. The topographic relations between populations of 20-30 axons in mesaxons were reconstructed for 3D representation.

Axon diameter ranged from 0.104 - 0.312 μm. The topography of axons in ON mesaxons was reasonably stable proximal to the OE. However, proximal to the OB a fluid topography was found; the axons bordering any given axon were more likely to change proximal to the OB. Moreover, existing axons left the subpopulation being reconstructed while new axons entered.

These data appear consistent with the hypothesis that the OB contains signals that contribute to the sorting of axons toward glomerular targets.

CARBOCYANINE DYES AS TRACERS IN THE ELASMOBRANCH OLFACTORY SYSTEM

*L. Dryer *and P.P.C. Graziadei, Florida State University, Tallahassee. FL 32306*

One of the obstacles in tracing neural pathways in sharks of the order carcharhiniforms is the difficulty in keeping specimens alive in captivity. We have previously shown using biocytin as a tracer *in vitro* that the primary olfactory projections are segregated into a sectorial arrangement onto the bulb. But the mechanisms of biocytin transport remain unknown, and we wished to confirm this observation using other tracing methods. Carbocyanine dyes are known to be excellent tracers of neural pathways in higher vertebrates, both in living and fixed tissues, but previous attempts to apply this method to elasmobranchs have failed. We have succeeded in tracing the olfactory pathway using DiI in fixed elasmobranch preparations. The results confirm our previous observation that the primary olfactory fibers project in a straight fashion onto the bulb. In bonnethead sharks, where the olfactory bulb is made of successive swellings (sub-bulbs) along the crescent-shaped organ, each sub-bulb receives afferents from 5-6 lamellae without the convergence or divergence observed in mammals. The elasmobranch olfactory bulb is clearly compartmentalized into several units, possibly serving different purposes. The resolution of carbocyanine dyes in this preparation is superior to biocytin, and the passive mode of transport of DiI makes it an excellent tracer in any direction. Supported by NS-20699.

LESIONS OF THE OLFACTORY NERVE AFFECT TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE OLFACTORY BULB OF *XENOPUS LAEVIS* TADPOLES. E. O'Campo, J.B. Angevine, Jr.*, and G.D. Burd. Depts. of Molecular & Cellular Biology and Anatomy, Univ. of Arizona, Tucson, AZ 85721.

Deafferentation of the olfactory bulb results in a reversible loss of tyrosine hydoxylase (TH) expression in the olfactory bulb of mammals (Baker et al. 1983. J.Neurosci. 3:69). The purpose of this present study was to investigate whether TH immunoreactivity in the olfactory bulb of *Xenopus* tadpoles is similarly dependent on afferent innervation. Unilateral and bilateral lesions of the olfactory nerve were performed on tadpoles at stage 58 (the beginning of metamorphic climax). Two weeks following the lesions, the animals were fixed, and the brains and nasal capsules were processed for immunocytochemistry. E7, an antibody that was raised against *Xenopus* nasal capsules and that recognizes olfactory receptor cells (Matheson and Burd. 1991. Soc. Neurosci. Abstr. 17:230), was used as a marker to confirm the presence of olfactory axons in the olfactory bulb and to test the extent of the lesion in the olfactory epithelium. The TH positive cells were present in the glomerular layer, mitral cell/external plexiform layer, and the superficial granule cell layer. Bulbs with unilateral lesions demonstrated a decrease in number of TH immunoreactive neurons relative to the unlesioned side. Bilateral deafferentation significantly reduced the number of cells expressing TH on both sides. We also noted that staining with the E7 antibody was lost in the olfactory epithelium when the olfactory nerve was cut, and that the staining failed to return within the 14-day survival period. In summary, TH expression in the developing olfactory bulb of *Xenopus laevis* is significantly reduced following sensory deafferentation. Supported by DC 00446.

EFFECTS OF DOPAMINE ON RESPONSES TO ELECTRICAL STIMULATION IN THE SALAMANDER OLFACTORY BULB: INITIAL RESULTS. K.A. Hamilton* and M.R. Gurski. Department of Cellular Biology and Anatomy, LSU Medical Center, Shreveport, LA 71130.

Recent evidence suggests that the afferent input to the olfactory bulb from the olfactory nerve may be modulated by dopamine (DA) (Nickell *et al.*, *Neuroreport*, 2:9, 1991). As a first step in investigating the function of putative dopaminergic cells that give rise to glomerular dendrites in the salamander bulb (K.A. Hamilton and S.S. Foster, *Neurosci. Abstr.*, 17:637, 1991), we have examined the effects of exogenous DA and the DA antagonist fluphenazine on field potentials evoked by electrical stimulation of the olfactory nerve and tracts.

Recordings were obtained from the granule cell layer in isolated hemibrain preparations during superfusion with normal medium, 1-10 min after superfusion with medium containing 0.05-100 μM DA or 5-100 μM fluphenazine, and 1-10 min after reperfusion with normal medium. The amplitude and latency of the large, positive wave was measured. With DA concentrations below 1 μM, significant effects were not generally observed (t-tests, α=0.05). With 1-100 μM DA, however, the amplitude of the nerve response was reduced by 21-79% and the latency increased by 4-24%. By contrast, the amplitude of the tract response was reduced by only 7-26% and there was little if any change in latency. With all concentrations of fluphenazine, the nerve response was blocked, but the tract response was apparently unaffected. During reperfusion following DA exposure, the nerve response did not recover as fully as the tract response. Following fluphenazine exposure, the nerve response showed no sign of recovery.

In agreement with the results of Nowycky *et al.* (*Neuroscience*, 8:717, 1983), the results indicate that exogenous DA suppresses olfactory bulb responses to electrical stimulation. The results also provide initial support for the hypothesis that DA may modulate the afferent input to the salamander bulb from the olfactory nerve.

IMAGING ODOR-EVOKED ACTIVITY IN THE SALAMANDER OLFACTORY EPITHELIUM (OE) AND BULB (OB): PHYSIOLOGICAL CORRELATES OF BEHAVIORAL OBSERVATIONS. J. White* and J.S. Kauer. Neuroscience Program, Tufts/NEMC, Boston, MA 02111.

Behavioral experiments suggest that tiger salamanders (*Ambystoma tigrinum*) discriminate between certain reagent grade odorants (butyl and propyl acetate; butyl and amyl alcohol; butyl acetate and butyl alcohol) but do not discriminate between others (butyl and amyl acetate; butyl and propyl alcohol) (Mason and Stevens, 1981, *Physiol. Behav.* 26:647). To determine whether these same odorants elicit similar and/or different physiological responses in the olfactory system, we have investigated their effects on salamander OB and OE by video imaging voltage-sensitive dye signals with high spatial (up to 256x240 pixels) and temporal resolution (16ms per frame). OE and OB were stained with the styryl dye Di-4-ANEPPS, which produced OB signals similar to those produced by the dye RH-414. In the ventral OE, each odorant elicited optical signals with time courses and spatial distributions similar to electro-olfactograms recorded in the same animal after the optical recordings. Propyl, butyl, and amyl acetate each elicited similar patterns of widespread activity with peaks anteriorly and posteriorly, while propyl, butyl, and amyl alcohol each elicited a much smaller area of activity with a peak anteriorly. In the OB, amyl, butyl, and propyl acetate each elicited long lasting depolarizations; however, the propyl acetate response tended to be smaller and at longer latency than the responses to the other two odorants. Propyl and butyl alcohol elicited large, long-lasting hyperpolarizations in the OB, while the amyl alcohol response was small and depolarizing. Thus, the differences in OB activity patterns evoked by these odors paralleled the behavioral responses of the animal, while the differences in OE activity were more subtle.

OLFACTION IN RATS WITH REMOVAL OF 50-95% OF THE OLFACTORY BULB. X-C. M. Lu and B. M. Slotnick*. Department of Psychology, The American University, Washington, DC 20016.

Are odors processed at specific sites in the olfactory bulb? Available behavioral studies indicate that removal of odor activated bulbar sites identified with 2-DG or with electrophysiology does not produce deficits in detection of the target odor. We have examined the extent to which reduction of topographical organization of the olfactory bulb affects detection and discrimination of different odors in 21 experimental and 8 control rats.

Rats with unilateral bulbectomy plus removal of approximately 50%-97% of the remaining bulb (assessed by measuring total linear extent of remaining glomeruli) were tested for detection of amyl acetate, butanol, citral and proprionic acid vapor and then trained to discriminate these odors from cineole. Odor concentration was varied from 1-.01% of vapor saturation.

Some but not all rats with less than 5% of glomeruli remaining were anosmic. Those with approximately 25% of remaining glomeruli were able to perform all tasks as well or almost as well as unilateral bulbectomized controls. Experimental rats with 10-25% of glomeruli remaining failed on low odor concentrations but otherwise most performed nearly as well as controls. In general, deficits were related to the amount of remaining bulbar tissue but not to which segment (dorsal, lateral, medial or anterior) of the bulb was removed.

This study indicates that rats with up to 90% reduction of the olfactory bulb input to the forebrain retain significant olfactory abilities and may perform as well as controls on simple odor detection and discrimination tasks. The results provide no evidence that any one segment of the bulb is essential for detection of the odors tested.

***IN VITRO* SYNAPTIC ACTIVATION OF ADULT RAT OLFACTORY BULB MITRAL CELLS RECORDED BY CONVENTIONAL AND WHOLE CELL PATCH TECHNIQUES.** W. T. Nickell,* M. M. Behbehani, and M.T. Shipley. Univ. of Cincinnati Col. of Med., Cincinnati, Ohio 45267.

Responses of rat olfactory bulb mitral cells to stimulation of the olfactory nerve layer (ONL) were recorded *in vitro*. Olfactory bulbs were cut into 400 μm thick slices in the horizontal plane and submerged in a recording chamber. Patch clamp electrodes (1-2 μm tip diameter) were guided into the mitral cell layer under a dissecting microscope. A bipolar stimulating electrode was placed onto the ONL rostral to the recording electrode. Extracellular records of spontaneous and ONL evoked activity were obtained from 75 mitral cells. Most of these neurons responded to ONL stimulation. Some responded with one, or a short burst of spikes followed by a period of inhibition. In most cells, however, these initial events were followed by a long period (1-2 sec) of excitation. Intracellular whole-cell patch recordings were used to observe the synaptic events underlying this activity. ONL stimulation caused a prolonged depolarization accompanied by action potentials. Hyperpolarization blocked all but one spike, which preceded an EPSP. Under voltage clamp, ONL stimulation caused a long duration inward current. In some cells spontaneous EPSCs were present. High magnesium solution blocked these spontaneous currents. It is concluded: 1) There is a significant tonic excitatory synaptic input to olfactory bulb mitral cells. 2) The long period of excitation following ONL stimulation is caused by an unusually long duration depolarization. 3) ONL stimulation may generate spikes in the apical dendrites that are propagated to the soma with little decrement. *Supported by NIDCD DC00347 and DAMD17-91-C-1071.*

LAMINAR CONTRIBUTIONS TO INHIBITION DURING OLFACTORY BULB REPONSE TO ODOR: COMPUTER SIMULATION M. MEREDITH* Dept. Biological Science, Florida State University, Tallahassee, FL 32306

Previous work with a computer model based on olfactory bulb anatomy and physiology (Chem.Senses 16:556) showed complex spatial and temporal patterns of activity generated in response to relatively simply patterned olfactory input. Here the contribution of glomerular (superficial) and granule (deep) inhibitory circuits is examined in more detail. Lateral inhibition between glomeruli via PG cell axons is a potent contributor to spatial patterns of inhibition. ***Feedforward*** inhibition due to direct activation of PG cells by olfactory nerve fibers is especially important. When direct activation of PG cells is restricted, their effect is mainly by feedback inhibition and is, thus, self limiting. Intraglomerular inhibition between output cells of the ***same*** type (via PG dendrites) attenuates output with little effect on overall spatial patterns. However, spatial patterns can be created within the output cells of one lamina connected to one glomerulus. Intraglomerular inhibition ***between*** output cell types within one glomerulus, can produce different patterns of activation in the different laminae of output cells. Granule cells have feedback dendro-dendritic connections to output cells and thus have less potent afferent inhibitory action (although potentially more important in efferent inhibition). Their influence (via output cell secondary dendrites) is not restricted by glomerular boundaries. To the extent that they are divided into populations connecting selectively with one output cell type, granule cells also contribute little to the generation of different activity patterns in different output cell laminae. Output cell collaterals, however, could generate interlaminar differences in output by cross-connecting asymmetrically between output cells of one type and granule cells selectivly connected with another output cell type. The specificity of these connections is not yet known but the potential for complex pattern generation is considerable. Supported by NIH, DC00906 and NSF, BNS-8615159.

ORGANIZATION OF INHIBITION ON ASYMMETRIC TUFTED CELLS OF RAT OLFACTORY BULB. Patrick I. Ezeh and John W. Scott.* Department of Anatomy and Cell Biology, Emory University School of Medicine, Atlanta, Georgia 30322

Olfactory bulb tufted cells exist in several subtypes. Of those with basal dendrites, the most superficial cells extend their basal dendrites in the direction opposite that of the apical dendrite, and their basal dendrites do not mix with those of other mitral/tufted cells. We made intracellular recordings of 18 biocytin-labeled asymmetric, superficial tufted cells. These cells do not appear to share granule cells with mitral cells, because they respond with small IPSPs to stimuli that activate large IPSPs in mitral cells. The asymmetry of their basal dendrites offered a chance to study the contribution of the arrangement of dendritic shape to the organization of lateral inhibition in this system. This was investigated with localized olfactory nerve layer (ONL) stimulation. Although the effectiveness of stimulation at a particular ONL site decreased with distance from the tufted cell somata, the distribution of inhibitory influence was not determined solely by the direction of the basal dendrite. This observation, coupled with the fact that many granule cells are activated at short latencies by ONL stimulation, suggests that granule cells inhibiting superficial tufted cells may receive excitatory inputs from tufted cell axons.

OLFACTORY BULB GRANULE CELLS DECREASE IN SIZE AND INCREASE IN DENSITY WITH EARLY OLFACTORY EXPERIENCE. J. F. McCollum*, C.C. Woo, and M. Leon. Department of Psychobiology, University of California, Irvine, CA USA 92717.

Young rats learn to approach an odor that had been experienced in the presence of tactile stimulation. Subsequent presentation of the familiar odor evokes an enhanced focal uptake of 2-deoxyglucose (2-DG) in the glomerular layer of the olfactory bulb. This enhanced uptake is associated with an increase in the focal glomerular-layer cell population (Woo and Leon, 1991). Since odors evoke a columnar response in the bulb (Guthrie, Anderson, Leon and Gall, 1991), we determined whether there were morphological changes in other bulb lamina. We investigated the size and density of mitral and granule cells found within columns both associated with the 2-DG foci and closely adjacent to these foci. We compared mitral and granule cell size and density in Nissl-stained sections from PND 19 odor-familiar pups with sections from controls. We found no difference between these groups in mitral cell nuclear area, perikaryal area, or density. Odor-familiar pups, however, had an increase in the density of superficial, but not deep granule cells within the foci-associated columns. These superficial granule cells also showed a decrease in soma size. The superficial granule cells within the foci-adjacent columns remained unchanged. A change in the density and size of superficial granule cells may contribute to the modification of olfactory bulb responses to familiar odors. These data suggest that early odor experience triggers restricted but multiple processes in the developing olfactory bulb.

502.13

THE ROLE OF THE LATERAL OLFACTORY TRACT (LOT) IN A TWO-ODOR DISCRIMINATION TASK. P.K.Thanos* and B.M.Slotnik. Psychology, The American University, Washington, D.C 20016.

It has been shown that odor memory in rats can be long lived as long as the animal has sufficient exposure to the odor. Little evidence however, exists as to the neuroanatomical stuctures. This study examined rat performance in a 2-odor discrimination task during short (10 sec.) and long (10 min.) inter-trial intervals (ITI). Each session consisted of a novel pair of odors presented over 30 trials. Trials began with the rat being placed at the start of a runway, at the end of which were two sample ports. Each port semi-randomly delivered one of the two odors. The trial terminated when the rat made a total of three lick responses to one port or 30 sec. had elapsed. If the rat responded to the port delivering the S+ odor, it was rewarded with 0.1 ml of water, and a correct response was recorded. A criterion of ten correct out of twelve consecutive trials was used as another measure of memory. The experimental group received unilateral lesioning of the LOT along with a contralateral bulbectomy, while controls received only a unilateral bulbectomy.

Preliminary results show LOT lesioned rats made more errors per session and it took longer to reach criterion. This effect was amplified in the 10 min. ITI.

SEROTONIN AND OLFACTORY LEARNING IN THE NEONATAL RAT. J.H. McLean[1], A. Darby-King[1], R.M. Sullivan[2] and S.R. King[1]. [1]Div. of Basic Med. Sci., Memorial Univ. of Newfoundland, St. John's, Nfld., Canada A1B 3V6 and [2] Dept. Psych., Univ. of Oklahoma, Norman, OK 73019.

There has been accumulating evidence that norepinephrine is necessary for the acquisition of learned olfactory behavior (Sullivan et al.1991; Sullivan et al.1989). The serotonergic input to the olfactory system has been given little attention in olfactory behavior although it densely innervates the olfactory bulb. In a previous paper we reported that serotonergic axons arrive in the olfactory bulb postnatally and densely innervate the glomeruli, the first site where olfactory information is integrated with circuitry of the olfactory system (McLean and Shipley, 1987). Thus, we hypothesize that serotonin could have important effects on olfactory learning.

In this study, the serotonergic input to the olfactory bulb of rats was depleted by bilateral injections of 5,7 dHT into the anterior olfactory nucleus on postnatal day 2 (birth=PND1). On PND 8, the depleted animals, shams or unoperated controls received one-trial conditioning to a peppermint odor (conditioned stimulus) paired with stroking (unconditioned stimulus). Half of the pups received no odor training. The next day the pups were tested to determine the amount of time spent over peppermint odor or normal bedding. The serotonin-depleted pups spent significantly less time over the peppermint odor than trained controls. The serotonin depletions of the olfactory bulb did not affect locomotion of the pups nor the noradrenergic input to the bulb. These results suggest that serotonergic input into the bulb is important for the acquisition of a learned olfactory behavior in the neonate. Supported by MRC of Canada.

DEVELOPMENT AND DECAY OF SELECTIVE LONG-TERM POTENTIATION IN THE PIRIFORM CORTEX AND OLFACTORY BULB. J. S. Stripling* and M. P. Galupo. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

High-frequency stimulation of cortical association fibers in the piriform cortex (PC) produces a selective long-term potentiation (LTP) of late components in potentials evoked in the PC and olfactory bulb (OB). The present study examined in detail the time course of the development and decay of selective LTP. Male Long-Evans rats were chronically implanted with a stimulating electrode in the association fiber system of the anterior PC and recording electrodes in the OB and a more caudal PC site. LTP was induced by 8 daily treatments of high-frequency stimulation (30 trains of 10 pulses at 100 Hz). The expression of LTP was monitored by continual stimulation at 0.1 Hz before, during, and after each LTP treatment. This testing revealed both a short-term potentiation that peaked during the daily LTP stimulation and decayed within 3 min, and a long-term potentiation that decayed very slowly and was still evident 24 hr later. The short-term component reached asymptotic levels well before the last LTP treatment, while the long-term component continued to grow in magnitude across the course of the experiment. Expression of the long-term component gradually diminished across an 8-day period following the last LTP treatment, but could be reinstated to a substantial degree by repeated stimulation at 0.1 Hz (latent potentiation). A single LTP treatment given on the eight day after the last daily LTP treatment completely restored LTP to its maximal level. Our results indicate that selective LTP is a very robust and long-lasting phenomenon that persists in latent form for a minimum of 8 days with little or no decay. These characteristics make selective LTP a suitable candidate for participation in long-lasting functional changes in the olfactory forebrain. Supported by NSF grant BNS 85-19700 and the Marie Wilson Howells Fund.

RELATIONSHIP BETWEEN SPONTANEOUS AND EVOKED POTENTIALS FOLLOWING SELECTIVE LTP IN THE PIRIFORM CORTEX AND OLFACTORY BULB. M. P. Galupo* and J. S. Stripling. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

High frequency stimulation that activates association fibers in the piriform cortex (PC) produces a selective long-term potentiation (LTP) of late components in potentials evoked in the PC and olfactory bulb (OB). This potentiation is accompanied by the appearance of spontaneous potentials that resemble potentiated components of the evoked potential (Brain Research 542; 107-122, 1991). The present study characterized these spontaneous potentials in detail and investigated their association with selective LTP. Male Long-Evans rats received LTP stimulation through chronically implanted electrodes in the anterior PC which produced either selective activation of PC association fibers or co-activation of PC association fibers and the lateral olfactory tract (LOT). LTP stimulation consisted of 30 10-pulse trains (100 Hz) administered on 4 consecutive days. Either type of stimulation reliably induced selective LTP. However, only stimulation that produced coactivation of PC association fibers and the LOT triggered the occurrence of prominent spontaneous potentials. Spontaneous potentials, when present, occurred in the first few minutes following LTP stimulation, coincided with the onset of selective LTP, and closely resembled potentiated components of the evoked potential. These results indicate that activation of PC association fibers is both necessary and sufficient for the induction of selective LTP, but that co-activation of LOT and association fibers is required to produce spontaneous potentials. Although these potentials may be a reflection of the same membrane conductances that underlie selective LTP, the dissociation between the two indicates that the induction of selective LTP does not require the generation of spontaneous potentials. Supported by NSF Grant BNS 85-19700 and the Marie Wilson Howells Fund.

CELL TYPES IN THE PRIMARY OLFACTORY CORTEX OF THE FROG. F. Scalia* and J.Y. Lettvin. Dept. of Anatomy and Cell Biology, SUNY Health Sci. Center at Brooklyn, Brooklyn, NY 11203 and Dept. of Biomedical Engineering, Rutgers, Piscataway, NJ 08855.

Rapid Golgi and modified Golgi-Kopsch preparations of adult R. pipiens reveal the presence of four distinct types of olfactory cortical neurons not previously distinguished in earlier studies on this amphibian. The first is a cell whose dendrites are covered densely with moderately short spines. A second type of cell has distinctly fewer and often longer spines, mixed with club-like processes. A third cell, is aspiny. Its dendrites are beaded at irregular intervals and varicose throughout their length. These three types of neuron have multiple apical dendrites that radiate obliquely toward the pia from a periventricular location. The dendrites of the aspiny cells often show a broader horizontal spread within the superficial neuropil. After crossing the superficial neuropil, the cortical dendrites may bend sharply beneath the pia to course parallel to the surface for as yet undetermined distances. The fourth cell is a small stellate neuron, which appears axonless. Its numerous primary dendrites branch repeatedly, and the branchlets are serially decorated with closely spaced small beads resembling axonal boutons. (Supported by PHS grant EY05284).

3-HYDROXY KYNURENINE RELEASE IN PREPYRIFORM CORTEX: A NEURAL RESPONSE TO AMINO ACID DEFICIENCY? **D.W. Gietzen*, B.L. Lee and M.P. Thomas. Dept Physiol Sci & Food Intake Lab, Sch of Vet Med, Univ Calif Davis, Davis, CA 95616.**

Recognition of amino acid (AA) deficiency induced by ingestion of AA imbalanced diets (IMB) has been localized to the prepyriform cortex (PPC), but the mechanisms underlying this recognition are not well understood. To determine what neuroactive substances were released in PPC after eating IMB, rats were implanted stereotaxically with bilateral guide cannulae (Plastics One, Roanoke VA) directed toward the PPC (coordinates: A: 9.8mm, L: 4.0mm and D: 5.5mm; perfusion needle extended 1mm). After prefeeding a low protein control diet for 7-10 days, rats were fed IMB and PPCs were perfused with artificial CSF (11 μl/min for 5 min) at varying times. Perfusates were analyzed by HPLC with electrochemical detection. Compounds were identified by peak conformation and retention time (RT); samples were spiked with external standards to verify RT. External standards included: norepinephrine (NE), dopamine, serotonin and the metabolites: DOMA, DOPAC, DOPEG, 5HIAA, HVA, L-DOPA, MHPG, 3-methoxytyramine, MOPET, normetanephrine, 3-OH-kynurenine (3HK), tyramine and VMA. NE was in the noise level in all chromatograms. 3HK was significantly increased at 1.5hr after introduction of IMB diet vs basal at 1.5hr IMB: 441±65 fg/μl vs control: 201±85 fg/μl ($p<0.05$, paired t, $N=8$). Previous results suggesting that NE was increased 1.5 hr after feeding IMB were based on HPLC conditions that did not allow separation of NE and 3HK. NE and 3HK were separated by 6 minutes in the present chromatograms. We conclude that 3HK may play a role in the recognition of essential AA deficiency in the rat. Parallel electrophysiological studies are in progress using the PPC slice preparation. **Supported by NIH: DK35747 (UCDavis Clin Nutr Res Unit) and USDA: CSRS 90 37200-5440.**

THE CELLS OF ORIGIN OF THE ENDOPIRIFORM-TECTAL PATHWAY IN THE RAT. W. Chen*[1] and N. Sahibzada[1,2]. [1]Dept. of Psychology, Univ. District of Columbia and [2] Dept. of Pharmacology, Georgetown Univ. Medical Center, Washington DC 20007.

In an animal such as the rat, olfactory stimuli play an important role in behavioral activities concerned with attention and orientation. A likely structure through which these activities may be expressed is the superior colliculus (SC). This structure, in a variety of species, has been shown to play a seminal part in the mediation of attention and orientation. There is some indication (Neasfey, et al., 1986) that a possible source of olfactory information, received by the SC, originates from Endopiriform nucleus (EN). Therefore, the purpose of this initial study was to identify the cells of origin of this pathway that projects to the SC.

Injections of Fluoro-Gold in the SC, besides labeling know collicular afferents, also label cells in the endopiriform nucleus (EN). Our preliminary results show that label in this nucleus appears to be related to the injection site in the colliculus. Thus, anterior collicular injections result in faint label in the anterior EN, whereas posterior SC injections result in dense label in the posterior EN.

On basis of our preliminary findings, we are in the process of verifying this topographical connection by injecting anterograde and retrograde tracers in the EN. These experiments should not only give us a map of the distribution of terminals in the SC, but will also determine if any reciprocal connections are present between the two structures.

DEVELOPMENTAL STUDY OF LECTIN BINDING TO THE VOMERONASAL AXONS IN THE RAT ACCESSORY OLFACTORY BULB. M. Ichikawa*[1], S. Takami[2], T. Osada[3] and P. P. C. Graziadei[2] [1]Dept. of Anat & Embryol., Tokyo Metropolitan Inst. for Neuroscience, Tokyo, [2]Dept. of Biol. Sci. The Florida State Univ, Tallahassee, Florida. and [3]Dept. of Biol. Sci, Fac. of Biosci & Biotechnol, Tokyo Inst. of Technol, Yokohama, Japan.

Bandeiraea simplicifolia lectin-I (BSL-I) and *Vicia villosa* aggulutinin (VVA) specifically bind to the vomeronasal (VN) axons (Ichikawa et al., 1992). The binding of these two lectins to VN axons was studied in the developing accessory olfactory bulb (AOB) of rat. Fetal (Embryonic day (ED) 16, 18, 20), postnatal (postnatal day (PD) 0, 3, 7, 14, 28), and adult (2 and 6 month old) rats were sacrificed and the binding of BSL-I and VVA to the vomeronasal nerve layer (VNL) and glomerular layer (GL) of the AOB was examined histochemically. In the adult, BSL-I bound to the whole VNL and GL, while VVA bound strongly to the posterior 2/3 of these layers but very weekly to the anterior 1/3 of them. During development the binding sites of VVA could be visualized earlier than those of BSL-I; the first day of VVA binding was at ED 18 and BSL-I was at PD 0. The staining pattern of two lectins found in adult AOB has been established by PD 14. These results suggest that the rat VN axons have two subpopulations in terms of binding sites to the two lectins and the binding sites are expressed differentially during development. (Supported by NIH Grants NS20699 and 1 R01DC01071-01, and a TMIN grant).

VOMERONASAL PATHWAYS ARE SELECTIVELY ACTIVATED DURING MATING BEHAVIOR IN MALE HAMSTERS. **G. Fernandez* and M. Meredith, Program in Neuroscience, Dept. Biol. Sci., Florida State Univ., Tallahassee, FL.**

Vomeronasal (VN) sensory input is important for male hamster mating behavior. The VN system projects via the accessory olfactory bulb (AOB) to the medial & posterior-medial cortical nuclei of the amygdala, the bed nucleus of the stria terminalis (BNST), and also to the medial preoptic area (MPOA), central structures shown to be important for reproductive behavior. In these experiments c-fos expression was used as a marker of neural activity to identify the pathways activated by mating behavior in intact animals, and in animals that had their vomeronasal organs removed (VNX). Sexually inexperienced male hamsters from each group were placed in clean boxes with fresh bedding and each exposed to a sexually receptive female for 45 mins. After an additional 45 mins they were perfused with 4% paraformaldehyde. Control animals from each group were put into clean boxes with fresh bedding and perfused 90 mins later. Fifty um vibratome sections were processed for immunocytochemistry using a polyclonal fos antibody. (Cambridge research). Results show a distinct difference in fos activation in stimulated animals compared to controls. Densely stained fos nuclei were evident in the AOB, medial amygdala, MPOA & BNST of stimulated animals. Unstimulated animals did not show this activation. VNX animals exposed to females did not mate, and had a dramatically reduced number of fos positive nuclei in all these areas. All animals (stimulated & unstimulated) showed activated nuclei in the main olfactory bulb and the paraventricular thalamus, suggesting that it is only the VN pathways and their central connections that are differentially activated as a result of mating. Ongoing studies involve double labelling for fos and LHRH to explore the participation of LHRH in the facilitation of mating behavior by VN sensory input. Supported by NIH Grant DC00906.

SEXUALLY DIMORPHIC DISTRIBUTION OF C-FOS IMMUNOREACTIVE CELLS IN THE MEDIAL NUCLEUS OF THE AMYGDALA AND MEDIAL PREOPTIC NUCLEUS MAGNOCELLULAR FOLLOWING EXPOSURE TO HAMSTER VAGINAL SECRETIONS. J.M. Fiber* and J.M. Swann, Institute of Animal Behavior and Dept. of Biol. Sciences, Rutgers Univ., Newark, NJ 07102.

Female hamster vaginal secretions (FHVS) strongly attract male hamsters, and stimulate copulatory behavior in males. FHVS do not have this effect on females. Using C-fos as a marker for cell stimulation, we previously reported stimulation in the bed nucleus of the stria terminalis (BNST), medial nucleus of the amygdala (M) and the medial preoptic area of male hamsters following exposure to FHVS. In this experiment we explored what regions within this mating behavior pathway of males differed in females in response to FHVS. Males, proestrus females and diestrus females were given a cotton swab with FHVS. Control animals received no stimulus.

Our results indicate that the BNST in both stimulated males (n=3) and proestrus females (n=3) showed similar distribution of C-fos immunoreactive cells. Medial preoptic nucleus magnocellular (MPN-Mgn) and M showed differential distribution of stimulated cells between males and proestrus females. Diestrus females (n=3) did not show stimulation in M or MPN-Mgn, and only one of the diestrus females showed some stimulation in the BNST. The differences between proestrus and diestrus females may be due to circulating steroid changes over the estrus cycle. Stimulated cells in M of the proestrus females are sparsely distributed throughout the nucleus whereas the stimulated cells in M of the males are clustered on the medial border of the posterodorsal part of this nucleus. Within MPN-Mgn of the female, stimulated cells are sparsely distributed within the ventromedial part of this nucleus. The MPN-Mgn of males has stimulated cells through the entire extent of the nucleus. In this experiment we have shown that MPN-Mgn and M are differentially stimulated in males and females in response to exposure to FHVS. These regions may regulate the sex difference in behavioral response to FHVS.

SEX DIFFERENCES IN INDUCTION OF FOS IMMUNOREACTIVITY IN THE BRAINS OF PRAIRIE VOLES EXPOSED TO BEDDING SOILED BY CONSPECIFICS OF THE SAME AND OPPOSITE SEX. T.P. Goodness*, M.A. Novak, G.J. De Vries. Program of Neuroscience and Behavior and Dept. of Psychology, Univ of Massachusetts., Amherst, MA 01003.

Prairie voles show sex-specific responses to conspecific sexual odors. Female reproduction is stimulated by male odors and inhibited by female odors. Group-housed sexually experienced males show increased mounting behavior when exposed to odors of females in estrus. Little is known about which brain areas are stimulated when a vole is exposed to conspecific odors. We identified such brain areas with fos immunocytochemistry. Male and female prairie voles were exposed to male or female soiled, or clean bedding. Two hours following exposure, voles were sacrificed and their brains processed for fos immunocytochemistry. Fos immunoreactive (fos-ir) cell nuclei were counted in all mid- and forebrain areas that showed fos-ir nuclei in at least some vole brains. Significantly more fos-ir cells were found in the medial amygdala, antero- and posteromedial bed nucleus of the stria terminalis, and ventral premammillary nucleus of males and females exposed to bedding soiled by either sex. In the medial amygdala and antero medial bed nucleus, males and females showed more fos-ir cells when exposed to bedding soiled by opposite than by same sex. In the septohypothalamic nucleus, males but not females showed more fos-ir cells when exposed to bedding soiled by either sex. Although fos-ir cells were found in several thalamic areas, no significant differences were found between bedding conditions. These results indicate that there are sex differences in how brain areas respond to odors of the same or opposite sex. These sex differences may reflect the different responses of males and females to odprs of conspecifics.

OPPOSITE EFFECTS OF RESERPINE PRETREATMENT ON AMPHETAMINE-INDUCED AND COCAINE-INDUCED EXPRESSION OF ZIF268 AND C-FOS mRNAs IN RAT STRIATUM AND CORTEX. Moratalla, R.* and Graybiel, A.M. Massachusetts Institute of Technology, Department of Brain and Cognitive Sciences, Cambridge, Mass. 02139

In previous immunohistochemical experiments on the rat caudoputamen (CP), we found that amphetamine induces Fos-like immunoreactivity (FLI) in a striosome-predominant pattern in rostral CP, whereas cocaine induces FLI nearly equally in both compartments. We also found that induction of FLI by cocaine was nearly abolished by pretreatment with reserpine, whereas induction of FLI by amphetamine was not blocked and in fact was enhanced. Here we report dramatic differences in the effects of reserpine on induction of zif268 and cfos mRNA by amphetamine and cocaine in the rat striatum and cortex. Rats were treated with amphetamine (5 mg/kg) or cocaine (25 mg/kg) with or without pretreatment with reserpine (10 mg/kg, i.p., 18 hr before), and brains were processed 1 hr later for in situ hybridization. Induction of zif268 by cocaine was sharply reduced by reserpine pretreatment; zif268 mRNA levels appeared lower than in saline-treated controls, except in ventral striatum. Induction of zif268 by amphetamine was greatly elevated in reserpine-pretreated rats relative to rats treated with amphetamine alone. It is likely that the enhancement involved not only increased intensity of expression but also recruitment of new responsive cells especially in the matrix and lateral CP. Interestingly, the striosome-selective pattern of zif268 induction by amphetamine was scarcely visible after reserpine pretreatment. In situ hybridization experiments showed that cocaine induction of c-fos mRNA was also decreased, and amphetamine-induced expression of c-fos was also enhanced, by reserpine pretreatment. Supported by United Parkinson Foundation and NIH Javits RO1 NS25529.

COCAINE EXPOSURE THROUGH THE MATERNAL CIRCULATION SELECTIVELY INCREASES FOS-LIKE IMMUNOREACTIVITY IN CELLS OF DOPAMINE ISLANDS/STRIOSOMES OF EMBRYONIC STRIATUM. E. Fusco and A.M. Graybiel* Massachusetts Institute of Technology, Dept. of Brain and Cognitive Sciences, 45 Carleton St., Cambridge, MA 02139.

Cocaine, a monoamine uptake blocker with high selectivity for the dopamine transporter, acutely induces Fos-like immunoreactivity (FLI) in striatal neurons in adult and neonatal rats. In neonates, the response is selective for striatal cells in dopamine islands/striosomes (Johnson et al., 1992). We asked whether cocaine would induce FLI in embryonic striatum when given to pregnant mice and, if so, whether the induction would be selective for developing striosomes. We found that cocaine (50 mg/kg or 25 mg/kg, s.c.) induced intense expression of FLI in cells of proto-striosomes in E18/E19 mouse embryos exposed through the maternal circulation, and that a similar dopamine island/striosome selectivity of FLI induction occurred at E20/P0. FLI-positive patches were aligned with DARPP-32-positive patches. In embryos of saline-treated dams, weak FLI was also detectable in striosomes/dopamine islands. Interestingly, cocaine induced FLI in cells that were scattered through the E17/E18 embryonic caudoputamen. It has been proposed that future striosomal cells in rat embryos (identified by early projections to the substantia nigra by Fishell and van der Kooy, 1987) first are scattered (E18-E19) and later aggregate into patches corresponding to future striosomes. We propose that future striosomal cells may already have a functional phenotype (responsiveness to maternally transmitted monoamine stimulation) before they form patches, and that this phenotype persists through the period in which striosomal clusters are formed. SELECTIVE MODULATION OF DYE-COUPLING IN RAT STRIATAL NEURONS *in vivo* BY D2 AGONIST ADMINISTRATION. S-P Onn*, T.W. Berger and A.A. Grace. Depts. of Behavioral Neuroscience & Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Using *in vivo* intracellular recording and Lucifer yellow staining, dye coupling in the striatum was observed in 17% (8/48) of the cells injected, which was twice that reported *in vitro* (9%; Cepeda et al., 1989). After i.v. apomorphine (0.1- 0.3 mg/Kg), we observed a significant increase in the incidence of dye-coupling (82%; 9/11) as well as an increase in the extent of coupling within sets of 3-7 cells often recovered after a single injection. It was unclear whether the apomorphine caused this enhancement of dye-coupling via a D1 and/or D2-specific action on striatal cells or by a presynaptic effect on dopamine (DA) terminals. Therefore, we examined the specificity of this response using the selective D1- or D2- specific DA agonists. Administration of quinpirole (2-3 mg/kg; i.v.) was found to increase the incidence of dye-coupling to 66% (6 out of 9 injections) and also resulted in dye-coupling among multiple cells in 3 cases, i.e., 3-5 cells were labelled. In contrast, administration of SKF 38393 (10 mg/kg; i.v.) did not significantly alter the incidence of dye-coupling from the control level (14%; 1/7). This apparent D2-specific enhancement of dye-coupling appeared to be mediated by a postsynaptic action of the drug instead of a decrease in D1 stimulation secondary to autoreceptor stimulation since a blockage of D1 receptors by administering the D1 specific antagonist SCH 23390 (10 mg/kg; i.v.) did not result in an increase in dye-coupling (0/5). Therefore, systemically applied dopamine agonists appear to exert different effects on dye-coupling within the striatum when compared to the results obtained by others *in vitro*, where DA depletions were reported to increase dye-coupling. It is unclear whether DA actions on other striatal afferent systems may have played a role in the response observed *in vivo*. (support by Tourette's Foundation grant, NS08288, NS19608, MH45156 & MH42217).

HETEROGENEOUS DISTRIBUTION OF 5-HT1C RECEPTOR mRNA IN STRIATUM AND SUBSTANTIA NIGRA. Z. Mikeladze and M-F Chesselet*. Dept of Pharmacology. University of Pennsylvania, Philadelphia, PA 19104.

The distribution of cells expressing the mRNA encoding the 5HT1C receptor was examined in the striatum and related areas by in situ hybridization histochemistry at the single-cell level. Sections from rat brain were hybridized with a ^{35}S-RNA probe complementary to the 3rd intracytoplasmic loop of the mRNA and processed for emulsion autoradiography as described (Chesselet et al. 1987). In the striatum, moderately labelled cells were observed in the ventral and ventrolateral part of the caudate-putamen and the rostral part of the nucleus accumbens. Labelled cells were less numerous in the caudal part of nucleus accumbens and virtually absent from dorsal caudate-putamen. Densely labelled cells were present in the subthalamic nucleus and the ventral pallidum, but not in globus pallidus. In the substantia nigra, 60% of neurons in both pars compacta and pars reticulata were densely labelled at caudal but not rostral levels. The data reveal a markedly heterogeneous distribution of 5HT1C receptor mRNA in striatum and substantia nigra, suggesting that this receptor subtype may be involved in regionally specific effects of serotonin in the basal ganglia. Supported by PHS grant MH48125. We thank D. Pritchett for the cDNA.

503.5

THE DEVELOPMENTAL MARKERS GAP-43 AND E-NCAM IN THE ADULT RAT STRIATUM: DISTRIBUTION AND EFFECTS OF CORTICAL LESIONS. F.G. Szele* and M.-F. Chesselet, Dept. of Pharmacology, U. of Pennsylvania, Philadelphia., PA 19104.

The expression of the Growth Associated Protein-43 (GAP-43) and the embryonic (polysialilated) form of the Neuronal Cell Adhesion Molecule (E-NCAM) is high during neuronal development but is limited to some areas capable of plasticity in the adult brain. The distribution of GAP-43 and E-NCAM was investigated with immunohistochemistry in the normal adult rat striatum and 5 days after thermocoagulatory lesions of the somatosensory cortex. Immunoreactivities to GAP-43 and E-NCAM were undetectable in most of the normal striatum except for its dorsomedial and medial parts where both proteins were found in topographically overlapping patterns. Cortical lesions did not result in changes in E-NCAM immunoreactivity but GAP-43 immunoreactivity was increased in the dorsolateral striatum, the area which receives inputs from the lesioned cortex. The data show that a discrete region of the striatum retains the markers of developing neurons GAP-43 and E-NCAM in adult rats. Lesions of cortical neurons projecting to a different striatal area result in increases in GAP-43 but not E-NCAM 5 days after surgery. Supp. by PHS grant NS 29230. We thank L. Benowitz and G. Rougon for the gift of antibodies to GAP-43 and E-NCAM, respectively.

503.6

EXPRESSION OF GAD (Mr 67,000) AND ITS mRNA IN BASAL GANGLIA AND CEREBRAL CORTEX AFTER UNILATERAL CORTICAL LESIONS IN RATS. P. Salin* and M-F Chesselet. Dept of Pharmacol., U. of Pennsylvania, Phila, PA 19104.

Glutamic acid decarboxylase (GAD) is present in most efferent neurons of the striatum and in interneurons both in the striatum and the cerebral cortex. We have examined the effects of lesions of the sensory-motor cortex by thermocoagulation of pial vessels in adult rats. Levels of GAD were measured in the striatum and its target areas with radioimmunohistochemistry and an antibody specific for GAD (Mr 67,000) (Kaufman et al. J. Neurochem.'91); levels of GAD mRNA were measured at the single-cell level by in situ hybridization histochemistry with a ^{35}S-RNA probe complementary to the corresponding mRNA (Kaufman et al. Science, '86). Five days after surgery, GAD immunoreactivity was markedly increased in striatal target areas on the side of the lesion. In the striatum, increases in immunoreactivity were small at 5 days, larger at 21 days, and accompanied by an increase in mRNA levels lasting up to 3 months after surgery. In contrast, in frontal cortex contralateral to the lesion, levels of GAD mRNA per neuron were decreased 21 and 90 days after surgery. The results suggest that local ischemic lesions of cerebral cortex in adult rats lead to prolonged and opposite alterations in GAD synthesis in basal ganglia and contralateral cortex. We thank A.J. Tobin UCLA for the gift of antibody and cDNA. Supp. by PHS grant NS 29230.

503.7

EFFECT OF EXCITATORY AMINO ACIDS ON DOPAMINE AND SEROTONIN RELEASE IN THE RAT STRIATUM. T. Nakazato[1],* and A. Akiyama[2], [1]Dept. Physiol., Juntendo Univ. School of Med., Tokyo, [2]Dept. Electrochem., Tokyo Inst. of Tech., Yokohama, Japan.

This study was designed to investigate whether dopamine (DA) and serotonin (5-HT) are released in the rat striatum by excitatory amino acid using microcomputer-controlled in vivo voltammetry. Glutamate (Glu), NMDA, quisqualate (Quis) and kainate (KA) were administered intrastriatally, extracellular releases of DA were measured every 3 min in freely-moving rats. Glu (10^{-3} M, 6 µl, 24 min) and NMDA (10^{-5} M, 6 µl, 24 min) were intrastriatally injected, DA was released soon after the start of the injection. However, 5-HT release was not found. NMDA-mediated DA release was significantly suppressed after the administration of APV (10^{-5} M). Quis (10^{-5} M) was also administered, DA release increased in almost the same time course as in NMDA. CNQX suppressed Quis-mediated DA release. KA was injected, DA release was small, although in 2 of the 5 cases releases of DA and 5-HT were much increased after the injection. This suggests that 10^{-5} M of KA sometimes induces striatal lesion. In conclusion, DA release in the striatum is increased by drugs in the following order: NMDA = Quis > KA.

503.8

SUBSTANCE P INCREASES EXTRACELLULAR ACETYLCHOLINE IN RAT STRIATUM. J.J. Anderson*, T.M. Engber, and T.N. Chase, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Neurons projecting from striatum to substantia nigra contain large amounts of the tachykinin substance P. These substance P-containing striatonigral neurons also possess axon collaterals which branch within the striatum. Recent evidence suggests that receptors for substance P (neurokinin-1) are selectively expressed in cholinergic neurons in the striatum (Brain Research 556:165, 1991). The relationship between substance P and extracelluar acetylcholine in striatum was examined using microdialysis in awake behaving rats. Rats were implanted with chronic guide cannulae and after at least a three day surgical recovery period, microdialysis probes were inserted through the guide and into striatum. The acetylcholinesterase inhibitor neostigmine (10 uM) was included in the perfusion solution to increase the recovery of acetylcholine. Following a baseline stabilization period and collection of control dialysates, 100 uM substance P was perfused through the probe. The concentrations of acetylcholine and choline in collected dialysates were analyzed by HPLC and electrochemical detection. Substance P significantly increased acetylcholine concentrations from baseline levels in striatal dialysates. In contrast, choline levels were not elevated relative to control concentrations. These results suggest that substance P stimulates release of acetylcholine in the striatum and support anatomical evidence suggesting the presence of substance P receptors on cholinergic neurons in the striatum.

503.9

NBQX AND MK-801 DIFFERENTIALLY MODIFY REGIONAL CEREBRAL METABOLIC RESPONSES TO L-DOPA. T.M. Engber*, J.J. Anderson, R.C. Boldry, S.M. Papa, S. Kuo and T.N. Chase. Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Excitatory amino acid receptor (EAA) antagonists have been proposed as potential antiparkinsonian agents, either alone or in combination with L-Dopa. We used the 2-deoxyglucose autoradiographic technique to examine the neural substrates for the interaction between L-Dopa and antagonists of either the AMPA or NMDA type of EAA receptor. Thus, we compared the effects of the AMPA antagonist NBQX (10 mg/kg, i.v.) and the NMDA antagonist dizocilpine (MK-801; 0.1 mg/kg, i.v.) on regional cerebral metabolic responses to L-Dopa (25 mg/kg, i.v. with 12.5 mg/kg benserazide) in rats with a unilateral 6-hydroxydopamine lesion of the nigrostriatal pathway. L-Dopa increased glucose utilization in substantia nigra pars reticulata and entopeduncular nucleus and decreased metabolic rate in lateral habenula; NBQX and MK-801 by themselves did not affect glucose utilization in these regions. Pretreatment with NBQX reduced the effect of L-Dopa in substantia nigra pars reticulata but not in entopeduncular nucleus, while MK-801 attenuated the effect of L-Dopa in both of these striatal output regions. Neither NBQX nor MK-801 altered the effect of L-Dopa in lateral habenula. These findings indicate that AMPA and NMDA antagonists differentially modify dopamine receptor-mediated striatal output. AMPA receptor blockade appears to reduce dopaminergic stimulation of the striatonigral but not the striatoentopeduncular pathway, while NMDA blockade appears to reduce dopaminergic stimulation of both of these striatal output pathways.

503.10

POTENTIATION OF SKF 38393-INDUCED ROTATIONAL BEHAVIOR BY MK-801 IS DEPENDENT UPON PREVIOUS DRUG EXPOSURE. R.C. Boldry*, T.N. Chase, and T.M. Engber Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Directly acting dopaminergic agonists produce contralateral rotations in rats with a unilateral 6-hydroxydopamine lesion of the nigrostriatal pathway. Previous studies have shown that the noncompetitive NMDA antagonist dizocilpine (MK-801, 0.1 mg/kg i.p.) can potentiate the stimulation of rotational behavior produced by the dopaminergic D-1 agonist SKF 38393 (1.5 mg/kg s.c.), and inhibit the stimulation of rotation produced by the D-2 agonist quinpirole (0.1 mg/kg i.p.) (Morelli et al. JPET 260:402-408, 1992). We have confirmed that MK-801 decreases the stimulation of rotation produced by quinpirole regardless of previous drug exposure and increases the rotational response to SKF 38393 when given three days after screening with a single high dose of L-DOPA (50 mg/kg with 30 mg/kg benserazide, i.p.). However when MK-801 is co-administered with SKF 38393 one week after screening with a single low dose of apomorphine (0.05 mg/kg s.c.), no potentiation of the rotational response is observed. This negative finding at one week after apomorphine is independent of the dose or route of administration of MK-801. Since rats which have been treated 3 days previously with L-DOPA display significantly less rotational behavior than those treated 1 week earlier with apomorphine, we have concluded that MK-801 can reverse the suppression of rotational behavior caused by recent exposure to L-DOPA.

503.11

MK-801 DIFFERENTIALLY MODIFIES REGIONAL CEREBRAL METABOLIC RESPONSES TO D1 AND D2 DOPAMINE AGONISTS. S.M. Papa*, J.J. Anderson, R.C. Boldry, S.Kuo, T.N. Chase and T.M. Engber, ETB, NINDS, NIH, Bethesda, MD 20892.

Dopamine and excitatory amino acids play important roles in the basal ganglia control of motor behavior; elucidating the manner in which these transmitters interact may provide new therapeutic approaches to the treatment of Parkinson's disease. We used the 2-deoxyglucose (2-DG) autoradiographic technique to examine the effect of the NMDA antagonist dizocilpine (MK-801) on regional cerebral metabolic responses to D1 and D2 dopamine agonists in rats with a unilateral 6-hydroxydopamine lesion of the nigrostriatal pathway. The D1 agonist SKF 38393 (5 mg/kg, i.v.) increased glucose utilization in substantia nigra pars reticulata and entopeduncular nucleus. The D2 agonist quinpirole (1 mg/kg, i.v.) was without effect in these regions, but decreased 2-DG uptake in the nucleus accumbens. Pretreatment with MK-801 (0.1 mg/kg, i.v.), which had little effect on cerebral metabolism by itself, reduced the effect of SKF 38393 in both substantia nigra pars reticulata and entopeduncular nucleus and prevented the effect of quinpirole in the nucleus accumbens. Both SKF 38393 and quinpirole decreased glucose utilization in the lateral habenula. MK-801 pretreatment did not alter the effect of SKF 38393 in the lateral habenula but substantially reduced the effect of quinpirole in this structure. These results indicate that D1 and D2 receptor-regulated brain mechanisms are differentially influenced by NMDA receptor stimulation. D2-mediated cerebral metabolic responses appear to require concurrent NMDA receptor stimulation, while D1 receptor-regulated neuronal pathways exhibit varying degrees of sensitivity to NMDA receptor blockade.

503.12

IMMUNOCYTOCHEMICAL STUDY OF NONPHOSPHORYLATED NEUROFILAMENT PROTEIN DISTRIBUTION IN MONKEY BASAL GANGLIA. M.J. Campbell*, Mt. Sinai, NY, NY 10029

SMI-32 (Sternberger Monoclonal Inc.), is a monoclonal antibody that avidly recognizes the KSP segment of NF-H and weakly recognizes the KSP2 segment of NF-M in their nonphosphorylated state (J. Neurosci. Res. 30:47). Unlike some NFP antibodies it lacks cross-reactivity to the microtubule associated proteins (PNAS 85: 1998, & PNAS 84: 3410). In studies of primate neocortex, SMI-32 labels primarily the soma and dendrites of a subpopulation of pyramidal neurons whose distribution differs markedly across cortical areas (eg., J. Comp. Neurol. 282:191). This examination of the basal ganglia reveals striking differences between the striatal and pallidal compartments. The caudate and putamen are relatively unique brain regions in that there is an absence of immunoreactive neurons. Rather, there is a dense staining of the neuropil which exhibits some regional variation (generally, the dorsal striatum is more densely stained than the ventral striatum), but importantly it exhibits variations in intensity that correspond to the patch/striosome and matrix organization of the striatum as revealed by AchE or calbindin immunoreactivity for example (PNAS 75:5723 & PNAS 82:8780). In contrast in pallidal segments, a large subpopulation of neurons and their extensive dendrites are immunoreactive. These observations suggest that one or more of the terminal projections delineating a subcompartmentalization of the striatum also requires this form of NFP. Whereas, in the pallidum, as in the neocortex, it is a cytoskeletal specialization in the soma and dendrites of a large subpopulation of projection neurons, despite differences in neurotransmitter used by neurons in these two regions (GABA versus excitatory amino acids).

503.13

5'-NUCLEOTIDASE ACTIVITY IN THE DEVELOPING CAUDOPUTAMEN: ASSOCIATION WITH DOPAMINE ISLANDS AND STRIOSOMES IN RAT, BUT EXTRASTRIOSOMAL MATRIX IN MOUSE. S.W. Schoen* and A.M. Graybiel, Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

In the striatum, patchy compartments (the striosomes and their developmental forerunners, the dopamine islands) can be distinguished from the surrounding tissue (the extrastriosomal matrix) by their differential content of numerous neurochemical compounds. The adenosine-producing ectoenzyme 5'-nucleotidase (5'N) is a new marker for striosomes in the mature rat caudoputamen, revealed with a histochemical lead technique (Schoen and Graybiel, Soc. Neurosci. Abstr. 17, 452). On the basis of serial-section comparisons with the distributions of tyrosine hydroxylase and calbindin-D_{28k} immunoreactivity (marking dopamine islands and matrix), we show here that 5'N is selectively enhanced in the neuropil of dopamine islands/striosomes of the rat caudoputamen from postnatal day 1 to adulthood. This holds for all but the caudal caudoputamen. In mouse, by contrast, 5'N activity is associated with extrastriosomal matrix of the anterior and middle caudoputamen from embryonic day 18 until postnatal day 21; rarely, zones of enhanced 5'N reaction product overlap with dorsally located dopamine islands. In adult mice, most of the caudoputamen is filled with dense histochemical reaction product, but rostral striosomes remain visible by low 5'N activity. These results indicate a converse enzyme architecture of the caudoputamen in rat and mouse. As 5'N is associated with glia and malleable synapses, this enzyme could reflect specific glial compartmentalizations or sites of synaptic plasticity within striatum. Roles of 5'N in purinergic neuromodulation and cellular contact-formation may contribute to activity-dependent or adhesive mechanisms underlying the differentiation and maintenance of the striosome and matrix compartments. Supported by NIH (RO1 NS25529) and DFG.

GRADIENTS IN THE DOPAMINE-REGULATED SYNTHESIS OF NEUROPEPTIDES AND DOPAMINE RECEPTORS IN RAT NUCLEUS ACCUMBENS. P.Voorn* and G.J. Docter. Dept. of Anatomy and Embryology, Vrije Univ., Amsterdam, the Netherlands.

Quantitative in situ hybridization histochemistry was used to study the effects of unilateral 6-hydroxydopamine lesions of the ascending dopaminergic fibers on the synthesis of enkephalin (Enk), dynorphin (Dyn), substance P (SP) and the dopamine D-1 and D-2 receptors in projection neurons in subregions of the nucleus accumbens (Acc) and in the caudate-putamen (CP). In CP of control animals a systematic increase of mRNA along the rostrocaudal axis was found for Dyn and D-1, whereas in Acc a decrease in mRNA was noted in the rostral to caudal direction for all three neuropeptides and the two dopamine receptors. Two weeks after the lesion an increase was found in Enk and D-2 mRNA, both in CP (Enk +130%, D-2 +36%) and in Acc (Enk +73%, D-2 +13%), in the lesioned side compared to the non-lesioned side. A decrease was observed for Dyn, SP and D-1, which was the same in CP and Acc for D-1 (-15%) and Dyn (-58%), and slightly higher for SP in CP (-44%) than in Acc (-39%). The adaptive changes in mRNA levels appeared to be proportional along the rostrocaudal axis for all neuropeptides and receptors except for Enk. For Enk mRNA the increase in Acc was rostrally higher than caudally, indicating regional differences in the effects of blockade of the dopaminergic neurotransmission.

CHARACTERIZATION OF A NEW BRAIN-SPECIFIC PROTEIN TYROSINE PHOSPHATASE IN RAT STRIATUM AND CEREBRAL CORTEX. J. R. Naegele*, M. Lerner. and P. J. Lombroso. Dept of Biology, Wesleyan University, Middletown, CT 06457 and Child Study Center and the Howard Hughes Medical Institute, Yale University School of Medicine, New Haven, CT 06510.

Protein tyrosine phosphatases (PTPs) act in opposition to tyrosine kinases to regulate phosphorylation of tyrosine residues. These two classes of enzymes are implicated in cell differentiation but may have additional functions in mature cells. We have explored the possibility that different PTPs might be present within functionally distinct regions of the brain. A novel intracellular PTP was cloned from a rat striatal cDNA library (Lombroso et al. '91, PNAS 88: 7242-7246). Northern analyses of brain revealed a 3 kb and a 4.4 kb mRNA. The 3 kb mRNA was highly enriched in the striatum relative to other brain regions and was termed STriatal Enriched Phosphatase (STEP). An amino acid consensus sequence found in all protein tyrosine phosphatases and tyrosine phosphatase activity identified STEP as a PTP. Rabbit polyclonal antisera against STEP recognized a major band of 46 kDa and minor bands of 37 and 33 kDa on Western blots of adult striatum. In sections of fixed rat brain, STEP antiserum stained striatal neurons and neuropil. In cerebral cortex, a subset of neurons were stained in layers 2+3, 5 and 6. Staining was also found within the neuronal subsets in hippocampus and lateral septal nucleus. These findings suggest the existence of other brain specific PTPs showing regional heterogeneity.

CHOLINERGIC REGULATION OF SUBSTANCE-P/NEUROKININ A GENE EXPRESSION IN RAT STRIATUM L.R. Lucas* and R. E. Harlan. Neuroscience Training Program, Tulane Univ. Sch of Med., New Orleans, LA 70112.

Cholinergic interneurons and substance P/neurokinin A medium spiny projection neurons comprise 5% and 40%, respectively, of the total number of neurons in the rat caudate-putamen (CPu). Since the influence of cholinergic interneurons on neuropeptidergic projection systems in the striatum is poorly understood, this study explores the relationship between cholinergic receptor activation or inhibition on tachykinin gene expression.

Adult male Sprague-Dawley rats were treated chronically either with a cholinergic agonist (physostigmine: 0.5mg/kg/3Xday), a muscarinic antagonist (scopolamine HCl: 0.4mg/kg/3Xday), or vehicle (PBS: 0.1ml/100g) administered for 6 days (s. c.). Rats were perfused with 3% paraformaldehyde and coronal cryostat sections (20μm) were cut and mounted on Vectabond (Vector) coated slides. *In situ* hybridization was performed with a full-length (560nt) ribonucleotide probe directed against ß-ppt (a transcript containing substance P, neurokinin A, and other tachykinins). Physostigmine administration resulted in a small decrease in tachykinin expression in the CPu and olfactory tubercle, while scopolamine treatment resulted in an increase in expression in both regions, as compared to vehicle treated animals. The increases after scopolamine treatment appeared to be greatest ventrolaterally in the CPu, paralleling the distribution of ChAT-mRNA positive cells. The results suggest that acetylcholine in the striatum may regulate levels of tachykinin expression in a manner opposite to that observed with dopamine. Supported by NS24148.

STRIATAL c-*fos* EXPRESSION AND D1/D2 SYNERGISM. G.J. LaHoste*[1,3], Jen Yu[1,3] & J.F. Marshall[2]. Depts. of [1]Phys. Med. & Rehab. and [2]Psychobiology, University of California, Irvine, CA 92717, and [3]State Developmental Research Institutes.

Dopamine (DA) agonists have been shown to induce c-*fos* gene expression in the caudate-putamen (CPu) of rats. To test for a synergistic interaction between D1 and D2 receptors in DA-mediated c-*fos* expression, we injected neurologically intact rats with either the D1 agonist SKF 38393 (20 mg/kg), the D2 agonist quinpirole (3 mg/kg), the combination of both SKF 38393 and quinpirole, or saline. Two hours later, rats were perfused (4% paraformaldehyde) and the brains prepared for immunohistochemical visualization of Fos, the protein product of the c-*fos* gene using Cambridge Research Biochemicals antibody OA-11-823 (1:1000). Striatal Fos immunoreactivity (Fos-ir) was virtually undetectable in rats injected with saline, SKF 38393, or quinpirole. In rats given the combination of D1 and D2 agonists, however, patches of nuclear Fos-ir were readily detectable, particularly in the posterior CPu. In a second experiment, rats were given daily injections of vehicle or reserpine (1 mg/kg), a treatment that results in a breakdown in D1/D2 synergism. On the fifth day, they were injected with either SKF 38393 (20 mg/kg) or saline and perfused 2 hours later. SKF 38393 alone elicited pronounced Fos expression homogeneously throughout the CPu of rats pre-treated with reserpine, but not vehicle. The 5-day regimen of reserpine treatment did not itself elicit Fos expression. These data suggest that DA-mediated c-*fos* expression is a histochemical indicator of the state of D1/D2 synergism.

DIFFERING CLIMBING FIBER LENGTH IMPLIES VARIABLE CONDUCTION VELOCITY TO ESTABLISH ISOCHRONICITY OF CLIMBING FIBER CONDUCTION TIMES. I. Sugihara*, E. J. Lang, C. I. de Zeeuw and R. Llinás. Dept. of Physiology & Biophysics, New York University Medical Center, 550 First Avenue, New York, N.Y. 10016.

Previously we demonstrated that the climbing fiber conduction times are tuned closely to 4.0 ms in lobule crus 2a regardless of path length from the inferior olive (IO) to the cerebellar cortex, and that the rostro-caudal banding pattern of synchronous spontaneous complex spike (CS) activity in Purkinje cells (PCs) extends down the side of the cerebellar folia (Soc. Neurosc. Abs., 1990). We investigated this isochronicity further in ketamine-anesthetized adult rats. Conduction times for the other hemispheric and vermal lobules were also found to be about 4.0 ms (4.0 ± 0.4, mean $\pm$ SD, n=660 cells). Although CS activity in the vermal and hemispheric PCs are not strongly correlated in control condition, systemic application of picrotoxin can increase synchronicity of their CS activity by increasing the electrotonic coupling between olivary cells. In that situation, the CS activity of vermal and hemispheric PCs, recorded simultaneously using a multi-electrode technique, are synchronous to within 1 msec as determined from the peak of the cross-correlograms. To investigate the basis of CS isochronicity, PHA-L injections into the IO were made to visualize the climbing fibers to the vermis and hemisphere. The coordinates of the center of the stained fiber bundles in 90 µm thick coronal sections were measured and reconstructed in three-dimensional space. The length of the fiber bundles to the vermis (zone A) ranged from 9.5 to 14.0 mm while the bundles to the hemisphere (zone D) were shorter, 7.0 to 11.0 mm. These results further confirm the finding that the conduction velocity of a climbing fiber is correlated to its length so as to establish isochronic conduction times. Supported by NIH grant NS13742.

BISTABLE DISCHARGE PROPERTIES OF PURKINJE CELLS IN THE *IN VITRO* TURTLE BRAIN. R.R. Carter*, Y. Kwon, S.B. Arnold, R.R. Matsumoto, and J.C. Houk. Department of Physiology, Northwestern University School of Medicine, Chicago, IL 60611.

Purkinje cells of the cerebellar cortex were recorded extracellularly in the *in vitro* turtle brain preparation. The spontaneous activity of these cells was examined for evidence of bistable states of discharge. One group of Purkinje cells demonstrated sudden onsets and offsets of bursts of action potential discharge interspersed between periods of silence. Both the ON periods and OFF periods were typically 2-30 s. When in the ON state a given cell's inter-spike-interval varied as much as 20% with the mean rate between 10-60 imp/s. However, for each Purkinje cell the mean ON discharge rate was typically repeatable to within 10% for successive bursts. Thus the Purkinje cells functioned as bistable units. In another group of Purkinje cells the mean discharge rate in the ON state began at 60-80 imp/s and increased to about 100 imp/s at which point the ON period was punctuated by a series of several short bursts and pauses.

Two series of experiments suggest that the presence of two stable states of discharge and the cycling between them are due to intrinsic Purkinje cell properties. First, we recorded both groups of Purkinje cells in the isolated cerebellum and thus in the absence of influence from other brain regions or peripheral feedback. Second, when synaptic transmission was blocked by altering the bathing solution to contain high Mg^{2+} and low Ca^{2+} concentrations, we again recorded both groups of Purkinje cells although in some cases the timing of the cycling was altered.

It is possible, however, for external influences to take advantage of the intrinsic properties of the Purkinje cells. Experiments have indicated that single pulses of electrical stimulation delivered to the spinal cord often caused a unit in the OFF state to switch to the ON state, and, occasionally, a unit in the ON state to switch to the OFF state. These results are consistent with theories suggesting that Purkinje cells may contribute to the stable, controlled expression of motor programs and that peripheral feedback may modulate a motor program through influence of Purkinje cells.

QUALITATIVE DYNAMICAL MODEL OF BISTABILITY IN PURKINJE CELL DENDRITES. G. L. F. Yuen*, P. E. Hockberger, L. E. Massone and J. C. Houk. Dept. of Physiology, Northwestern University Medical Center, 303 E. Chicago Ave., Chicago, IL 60611-3008.

Previous computational and electrophysiological studies suggest that cerebellar Purkinje cells may function as bistable elements with hysteresis in the context of movement control (see Carter et al, this meeting). To develop more realistic models of this bistability, a phase-plane analysis was carried out using recent whole cell and single channel data. In particular, combinations of calcium and potassium channels were introduced into a dendritic compartment [with reasonable impedance loads] and the possibility of generating bistability was investigated.

Preliminary results from the use of high-threshold calcium and delayed rectifier potassium channels, which have been described in these neurons, suggest that they can support bistability in a dendritic compartment. In this model, the dynamic state variables are membrane potential and potassium channel activation. Calcium activation is assumed to be instantaneous and a sigmoidal function of membrane potential. The nullclines of the state variables have three intersections or equilibrium points, of which two are stable (representing the excited and the rest state) and one is unstable. State transitions can be induced by either short or long current pulses. For example, a depolarizing current pulse can send the system into the excited state (at a higher membrane potential) where it will remain stably until a hyperpolarizing pulse returns it to the resting state. A larger stimulus was needed to effect the {excited->rest} transition compared to excitation {rest->excited}. Thus the voltage-current relationship exhibited both bistability and hysteresis in that different stimulus thresholds were observed for excitation and recovery. These properties may allow Purkinje cells to participate in delayed feedback pathways without causing system instability.

CEREBELLAR CONTROL OF CONDITONED EYEBLINK TIMING. G.T. Bartha* and R.F. Thompson. Neural, Informational, and Behavioral Sciences Program, University of Southern California, Los Angeles, CA 90089.

It is of general significance for sensorimotor control that rabbits can learn to delay peak nictitating membrane/eyeblink responses from 100 ms to over one second from the time of conditioned stimulus (CS) onset. This delay is adaptive in that the peak eyeblink amplitude occurs near the time of the unconditioned stimulus (US) onset used in training. Our objective is to develop a new model of conditioned eyeblink timing that is consistent with the extensive data on the synaptic organization and physiology of the underlying neural circuitry.

We propose that the cerebellum is the major contributor to adaptive timing of eyeblink responses for CS-US intervals less than 500 ms. The primary mechanism subserving the delay is prolonged feedback inhibition of granule cells by Golgi cells. This depresses the firing of the Purkinje and basket cells they tonically activate. Purkinje cells inhibited by these basket cells, but activated by another population of granule cells, increase their activity. Appropriate integration of depressed and excited Purkinje cells by interpositus neurons yields adaptively delayed responses. Our hypothesis implicates Purkinje, interpositus, and basket cells as sites of plasticity.

Computer simulations demonstrate that our model accounts for the single neuron activities observed experimentally in trained rabbits. The simulated cerebellar circuitry is constructed using conductance based, single compartment neuron models.

Our model is among the most biologically plausible accounts of eyeblink timing. The model is also a rare example of how a single neuron property beyond simple leaky integrator models can be crucial for behavior. The timing mechanism could apply to all conditioned somatic motor responses and may be a general cerebellar function.

SIMULATION OF CEREBELLAR-VESTIBULAR INTERACTIONS DURING VOR ADAPTATION. K.J. Quinn*, J.F. Baker and B.W. Peterson. Northwestern Univ., Chicago, IL 60611

Both brainstem and floccular sites have been proposed as principal locations for plasticity resulting in vestibulo-ocular reflex (VOR) adaptation. In each case, specific predictions have been made concerning the nature of the error signal required for the adaptation process. Here we explore the computational characteristics of simple neural network models simulating these locations and conditions. We constructed a network based on the original formulation of Miles and Lisberger (Ann.Rev. Neurosci.,1981,4,273) and tested its ability to generate normal and adapted eye velocity signals in response to a variety of head velocity step inputs. Tuning the network using an unphysiological global optimization method indicated that the most accurate adapted response occurs when synaptic weights are allowed to change at both sites.

Turning to more physiological learning rules, we found that using output of gaze-velocity purkinje cells isn't effective as a teacher signal for driving plasticity at brainstem locations. Rather, it leads to wildly oscillating behavior because this output is part of a positive feedback loop. Optimal adaptation occurred when retinal slip velocity, representing output of the accessory optic system, was used to directly instruct changes in vestibular input weights at brainstem and cerebellar sites using a Widrow-Hoff learning rule. Unsupervised Hebbian rules are inadequate and cause the system to adapt to inappropriate gains. This finding on learning rule efficacy confirms for a specific instance the general observations of Sutton and Barto (Psych.Rev., 1981,88,135). Supported by EY06485, EY07342, DC01559.

A NEW TREATMENT OF SPATIO-TEMPORAL STRUCTURE IN ARRAY RECORDING OF THE RAT INFERIOR OLIVE.

A. Sivaramakrishnan, E. J. Lang, I. Sugihara, S. Sivaramakrishnan*† & R. Llinás, Department of Physiology and Biophysics, New York University Medical Center, 550 First Avenue, New York NY 10016 & † Biology Department, 139-74, California Institute of Technology, Pasadena CA 91125.

Statistical tools developed for data with continuous or many-valued data are often inappropriate for binary data that may be the best representation of neural on/off states. We present an approach that incorporates a non-linear prefiltering of data from microelectrode array recordings of Purkinje cell complex spikes from the surface of the rat cerebellar cortex, followed by calculation of a correlation-type statistic that is tailored to binary data. This statistical approach appears to be better in many ways than the traditional forms of correlation. Data from such recordings are known to show a 10Hz oscillation and rostrocaudal banded patterns of Purkinje cell climbing fiber activation that seem to form the "grammar" of neuronal organization of the inferior olivary nucleus, the site of origin of the climbing fiber system. This statistical approach is robust in the sense that it is not affected by the considerable variation in the corresponding 100ms "periods" between spike trains. The method shows structure in the data that is often washed out by the usual approaches of autocorrelation and cross-correlation. (NINCDS-13742)

MICROCIRCUIT ASSOCIATIVE MEMORY MODEL OF THE CEREBELLAR CORTEX. Coe F. Miles and H. B. Nudelman*, Stuttering Center & Speech Motor Control Laboratory, Department. of Neurology, The Methodist Hospital/Baylor College of Medicine, Houston, Texas, 77030.

In this work, information and analytical techniques from the fields of biology, mathematics, computer science, and engineering are used to model the information processing characteristics of the mammalian cerebellar cortex. While previous studies have provided a foundation upon which to model and analyze the functional characteristics of the cerebellum, they do not account for many recently discovered physiological and structural aspects of the cerebellum. This work extends these earlier efforts by formalizing putative computational operations using mathematics.

By viewing anatomically different neurons as representing network elements whose input-output functions are different, a mechanism for distributing information throughout the memory is proposed. The functional circuitry developed here to implement this feature is called the MicroCircuit. The MicroCircuit provides a means of combining sensory input signals from different modalities. Unique to the MicroCircuit construct is its use of interneuron arborization patterns to establish intermodel communication links and a proposed functional role for climbing fiber activation during memory recall.

Interconnected MicroCircuits form the MicroCircuit Associative Memory (μAM) architecture, which can be viewed as a distributed associative memory or as a sparsely interconnected feed forward neural network. Key features of the μAM include 1) its ability to manipulate very large input patterns, 2) its distributed storage of input data patterns, and 3) its statistical reconstruction of stored patterns during memory read operations.

Analytic results describe the μAM's read and write operations, pattern fidelity, capacity and immunity to noise. Computer simulations, using a 4096 processor Connection Machine, are used to verify our theoretical predictions.

REALISTIC COMPUTER SIMULATIONS OF MEDIAL VESTIBULAR AND DEEP CEREBELLAR NUCLEI NEURONS. R. Quadroni, J. Simonet and Knöpfel, T.*. Federal Institute of Technology, Dep. of Physics, CH-8093 Zürich and Brain Research Institute, University of Zürich, CH-8029 Zürich.

We have developed a user-friendly program running on UNIX workstations for computer simulations of single nerve cells, involving an X-window-based editor permitting design and variation of morphological and membrane parameters. An integration routine based on an implicit second order algorithm allowed fast and stable integration of coupled differential equations describing the kinetics of ion-channels as well as concentrations, diffusion and buffering of Ca^{2+}.

We have designed compartmental models of Type A and B guinea pig medial vestibular nuclei neurons (Serafin et al., Exp. Brain Res. 84:417-433) and of rat deep cerebellar nuclei neurons. Compartments comprise up to eight active ionic conductances (g_{Na}, $g_{Ca(LVA)}$, $g_{Ca(HVA)}$, $g_{K(DR)}$, $g_{K(A)}$, $g_{K(AHP)}$, $g_{K(C)}$ and g_Q) whose kinetics were obtained from voltage-clamp studies in a variety of preparations. Synaptic inputs of the AMPA-, NMDA- and $GABA_A$-type were simulated by appropriate changes in conductance. Some kinetic parameters as well as distribution and density of ion-channels were modified to faithfully reproduce the responses of living neurons as revealed in current-clamp experiments.

HAPTIC INFORMATION TRANSFER DEFICITS ASSOCIATED WITH CLOSED HEAD INJURY: DOES CALLOSAL DYSFUNCTION DISCONNECT ACCESS TO THE MEMORY OF A TACTILE STIMULUS? C.M.Fernandez-Carol* and B.D.Fantie, Human Neuropsychology Laboratory, The American University, Washington, DC.

Neuropathological studies have consistently indicated there is disproportionately severe damage to the corpus callosum in closed head injury (CHI) and that this can occur when the trauma seems relatively minor. To determine if we could detect callosal dysfunction in the interhemispheric processing of tactile manual stimuli, we employed a haptic information transfer test that required subjects to match small patterns of pinheads utilizing only their sense of touch. Each person used either the same hand (Right-Right and Left-Left) or opposite hands (Right-Left and Left-Right) to examine a model stimulus and find its matches from within an array of distractors. One phase of the experiment (Simultaneous) allowed participants to leave one hand on the model while searching with the other, or, in the 1-hand condition, return to the model as often as desired. Another phase required that the subject search for matches from memory only (Successive).

In the Simultaneous condition, the performance of the CHI group (n=30, mean age=27.4 years) did not differ significantly from that of Controls (n=20, mean age=24.8 years) although there appeared to be a trend for the CHI group to make more errors than Controls in the 2-hand condition. In the more memory-dependent Successive condition, the CHI group was significantly slower and made more errors than Controls when searching for targets with the right hand. We propose that this pattern of results is compatible with a retrieval deficit resulting from a disconnection between the left hemisphere's motor control of the right hand and transcallosal access to the representation of the target stimulus presumably encoded spatially in the right hemisphere.

505.2

SPECIFICITY OF INTERHEMISPHERIC TRANSFER FOLLOWING A PARTIAL LESION OF THE CORPUS CALLOSUM. K. Baynes, M.J. Tramo,† R. Fendrich,*†† A. G. Reeves, and M.S. Gazzaniga,††
Program in Cognitive Neuroscience, Dartmouth Medical Schoool, Hanover, NH 03755, † Dept. of Neurobiology, Harvard Medical School, Boston MA , and ††Center for Neurbiology, UC Davis, Davis, CA.

Evidence is presented to demonstrate partial sparing of somesthetic transfer with relatively intact visual transfer following ischemic infarction of the central four fifths of the corpus callosum, most of the right calcarine cortex, right hippocampal region, and right posteriomedial parietal lobe. Intermanual judgments of weight and texture were accurate, but those concerning the location of tactile stimulations were not. The right hemisphere was able to build representations of objects via the tactile modality that could be used for tactile matching, but could not be accessed consistently for naming or auditory comprehension. Palpated objects could be matched to pictures with a left hand pointing response. These findings indicate that 1) somesthetic information within the right hemisphere could be used to perform unimodal and crossmodal intra- and inter-hemispheric recognition tasks, 2) transfer of somesthetic information within the right hemisphere to left hemisphere language areas was disrupted, and 3) different regions of the callosum mediate the transfer of somesthetic information about texture vs. tactile location.

505.3

SELECTIVE IMPAIRMENT OF CONCEPT RETRIEVAL THROUGH A TACTILE CHANNEL. H. Damasio,* D. Tranel, U. Bellugi, A.R. Damasio and J.P. Brandt. Div. of Behav. Neurol. & Cogn. Neurosci., Univ. Iowa Col. of Med., Iowa City IA 52242.

In a recognition task in which 215 objects from varied conceptual categories were presented visually, a patient with a lesion in right parietal cortices (areas 5 and 7) performed at the same level as controls (98%). However, when the patient was blindfolded and 100 such stimuli were presented in the tactile mode, to the left and right hands independently, there was a severe entity-selective impairment. When the stimuli were grouped into those that are manipulable and those that are not, we found that right- and left-hand recognition of manipulable items was 94% and 92%, respectively (comparable to controls), while the performance on nonmanipulable items was only 57% and 47%, respectively (severely defective). Thus, the patient could nearly always retrieve the concept behind a manipulable entity, but was often unable to retrieve the concepts behind nonmanipulable entities. We propose that the lesion prevents signals from left and right somatosensory cortices from accessing right inferotemporal systems that are critical for mapping the conceptual structure of *visually ambiguous, nonmanipulable entities*. However, such signals can still access the motor system through a frontal route and thus activate part of the conceptual structure for manipulable entities.

505.4

LAUGHTER PUNCTUATES SPEECH: LINGUISTIC AND SOCIAL CONTEXTS OF LAUGHTER IN CONVERSATION. R. R. Provine*, L. A. Greisman and C. N. Runyan. Dept. of Psychology, UMBC, Baltimore, MD 21228.

The stereotypic, species-typical character of laughter facilitates the analysis of the neurobehavioral mechanisms for the production, perception and evolution of human auditory signals of which speech is a special case (Ethology, 89 (1991) 115-124). Laughter and speech are seldom considered in the same context, a tradition that limits our understanding of both behaviors. This study describes the position of naturally-occurring laughter in the speech stream of anonymous, mostly adult subjects, observed in public places. Laughter of both speaker and audience occurred during pauses at the end of sentences in over 99% of the sample of 1200 episodes of laughter, indicating that speech has priority access to the single vocalization channel and that a lawful neurobehavioral process governs the placement of laughter in the speech stream. Laughter by speaker or audience rarely interrupted the phrase structure of speech. Because laughter followed both statements (84.3%) and questions (15.7%), it was not restricted to a specific type of preceding sentence. Contrary to experience with professional comedians, most laughter was not preceded by jokes or material that seemed humorous outside of the conversational context. Another counterintuitive finding was that speakers laughed more than audiences. Speakers, especially females, laughed more than their audiences, but the relative amount of speaker and audience laughter depended on the gender composition of a group. Audiences of both males and females laughed more to male than female speakers. This may be why most professional comedians are male. These baseline data define the variables for future studies of laughter in neuro- and psychopathology. Laughter may provide novel insights into the neurobehavioral mechanisms of normal and abnormal emotional communication in humans.

ELEMENTS OF ATTENTION: PERFORMANCE OF HEALTHY ADULTS AND NEUROPSYCHIATRIC PATIENTS ON THE NIMH-LPP ATTENTION BATTERY. J.E. Tatman†, B.D. Fantie*†‡ and A.F. Mirsky‡. †Human Neuropsychology Laboratory, The American University, Washington, DC and ‡Laboratory of Psychology and Psychopathology, NIMH, Bethesda, MD.

Healthy adults (n=103), aged 18 to 90 years, performed the NIMH-LPP Attention Battery; a set of neuropsychological tests tapping a broad range of attentional abilities. Extending and refining the four elements of attention that Mirsky et al. (1991) identified in the battery (i.e., 1-Focus/Execute, 2-Shift, 3-Sustain, and 4-Encode), a new five-component solution best resolved the variance in these data. We derived the newly-identified factor from variance and error scores on the Continuous Performance Task (i.e., 5-Reliability of Performance) and renamed the original 4 factors 1-Scan/Focus Speed, 2-Flexibility/Shift of Set, 3-Arousal/Effort, and 4-Encode/Retain, respectively. A reanalysis of a subset of Mirsky et al.'s data resulted in a comparable 5-component solution among 52 neuropsychiatric patients (i.e., patients with petit mal and complex partial seizure disorders, anorexia nervosa and bulimia nervosa, affective disorders, and closed head injuries), aged 20 to 63. Despite interesting differences, we argue that the underlying components reflect congruent cognitive processes in each group. We also propose that the disordered attention in these clinical subjects may be primarily attributable to poor executive regulation of attentional shifts, i.e., an impaired flexibility of cognitive set. In summary, we obtained general support for the reliability of Mirsky et al.'s original four elements while the new 5-component solutions cast several new lights on the performance of both healthy and neuropsychiatric subjects on tests of attention.

EXTINCTION OF TRACE CONDITIONED EYE-BLINK RESPONSES IS IMPAIRED IN ANTEROGRADE AMNESIA. R. A. Deyo* and M. J. Jacobson. Department of Psychology, Winona State University, Winona, MN 55987.

Lesion studies involving rabbits have shown that the cerebellum is required for acquisition of delay conditioned eye-blink responses, while lesions to the hippocampus block acquisition of trace conditioned responses (Moyer, et al., 1990; *Behav. Neurosci. 104*: 241-250). These data suggest that different classical conditioning tasks may require different combinations of neural systems. The question of whether a similar dissociation applies in human learning has not been addressed. Thus, the purpose of the present study was to examine the retention and extinction of trace conditioned eye-blink responses in a subject with anterograde amnesia.

A 32 year old female with anterograde amnesia (following an automobile accident) served as the amnesic in the present study. Five females (controls) were selected to match the age and intelligence of the amnesic.

The apparatus consisted of a microcomputer programmed to record behavioral responses and to control the presentation of stimuli. Each acquisition trial consisted of a tone presented for 100 ms followed 500 ms later by a 100 ms corneal air puff. Extinction trials consisted of the tone presented alone.

Two weeks prior to the accident, the amnesic (D01) had received 60 acquisition trials, as a participant in an earlier study. Sixteen months after the accident D01 received an additional 50 acquisition trials followed by 20 extinction trials. Controls received the same number acquisition and extinction trials at the appropriate conditioning intervals.

Statistical analyses indicated that there were no pre-injury differences between D01 and controls. Analysis of performance 16 months after the injury indicated that while retention of the conditioned eye-blink response was not altered, D01 did show a much higher resilience to extinction relative to the matched controls.

AUDITORY STREAMING REDUCES REACTION TIMES TO INFREQUENT TARGETS. C. Alain* and D. L. Woods. Clinical Neurophysiology Laboratory, Dept of Neurology, UC Davis, VA Medical Center, Martinez, CA 94553, USA.

When a sequence of different tones is presented rapidly, the sequence may split into two or more perceptually concurrent streams. The tones that are similar in frequency will tend to be perceived as a group. This phenomena is called "auditory stream segregation" or "streaming" and is sensitive to stimulus rate and tonal separation. In two experiments we examined whether streaming would affect reaction times as well as other measures of auditory perception. Stimulus sequences consisted of tones (40 ms, 78 db SPL) of three different pitches presented in random order. Tones were delivered in blocks at either fixed (180 ms) or at variable interstimulus intervals (ISI, 140 to 220 ms). In the ***BASELINE*** condition, the three pitches were evenly spaced in frequency (by six semitones, 1048, 1482, 2096 Hz). Subjects responded to infrequent (2.5%) longer duration tones (65 ms, Exp. 1) or infrequent louder tones (85 db SPL, Exp. 2) of a designated extreme pitch (1048 or 2096 Hz). In the ***GROUPING*** condition, the middle pitch was unchanged (1482 Hz) whereas the low or high pitched tones were made more similar (by one semitone) to tones of the middle pitch. It was hypothesized that the increased proximity of the irrelevant pitches would segregate them into a separate stream, thereby facilitating the monitoring of the target belonging to the relevant pitch. In both experiments, tonal grouping increased the number of correct responses and decreased RTs compared to the ungrouped condition. This grouping effect on RT was similar at a fixed or variable ISI. This result suggest that stream segregation is a general phenomenon that influences the speed as well as the accuracy of auditory identification.

LATERALIZED PROCESSING OF CENTRALLY PRESENTED VERBAL AND SPATIAL TASKS. F.G.Freeman‡ G.Pearson and D. Evans. Psychol. Dept., Old Dominion Univ., Norfolk, Va. 23529-0267.

In three separate experiments, subjects were required to attend to either their right or left ear in a dichotic listening, target ID task. In Experiment one, subjects simultaneously were required to perform a verbal task in which word pairs were centrally presented on a monitor. The words were to be identified as either antonyms or unrelated. In Experiment two, subjects simultaneously had to perform a mental rotation task in which two histograms were presented successively and had to be identified as being identical or mirror images. In Experiment three, subjects simultaneously performed a two dimensional tracking task in which two cursors had to be kept in the center of the video screen.

Results of Experiment one indicated that, for male subjects, attending to the right ear interfered with performance of the verbal task more than attending to the left ear. Ear attention did not differentially effect female performance. For Experiments two and three, for females, left ear attention interfered with performance on the spatial tasks more than right ear attention. For males attention did not effect spatial tasks.

NONTRIVIAL SEX DIFFERENCES IN BRAIN WEIGHT AND CRANIAL CAPACITY CONTROLLING FOR BODY SIZE. J.P. Rushton*. Department of Psychology, University of Western Ontario, London, Ontario, N6A 5C2, Canada.

Although it has long been known that human females have absolutely smaller brains (mass or volume) than do human males, it is widely thought that after correcting for body size the differences disappear. Two large data sets show that after covariance adjustment for body size, women's brains average 100 g lighter and 110 cm^3 smaller than men's.

First, Ankney (in press, Intelligence) reanalyzed autopsy data published in 1980 on 1,261 subjects between the ages of 25 and 80. Second, Rushton (in press, Intelligence) analyzed external head measurements (length, width and height) collected on a stratified random sample of 6,325 U.S. Army personnel in 1988. The sex difference in brain size was replicated across Black and White samples in the first study and across Asian, White, and Black samples in the second. These differences may be related to human evolution and those intellectual abilities at which males excel.

505.10

DEFECTIVE ORGANISATION OF KNOWLEDGE IN NON-DEMENT PARKINSONIANS: EVIDENCE FROM A SCRIPT PRODUCTION TASK. L. Godbout and J. Doyon*. Univ. Laval, Ecole de psychologie, Quebec, QC., Canada, G1L 7P4.

Shallice (1982,1988) and Grafman (1989) proposed that the frontal lobes are involved in organizing the representation of large-scale conceptual units, called scripts (Schank, 1975). Scripts refer to rehearsed sequences of events that have a typical temporal and semantic structure (eg. going to a restaurant). The purpose of this study was to examine whether the organisation of scripts would be affected in patients with Parkinson's disease. 16 Parkinson's patients and 16 normal control subjects were required to produce verbally scripts of common activities (eg. going to see a movie, shopping for grocery) in a forward and reversed order. According to Grafman, frontal-lobe dysfunction should affect both forward and reverse scripts. In contrast, Shallice predicted that frontal-lobe dysfunction should affect the production of non-familiar (reverse) scripts, resulting in sequencing errors. Basal ganglia dysfunction, on the other hand, should impair production of well-rehearsed (forward) scripts by the intrusion of non pertinent elements. Sequencing errors and alterations in the semantic structure of the script (eg. adding or deleting an element) were found in Parkinson's patients, but not intrusions. The semantic and sequencing errors found in both the forward and reverse condition were correlated with performance on others frontal-sensitive tests such as verbal and non-verbal fluency tests. The results indicate that the type of error made by the Parkinson's patients is the same as the one found in a group of patients with circumscribed frontal-lobe lesions (Godbout & Doyon, 1992), and are thus consistent with Grafman's, but not Shallice's hypothesis.

505.11

HABITUATION AND SENSITIZATION FOLLOWING BILATERAL ANTERIOR CINGULOTOMY. M.E. Meadows, R.A Cohen*, R.F. Kaplan, and H. Wilkinson. Dept. of Neurology, UMMC, Worcester, MA 01655

We studied habituation and sensitization of the orienting response (OR) following bilateral anterior cingulotomy. Skin conductance response (SCR) was measured during an orienting response paradigm in 4 pre- and 10 post-cingulotomy, and 10 age-matched control subjects. Pre-surgery, no patient exhibited impaired OR, habituation or sensitization. Post-surgery, patients exhibited abnormalities of habituation maintenance. Paradoxically, the initial rate of habituation after cingulotomy was more rapid compared to normal controls, yet slower relative to the criterion of complete habituation. Extended habituation training did not produce different effects on spontaneous recovery for patients and control subjects, nor was sensitization to new stimuli increased post-cingulotomy. A greater frequency of spontaneous activation and greater SCR variability over trials occurred post-cingulotomy. These results suggest that the cingulate cortex influences maintenance rather than rate of habituation.

505.12

DISRUPTION OF SHORT-DURATION TIMING FOLLOWING DAMAGE TO THE HUMAN SUPRACHIASMATIC REGION (SCN). R.A. Cohen and H.J. Barnes. Dept. Neurol., Univ. Mass. Med. Sch., Worcester, MA 01655, and H.E. Albers*. Dept. Biol, Georgia State Univ., Atlanta, GA 30303.

We previously demonstrated impairment of sleep-wake and temperature rhythms, and temporal attention dynamics in a human (AH) following SCN region destruction. We have since studied AH's short-duration timing. Severe disruptions of motor timing and time estimation compared to a age-matched controls was found. A tapping continuation paradigm was employed. The Wing & Kristofferson model was used to derive clock and motor-delay variance estimates. AH exhibited greater clock variances than previously reported after cerebellar lesions. AH's clock variances increased dramatically on a divided attention task, indicating that short-duration timing was greatly influenced by attentional biases. These results indicate that other neural systems, in addition to the cerebellum, may influence short-duration timing and also suggest a hierarchical role for the SCN in such timing.

505.13

DICHOTIC AND MONAURAL LATERALITY EFFECTS IN CALLOSAL AGENESIS. C. Paquette, I. Peretz* and M. Lassonde. Dept. of Psychology, Université de Montréal, C.P. 6128, Succ. A, Montréal, Qué. H3C 3J7, Canada.

In a recent study (Lassonde et al., B&L 1991), we reported that language functions, as assessed by dichotic listening performance, are more strongly lateralized in callosal agenesis subjects than in IQ-matched normal controls. However, the task used (CV detection) was so demanding that it produced a performance at chance in some of the subjects. The present study was thus designed to verify whether the stronger lateralization effect found in acallosals could be observed regardless of task difficulty. Four adult acallosal Ss and four IQ-matched controls were tested on two simple dichotic tests. The tasks consisted of word and musical timbre detection and were devised such that they would yield both laterality effects and high accuracy levels. The two tests were also presented monaurally since this easier procedure has occasionnally been reported to produce laterality effects. In terms of accuracy, the two groups performed at ceiling under both monaural and dichotic presentations (average performance: 96% correct). Analysis of response times, however, revealed different patterns for the two groups in the dichotic and the monaural conditions. In the dichotic condition, controls as well as acallosals, showed reliable laterality effects. In the monaural condition, controls did not demonstrate any ear advantage while acallosals still exhibited ear advantages of the same magnitude as in the dichotic condition. These findings suggest that callosal absence may weaken, rather than reinforce, the influence of ipsilateral auditory pathways. The results further suggest that the ipsilateral suppression normally observed under dichotic presentation is not related to callosal inhibition.

505.14

LOSS OF VISUAL IMAGERY BUT NOT SPATIAL LOCALIZATION IN A CASE OF VISUAL AGNOSIA IN CHILDHOOD. M. Lassonde*, A. Schiavetto, J. Flessas and G. Geoffroy. Dept. of Psychology, Université de Montréal, C.P. 6128, Succ. A, Montréal, Qué. H3C 3J7, Canada and Hôpital Ste-Justine, Montréal, Canada.

A.R. contracted a viral encephalitis at age 9. She was evaluated over a period of 4 years. CT scan revealed a right temporal hypodensity affecting gray and white matter and hyperdense sub-cortical zones in the left temporal and right parieto-occipital areas. A.R. showed evidence of associative visual agnosia, prosopagnosia and color agnosia. At first, she was unable to name objects from visual inspection but could do so by verbal description, tactual and auditory cues. Moreover, she could not recognize familiar faces or identify colors. With time, A.R. has shown limited improvement. She can now recognize familiar objects although occasionnally making intra-categorical mistakes. She can also name colors but cannot associate them to objects. Her prosopagnosia has not resolved. In fact, while she can match and copy visual representations of objects, she cannot do so in the case of faces. A clear dissociation between object and spatial representations is present in this patient. A.R. is unable to draw an object from memory but she can draw a map of familiar routes. She cannot correctly reproduce shapes that she has manipulated on a board but can accurately reproduce their localization. A.R.'s inability to recognize objects is interpreted as reflecting a deficit in the inferior temporal ventral pathway specialized for object perception, whereas the posterior parietal dorsal pathway specialized for spatial perception remains functional. Finally, the little recovery displayed by A.R. indicates limits in cerebral plasticity for visual agnosia.

A REACTION TIME BASED CONTINUOUS PERFORMANCE TASK FOR MEASUREMENT OF LATENT INHIBITION IN HUMAN SUBJECTS. L. A. Dunn*. Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

Latent inhibition (LI) occurs when repeated exposure to a non-reinforced stimulus inhibits later learning of associations to that stimulus. LI is an indirect measure of selective attention. Interest in the measurement of LI in humans has increased because of the finding that LI is reduced in acutely psychotic patients, and that LI in rats is sensitive to drugs that are dopamine agonists and antagonists. LI paradigms are limited in that they measure across groups of subjects and are difficult to repeat because of the learning effects of the preexposures and the subsequent associations. A continuous performance task for LI measurement that overcomes some of these limitations has been developed through a series of pilot studies. The task is divided into four phases. Subjects are instructed to watch a monitor and press a button each time a target X appears. Stimuli appear for 1 second with a 0.25 second inter-stimulus interval. During phases 1 and 3 20% of the stimuli are targets, 60% are letters, and 20% are a non-letter preexposure stimulus. During phase 2 a novel symbol always cues the target. The subject learns this through repetition and reaction times decrease. Phase 2 continues until the computer records 3 reaction times that are lower than those recorded in phase 1 or the subject has responded 99 times. During phase 4 the preexposed stimulus cues the target. Reaction times decrease as in phase 2. Reaction times are averaged for each phase. A subject demonstrates LI when the reaction time in phase 4 is slower than in phase 2. Pilot work shows that normal controls show LI in aggregate ($p<.0001$), and individually in 60% of normal controls at the 0.95 significance level. LI is robust after 3 weekly repetitions but learning effects appear to confound the test on the fourth repetition. (Supported by MH47503)

PERCEPTION OF HAND MOVEMENTS AFTER LEFT-HEMISPHERE DAMAGE. Doreen Kimura*. Psychology, Univ. Western Ont., London Canada N6A 5C2.

Left-hemisphere pathology often results in manual apraxia, a difficulty in selecting movements, to command or imitation. The author has proposed that the deficit relates to control of movements within personal space, with the body as framework. The question arises whether perception of movements is adequate in such cases. Since the processing of movements which can be reproduced might employ the same defective selection mechanism which impairs their production, the question is better asked outside the movement-generating framework.

Patients with left- or right-hemisphere damage (N= 77, 59) were scored on two tests: 1. Copying of meaningless hand movements, reliably sensitive to manual apraxia. 2. A test requiring them to point to which one of 4 unfamiliar symmetrical shapes was outlined in the air by E, using both hands. As before, left-damaged patients were significantly poorer at copying movements; but not in identifying hand-generated shapes. Manual apraxia is thus not a result of a deficit in processing hand movements in extra-personal visual space.

HOMOSEXUALITY, COGNITIVE ABILITIES AND THE ORGANIZATIONAL HYPOTHESIS. J. A. Hall* and D. Kimura. Dept. of Psychology, Univ. of Western Ontario, London, Canada, N6A 5C2.

Previous research has suggested that, due to potential differences in pre and/or perinatal levels of sex hormones, homosexual males may possess patterns of brain organization and cognitive abilities which fall intermediate between those of heterosexual males and females. The performance of 17 homosexual male undergraduates was compared to a heterosexual male control group (N=69) on spatial and verbal tasks which reliably show sex differences. Unlike previous studies, homosexual males showed no significant reduction on a task of spatial rotation; however, they were significantly outperformed by heterosexual males on a practical throw-to-target task. Additionally, a significant gay male advantage on an ideational fluency task and a significant non-gay advantage on a test of mathematical reasoning were found. Testosterone levels, assayed from saliva, showed no difference between gay and non-gay males. These data do not support the idea that homosexual males have ability profiles which are simply intermediate between heterosexual male and female extremes.

NICOTINE EFFECTS INTERHEMISPHERIC PROCESSING IN SIMPLE RECOGNITION VERSUS ARITHMETIC RELATED TASKS IN A SEXUALLY DIMORPHIC PATTERN. S.Demirgören*, M.Pehlivan, H.Aydın, Y.Çete, Ş.Pöğün. Dept. of Physiology, Ege University School of Medicine, 35100 İzmir, Turkey

Cerebral hemispheric specialization differs between sexes and the improving action of nicotine on cognitive functions may show sexual dimorphism. The aim of this study was to study the effects of cigarette smoking on interhemispheric processing. Male(M) and female(F) smokers and non-smokers were tested using a computer-based program where numbers were projected randomly to different visual fields. In one set of trials, the subjects had to recognize matching pairs; in the other set, they had to perform a simple calculation. For all groups, the trials were repeated with a 15 min. interval during which the smokers, deprived for 12 hrs, smoked a standard cigarette. Reaction times and the number of correct responses were evaluated(ANOVA). In simple recognition tasks(SRT), F smokers performed better in tasks designed to test right hemisphere function ($p<0.05$) with regard to reaction time. In arithmetic related tasks(ART), however,F smokers had more correct responses in tasks designed to test left hemisphere function($p<0.005$). In SRT, smoking shortened reaction times during the second trial more prominantly in Fs ($p<0.005$). In ART however, M smokers benefited more from nicotine regarding reaction times($p<0.05$). M smokers were affected more from nicotine deprivation in ART($p<0.05$)and F smokers more in SRT($p<0.05$). Our results imply that nicotine improves interhemispheric processing of SRT and ART in a sexually dimorphic pattern.

505.19

TYROSINE REVERSES A COLD-STRESS-INDUCED MEMORY DEFICIT IN HUMANS. D. Shurtleff*, J.R. Thomas, J. Schrot, K. Kowalski, R. Harford, M.O. Thornton, P.A. Shea and M. Malik. Naval Medical Research Institute, Bethesda, MD 20889-5055.

Eight male subjects performed a delayed matching-to-sample (DMTS) task at an ambient temperature of 4°C (cold) or 22°C two hours after ingesting the catecholamine precursor tyrosine (150 mg/kg) or placebo, administered double-blind. The DMTS task required a correct choice to one of two simultaneously presented matrices, one of which had been presented as a sample matrix 2, 8 or 16 sec before. Each matrix was composed of 32 red and 32 green squares, randomly distributed. After ingesting placebo at 22°C, subjects demonstrated a characteristic delay gradient in which accuracy declined as the delay interval increased between sample and comparison stimuli from 2 (Mean percent correct=83.76% ± SEM=1.38) to 8 (80.21% ± 1.66) to 16 (69.31% ± 2.60) sec. A one hour cold exposure following placebo ingestion significantly reduced matching accuracy at the 16-sec delay interval (50.41% ± 2.06), which is attributed to cold's effect on short-term, or working, memory. Administration of tyrosine significantly improved matching accuracy at the delay interval affected by cold exposure (16-sec), such that mean matching accuracy was 65.76% ± 2.8, equal to that at 22°C following placebo ingestion. Plasma norepinephrine, epinephrine and tyrosine levels during cold and 22°C exposure were also measured and will be presented. These results indicate that tyrosine was effective in ameliorating cold stress effects on DMTS performance, possibly by preventing a cold-stress-induced reduction in brain catecholamine levels.

DYNAMICS OF MODULATED NOISY BIOLOGICAL SYSTEMS. D.R. Chialvo, C.J. Hodge* and A.V. Apkarian. Computational Neuroscience Program, Dept. of Neurosurgery, SUNY Health Science Center, Syracuse, New York 13210.

The output signal from noisy bistable systems can be modulated in time by applying a weak external periodic forcing. Such systems when driven with noise exhibit Poisson distributed intervals (ISIH). When a sine wave is added to the input noise, the ISIH is multipeaked at multiples of the sine wave period with an exponential envelope. For certain amplitudes of noise and signal, bistable systems exhibit an increase in signal-to-noise ratio with an increase in input noise (stochastic resonance). Here we present: 1. numerical simulations of a neuron, 2. single unit recording experiments, and 3. a visual perception task, to show that the theory of bistable systems can be applied to information processing in the brain.

1. A two dimensional difference equation model of excitable tissue driven with white noise results in spike trains with a Poisson ISIH. For a fixed noise amplitude, increasing the amplitude of an additional sine wave input results in spike trains with multipeaked ISIHs which become single peaked at higher sinusoidal amplitudes.

2. In anesthetized cats, single unit responses were studied in the spinal cord and the somatosensory cortex. Rapidly adapting type neurons showed multipeaked ISIHs during sinusoidal vibrotactile stimulation of the receptive field. The envelope of these ISIHs had an exponential decay which increased with stimulus amplitude.

3. A cognitive visual task was developed to study hysteresis in viewing ambigous figures. Subjects were familiarized with and tested to rank images consisting of a smooth transiton from the face of a man to the body of a woman. The input/output map for ranking random sequences of these images showed hysteresis and was modeled as a 1-D piecewise linear map. When the images were presented iteratively with underlying noise and periodic modulation, increases in noise amplitude increased the perceptual signal-to-noise ratio, exhibiting bistable stochastic resonance. This paradigm can be used to study short term memory.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS—MODELS

506.1

NEUROPOPULATIONAL MECHANISM OF PARALLEL CORTICAL PROCESSING IN THE MILLISECOND RANGE. K. Nakamura*. Grad. School of Sci. & Eng., Tokyo Inst. of Tech., 4259 Nagatsuta, Yokohama 227, Japan.

The cerebral cortex is capable of processing sensory signals to work the motor system in a few hundred milliseconds, though single neurons relatively slow to respond (several milliseconds). A mathematical model of the cortical processing is presented to show the processing is performed in an optimal parallel style. The cortex is represented by a sequence of areas consisting of cortical columns. Each column includes two populations of pyramidal cells and interneurons inhibiting the cells. Membrane characteristics of the model neurons is represented by the Hodgkin-Huxley electric circuit. Analysis of the model shows (1) the columns are capable of detecting several milliseconds with ratios of firing cells in the populations, even though firing of single cells fluctuates, (2) the areas perform *competitive parallel computation* using the temporal resolution, where only the first activated columns are allowed to fire out of the columns activated in parallel, and (3) synaptic plasticity regulated by the hypothalamic reward system reinforces association connections between the areas so that the competitive computation may lead to rewarding move of muscles. (1) and (2) indicate processing of each area completes in several milliseconds. This and (3) suggest repetitive rewards reinforce the whole cortex to respond to sensory stimuli within a few milliseconds.

506.2

EXPECTATION LEARNING IN THE BRAIN USING DIFFUSE ASCENDING PROJECTIONS

S. R. Quartz*, P. Dayan, P. R. Montague, T. J. Sejnowski, The Salk Institute, La Jolla, CA, 92037.

Diffuse projections originating in subcortical nuclei are known to influence activity-dependent cortical plasticity and learning both during and after development. These signals may report to the cortex important events in the world as well as which activity patterns in the cortex result from actions taken by an organism e.g. proprioceptive signals associated with a movement. Although a number of physiological actions have been attributed to the neurotransmitters used by these pathways (acetylcholine, norepinephrine, serotonin, etc.), their precise functional effects on learning within a large network of neurons are unknown. We explore here a theory in which the derivative of the activity of the ascending pathway drives learning at cortical synapses. This learning is gated locally by a rapid diffusible signal produced by glutamate transmission in a local volume of tissue. We call this effect *volume learning*. This scheme forces the cortical networks to *learn to predict the future changes in activity in the ascending pathway*. Moreover, a powerful influence driving cortical learning obtains when one part of the cortex captures control over the mid brain structures that release the neuromodulators. This occurs by allowing for modifiable NMDA synapses on the path from cortex to the midbrain nuclei. Using a large scale computational model we demonstrate the theory and test it in a variety of tasks including visual recognition. This scheme may result in impoverished cortical representations in the absence of some way by which cortical patterns can be combined, recoded, and redistributed to the cortex. We show how the hippocampus can play a natural role in restructuring representations to make this prediction possible.

506.3

HOW PLACE CELLS CONNECTED BY HEBBIAN SYNAPSES CAN SOLVE SPATIAL PROBLEMS. R. Saypoff, R.U. Muller* and J.L. Kubie. Depts of Anatomy and Physiology, SUNY, Brooklyn. Brooklyn, N.Y. 11203

If place cells are connected by Hebbian (eg, LTP-modifiable) synapses, the strength of the synapse between a pair of cells will come to encode the distance between the firing fields of the twocells. A synapse between cells with overlapping fields will strengthen because the two cells will fire together at intervals short enough for LTP to occur. In contrast, synapses between cells with separated firing fields will remain weak because the two cells never fire in close temporal order. In this preliminary approach, such synapses do not affect the firing of the post-synaptic cells; they only register the degree to which the two cells fire together in time.

If strength/distance encoding is added to a network that models the recurrent connections of CA3 (Traub and Miles, 1991), the result is an environmental representation that has the properties of a weighted graph. If a starting point and an end point in real space are specified, a searching algorithm can be used on the graph to find the shortest path in reciprocal synaptic weight space. The sequence of place cells on this path corresponds to a path through real space. The length of the path in real space is very long if the network is small or sparsely connect. As the network becomes richer, however, the algorithmically computed path length converges on the Euclidian distance between the starting and end points. The size and connectivity of adequate networks compare reasonably to the real thing. We conclude that graph-like networks of the proposed type contain enough information to make it possible to compute the shortest distance between any pair of points in the environment. They therefore fulfill many of the requirements for the hippocampal mapping system first proposed by O'Keefe and his colleagues.

506.4

INFORMATION PROCESSING IN EXCITABLE DENDRITES. B. W. Mel*, Computation and Neural Systems Program, Caltech, 216-76, Pasadena, CA, 91125.

Compartmental modeling studies of the input-output behavior of NMDA-rich neocortical pyramidal cells have previously shown that their dendritic trees were "cluster-sensitive", i.e., gave rise to larger cell responses when synapses were activated in clusters, rather than diffusely scattered about the dendritic arbor. This work has been extended to cells containing fast sodium and slow calcium spiking mechanisms in various distributions throughout the dendritic tree. Results of simulations show that strong cluster sensitivity can result when the dendrites contain 1) only NMDA channels, 2) only fast spiking channels, 3) only slow-spiking channels, or 4) combinations of any two or three of these voltage-dependent mechanisms in a variety of spatial distributions.

A model neuron called a "clusteron" was used to abstract the cluster-sensitive behavior of a dendritic tree containing excitatory membrane mechanisms, and to explore a family of Hebb-type synaptic learning rules capable of manipulating the ordering of afferent synaptic connections onto the dendritic arbor. It is shown that the dendritic tree of a single pyramidal cell, if richly endowed with excitatory voltage-dependent nonlinearities, is capable of reliably discriminating thousands of learned complex patterns from unfamiliar controls. It is also shown that a cluster-sensitive dendritic tree can approximatively implement a cross-correlation operation, relevant to biologically significant nonlinear sensory processes such as binocular disparity selectivity.

SIMULATIONS OF ADAPTIVE INTERACTIONS BETWEEN LIMBIC AND NEOCORTICAL STRUCTURES. S. D. Murphy and E. W. Kairiss*, Department of Psychology and The Interdepartmental Neuroscience Program, Yale University, Box 11A Yale Station, New Haven, CT 06520.

Current views of long-term memory storage in mammals emphasize the importance of dynamic interplay between limbic structures (amygdala and hippocampus) and cortical areas (e.g. L.R. Squire & S. Zola-Morgan, *Science*, 253:1380, 1991). The goals of this study were to construct a computational model that incorporates selected features of temporal lobe physiology and anatomy, and to examine the dynamical behavior of the adaptive processes that might support memory formation.

Hippocampal subfields (fascia dentata, CA3, CA1) were represented as networks of compartmental neurons, whose physiological properties, statistical connectivity and principal neuron:interneuron ratio were abstracted from physiological studies. A simplified cortical region was constructed as a multilayer network of cortical pyramidal and non-pyramidal neurons; this network was reciprocally connected with the hippocampal networks. Input patterns were applied to the cortical and hippocampal structures in tandem, and stable cortical activity patterns (cell assemblies) were used as measures of information storage. Our studies focussed on two properties thought to be important for mnemonic function: use-dependent synaptic plasticity (particularly at the hippocampo-cortical connections) and the role of theta rhythm in synchronizing connected systems. The spatio-temporal interactions between these phenomena were found to be important for the emergence of dynamic assemblies in the cortical network.

These computational studies will provide a framework for future analytical and experimental investigations of the dynamic processes underlying distributed memory storage in cortical systems.

506.6

IS FIELD CA3 A REVERBERATING SHORT TERM MEMORY SYSTEM? M. Taketani, J. Ambros-Ingerson, R. Myers, R. Granger and G. Lynch*. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

Given its placement on the olfactory-hippocampal circuit and unique anatomical features, it has been hypothesized that field CA3 of hippocampus maintains cue-specific activity after the cue is gone (and behavior continues) by generating recurrent and specific patterns of activity set in motion by momentary perforant path input, thus providing a short term memory system that can be used to form associations between cues that are separated in time and space.

To explore this hypothesis, we have constructed a computer model that incorporates many salient anatomical and physiological features of this region. CA3 has a large population of pyramidal cells and is unique in its extremely dense recurrent associational system which comprises ~70% of the synaptic population (ipsilateral and contralateral). A smaller population of interneurons mediate fast and slow inhibitory currents. The model consists of 300 pyramidal cells, mossy fiber inputs, and a collection of interneurons. Total connectivity is less than 10% and is divided into global (random across the network) and local (random but spatially restricted) patterns for the various kinds of cells. Cells are modeled as single compartments (1) incorporating driving force effects, multiple synaptic currents overlapping in time, axonal delays and frequency facilitation. Baseline theta activity (5Hz) is generated by extrinsic input and on its own does not reliably trigger pyramidal cells.

Preliminary results indicate that recurrent patterns of activity can be generated in this network. Perforant path stimulation that resulted in activation of a few (~1%) pyramidal cells can generate recurrent activation, specific to the initial input, that can last for ~100 ms. Further experimentation with the model and network scaling is expected to improve performance. Thus, in principle, salient anatomical and physiological features of CA3 can be integrated to form a reverberating short term memory system. (supported by grants from ONR and Matsushita Electric Industrial Co., Ltd.)

SEQUENTIAL CONFIGURATION MODEL AND TRACE DISRUPTION IN LOCAL NEURAL NETWORKS. K.A. Flach[1], R.J. MacGregor[1], G.A. Gerhardt*[2]. [1]Dept. Of Aerospace Engineering, University of Colorado, Boulder, Colorado, 80309, [2]Dept. of Psychiatry, Denver, University of Colorado Health Sciences Center, Denver, CO 80262.

The sequential configuration model is an explicit model of coordinated multi-unit firing patterns for representing information in neural populations. A sequential configuration is an ordered sequence of sets of cells whose temporal firing relationships define its pattern. This work applies the sequential configuration model to represent memory storage and retrieval in two interconnected and recurrently connected populations of cells, one excitatory and one inhibitory, representative of cortical modules. Individual traces can be selectively recalled by extrinsic stimulation of the network. The recurrent connections inherent in the trace produce internally sustained recalls of the sequential configurations. A theoretical derivation of memory capacity has shown the level of cross talk, produced when cells participate in more than one trace, is a random variable with mean and variance functions of network size. Calculations of storage capacity show that the variance of the cross talk becomes small for cortical module size nets (30,000 cells). Random noise reduces the storage capacity to 1/3 the value from cross talk alone. Results from computer simulations are accurately predicted by this theory. Detailed simulations have shown how cross talk can limit the number of traces that can be successfully recalled. The cross talk raises the average cell potential, producing a burst of activity. This burst causes many cells in the trace to be refractory at the same time, and produces simultaneous activation of a large population of inhibitory cells. This renders the trace nonrecallable. MacGregor, R.J. Sequential configuration model for firing patterns in local neural networks Biol. Cybern. 65, 339-349, 1991.

A MODEL OF FRAGMENTED SPATIAL MEMORY. Catherine Thinus-Blanc* & Marielle Krimm Cognitive Neuroscience Laboratory, CNRS, 31, ch. J. Aiguier 13402 Marseille Cedex 9 France. Tel: 91 16 40 88

Although the old opposition between behaviorists and cognitivists is now obsolete, the dual conception of two extreme and sometimes mutually exclusive forms of spatial memory is still alive. We propose another conception based on several inter-related levels of processing of a common "material", namely frontal local views whereby any terrestrial vertebrate, including human, has visual access to the environment. Some of these local views (or topographical maps), stored in long-term memory, are the building-blocks of different forms of spatial knowledge.

This conception calls for several remarks. First vision is endowed with a definite spatial function supported by data from studies of unsighted adult subjects.

Second, since topographical maps are assumed to be processed in different ways by the same individual, their storage and handling should be executed by distinct brain structures. In line with recent hypotheses, the topographical maps would be stored in visual areas whereas associative structures such as the hippocampus would be the repository of their "combinatorial" code.

This model leads to several hypotheses and predictions which will be evoked.

506.9

PHYSIOLOGICAL MEASUREMENTS PREDICT THE LIFETIME FOR HUMAN AUDITORY MEMORY OF A TONE

Z.L. Lü, S.J. Williamson* and L. Kaufman. Neuromagnetism Lab., Depts. of Physics and Psychology and Center for Neural Science, N.Y.U., New York, NY 10003**.

Using the Magnetic Source Imaging (MSI) technique, we found that responses to tone stimuli observed in the primary and association areas of human auditory cortex provide evidence that the neuronal activation trace established by a stimulus decays exponentially with time, and the lifetime in association cortex is significantly longer than that in primary cortex in individual subjects. The strength of the activation trace at a time t following a stimulus was defined as the difference between the averaged response amplitude for a very long interstimulus interval and the averaged response amplitude for a given interval t. The difference was found to decrease exponentially according to $e^{-(t-t_0)/\tau}$, where τ is identified as the lifetime of the cortical activation trace. Behavioral measurements on the same subjects reveal that the short-term loss of auditory memory shows a central tendancy, namely, the internal representation of the loudness of a sound evolves as a decaying exponential toward the mean of all the stimuli experienced in the recent past. The time course is well predicted from the MSI measurements of the lifetime of the activation trace in human primary auditory cortex. This close agreement suggests that primary auditory cortex plays a significant role in echoic memory. This application of MSI and behavior studies opens new opportunities to relate human physiology and cognition.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS—NEUROPSYCHOLOGY II

507.1

HUMANS, LIKE RATS, HAVE SPATIAL WORKING MEMORY CAPACITY GREATER THAN SHORT-TERM MEMORY CAPACITY OF 7±2.

R. B. Glassman* and R. C. O'Connor. Dept. of Psychology, Lake Forest College, Lake Forest, IL 60045.

Although humans show short-term memory capacity of 7±2 items for a wide variety of tasks (Miller, Psychol. Rev., 1956; recent review: Baddeley, Science, 1992), rats have a working memory capacity of ≥12 in the radial maze (Olton, Collison, & Werz, Learn. Motiv., 1977). Is this a species or situational difference? Using a 17-arm radial maze analog drawn on paper, human subjects attempted to lift in random order each of 17 cardboard flaps arranged radially around a center. Fifteen undergraduates, each tested on 14 trials (each trial limited to 17 choices) averaged 15.4 correct responses. This suggests memory capacity comparable to rats. Miller's (1956) discussion of information load in absolute judgments implies a reason for greater spatial working memory capacity, in the two-dimensionality of the radial maze by comparison with the "linearity" of verbal sequences. Our finding presents a difficulty for the hypothesis that STM is a neurocognitive constant, based on widespread characteristics of mammalian cortex (Glassman, Neurosci. Abs., 1991).

507.2

ATTENTIONAL DEFICITS IN KORSAKOFF'S DISEASE.

H.L. Young* & R.G. Mair. University of New Hampshire, Department of Psychology, Durham, NH 03824.

Response times were measured for Korsakoff and alcoholic control subjects to execute key-press responses following presentation of a visual target preceded by a cue. Korsakoff patients responded more slowly in all conditions, however, their performances were significantly more impaired when cue and target occurred in different locations and when endogenous processing was required to interpret a cue. Comparable results were obtained when cues were not presented, but were expected in a location different from the target. We argue that the Korsakoff patients are impaired in their ability to disengage attention and shift it to a spatially distinct location.

507.3

THE ROLE OF THE PREFRONTAL CORTEX IN HUMAN WORKING MEMORY: rCBF ACTIVATION DURING A SPATIAL DELAYED RESPONSE TASK.

C. Randolph*, K.F Berman, T.E. Goldberg, and D.R. Weinberger. Clinical Brain Disorders Branch, NIMH, Washington DC 20032.

Numerous animal studies have suggested a role for the prefrontal cortex in working memory processes. We developed a computer-administered human analogue of a spatial delayed response (SDR) task in order to study patterns of blood flow activation associated with the cognitive demands of this task. Subjects were required to remember the locations of 4 identical stimuli within an array of 20 possible locations, over a delay of 7 seconds. Patterns of regional cerebral blood flow (rCBF) during this task were compared to rCBF during a no-delay control task. Fourteen normal volunteers were studied using a PET $H_2{}^{15}O$ water technique. The results of this study support the hypothesis that the prefrontal cortex is involved in the cross-temporal maintenance of response-relevant information.

507.4

DISSOCIABLE COMPONENTS OF SENSORY-MOTOR SKILL LEARNING IN PATIENTS WITH HUNTINGTON'S DISEASE.

J. Singh*, J.D.E. Gabrieli, D.B. Willingham, K. Kirschner, G.T. Stebbins and C.G. Goetz. Dept. of Neurological Sciences, Rush-Presbyterian-St.Luke's Medical Center, Chicago IL 60612 and Rehab. Institute of Chicago, Chicago, IL 60611.

Sensory-motor skill learning has been dissociated from explicit memory in global amnesia and from repetition priming in Alzheimer's disease (AD). Patients with Huntington's disease (HD) learn poorly on some sensory-motor skill learning tasks, and these results suggest a critical role for the frontal-striatal system in these tasks. The present study examined whether two different kinds of sensory-motor skill learning, rotary pursuit and mirror tracing, are neurologically dissociable from one another. The subjects were 6 early-stage HD patients and 6 normal control (NC) subjects. For the rotary pursuit task, speed of rotation was adjusted for all subjects to equalize initial levels of performance, and subjects performed 4 20-second trials in each of 6 blocks. The main measure of learning was time on target. For the mirror tracing task, subjects traced a star seen in a mirror for 5 trials. The measures of learning were time to trace the star and the number of departures from the star. The HD patients showed impaired learning on the rotary pursuit task, but not on the mirror tracing task. These results suggest that there are at least two dissociable components of sensory-motor skill learning, and that one component, critical for rotary pursuit learning, is mediated by the frontal-striatal system. Preliminary data from two patients with cerebellar lesions suggest that another component, critical for mirror tracing, is mediated by a cerebellar system. Supported by a grant from the McDonnell-Pew Cognitive Neuroscience Program.

507.5

IMPAIRED WORKING MEMORY IN UNMEDICATED ADULTS WITH GILLES DE LA TOURETTE'S SYNDROME. G.T. Stebbins*, J. Singh, J.D.E. Gabrieli, C.L. Comella, and C.G. Goetz. Department of Neurological Sciences, Rush-Presbyterian-St.Luke's Medical Center, Chicago, IL 60612 and Department of Psychology, Stanford University, Stanford, CA 94305

We assessed memory performance (including working memory (WM), immediate and long-term memory, and motor skill learning) in a sample of 13 unmedicated adult GTS patients, and 10 healthy controls (NC) matched for sex, mean age and education. WM was assessed using a verbal working memory task (Salthouse & Babcock, 1990) which required the subject to answer questions about orally presented sentences, while simultaneously remembering the last word in the sentences. Immediate memory was assessed with forward and backward word span tasks. Long-term memory was assessed with free-recall and forced-choice recognition of word lists, and vocabulary knowledge (WAIS-R Vocabulary subtest). Motor skill learning was assessed with the rotary pursuit task. GTS patients were impaired on working memory ($p<0.01$), word span backwards ($p<0.005$), long-term free recall ($p<0.05$), and rotary pursuit learning ($p<0.005$). In contrast, GTS and NC performed comparably on long-term recognition memory (forced-choice recognition), long-term semantic memory (WAIS-R Vocabulary subtest), and one test assessing immediate memory (word span forward). This pattern of memory performance is similar to that seen in diseases of the basal-ganglia (Parkinson's disease and Huntington's chorea), and suggests that the memory deficits in GTS may be due to selective frontal-striatal dysfunction.

Supported by the Tourette Syndrome Association.

507.6

PREFRONTAL CORTEX INVOLVEMENT IN WORKING MEMORY. L. Nielsen-Bohlman* and R. T. Knight; Neurology Dept., UC Davis, VAMC, 150 Muir Rd, Martinez CA 94553

We examined prefrontal contributions to immediate and sustained components of working memory by recording long latency ERPs in patients with lesions in dorsolateral frontal cortex (n=10, mean age=64 years; controls n=10, mean age 71 years) in a recognition memory paradigm. Stimuli were line drawings of familiar objects presented in quadrafields (duration 800 msec, ISI 1200 msec). Eighty percent of the images were presented twice. The second presentation occurred at 1.2 sec with no intervening images (immediate), or at delays of 4-158 sec with a mean of 40 intervening images (delayed). Subjects indicated whether an image had been previously presented by pressing a 'yes' or 'no' button. Control subjects showed enhanced frontal positivity to all stimuli (at Fpz 15.9uV) which was reduced in the frontal patients at all intervals (7.8uV, $p<0.025$). Stimulus identification was impaired for the immediate repetition, but was normal for delayed repetition. Long latency parietal activation (P600) was normal at all delays while an earlier latency P400 component generated by immediate stimulus repetition was selectively reduced by prefrontal lesions. The data support prefrontal activation during working memory and indicate that prefrontal lesions result in selective behavioral and electrophysiological deficit during immediate recognition.

507.7

INFLUENCE OF FRONTAL LOBE LESIONS ON SUBJECTIVE ORGANIZATION IN VERBAL LEARNING. P.J. Eslinger* & L.M. Grattan. Depts. of Neurology, Penn State Univ. College of Medicine, Hershey, PA 17033, & Univ. of Maryland Medical School, Baltimore, MD 21201.

Subjective organization (SO) refers to the extent to which subjects spontaneously impose a sequential structure on the free recall of unrelated words. It is well established that SO is important to efficient learning and memory in normals; however, the neuroanatomic underpinnings of this process are minimally known. In light of recent findings implicating the frontal lobes in spatial-temporal processing, we hypothesized that frontal lobe lesions may cause a disproportionate deficit in subject-imposed sequential organization. To investigate this possibility, we compared the SO of 30 patients with stable, focal lesions to frontal and non-frontal cerebral regions. Using a free recall paradigm, each subject was administered a 15 word list for 5 learning trials. We tabulated the extent to which each subject imposed a second-order sequential organization among recalled words, using the standardized formula derived by Tulving (1962). Results indicated: 1) A diversity in SO performance amongst the frontal lesion group depending upon specific lesion site. Subjects with dorsal lateral frontal lesions obtained lower SO scores than the orbital frontal lesion group; and 2) Subjects with dorsolateral frontal lesions also obtained lower SO scores than non-frontal lesion subjects, but the SO of the orbital frontal and non-frontal lesion groups did not differ. We propose that the dorsal lateral frontal lobe plays an important role in the subjective organization of unrelated words in free recall, but the orbital sector does not.

507.8

EVIDENCE FOR A DOUBLE DISSOCIATION AMONG LEARNING PARADIGMS IN PATIENTS WITH FRONTAL AND NON-FRONTAL CEREBRAL LESIONS. L.M. Grattan,[1] *P.J. Eslinger[2] & K.E. Mattson.[1] Depts. of Neurology, [1]Univ. of Maryland Medical School, Baltimore, MD 21201 & [2]Penn State Univ. College of Medicine, Hershey, PA 17033.

A variety of experimental procedures have been identified for investigating the conditions under which learning occurs. Studies have commonly employed three major learning paradigms: free recall, paired associate learning, and serial learning. Factor analytic study of normals has demonstrated that serial learning may operate independently from paired associate and free recall learning, clustering with executive measures on a "frontal lobe" factor (Eslinger, Grattan, Benton, 1988). This difference raises the possibility that these learning paradigms are subserved by different neural systems. To test this hypothesis, we examined 30 patients with CT/MR verified frontal and non-frontal lobe lesions with standardized measures of verbal free recall, paired associate learning and serial digit learning. Results indicated a dissociation amongst the 3 learning paradigms. The frontal lobe group demonstrated significantly greater impairment on the serial learning task while the non-frontal lobe group had more deficiencies on associate learning and free recall tasks. The results support the hypotheses that 1.) serial learning may involve distinctive processes from other learning paradigms and 2.) the frontal lobes may have a specialized role in establishing the stable temporal-spatial positions necessary for serial learning.

507.9

CASE-STUDY EVIDENCE FOR A CRITICAL AND SPECIFIC RIGHT OCCIPITAL-LOBE CONTRIBUTION TO PERCEPTUAL IDENTIFICATION REPETITION PRIMING. D.A. Grosse*, J.D.E. Gabrieli, and S.L. Reminger. Rush Medical College, Chicago, IL. 60612.

Two case studies are reported that suggest right occipital mediation of one form of visuoperceptual implicit memory but no critical role for that same brain region in conceptual implicit memory or in explicit memory. Subjects were 2 patients with unilateral left or right occipital resections. The performance of the left occipital patient was compared to 3 matched controls on a perceptual implicit test of word perceptual identification (PI), with a matched yes/no explicit memory recognition test, and a conceptual implicit memory test of category exemplar generation (CE), with a matched cued recall explicit memory test. For the PI and recognition study, subjects read aloud 24 words each presented twice. For the PI test, subjects identified briefly presented and masked words (24 repeated, 24 baseline). Perceptual priming was measured as the advantage in identifying repeated versus baseline words. For the recognition test, subjects judged whether 48 words (24 repeated, 24 foils) were seen in the study phase. For the CE and cued recall study, subjects made semantic or surface-level judgments about 48 low-typical exemplars in 6 semantic categories. For the CE test, subjects were given 12 category names and asked to provide 8 exemplars; 6 categories provided a baseline measure. Conceptual priming was measured as the number of study-list exemplars generated relative to baseline. For the recall test, category names were used as cues to recall study list words. The right occipital patient showed normal levels of conceptual priming, yes/no recognition accuracy, and cued recall accuracy, but no PI priming. The left occipital patient showed normal magnitudes of priming and normal levels of recall and recognition accuracy. These results (1) show a dissociation between the neural substrates supporting perceptual and conceptual implicit memory; (2)suggest that right occipital cortex mediates at least one component of perceptual implicit memory; and (3) provide a reverse dissociation to that seen in global amnesia, with impaired implicit memory on the PI test despite intact explicit memory on the recognition test. Supported by McDonnell-Pew Cognitive Neuroscience Program.

507.10

VERBAL IMPLICIT RECALL OF SUBJECT PERFORMED TASKS BUT NOT VERBAL TASKS IN ALCOHOLIC KORSAKOFF'S AMNESICS. T.W. PARKER*, Department of Psychology, Augustana University, Camrose, Alberta, T4V 4A2

Implicit recall of subject performed tasks (SPT's) versus verbal tasks (VT's) was tested for alcoholic Korsakoff patients with dense amnesia and for normals. Tasks involved having subjects either perform (SPT) or describe (VT) an unusual manipulation of pairs of common objects. Implicit recall tests, which made no mention of the earlier study phase, were then conducted after 10 minutes, 24 hours and 30 days for each subject. No feedback was given during the tests.

An overall ANOVA for repeated measures showed significant main effects for tests and for task type, and a significant test by task interaction. These results indicated that for both groups implicit recall of SPT's was markedly superior to that of VT's and that more decay over tests occurred for VT recall. This decay was more pronounced for Korsakoff subjects. However overall Korsakoff performance did not differ from normals, especially in recall of SPT's.

These results are seen as supporting the proposal that SPT's involve implicit memory components (Nilsson & Backmann, 1989) and hence are recalled normally by amnesics, in contrast to verbally mediated tasks. On the other hand, better recall of VT's by the normals suggests they may be using explicit memories to aid their recall.

507.11

SEPARATING DECLARATIVE MEMORY AND PROCEDURAL LEARNING IN ALCOHOLIC AMNESICS. A.G.M.Canavan, V. Hömberg and G.E. Stelmach* Neurological Therapy Centre, University of Düsseldorf, Federal Republic of Germany, W4000 Düsseldorf 13.

Abstinent alcoholic amnesics (n=10), as defined by performance on a battery of verbal and visuospatial declarative memory tasks (e.g., memory for stories, memory for abstract designs), were also severely impaired in the Sternberg memory scanning paradigm compared to alcoholic non-amnesics (n=8) and healthy controls (n=9). Standard tests of short term memory (e.g., digit span, block tapping span) yielded mixed results.

Procedural learning was intact in the amnesics. Learning to draw with only a mirror image as visual guidance improved normally within and between two consecutive daily sessions, with the amnesics eventually achieving performances identical to those of controls, despite the fact that they were initially much poorer.

On a new computerised version of the fragmented pictures task, administered over three consecutive days, the amnesics were unable to say (free recall) which famous faces they had seen the day before, but they were able to identify the masked pictures sooner (i.e., with a higher degree of masking) if they had seen them the day before than if the pictures were novel. Visual scanning of the facial stimuli, as assessed with an infrared eye-movement recording system (ASL EM-Monitor 210) was not abnormal in either alcoholic group, providing yet another dissociation between procedural and declarative elements of task performance, and ruling out an attentional deficit as underlying impaired recall.

507.12

SPEECH ONSET IN BOY AGED 10 FOLLOWING LEFT HEMISPHERECTOMY AND WITHDRAWAL OF ANTICONVULSANTS. F. Vargha-Khadem and E. Isaacs. Institute of Child Health and Hospital for Sick Children, London, England. (SPON: European Brain and Behaviour Society)

Patient PO, born with port-wine stain characteristic of Sturge-Weber Disease, developed seizures neonatally that later turned intractable. By six months of age, PO exhibited right hemiplegia and hemianopia. By age 8½, though PET and MRI-scans revealed a normal right hemisphere, PO's developmental age was less than 2, and his only spoken word was "mama". Left hemispherectomy, performed when PO was nearly 9, arrested all seizures, but anticonvulsants were continued as prophylaxis for one year. Follow-up at this time showed virtually no change in cognitive development, at which point anticonvulsants were withdrawn. One month later, PO began speaking, initially in single words but then progressing rapidly to phrases and long sentences. Now age 11, his mental age is 6 years, receptive vocabulary 5.11 years, productive grammar 6.6 years, and mean length of utterance nearly 7 years. PO's rapid and constant improvement to date indicates that further progress is to be expected. This surprising outcome challenges the traditional view pertaining to critical periods for the development of language and speech.

507.13

SLOW CORTICAL POTENTIALS IN CLASSICAL CONDITIONING. H.Flor, N.Birbaumer, W. Lutzenberger, and T.Elbert*. Inst. of Medical Psychology, Univ. of Tübingen, 7400 Tübingen, FRG.

The repeated occurrence of events with high probabilistic associaton elicits a distinct brain reponse, the contingent negative variation (CNV), which may be used as a tool in the description of the associative process during conditioning. It was assumed that the early component of the CNV (initial CNV, iCNV) might represent the amount of anticipatory arousal with respect to the US that is elicited by the CS and would thus be especially sensitive to changes in meaning of the CS over time. The late component of the CNV (terminal CNV, tCNV) should indicate preparation for the CR.

Experimental evidence from a differential conditioning study in humans that used slides with varying emotional content as CS, electric shock as US, and autonomic and motor responses as UR/CR, indicated a clear lateralization of the tCNV on the side of the CR. A significant differentiation between the CS^+ and CS^- could be observed. The quality of conditioning was reflected in the height of the tCNV.

The data from this experiment suggest that the CNV may be regarded as a valid measure of the associative strength during classical conditioning.

ELECTROPHYSIOLOGICAL INDICANTS OF READING DISABILITY OBTAINED IN THE FIRST AND THIRD GRADE. S.L. Miller*. Dept. of Psychology, University of North Carolina at Greensboro, Greensboro, NC 27412.

Fifteen reading disabled (RD) and fifteen non-reading disabled (NRD) subjects, selected as being "at-risk" for later reading problems, were compared on event-related potentials (ERPs) and behavioral measures. ERPs were recorded during a black-white discrimination task of visually presented letter and non-letter stimuli when the subjects were an average age of 6.7 years and again two years later. The RD, as compared to the NRD group, showed longitudinally stable reductions in neural activity (a) present within the initial 100-140 msec after stimulus presentation and (b) greater for letter than non-letter stimuli and larger over the left than right hemisphere at 180-240 (N2) and 460-600 (P3) msec after stimulus presentation. Behaviorally, individuals with a reading disability demonstrated slower and less accurate task performance. Both groups, however, did demonstrate a high level of task accuracy and showed faster performance during the black-white discrimination of letters as compared to non-letter patterns. These reductions in ERP amplitude are considered to reflect a reduction in selective neural processing for the reading disabled group during the task. The data suggest further that these deficits involve multiple levels of neural processing in the geniculate-striate visual processing system and are frequently greater over the left than right hemisphere. COORDINATE FRAME FOR IMAGE DESCRIPTION STORED IN MEMORY. M.B. Pavlovskaya* and I.A. Vol. Dept. Physiol. and Pharmacol., Sackler Sch. Med., Tel Aviv Univ., Tel Aviv, 69978, Israel.

We have recently found that an appropriate description of the object seems to be magnitude of its spectral description in a frame of reference whose origin point is chosen for each object separately. We have now carried out psychophysiological experiments to test the hypothesis if the performance is better with attention allocation to this point. Observers were presented under time-pressure condition with one of five pre-learned stimuli. Stimulus presentation was preceded by a precue signal that was relevant for one of the stimuli, in that it coincided with the origin point for this stimulus. The results show that percentage of correct identification for all stimuli is significantly higher for relevant as compared to other precuing. We calculated the Euclidean distances between the relevant stimulus description assumed to be stored in memory and the Fourier spectrum with the actual precue. A good fit of experimental to theoretical confusion matrices generated on the basis of these distances is manifested by the high values of correlation coefficients. We conclude that attention allocation by precuing the origin point of the object's reference frame improves significantly the recognition process.

508.1

ANALYSIS OF SINGLE UNIT RECORDINGS FROM CEREBELLAR CORTEX OF CLASSICALLY CONDITIONED RABBITS. M.R. Foy*, D.J. Krupa, J.Tracy and R.F. Thompson. *Dept. of Psychology, Loyola Marymount University, Los Angeles, CA 90045 and Neurosciences Program, Univ. So. Calif., Los Angeles, CA 90089.

The cerebellum forms an essential portion of the neural circuitry necessary for the development and expression of the associative elements which mediate rabbit eyeblink conditioning. An analysis of extracellular single unit activity recorded primarily from hemispheral lobule VI (HVI), but also from portions of ansiform cortex (Crus I and II) and the paramedian lobule (PM) of cerebellar cortex in classically conditioned rabbits was done to characterize neural responses to the various components of the stimulus events (tone CS and airpuff US) and the behavior exhibited on the trial (CR and UR). Through a raster analysis of unit activity sorted by onset of behavior in the well-trained rabbit, we have found units that display either a decrease in rate of simple spike discharge that preceded and modeled the learned behavioral eyelid response, along with a smaller population of cells which displayed an increase in the rate of simple spike firing that preceded and modeled the CR. A third population of units displayed neither an increase or decrease in their rate of firing to the stimuli events. These analyses reveal several classes of neural responses correlated with behavior in well-trained rabbits which may play important modulatory roles in the activity of "deep" cerebellar nuclei to which they project. 508.2

ASSOCIATIVE LONG-TERM DEPRESSION REVEALED BY FIELD POTENTIAL RECORDING IN RAT CEREBELLAR SLICE. C. Chen* and R. F. Thompson. Neurosciences Program., University of Southern California., Los Angeles, CA 90089-2520.

Field potential recording in the brain slice is essential for understanding long-term plasticity because it reflects population changes and it is stable. The difficulty in obtaining well-defined field potentials in cerebellar slice has been a major obstacle in studying long-term depression (LTD) (Ito, *Ann. Rev. Neurosci.*, 1989). We have reliably recorded the field potential of Purkinje cell (PC) dendrites evoked by parallel fiber (PF) stimulation in young adult rat cerebellar slice (sagital section of 400 um), and have identified TTX-sensitive action potentials and AMPA receptor-mediated EPSP (blocked by 10 uM CNQX). The response evoked by activating the climbing fiber (CF) through the white matter stimulation can also be blocked by CNQX. By using the field potential recording in the absence of GABA blockers, consistent LTD (30±12% decrease from baseline EPSP amplitude, 60 min post pairing, n=9) of PF-PC synapses can be induced by 600 pairings (1 Hz) of a PF stimulus (0.1 ms) followed 250 ms later by a CF stimulus. The PF-EPSP in the nonpaired pathway recorded 300 um away from the paired one shows a small increase (18+15%, n=9), indicating that the LTD is localized in the paired pathway and the slice is healthy over the course of study. This new interstimulus interval for LTD induction may have some relevance to behavioral motor learning.

508.3

CHANGES IN THE BINDING PROPERTIES OF GLUTAMATE RECEPTORS FOLLOWING LONG-TERM ENHANCEMENT (LTE) OF PERFORANT PATH SYNAPTIC TRANSMISSION IN AWAKE RATS. G. Rao*[1], S. Maren, G. Tocco, M. Baudry, R. F. Thompson, B. L. McNaughton[1], and C. A. Barnes[1]. Neurosciences Program, Univ. So. Cal., Los Angeles, CA 90089, and [1]ARL Div. Neural Systems, Memory and Aging, Univ. Arizona, Tucson, AZ 85724.

The mechanism of long-term synaptic enhancement (LTE) is still vigorously debated, and there is evidence for both pre- and postsynaptic changes. We have examined the binding properties of glutamate receptors following induction of LTE at perforant path-granule cell synapses of awake rats. Anesthetized adult male Fisher-344 rats were implanted bilaterally with a monopolar stimulating electrode in the perforant path and a recording electrode in the hilus of the dentate gyrus. Following recovery, 8 rats received 11 high-frequency perforant path stimulation sessions (10 25 msec 400 Hz bursts separated by 10 sec per session) over 3 days, and 6 rats received 10 high-frequency sessions over 6 days. An equal number of stimuli were delivered to the opposite hemisphere at low frequency (1 Hz) to yield an internal control. Either 4 hours (8 rats) or 24 hours (6 rats) following the final stimulation session, rats were sacrificed and their brains rapidly dissected and frozen. Quantitative autoradiography of [^{3}H]-AMPA and [^{3}H]-TCP binding to frozen brain sections was used to examine the AMPA and NMDA subclasses of glutamate receptors, respectively. LTE induction resulted in a significant increase in AMPA binding in the dentate gyrus (stratum moleculare) as compared to the hemisphere receiving low-frequency stimulation. No significant changes in [^{3}H]-TCP binding were observed in any treatment group. These results suggest that the expression of hippocampal LTE involves a persistent modification in some properties of postsynaptic AMPA receptors. 508.4

SYNAPTIC ACTIVATION OF TRANSCRIPTION FACTORS: DISSOCIATION OF STIMULUS REPETITION AND LTE IN HIPPOCAMPUS OF AWAKE BEHAVING RATS. P.F. Worley[1], R.V. Bhat[1], J.M. Baraban[1], G.D. Stevenson*, B.L. McNaughton, G. Rao and C.A. Barnes. [1]Dept. Neuroscience, Johns Hopkins University, Baltimore, MD 21205, and ARL Div. Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

High-frequency synaptic activation of hippocampal granule cells induces a rapid increase in mRNA of specific transcription factors, suggesting a role in long-term synaptic enhancement (LTE or LTP; Cole et al., Nature 340:474, 1989). This genomic response appears to include *zif*268, c-*fos*, and *jun*-B; however, the reproducibility and magnitude of these responses has been variable and may be altered by anesthesia, injury and the stimulation protocol. To evaluate the relationship between LTE and genomic responses further, we have used chronically implanted, unanesthetized animals that receive a stimulation protocol sufficient to induce LTE lasting about 3 days (10, 25 msec trains at 400 Hz, separated by 10 sec). In each of 18 preparations, *zif*268 mRNA was induced to levels identical to those induced by maximal electroconvulsive seizures (MECS) 30 min after the stimulus. By contrast c-*fos* and c-*jun* were not detectably increased in any of the high frequency preparations but were strongly induced by MECS. *Jun*-B mRNA was weakly induced, relative to MECS in all preparations. With more repetitions of high frequency stimulation at a shorter interval (i.e., 50, 20 msec trains at 400 Hz, separated by 20 sec), there was no further LTE induction; however a weak c-*fos* mRNA response was observed. Our results indicate a differential threshold for synaptic activation of these transcription factors and suggest a special role for *zif*268 in LTE. [Supported by AG09219 and ONR]

NITRIC OXIDE SYNTHASE INHIBITION *IN VIVO* HAS NO EFFECT ON HIPPOCAMPAL SYNAPTIC ENHANCEMENT OR SPATIAL MEMORY C.A. Barnes*[1], B.L. McNaughton[1], D.S. Bredt, C.D. Ferris and S.H. Snyder [1]ARL Div. Neural Systems, Memory & Aging, U. Arizona, Tucson, AZ 85724, and Dept. Neuroscience, Johns Hopkins Sch. Med., Baltimore, MD 21205.

In vitro studies suggest that nitric oxide translates induction events into expression of long term enhancement (LTP/LTE) of hippocampal synapses (Bohme et al., 1991; Shuman & Madison, 1991; O'Dell et al., 1991). NO synthesis is induced post-synaptically by an NMDA receptor dependent mechanism, but appears to increase transmitter release from terminals near the site of NO release; however, such a presynaptic mechanism for LTE has been the subject of controversy (Malinow and Tsien, 1990; Bekkers and Stevens, 1990; Foster and McNaughton, 1991; Menabe and Nicoll, 1992). We have studied the effects of *in vivo* treatment with L-N^G-nitroarginine (NO_2ARG), an irreversible inhibitor of NOS (Dywer et al., 1991). Rats were implanted bilaterally with electrodes for stimulation and recording of perforant path synaptic potentials in fascia dentata. Responses were collected daily over a 14 day period. On day 6, daily i.p. injections of NO_2ARG (20-50 mg/kg) [n=7 rats] or vehicle [n=6 rats] were begun. On days 10 and 11, spatial memory was tested using the Morris water task. On day 12 and 13, unilateral high frequency stimulation (HFS) was given twice at a 2 hr interval. Fractional enhancement of the EPSP and population spike 24 hours after HFS were compared with the control hemispheres between groups. Enzymatic assay indicated at least 90% inhibition of NOS. There was no effect of NOS inhibition on either control responses or the enhancement of the EPSP or population spike, and no effect on spatial learning. We conclude that either there is an additional source of NOS activity in hippocampus, or that the form of LTP blocked *in vitro* in CA1 by NOS inhibition does not reflect the same process as is induced *in vivo* in FD. LACK OF AN EFFECT OF TEMPERATURE ON TETANUS INDUCED ENHANCEMENT OF SYNAPTIC FIELD POTENTIALS IN CA1. J. Shen*, G. Rao, C.A. Barnes and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Previous studies (Foster & McNaughton, 1991) suggest that low temperature (22°C) results in a substantial increase (compared to 32°C) in the magnitude of synaptic enhancement induced by pairing 2 Hz stimulation of single or small numbers of presumed Schaffer collateral axons with intracellular depolarizing current pulses. The excess EPSP enhancement was associated with an apparent increase in quantal content that was not seen at 32°C, where only changes in quantal size were observed. Curiously, although quantal size changes were apparently blocked by APV or the omission of the depolarizing pulses during 2 Hz stimulation, the apparent increase in quantal content was not. Because reduced temperature in some systems leads to a very marked prolongation of PTP (Schlapfer et al., 1975), we have investigated the effects of temperature on tetanus (100 Hz, 1 sec x 2) induced potentiation and enhancement of field EPSPs in CA1. Low temperature led to an increase in the initial elevation of the field EPSP (PTP), but there was little effect on its apparent decay rate, and no effect on the magnitude of the persistent phase of enhancement (about 40%). Apart from the possibility that the previous results reflect statistical error (i.e., false positive results), we see two possible explanations. There could be important differences between pairing induced synaptic enhancement and the response to synchronous high frequency stimulation. Alternatively, it is quite possible that there are persistent, temperature dependent effects of repetitive stimulation on axonal excitability. If there were fewer conduction failures following 2 Hz stimulation at 22°, this would appear as an apparent increase in quantal content. These possibilities are under investigation. COMPLEMENTARY ROLES OF HIPPOCAMPUS AND NEOCORTEX IN LEARNING AND MEMORY. J.L.McClelland, B.L.McNaughton*, R. O'Reilly, & L.Nadel. Dept. Psych., Carnegie-Mellon U., Pittsburgh PA 15213 & ARL Div. Neural Systems, Memory & Aging, U. Arizona, Tucson, AZ 85724.

We think of experiences as samples drawn from a probabilistic environment, and suggest that the neocortex adjusts its synaptic strengths to maximize its ability to respond appropriately to future inputs drawn from the same environment. Finding satisfactory connection strengths requires gradual adjustment to allow the overall direction of weight changes to be guided by an adequate sample of the environment. In simulations, such gradual learning leads to powerful cognitive representations, but a key requirement is that new information must be accommodated slowly. Weight changes large enough to store arbitrary aspects of individual events derail the sampling, producing 'catastrophic interference'. We suggest hippocampus is specialized for rapid storage of just such information. Such information is at the same time treated like any other sample by the cortex and if the information recurs in the mix of other experiences, it gradually becomes integrated into the cortex. One way the information may recur is via recall from hippocampus; in such cases hippocampus acts as teacher to the cortex. Because cortical learning must be gradual, memories initially dependent on hippocampus can only gradually lose this dependence. Thus, graded retrograde amnesia is seen as a reflection of a key design characteristic of the two-part memory system. A further consequence is that the connections in the pathways between the cortex and the hippocampus must themselves be stable. This notion has led us to consider a new possible function for area CA1, for its relatively point-to-point reciprocal connections (Tamamaki pers. com.) with entorhinal cortex, for the low density of NMDA receptors found in stratum lacunosum, and for the ability of direct EC inputs to drive CA1 pyramidal cells (Yeckel & Berger, 1991). LARGE SCALE PARALLEL RECORDING OF MULTIPLE SINGLE UNIT ACTIVITY IN THE HIPPOCAMPUS AND PARIETAL CORTEX OF THE BEHAVING RAT. M.A. Wilson*, B.L. McNaughton, K. Stengel. ARL Div. of Neural Systems, Memory and Aging, Univ. of Arizona, Tucson, AZ 85724.

A microdrive array capable of independent vertical adjustment of 12 recording electrodes ("tetrodes") each containing 4 recording sites and separated by 250 μm was used to simultaneously isolate multiple single unit activity from the somatosensory regions of parietal cortex and hippocampal formation of the freely moving rat. Spike and EEG data were preprocessed using a custom built, computer controlled, 56 channel amplifier/filter array, and collected using seven synchronized 80486 computers. Animals were trained to perform a forced-choice alternation task on a two-armed maze for food reward. Animal position and head direction were recorded by video camera while single unit activity was monitored. Activity has been successfully recorded from both cortical and hippocampal regions; however, only the cortical data have been analyzed to date. During a single recording session, 61 cells in sensory-motor cortex were simultaneously monitored while the animals either performed the task or were subjected to somatosensory stimulation. Of these cells, 30% showed various degrees of turn biased firing, 20% had preferred responses during linear running behavior, and 50% had non-specific or non-movement related responses. A preliminary analysis of the ensemble activity was performed by constructing population vectors composed of firing rates for each cell over 100 msec to 10 sec time bins. The correlations between vectors at different times over the course of a single maze trial were compared and repeating vector patterns which encoded turning direction were identified. Ongoing work involves extending the analyses of ensemble encoding of behavioral state and spatial information. [Supported by NSF, NS20331 and MH46823].

QUANTIFICATION OF WHAT IT IS THAT HIPPOCAMPAL CELL FIRING ENCODES. W. E. Skaggs*, B. L. McNaughton, ARL Div. Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

We describe an information theoretic approach to determining what it is that neural firing encodes, obtaining a measure of the amount of information (in bits) that each spike conveys about any particular measured variable(s). The technique treats the cell as a communication channel whose input is the variable(s) and whose output is the spike train. Using data recorded from hippocampal cells in freely moving rats, this *information* measure is compared to several other possible measures of position-dependency of activity, including *sparsity* (the mean square spatial firing rate divided by the square of the mean), *coherence* (the correlation of firing rate with the firing rate at neighboring locations), *dispersion* (the RMS distance of location from the centroid of the firing-rate distribution, weighted by firing rate), and *existence of a place field*, determined using a method described by Muller et al. (1987). As a control, each measure is also computed 100 times with the spike data randomly time-shifted relative to the animal's position and behavior data, and a Z-score is obtained from which the significance can be determined. The information measure is the most sensitive detector of place-dependency, with sparsity following closely. Dispersion is only useful when the cell has a single strong place field. Coherence is less sensitive and depends on selecting the right spatial scale. The existence measure is easy to understand, but difficult to treat statistically, and depends on selecting good thresholds for firing rate and field size. We discuss several issues, including: how to bin data to obtain the most meaningful measures; what to use as the *a priori* probability distribution for the information measure; and the critical importance of an appropriate control. Finally, we use the information measure to disentangle the contributions of place, head direction, and velocity to a cell's activity, and compare the results with the outcome of a multiple regression analysis. PLACE FIELD SPECIFICITY DEPENDS ON PROXIMITY OF VISUAL CUES. K.M. Gothard*, W.E. Skaggs, B.L. McNaughton, C.A. Barnes and S.P. Youngs. ARL Division of Neural Systems, Memory, and Aging, University of Arizona, Tucson, AZ 85724.

Gaese et al. (1991) showed that the "place fields" of hippocampal complex spike cells are more specific when visual cues are proximally situated. Using a quantitative measure of place field specificity (see preceding abstract), we investigated how this difference reflects the animal's previous experience and the information provided by the visual world. Place cells were recorded with the stereotrode technique consecutively in an opaque cylinder with cue cards on the walls of the cylinder (proximal cues), and in a transparent plexiglass cylinder with a visually similar array of cues on the walls of the recording room (distal cues). The order of the two environments was alternated. Between trials, the animals were allowed to experience the whole room. Using either multiple regression or factorial ANOVA to account for contributions of mean running speed, mean firing rate, trial order, and environment, we found that place cells (89) showed significantly ($p < .005$) higher specificity in the opaque cylinder. We also found that the overall distribution of place cell mean firing rates is 25% more sparse in the transparent cylinder. These results suggest that the distal-cue environment is represented by a smaller population of cells with less specific place fields. This outcome supports the theory that place cell activity is partially determined by the "local view" seen by the animal, because in the distal-cue environment there is less parallax of visual cues as the animal moves from place to place. Order also had a significant ($p < .01$) effect on specificity, with place fields more specific in the second of the two consecutive sessions. As the second session was always preceded by exploration of the entire room, this may reflect the short-term effect of the intertrial experience. [Supported by NS 20331].

SPATIAL FIRING CHARACTERISTICS OF DENTATE GYRUS GRANULE CELLS. M.W. Jung*, B.L. McNaughton and T.W. Abel. ARL Division of Neural Systems, Memory and Aging, Univ. of Arizona, Tucson, AZ 85724.

Theoretical arguments concerning the role of the dentate gyrus in pattern separation and associative memory (Marr, 1971; McNaughton and Nadel, 1990) suggest that granule cells should exhibit sparse coding, i.e., they should fire only rarely at high rates, and should have tight 'place' fields. In contrast, several previous attempts to characterize granule cells *in vivo* have concluded that they fire at high rates, have no obvious place fields, and are similar to 'theta' cell interneurons found throughout the hippocampus; however, Mizumori et al. (1989) found, in anaesthetized animals, that the high rate and low rate cells in the granular layer could be separated on the basis of the failure of high rate cells to be inhibited during paired-pulse inhibition of the population spike, and the ability to drive high rate cells (but not low rate ones) below population spike threshold. They concluded that granule cells fire at low rates. We have studied the spatial and temporal firing properties of cells located (on the basis of histology and field potential profiles) in or very near the granular layer. Using stereotrode recording and real-time cluster plotting of spike parameters that facilitates the detection of very low rate cells, we find that most (38/44) cells in the layer have low rates (0.01 - 0.5 Hz), cannot be driven orthodromically below population spike threshold, and exhibit spatial selectivity equal to or better than the average CA3 pyramidal cell. Firing fields are highly directional. A number of these cells exhibit unusual spatial firing distributions consisting of three or four very tight fields distributed over the radial maze surface. Although the issue of the identity of low and high rate cells is by no means definitively resolved, the weight of evidence currently supports the conclusion that granule cells exhibit temporally and spatially sparse encoding. [Supported by NS20331].

DECREASE IN THE INFORMATION CONTENT OF HIPPOCAMPAL CA1 CELL SPATIAL FIRING PATTERNS IN THE DARK. E.I. Markus*, C.A. Barnes, B.L. McNaughton, V. Gladden, T.W. Abel and W.E. Skaggs. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

In adult rats some hippocampal cells exhibit similar "place fields" in a given environment both under light and dark conditions as long as the light condition precedes the dark (McNaughton et al., 1989; Quirk et al., 1990). We were interested in quantifying the relationships between spatial firing in the light and dark and comparing young and old rats.

Young adults (9 month) and old (22 month) F-344 rats were trained to perform a forced choice task on an eight arm radial maze in a soundproof room. The rat was placed on the center of the maze in an illuminated room and subsequently ran alternate trails with the room either illuminated or darkened. Cells were recorded in the CA1 pyramidal cell layer using stereotrode recording methods.

Place fields were less specific and less reliable in the old rats and both age groups exhibited reduced place field specificity and reliability in the dark. There was no significant interaction between age and light condition. [Supported by AG03376 and NS 20331].

EXPLORATION-INDUCED CHANGES IN SYNAPTIC STRENGTH IN HIPPOCAMPUS CAN PREDICT SPATIAL MEMORY IN THE MORRIS WATER TASK. C.A. Erickson*, D.L. Korol, C.A. Barnes & B.L. McNaughton. ARL Div. Neural Systems, Memory and Aging, U. Arizona, Tucson, AZ 85724.

Exploratory behavior results in increased perforant path evoked EPSPs and decreased population spike area and onset latency. These changes, collectively called short-term exploratory modulation (STEM), can be predicted from the amount of exploratory behavior (Green, et al., 1990; Sharp, et al., 1989). It is unknown whether STEM reflects information storage *per se* or some less specific process. We compared the magnitude of STEM with the amount of exploration during recording sessions in a cue-filled environment and with spatial learning ability in the Morris water task in young and old Fisher-344 rats. There was a strong relationship between the amount of STEM and spatial learning ability: EPSP growth was significantly correlated with spatial learning, measured by latency to escape to a hidden platform ($r^2 = 0.308$, $p = 0.002$) and percent of time spent in the target quadrant during a free-swim probe trial ($r^2 = 0.434$, $p = 0.011$). There was also a correlation between exploration and probe trial quadrant search ($r^2 = 0.562$, $p = 0.003$). When changes in the EPSP (STEM), age, and exploratory behavior were entered into a stepwise regression analysis, synaptic change (STEM) emerged as the best predictor of the variability in spatial learning. The relative spike attenuation in a recording session was significantly correlated with the amount of exploratory behavior ($r^2 = 0.170$, $p = 0.025$), but not to spatial ability. These data provide support for the hypothesis that STEM may be involved in spatial memory. It remains to be determined, however, whether this relationship reflects the actual storage of spatial information via specific synaptic alteration, or whether STEM reflects an important, but non-specific modulator of information transmission through the hippocampus. THE ROLE OF NORADRENERGIC INPUT IN THE GENERATION OF SHORT-TERM SYNAPTIC PLASTICITY IN THE DENTATE GYRUS. S. Davis*, G.L. Wenk, A. Sage, C.A. Barnes and B.L. McNaughton. ARL Div. Neural Systems, Memory and Aging, Univ. of Arizona, Tucson, AZ 85724.

Short-term exploratory modulation (STEM) is a form of naturally occurring synaptic plasticity that has been observed in the rat dentate gyrus (Sharp et al., 1989). It occurs during exploration, learning of a task or simply if the rat is placed in a novel environment. STEM shares some, but not all properties of LTE induced by high frequency stimulation (Erickson et al., 1991; McNaughton et al., 1991). Typically, when using only low frequency stimulation of the perforant path, the population EPSP increases and the population spike (PS) decreases during exploration. These effects persist for many minutes. Norepinephrine (NE) has been shown to modulate the induction of LTE (Bliss et al., 1983) and also produces lasting effects of its own (LaCaille & Harley, 1985; Stanton & Sarvey, 1985). We tested the effect of DSP4, a neurotoxin that depletes forebrain NE, on the generation of STEM. Rats with chronically implanted electrodes (N=10) were trained to run a forced choice (FC) task on the radial arm maze. The perforant path evoked response was measured before and after behavioural testing to assess the amount of STEM generated, both before and after DSP4 treatment. This treatment had no overt effect on the behavior or the baseline EPSP and PS. It did, however, reduce the magnitude of the increase in the EPSP by approximately 50% and the decrease in the PS by approximately 50%. Systemic administration of either α or β adrenergic antagonists resulted in dose-dependent reductions in STEM. These results indicate that NE is necessary for the full expression of STEM; however, whether NE produces STEM directly or whether it modulates the neuronal activity required for STEM is not as yet known. DOES SATURATION OF LONG-TERM ENHANCEMENT OF PERFORANT PATH SYNAPSES IMPAIR SPATIAL LEARNING IN THE MORRIS WATER TASK? A FAILURE TO REPLICATE. D.L. Korol*, T.W. Abel, L.T. Church, C.A. Barnes and B.L. McNaughton. ARL Div. Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Electrically induced hippocampal synaptic enhancement (LTE/LTP) is believed to reflect activation of a physiological memory mechanism. One of the cornerstones of this theory relies upon the observation that experimental saturation of LTE at a substantial fraction of perforant path terminals leads to an impairment in the acquisition of different spatial memory tasks. Two of these tasks include the Barnes circular platform task, in which animals seek to escape from a brightly illuminated uniform surface to a dark tunnel located under one of 18 peripherally located holes (McNaughton et al., J. Neurosci., 1986), and the Morris water task, in which rats are required to learn the location of an escape platform located just below the surface of a pool of water (Castro et al., Nature, 1990). Recently, several groups of investigators have attempted, without success, to replicate the results of Castro et al. (Morris et al., pers. com.; Cain et al., pers. com.; Sutherland et al., pers. com.). In the belief that these failures might reflect strain differences in the animal subjects used, we have attempted to replicate the Castro et al. study using both (albino) F-344 and (hooded) Long-Evans rats. We found no effects of LTE induction on probe-trial quadrant search time, regardless of whether the animals were tested immediately (14 rats total) or 24 hours (21 rats total) following the last stimulation session. There were also no strain differences. At present, we have no good explanation for the discrepancies, apart from the smaller number of rats used by Castro et al.; however, there are several variables under investigation including pool size and previous experiential history of the animals. Any further results will be reported. [Supported by AG03376, AG05540, and ONR]

SHORT-TERM EXPLORATORY MODULATION (STEM) OF DENTATE GYRUS EVOKED POTENTIALS IN SIMPLE AND COMPLEX ENVIRONMENTS. S.D. Croll* and E. Bostock, Dept. of Psychology, Queens College - CUNY, Flushing, NY 11367.

Dentate gyrus evoked responses of rats transferred into different environments show rapid increases in EPSPs and decreases in population spikes termed short-term exploratory modulation (STEM). Rats exposed to complex environments show increases in EPSPs and spikes. We studied STEM in complex environments. Rats were chronically prepared for stimulating in the perforant path and recording from the dentate gyrus. Rats were transferred into simple or complex environments for 7 daily 20 min sessions. Complex environment rats received either novel or the same daily stimuli. Simple environment rats were in either dim or normal lighting. During all sessions comparable STEM occurred in all groups, confirming that STEM occurs after any environmental transfer, including to a complex environment. EPSP enhancements decreased across daily sessions for all groups, suggesting that STEM may decrease in magnitude with repeated exposure to similar environments. Further analyses will examine whether EPSP and spike values change between days independent of STEM.

THE SHORT-TERM EXPLORATORY MODULATION (STEM) OF PERFORANT PATH SYNAPSES REFLECTS INCREASED BRAIN TEMPERATURE. E.I.Moser*, I.Mathiesen & P.Andersen, Inst. of Neurophysiology., Univ. of Oslo, Box 1104 Blindern, 0317 Oslo, Norway.

During free exploration, the field synaptic potential (epsp) in the rat dentate gyrus gradually increases whereas the spike amplitude and latency is reduced (Sharp et al.,1989, *Psychobiol.,17*, 257-69; Green et al.,1990, *J.Neurosci.,10*, 1455-71). These effects (STEM) outlast the exploration and have been interpreted as altered synaptic efficiency associated with temporary memory for recent events.

We asked whether STEM is related to increased brain temperature, which gives similar changes of potentials. Rats were chronically implanted with a stimulation electrode in the perforant path, a recording electrode in the dentate granular layer and a thermistor at the same depth in the contralateral hemisphere. Field potentials, brain temperature and exploratory activity were recorded simultaneously. Exploration in a novel environment produced both STEM and enhanced brain temperature (<2.0°C) which increased and decayed with identical time courses. In spite of vigorous exploratory activity, STEM was prevented by keeping the rat at a constant brain temperature using radiant heating. This temperature was equal to the maximal value observed in the same rat during control exploration. In other experiments, the changes in field potentials were larger the lower the brain temperature at the start of exploration. Walking on a motorized treadmill produced both STEM and increased temperature.

Taken together, our results imply that STEM is due to increased brain temperature and also question any relation to memory processes.

509.1

A Ca^{2+}-DEPENDENT PROCESS MEDIATES 1S,3R-ACPD-INDUCED POTENTIATION OF NMDA RESPONSES IN RAT HIPPOCAMPUS.
J. Harvey and G.L. Collingridge. (SPON: Brain Research Association). Dept. of Pharmacology, The Medical School, Univ. of Birmingham, Birmingham, UK.

We have reported previously that 1S,3R-ACPD selectively potentiates responses to NMDA but not AMPA in hippocampal slices (Harvey et al 1991, Br. J. Pharmacol. 104, c79) and these findings have been confirmed in single cells by Anikszteljn et al (Eur. J. Pharmacol. 1991, 205, 327). We have gone on to investigate the mechanisms of this potentiation, using a grease gap method for hippocampal slices. Experiments were performed on slices obtained from female rats (5-8 weeks old) and perfused with a standard Mg^{2+}-containing solution at 28 °C. Staurosporine (1 μM), a PKC inhibitor, thapsigargin (10 μM), which depletes intracellular Ca^{2+} stores, and bromophenacyl bromide (50 μM), a PLA_2 inhibitor, did not affect this potentiation. However these compounds were active as they prevented full expression of long-term potentiation, as reported previously (Matthies et al 1991, Neurosci. Lett. 121, 259; Harvey et al 1992, Neurosci. Lett. in press; Massicotte et al 1990, Brain Res. 537,49).

In a further 5 slices perfused with Ca^{2+}-free medium there was no evidence of this 1S,3R-ACPD-induced potentiation of responses to NMDA. These findings suggest, therefore, the involvement of a Ca^{2+}-dependent process in this potentiation, although the actual mediator has yet to be identified.

509.2

EFFECT OF OLFACTORY LEARNING ON AMPA BINDING IN THE HIPPOCAMPUS AND PIRIFORM CORTEX.
F. Chaillan, F. Roman, B. Soumireu-Mourat, G. Tocco*. Laboratoire de Neurobiologie des Comportements, URA CNRS 372, Université. de Provence, 13388 Marseille cédex 13, FRANCE.

Modifications of glutamatergic synapses are likely to be involved in learning associated plasticity. We were interested in evaluating a possible change in binding properties of glutamate receptors in regions showing plasticity following an olfactory discrimination task, i. e. the hippocampus and piriform cortex. Radiolabelled AMPA and CNQX on one hand and TCP on another hand were used to label the AMPA and NMDA receptors respectively.

Rats were trained to associate a natural odor with a water reward while an other odor was associated with a light. Forty eight hours before the first training session, the rats were water-deprived. Training consisted in approaching a water delivering spout when one of two odors was delivered. Approach response to the second odor resulted in a 10 sec presentation of a non aversive light. Rats reached 80% of correct responses after 4 training sessions and were overtrained during a 5th session. Animals were sacrificed 3-4 hours after the last session, their brains rapidly removed and frozen in -20 °C isopenthane. Ten μm thick sections were cut in a cryostat and subjected to quantitative ligand binding autoradiography.

Olfactory training in rats produced a significant increase in the binding of [^{3}H]-AMPA in hippocampal regions, dentate gyrus as well as in the piriform cortex,.

These results suggest that an increased responsiveness of the AMPA receptors might be a possible substrate for the synaptic plasticity observed in hippocampus and piriform cortex after an olfactory discrimination learning.

509.3

QUANTITATIVE AUTORADIOGRAPHY OF ENHANCED [^{3}H]MK-801 BINDING IN TRACE CONDITIONED HIPPOCAMPUS.
L.T. Thompson*, M. Dubocovich, & J.F. Disterhoft, Depts. of CMS Biology & of Pharmacology, Northwestern University Medical School, Chicago, IL 60611.

NMDA receptors may be critical in the neuronal plasticity underlying associative learning, and are abundant in dendritic fields of hippocampal CA1 and dentate neurons. In rabbits, agonists of the glycine site on the NMDA receptor facilitated acquisition of hippocampally-dependent trace conditioning, while a non-competitive antagonist blocked acquisition (Disterhoft *et al.*, 1990; Thompson *et al.*, 1991). Preliminary work indicated delay conditioning enhanced [^{3}H]MK-801 binding in whole hippocampal homogenates (Thompson *et al.*, 1990). The present study used quantitative autoradiography to determine if learning-dependent changes in MK-801 binding are localized to discrete hippocampal neuronal populations after hippocampally-dependent 500 msec trace conditioning.

Brain sections (20 μm) from trace conditioned, pseudoconditioned, or naive rabbits were labeled with [^{3}H]MK-801 in 30 mM HEPES buffer (pH 7.4) containing 100 μM glutamate, 100 μM glycine, and 1 mM EDTA for 2.5 hr at 23°C (Subramanian & McGonigle, 1990). Nonspecific binding was determined in the presence of 200 μM ketamine. Autoradiographs were quantitated with a high resolution Macintosh™ imaging system and NIMH software (Image 1.44). Hippocampal [^{3}H]MK-801 binding (20 nM) exhibited no dorsoventral or left-right gradients in controls.

Trace conditioning significantly enhanced whole hippocampal [^{3}H]MK-801 specific binding in saturation studies (1—40 nM). Small enhancements were seen in the dentate gyrus, but much larger increases in binding were observed in CA1. This effect was lateralized, with somewhat greater increases in binding seen in the CA1 region contralateral to the conditioned eye. These results suggest that alterations in NMDA receptor number (or in functional receptor number) may underlie some of the CA1-specific learning-dependent changes reported earlier (deJonge *et al.*, 1990). SUPPORTED BY 1 R01 DA07633.

509.4

EFFECT OF MK801 ON LATENT INHIBITION OF THE CLASSICALLY CONDITIONED RABBIT NICTITATING MEMBRANE RESPONSE.
G.B. Robinson[1]*, R.L. Port[2] and E.J. Stillwell[1]. [1]Dept. of Psychology, Univ. New Brunswick, Fredericton, N.B., E3B 6E4, Canada and [2]Dept. of Psychology, Slippery Rock University, Slippery Rock, PA, 16057, U.S.A.

This study examined the effect of the NMDA antagonist MK801 on latent inhibition (LI), a paradigm wherein nonreinforced pre-exposure to a conditioned stimulus (CS) typically retards subsequent learning to that CS. New Zealand rabbits (2-2.5 Kg), deeply anesthetized with halothane, had a headgear assembly (to hold an airjet and potentiometer) attached to the skull and a nylon loop sutured in the NM. Following a 2 week recovery period, rabbits received either saline or MK801 (0.10 mg/kg; sc) 75 mins prior to each of 4 days of CS pre-exposure (108 nonreinforced presentations of a 1 KHz, 400 ms, 82 dB tone). The intertrial interval averaged 60 s. A third group received saline but no CS pre-exposure and served as controls for LI effects. Conditioning began the day after the fourth CS pre-exposure session. Each conditioning session consisted of 12 blocks of 9 trails each; 8 of the trials were reinforced with a corneal airpuff US (5 psi, 100 ms) that coterminated with the CS and 1 trial served as a nonreinforced test-trial.

As a consequence of nonreinforced CS preexposure, both MK801 and saline treated rabbits showed marked retardation of learning during the early stages of acquisition. Thus, NMDA receptor-mediated plasticity does not appear to be essential for animals to learn to ignore an irrelevant stimulus. This finding is compatible with recent speculation that LI is mediated by nucleus accumbens/medial raphe input to hippocampus (Weiner, 1990). Supported by NSERC.

NMDA ANTAGONIST MK-801 IMPAIRS ACQUISITION OF LATENT INHIBITION FOR A PREEXPOSED FLAVOR STIMULUS.
J. Willner*, P. S. Linker and M. Gallagher. Dept. of Psychology, Univ. of North Carolina, Chapel Hill, NC 27599.

Previous studies have shown that simple exposure to a stimulus will retard later conditioning of that stimulus (latent inhibition), and that septohippocampal circuits play a critical role in mediating the effect. The present study investigated whether the NMDA antagonist MK-801, which blocks induction of LTP in the hippocampus, would also impair acquisition of latent inhibition.

Rats were initially adapted to restricted water access (20 min/day). Separate groups then received injections of saline or MK-801 (0.08 mg/kg, sc) 35 min prior to exposure to a .2% (w/v) saccharin solution or to tap water. A fifth group of rats received MK-801 immediately after preexposure to saccharin. Two days later, all groups received a conditioning trial in which saccharin was paired with delayed illness (0.3M LiCl, 63.5 mg/kg, ip). Subsequent tests showed that rats preexposed to saccharin after receiving saline injections acquired significantly weaker aversions than did non-preexposed rats (latent inhibition). Rats that received MK-801 before or immediately after saccharin preexposure, however, displayed saccharin aversions like those seen in non-preexposed rats (no latent inhibition).

Various aspects of the data suggest that MK-801 disrupted latent inhibition because of its effects on learning, and not because of other possible effects of the drug (e.g., sensorimotor deficits). These results therefore support the idea that NMDA receptors in limbic system circuits play a critical role in certain forms of learning and memory.

NMDA ANTAGONIST MK-801 PRODUCES A DOSE-DEPENDENT IMPAIRMENT ON SPATIAL REVERSAL LEARNING IN THE RADIAL ARM MAZE.
L.H. White*, K.B. Austin, and M.L. Shapiro. Dept. of Psychology, McGill Univ., Montreal, Quebec, Canada, H3A 1B1.

Many experiments have shown that MK-801 blocks or retards spatial learning in an unfamiliar environment. The present experiment investigated the effects of MK-801 on learning a new subset of spatial relationships in a *familiar* environment. Rats were trained on a version of the radial arm maze task which requires the rat to enter only four of eight arms to retrieve a food reward (4/8 RAM). Upon reaching criterion performance, they were assigned to one of four groups; a saline control, and either 62.5 ng/kg, 100 ng/kg, or 125 ng/kg of MK-801 (n=9 per group). Injections were given I.P. 30 minutes prior to training. Performance was assessed for four days, and MK-801 had no effect on working and reference memory (WM and RM). Each rat was then tested on a RM reversal task by baiting the set of arms opposite to those used for the initial acquisition. No significant differences were found between the groups on blocked trials of RM or WM errors throughout training. However, the 125 ng/kg MK-801 group took significantly longer than the SAL group to learn the RM reversal task compared to acquisition (trials to criterion reversal minus trial to criterion acquisition). The 62.5 ng/kg, 100 ng/kg, and SAL groups did not differ significantly on this difference score. The delayed acquisition of the RM reversal task for the 125 ng/kg MK-801 group is consistent with one interpretation that MK-801 retards the acquisition of a new subset of spatial relationships in a familiar room by inhibiting the ability to suppress previously learned information.

NMDA ANTAGONIST MK-801 RETARDS REVERSAL PERFORMANCE IN THE RADIAL ARM MAZE TASK. K.B. Austin*L.H. White and M.L. Shapiro, Department of Psychology, McGill University, Montreal, CANADA.

Preliminary data from our laboratory has shown that MK-801 (62.5 ng/Kg, IP), administered to Long-Evans rats immediately after the first exposure to a spatial environment, alters the hippocampal place cell firing. To test the effects of MK-801 on spatial learning, we used a version of the radial maze task which requires the rat to enter only 4 of 8 arms to retrieve a food reward (4/8 RAM). 30 male Long-Evans rats were assigned to either a control (SAL), a pre-MK (given MK-801 30 min before each trial), or a post-MK (given MK-801 immediately after each trial) group. Rats were trained for 27 days and reached a criterion performance of less than 2 errors per day for 4 consecutive days. Analysis of reference memory (RM) errors, working memory (WM) errors and trials to criterion (TC) showed no group differences. Retention tests performed 15 days after training showed that there was no forgetting. During the reversal phase all of the previously baited arms were not baited and vice-versa. The TC difference scores for each animal (TC for acquisition minus TC for reversal) showed that both saline and post-MK groups reached criterion performance in fewer trials during reversal than during initial acquisition (5.5 and 5.8 trials sooner, respectively). In contrast, the pre-MK group took slightly longer to reach criterion in the reversal task (1.7 trials later). Thus, rats trained and tested under the influence of MK-801 did not show the same savings on reversal as rats receiving saline or MK-801 post-trial. The male Long-Evans rats given 62.5 ng/Kg of MK-801 did not show *any* overt behavioral side effects. Here, the deficit caused by MK-801 was relatively subtle compared to other RAM studies using higher doses of MK-801 and/or rats of different strain and sex. Which effects of MK-801 are the direct result of NMDA blockade as it relates to LTP and which effects may be attributed to other PCP receptor-mediated events remain unknown.

MK801 IMPAIRS MEMORY FORMATION IN THE 2 DAY-OLD CHICK. D.R. Smith, S.C. Fromont, M.R. Rosenzweig and E.L. Bennett*. Department of Psychology, University of California, Berkeley, CA 94720.

The amnesic effect of MK801, a NMDA receptor antagonist, was determined using 2 day-old chicks trained on a 1-trial passive avoidance task. Groups of chicks were given bilateral injections into the intermediate medial hyperstriatum ventrale 45, 30, or 15 min pretraining, using saline or 0.0015, 0.015, 0.15, 1.5 mM MK801, and tested at 24 h. 1.5 mM and 0.15 mM MK801 produced significant amnesia when injected 15 min or 30 min pretraining when compared to saline controls ($p<.01$). No other dose of MK801 produced amnesia. These results indicate that NMDA receptor activation is important for learning and memory formation in the chick. The appearance of amnesia after injections at 15 min or 30 min pretraining is consistent with the findings of other researchers, in that MK801 has been shown to have maximal effect at about 30 min. Further experiments are necessary to determine if activation of NMDA receptors is important for the acquisition or retrieval of a task.

EFFECTS OF L-GLUTAMATE AND N-METHYL-D- ASPARTIC ACID(NMDA) ANTAGONISTS ON ACTIVE AVOIDANCE TASK IN MICE.F.Motamedi* and M. Eslami ,Dept . of physiology , shaheed Beheshti Univ.of Med .Sci. P.O.Box 19835-181 , Tehran. Iran.

Systemic and central administration of glutamate agonists and antagonists are involved in memory in a variety of tasks . In the present study the effects of L-Glutamte(L-GLU) and NMDA antagonists 2-Amino -7- phosphonoheptanoic Acid (AP7)AND MK-801 on active avoidance task in mice were examined.Intracerebroventricular injection of L-GLU(5ug/Brain) before and after training sessions improved performance in a retention test 24 hour later .No such effect were seen at lower doses of L-GLU. pre - training administration of AP7 a competitive antagonist of NMDA (30mg/kg,i.p.) and MK-801 a non competitive antagonist of NMDA(0.2mg/kg. i .P)30 min prior to training sessions , significantly impaired memory , but immediately after post-training injection of these two antagonists no significant change in memory was observed.

Our results show that while NMDA receptors are involved in memory formation, the enhacement of memory seen after post-training administration of L- GLu is probably due to a non- NMDA receptor

509.10

DIFFERENTIAL REDUCTION OF FEAR CONDITIONING TO CONTEXTUAL AND AUDITORY CONDITIONAL STIMULI BY ICV ADMINISTRATION OF AN NMDA ANTAGONIST (APV). M. S. Fanselow*, J. J. Kim & J. Yipp. Dept. of Psychology, UCLA, LA, CA 90024.

Rats with cannula implanted in the lateral ventricle received infusions of DL-2-amino-5-phosphonovaleric acid (APV, 0, .625, 1.25, 2.5, or 5.0 µg/rat) prior to pairings of a tone with shock. The rats were later tested without drug, shock or tone for conditional fear of the original training context by scoring freezing. APV dose dependently reduced freezing with the 2 highest doses virtually eliminating the response. The next day the rats were placed in a different chamber and no freezing was observed until the tone was presented. The tone produced freezing in all animals. APV did not have a statistically reliable effect on freezing to the tone, although responding was reduced by 50% at the highest doses. A second study gave rats tone shock pairings or shock alone. The tone elicited freezing only in the paired animals. APV (5 µg) completely eliminated responding to the training context but only reduced responding to the tone by 50%. Contextual conditioning appears to be more susceptible to reversal by ICV administration of NMDA antagonists than does conditioning to discrete auditory cues. There appears to be some degree of divergence between the circuitry mediating the learning of fear to contextual and discrete auditory conditional stimuli.

NMDA-MEDIATED MECHANISMS IN AUDITORY FILIAL IMPRINTING IN CHICKS

K. Braun*, A. Wolf, J. Bock, Inst. for Neurobiology, Brenneckestr 6, 3090 Magdeburg and Inst. Zool., TH Darmstadt, 6100 Darmstadt, Germany

In the imprinting-relevant forebrain area medial neostriatum/hyperstriatum (MNH) the induction of LTP can be blocked by the NMDA-antagonist 2-amino-5-phosphonovaleric acid (APV) (Wang et al Proc. 20. Göttingen Neurobiol Conf, 1992). To test the behavioral influence of APV on auditory filial imprinting, newly hatched chicks received bilateral injections of 1μl APV (1μM-50μM) into MNH or into a reciprocally connected area, the caudal neostriatum (Nc). They were then exposed to rhythmic 400Hz tone pulses (imprinting session). During the following days, approach to different sound sources was tested (approach and discrimination test). Compared to the control groups the imprinting rate of APV-injected chicks decreased in a dose-dpendent manner to 0% with APV-concentrations >12.5μM for both, MNH- and Nc-injections. APV-treatment does not cause irreversible changes in these areas, since after termination of the APV-injections after the end of the congenital sensitive phase (4 days posthatch) 40% of these unimprinted APV-treated chicks could subsequently be imprinted on the 5th and 8th day posthatch (delayed imprinting). Furthermore, 2-deoxyglucose-autoradiography revealed that these chicks showed an increased MNH-activity when exposed to the imprinting tones. Successfully imprinted chicks with bilateral or unilateral injections of a single dose of 50μM APV into MNH no longer responded to the imprinting tones, but some of the unilaterally injected chicks still showed responses. After 24h, when the effects of APV had worn off, all chicks responded again. Our behavioral results together with the electrophysiological data indicate that NMDA-mediated LTP is one of the mechanisms which plays a role in auditory filial imprinting. *Supported by DFG (Br950/4-5) and BMFT.*

EXAMINATION OF METABOTROPIC RECEPTOR INVOLVEMENT IN SPATIAL LEARNING. T.C.Dumas*, R. Grimes and T.C. Foster Depart. of Psychology, U. of Virginia, Charlottesville, VA. 22901.

The glutamate metabotropic receptor is highly concentrated in the hippocampus. Receptor activation may influence synaptic plasticity during memory formation. Rats (n=12) were trained on the 8-arm radial maze. Prior to testing (30 min), the metabotropic receptor antagonist, 2-amino-3-phosphono-propionic acid (AP3) (1.0^{-6} - 0.1 M in ACSF, 3 L/cannula over 3 min) or ACSF was injected bilaterally ICV via chronic cannulae. Within dosages tested, AP3 had no effect on working memory errors or the latency to complete task. Acute injection did not influence acquisition of spatial information in a novel environment. No difference was observed between AP3 injection and control rats in latency to reentry on an inhibitory avoidance test. Rats chronically implanted with minipumps for ICV drug delivery (0.1 M AP3) exhibited visual cue and spatial discrimination learning on the Morris water task. Results indicate that AP3 does not effect spatial learning. Chronic effects on retention are currently being examined. FRS 441335.

EFFECTS OF PHENCYCLIDINE AND NALOXONE ON LEARNING OF A SPATIAL NAVIGATION TASK AND PERFORMANCE OF A SPATIAL DELAYED NON-MATCHING TO SAMPLE TASK.

M. Dakis, J. S. Martinez, R. P. Kesner and P. Jackson-Smith*, Dept. of Psychology, Univ. of Utah, Salt Lake City, UT 84112

Rats were trained on a dry-land version of a spatial navigation task (cheese board) under the influence of 1 µl injection of 10 µg of Phencyclidine (PCP, an antagonist of the NMDA receptors), 13 µg of naloxone (an antagonist of the opiate receptors), or saline, directly into the dorsal hippocampus. Rats received 2 blocks of 4 trials with different starting points, relative to the goal (food) per day, for three consecutive days. Based on a distance traveled measure, results indicated that relative to saline controls, the PCP group learned normally within a day, but displayed forgetting between days. Conversely, the naloxone group displayed disruption of learning within a day, but displayed normal learning between days. These preliminary results indicate that the NMDA receptors mediate consolidation of spatial information, the opiate receptors mediate short-term memory representations, and that the processes can operate independent of each other.

This conclusion is further supported by results obtained from rats previously trained on an 8-arm spatial delayed non-matching to sample task with delays of 1 and 30 minutes. The rats were treated exactly the same as in the previous experiment. In this case, PCP had no effect, however naloxone disrupted performance on the 30, but not the 1 minute delay. Because it is assumed that the latter task measures the operation of short-term memory representations, but not consolidation of spatial information, the results lend additional support to the hypothesis that opiate receptors mediate short-term memory and NMDA receptors mediate consolidation of spatial information.

NITRIC OXIDE SYNTHASE INHIBITION BY N^{w}-NITRO-L-ARGININE IMPAIRS LEARNING OF RATS IN A 14-UNIT T-MAZE.

D.K. Ingram*, E. Spangler, D. Roberts, S. Iijima, and E.D. London, NIA Gerontol. Res. Ctr., NIH and NIDA Addiction Res. Ctr., Baltimore, MD 21224.

N-methyl-D-aspartate (NMDA) receptor activation has been linked to enzymatic production of nitric oxide (NO) by nitric oxide synthase (NOS) (Garthwaite, *TINS*, 14:60, 1991). NMDA receptor antagonism retards formation of long-term potentiation (LTP) and impairs acquisition in maze tasks (Izquierdo, *TIPS*, 12:128, 1991). These observations have been linked to intracellular events involving NO production as a retrograde messenger increasing presynaptic glutamate release. Specifically, when NOS is inhibited, LTP is blocked *in vitro* (Schuman & Madison, *Science*, 254:1503, 1991). We examined whether NOS inhibition impairs learning of male F-344 rats (9 mo) in a 14-unit T-maze. Previous results in this maze indicated that NMDA receptor channel antagonism impairs acquisition but not retention (Spangler *et al.*, *Pharm. Biochem. Behav.* 40:949, 1991). In the present study, rats were pretrained in 1-way active avoidance to a criterion (13/15 avoidances) in a straight runway. The next day, rats received i.p. injections of 0.9% NaCl as controls or N^{w}-nitro-L-arginine (N-ARG) to block NOS (3.0, 4.5 or 6.0 mg/kg) 30 min before maze training. During 15 trials, rats were required to negotiate each of 5 segments within 10 s to avoid footshock (0.8 mA). Peformance variables included errors (deviations from correct pathway), runtime from start to goal, shock episodes and duration. N-ARG treatment impaired performance in all variables in a dose-dependent manner. Controls and rats treated with 3 mg/kg N-ARG were retested in the maze 7-10 days following training, with half being injected with N-ARG (6 mg/kg) 30 min in advance. Performance under these conditions was affected minimally indicating that NOS inhibition primarily impairs acquisition .

A NITRIC OXIDE SYNTHASE INHIBITOR RETARDS ACQUISITION OF THE CLASSICALLY CONDITIONED RABBIT EYELID RESPONSE.

M. Todd Allen* and J. E. Steinmetz. Program in Neural Science, Psychology Dept. Indiana University., Bloomington, IN 47405.

Nitric oxide (NO) may be involved in long term depression (LTD) processes in the cerebellum. In this present study, we tested the effects of L-nitro-arginine-methyl-ester (L-NAME), a NO synthase inhibitor on classical eyelid conditioning, a learning procedure thought to involve the cerebellum. Rabbits were given L-NAME at 3 doses (10, 25, 75 mg/kg) or the stereoisomer D-NAME (25 mg/kg) while being trained in the classically conditioned rabbit eyelid response paradigm (CS=tone, US=airpuff). The L-NAME groups had significantly lower percentages of conditioned responses than did the D-NAME controls over the first several days of training. No effect of L-NAME was obtained in rabbits that had been previously conditioned to criterion after injection of the control substance, D-NAME. Preliminary results from conditioning with L-NAME while recording multiple unit activity in the interpositus nucleus indicate that the training-related neuronal model characteristic of the interpositus nucleus is delayed similarly to the appearance of the conditioned response. These data suggest that blocking NO synthesis may disrupt cellular processes normally involved in the acquisition of classically conditioned responses.

INHIBITORY RESPONSES TO PRESSURE EJECTED NEUROPEPTIDE Y IN RAT SUPRACHIASMATIC NUCLEUS NEURONES *IN VITRO*

F.M Sidey and B. J. Jones SmithKline Beecham Pharmaceuticals, Coldharbour Road, The Pinnacles, Harlow, Essex, UK, CM19 5AD. SPON: Brain Research Association

Neuropeptide Y (NPY) has been shown exclusively to increase the spontaneous firing rate of suprachiasmatic (SCN) neurones in hamster hypothalamic slices *in vitro* when administered by pressure ejection (1), but predominantly to inhibit the firing of both rat (2) and hamster (3) SCN neurones when perfused in the bathing fluid. Using hypothalamic slices prepared from rats, and standard extracellular recording techniques we found that pressure ejection of NPY (50-200µM, 10 psi, 0.1 to 3 seconds) inhibited the spontaneous firing rate of 75% (51/68) of SCN neurones tested. This refutes the suggestion that method of application explained the discrepancies between rat and hamster. No stimulatory responses were seen, the remainder of the cells being unaffected by NPY.

Neurones could be distinguished by the depth and duration of the response to NPY, and by a monophasic or biphasic return to previous firing rate. In a second series of experiments designed to investigate NPY responses in the SCN at various circadian times, we found no difference in the frequency of inhibitory responses (to 50µM NPY) during the light phase (83%) and the dark phase (81%). However, whereas the durations of responses during the light phase were equally distributed between short and long, during the dark phase they were predominantly long (20 to 45 min).

NEUROPEPTIDE Y RECEPTOR DISTRIBUTION IN THE SUPRACHIASMATIC NUCLEUS OF THE GOLDEN HAMSTER: RELATIONSHIP TO RETINOHYPOTHALMIC TRACT.

H.I. Ryer[1]*, J.K. Johnson[2], D.I. Friedman[1], H.E. Albers[3] and E.G. Stopa[1]. [1]SUNY Health Science Center and VAMC, Syracuse, NY, [2]Vanderbilt University, Nashville, TN, [3]Georgia State University, Atlanta, GA.

The suprachiasmatic nucleus (SCN) receives direct visual afferent projections from the retina via the retinohypothalmic tract (RHT), as well as from the lateral geniculate nucleus via the geniculohypothalamic tract (GHT). Neuropeptide Y-containing fibers originating from the GHT appear to modulate circadian rhythmicity. Therefore we chose to investigate the relationship between neuropeptide Y (NPY) receptor density and RHT projections to the SCN in the golden hamster. The RHT was traced by implantation of carbocyanine dye DiI into the distal end of one optic nerve (n=7). NPY receptors were localized using receptor autoradiography (n=11). Sections were labeled with ^{125}I-peptide YY +/- unlabeled peptide YY. NPY receptor distribution was seen primarily in the ventral SCN in the rostral portion of the nucleus, but shifted laterally in more caudal sections. This pattern closely corresponded to RHT projections from the retina. These findings provide additional evidence that NPY is involved in circadian regulation within the SCN, and suggest that both the RHT and GHT project to the ventrolateral portion of the SCN. Supported by Hendricks Research Foundation,NS25512, AG09301.

SEROTONIN RECEPTOR GENE EXPRESSION IN THE RAT SUPRACHIASMATIC NUCLEUS. A.L. Roca*, D.R. Weaver and S.M. Reppert. Laboratory of Developmental Chronobiology, Children's Service, Mass. General Hospital, Boston, MA 02114.

The suprachiasmatic nuclei (SCN) receive a serotonergic (5HT) projection from the midbrain raphe nuclei. Quipazine phase shifts the SCN circadian clock in vitro in the presence of tetrodotoxin, suggesting that pacemaker cells in the SCN express 5HT receptors (*Brain Research* 573:336, 1992).

We used in situ hybridization to examine the expression of 5HT receptor subtypes in the rat SCN by film autoradiography. Rat serotonin receptor cDNAs were kindly provided by O. Civelli (5HT-1a) and D. Julius (5HT-1c, 5HT-2). Full-length ^{35}S-labeled cRNA probes were used for the 5HT-1a, -1c, and -2 receptors, while cRNA probes for the 5HT-1b and -1d receptors were generated from cDNA fragments cloned using PCR. 5HT-1c receptor mRNA showed intense hybridization in the SCN, as well as in caudate-putamen and choroid plexus. The mRNA for 5HT-1b receptor also displayed a consistent, though weak, signal in the SCN, and a stronger signal in the hippocampus, caudate-putamen, and thalamus. 5HT-1a and 5HT-2 receptor mRNAs were not readily detected in the SCN, even though an intense signal was seen in other brain regions. The 5HT-1d receptor mRNA was not detected in the SCN or anywhere else in the brain. There was no obvious circadian variation in signal intensity for any of the receptors examined. We conclude that 5HT-1c and -1b receptor mRNAs are the most highly expressed 5HT receptor subtypes in the rat SCN.

510.4

SEROTONERGIC REINNERVATION OF THE HAMSTER SUPRACHIASMATIC NUCLEUS AND INTERGENICULATE LEAFLET WITHOUT FUNCTIONAL CIRCADIAN RHYTHM RECOVERY. L.P. Morin and J. Blanchard*. Dept. Psychiatry, SUNY, Stony Brook, NY 11794.

Acute loss of serotonin changes several parameters of the circadian activity rhythm which persist in constant conditions (Brain Res. 515,9-19,1990; 566,173-185,1991). Serotonergic innervation of the suprachiasmatic nucleus (SCN) and intergeniculate leaflet (IGL), two nuclei involved in circadian rhythm regulation, may become re-established during long recovery periods. The present experiment tested a) whether serotonergic reinnervation occurs and b) if there is associated recovery of rhythm function.

Hamsters entrained to a LD 14:10 photoperiod received bilateral intraventricular injections of DHT after pretreatment with desmethylimipramine. The entrained circadian wheelrunning rhythm was studied for up to 20 wks post-lesion and related to the extent of serotonergic innervation.

Reinnervation of the SCN and IGL begins by 8 wks post-lesion and progresses to substantial, but not complete, levels by week 20. Four measures of the nocturnal activity phase of the circadian rhythm were rapidly modified by the lesions, consistent with previous studies, and persisted during the 20 wk recovery period. The circadian rhythm system of hamsters may be fundamentally different from other behavioral or neuroendocrine systems studied in rats with respect to its inability to recover from damage to its serotonergic innervation. Alternatively, the failure to demonstrate functional recovery may reflect a species difference or insufficient recovery time. Supported by NINDS 22168.

NMDA RECEPTORS IN RODENT SUPRACHIASMATIC NUCLEUS. M.D. Hartgraves, S.M. Grady and J.L. Fuchs*. Dept. Biological Sciences, University of North Texas, Denton, TX 76203.

NMDA receptors appear to be involved in mediating effects of light on circadian rhythms. Pharamacological studies indicate that glutamate may be a transmitter in the pathway from retina to suprachiasmatic nucleus (SCN), the primary circadian pacemaker. APV injected into the SCN diminishes light effects on the pineal (Ohi et al. '91), and systemic MK-801 injections can block effects of light on activity rhythms (Colwell et al. '90) and on fos-IIR in the SCN (Abe et al. '91).

The present study aimed to characterize NMDA receptors in the rat and hamster SCN. In addition, 34 rats were used to test for changes in NMDA binding which might contribute to the phase-dependency of light effects: comparisons were made between 4 time points in LD, and between L versus D near dawn or dusk. NMDA binding was also measured in 10 enucleated rats. Film autoradiographs were prepared from sections incubated with the NMDA antagonist [^{3}H]MK-801 (Monaghan '91). In both species, [^{3}H]MK-801 binding was moderately low in the SCN relative to other brain regions, was fairly uniform across the SCN region, and did not delineate the SCN. Scatchard analyses in SCN revealed similar binding properties in rat and hamster. ANOVAs showed no significant differences among treatment groups. The results demonstrate the presence of NMDA binding sites in the SCN; these binding sites could mediate NMDA antagonist-sensitive effects of light on rhythms. The absence of obvious changes attributable to enucleation, light condition or circadian time, suggests that in contrast to the phase-dependency of light effects on circadian rhythms, NMDA binding in the SCN is quite stable.

510.6

MELATONIN SENSITIVITY PERSISTS IN THE SCN IN VITRO. Russell R. Margraf and G. Robert Lynch*. Department of Biology, Wesleyan University, Middletown, CT 06459.

Past studies in the rat and Syrian hamster have shown that metabolic and electrical activity of the suprachiasmatic nucleus (SCN) is inhibited by melatonin (MEL) at about circadian time (ct) 8-11 h. This experiment examines the effect of MEL on the firing of SCN cells in brains slices prepared from 6 long day (LD 16:8) Djungarian hamsters (Phodopus sungorus). The primary aim of this study is to determine if MEL sensitivity persists in vitro with a period of about 24 h. Pressure ejection of MEL (0.2 mM in 165 mM NaCl) suppressed firing rate in 29% of SCN neurons, activated 9%, and had no effect on 62% (n=162). MEL elicited the highest percent response (71% of responding cells) during the 4 h time bin immediately preceding the projected "dark" phase on day 1 (ct 8-12 h). A similar pattern of MEL sensitivity was observed during this time bin on the second day of recording. Pressure ejection of vehicle alone had little effect (n=52) at all ct. These results demonstrate that MEL sensitivity persists with a period of about 24 h and does not require an endogenous MEL pulse the previous night to be expressed. Supported by NSF.

PARALLELISM BETWEEN NOCTURNAL CHANGES OF PLASMA MELATONIN AND TESTOSTERONE CONCENTRATIONS IN NORMAL MALE ADULTS. P.E. Schulz*, F. Chardon, M. Hugentobler and R.W. Rivest. Division of Clinical Psychopharmacology, Department of Psychiatry, Geneva University, IUPG, CH-1225 and Laboratory MNS, CH-1205, Geneva, Switzerland.

Differences or similarities in the temporal organization of hormones secretion in plasma reflect, among other phenomena, the activity of CNS pacemakers. We report on the simultaneous analysis of melatonin and testosterone concentrations. Five normal male subjects between 23 and 32 years old were studied during 2 non consecutive nights. Blood was withdrawn every 20 min during 12 hr, from 8:00 p.m. to 8:00 a.m. Testosterone concentrations during the night ranged from 3 to 10 ng/ml and melatonin from 20 to 200 pg/ml. The mean concentration of testosterone increased 1.5- to 2-fold during the second part of the night. For melatonin, this increase was 2.5- to 4-fold. The rhythms of melatonin and testosterone were similar. This was to the point of high synchrony in 5 of the 10 nights: the times of onset of secretion, as well as the slopes of increase in concentrations were the same for the 2 hormones. This positive relation between melatonin and testosterone nocturnal rhythms is in apparent contrast with the inhibitory action of melatonin on the reproductive system of several mammal species.
Dr. J. Arendt provided an antiserum for the assay of melatonin. The study was financed by grant No 3.811.0.87 from the Swiss national research foundation.

ROLE OF PROLACTIN AND TESTOSTERONE IN SEASONAL PHYSIOLOGICAL CHANGES IN COLLARED LEMMINGS. B. Gower*, T.R. Nagy, and M.H. Stetson. School of Life and Health Sciences, Univ. of Delaware, Newark, DE 19716.

Collared lemmings, *Dicrostonyx groenlandicus*, display several interesting physiological and morphological changes on a seasonal basis. During autumn and winter, or when exposed to an artificial short photoperiod, lemmings molt to a white pelage, increase in body mass, and develop a bifid "digging" claw. To determine the hormonal basis of these changes, we manipulated endogenous levels of prolactin (PRL) and testosterone (T) in animals exposed to short and long photoperiods. In animals transferred to 8L:16D, treatment with the dopamine antagonist sulpiride elevated PRL and prevented the molt to white pelage. Lemmings maintained under 16L:8D and displaying the summer pelage were treated with the dopamine agonist CB-154. When examined after both 3 and 6 weeks, treated animals had lower serum PRL than controls and had begun to develop the white winter pelage. Castration facilitated the pelage response to CB-154. CB-154 treatment had a negative effect on testes weights in intact animals, but had no effect on other parameters. Castration had a positive effect on body mass and claw size - an effect which was reversed by T administration. These results suggest that seasonal changes in PRL mediate changes in coat color, while body mass and claw size are regulated by steroid hormones.

ANDROGEN RECEPTOR MEDIATED SEXUAL DIMORPHISM OF SLEEP IN Tfm MICE. S.W. Yang*, J. Fang, and W. Fishbein. Dept of Psychology, The Graduate School of CUNY, N.Y., NY 10031

For the first time in 1987, we reported that sleep is sexually dimorphic in mice; prenatal stress sex reverses the sleep pattern of males, but not females. Prenatal stress reduces testicular enzyme activity with a reduction in plasma testosterone levels (Ward, 1984). In the present experiment we used androgen insensitive testicular feminized (Tfm) mice to investigate whether androgen receptors are involved in this phenomenon. EEG and EMG electrodes were implanted in four groups of adult animals: Normal males (Ta/y), normal females (Ta/Ta), heterozygous females (Tfm/Ta) and phenotypic female Tfm males (Tfm/y). Sleep recordings were taken continuously for 4 days.

Results: (1) Normal males spend less time in paradoxical sleep (PS) than normal females (3.95 vs 4.65 min/hr, p<.05). (2) PS in Tfm males is higher than all other groups (p<.05). (3) Daytime slow wave sleep is indistinguishable between all groups.

Conclusions: (1) The sexual dimorphism of sleep is replicated in another mouse strain. (2) Deficiency of androgen receptors causes genetic males to develop female sleep patterns.

NEUROCHEMICAL LESIONS OF THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS ACCELERATE PUBERTAL GONADAL GROWTH IN MALE FERRETS. Y.P. Tang* and C.L. Sisk. Neuroscience Program/Dept. Psychology, Michigan State University, East Lansing MI 48824.

Environmental photoperiod regulates the onset of puberty in male ferrets. Testicular growth is accelerated in ferrets that experience a transition from short to long days, compared to ferrets that are raised solely in short days. Daylength is transduced by the duration of the nighttime rise in pineal melatonin secretion. This circadian pattern of melatonin release is regulated by a neural circuit that includes the retina, suprachiasmatic nucleus (SCN), paraventricular nucleus (PVN), and superior cervical ganglion. In hamsters, the integrity of each of these structures is necessary for reproductive responses to photoperiod. In mustelids, the importance of the SCN for photoperiodic time measurement has been established, but other components of the circuit have not been functionally verified. In this experiment, axon-sparing neurochemical lesions of the PVN were made in short day-housed weanling (7 wk old) male ferrets by bilateral stereotaxic injections of N-methyl-D-aspartic acid (0.6 µl of 0.3M NMDA in artificial csf). The onset of pubertal testicular growth normally begins at about 18 wk of age in ferrets raised in short days. However, within 3 wk of the lesion, at 10 wk of age, mean testis width was significantly larger in ferrets with NMDA lesions compared to ferrets with sham lesions. At sacrifice (16 wk of age), mean testicular weight was greater in ferrets with lesions than in controls (0.92±0.08 vs 0.47±0.08 g; $p<0.05$), as was luteinizing hormone pulse frequency (5.0±1.6 vs 1.5±0.75 pulses/4 hr; $p<0.05$). Thus, pubertal activation of the reproductive system was accelerated by PVN lesions. These lesions result in reproductive responses that are similar to those induced in prepubertal ferrets by a short-to-long day transition. This is the first indication that the PVN is part of the photoperiodic time measurement system in a non-rodent species. Supported by HD26483 and HD00950.

THE EFFECTS OF ROTATING LIGHTING SCHEDULES ON ESTROUS CYCLICITY IN RATS. W.L. Woloshin and D.L. McEachron*.Biomedical Engineering and Science Institute, Drexel University, Philadelphia, PA 19104.

The activity patterns of females rats vary systematically with the days of the estrous cycle. Control of these sexual cycles is thought to involve a SCN-mediated circadian 'gate' interacting with an ovarian developmental clock. Given the strong ties between the SCN and photic environmental cycles,we examined the effects of different LD cycles on estrous rhythms.

Running wheel activity was monitored for 3 groups of female Sprague-Dawley rats. All were initially exposed to LD 8:16 for 4 weeks. All rats showed a circadian period of near 24 hours and an estrous cycle of 4 or 5 circadian cycles. Group 1 continued under this cycle for the remainder of the experiment, 13 weeks. Group 2 was exposed to rotating shift cycle which mimicked a typical human shiftworker's pattern, i.e., day, swing, and night shifts with weekends equivalent to day shift. Group 3 was exposed to a rapidly rotating schedule of 8 hour advances every 2 days.

Preliminary results indicate that Group 1 maintained a 24-hour circadian cycle and an estrous cycle equaling 4 or 5 circadian cycles. Group 2 animals consistently lengthened their circadian cycle to 25.2 hours and their estrous cycle to 5 circadian cycles. Group 3 animals displayed highly variable results: circadian cycles ranged from 24.2 to 25 hours and estrous cycles from 3 to 5 circadian cycles. We conclude that despite the speed of the 3-shift cycle, Group 2 animals entrained to the LD cycles. The consistent lengthening of circadian and estrous cycles in Group 2 and the discovery of estrous cycles equaling 3 circadian cycles (≈74 hrs) in Group 3 suggests that the relationship between circadian and reproductive cycles in female rats is more complex than has been suggested.

SEX DIFFERENCES IN SLEEP: EFFECTS OF ESTRUS CYCLE AND OVARIECTOMY. J. Fang*, S. J. Tien, S. W. Yang and W. Fishbein. Dept of Psychology, Graduate School of CUNY, New York, N.Y. 10031

Sleep is sexually dimorphic in rats: Males have more paradoxical sleep (PS) than females. However, it is not clear whether this sex difference is influenced by ovarian hormones and the 4-5 day estrus cycle. The present experiment examines this possibility.

Adult Male and female Sprague-Dawley rats were implanted with EEG/EMG electrodes. Sleep recordings were taken for 20-30 days in females and 4 days (randomly distributed in the same period) in males and ovariectomized females.

Results: (1) Males have more PS (3.86 min/hr) than females (2.98 min/hr; p<.02) in both daytime and nightime; (2) the sex difference in daytime PS is not influenced by estrus cycle or ovariectomy; (3) the sex difference in nighttime PS is due mainly to a decrease of PS during the proestrus phase (.88 min/hr vs 1.83 min/hr; p<.003); (4) ovariectomy eliminates the proestrus phase difference (2.06 min/hr); (5) SWS is indistinguishable between sexes.

Conclusion: (1) Nighttime PS depends upon the activational effect of ovarian hormones. (2) Ovarian hormones during daytime do not effect the sex difference in PS.

SUPRACHIASMATIC NUCLEUS (SCN) LESIONS INCREASE SUSCEPTIBILITY TO ACTIVITY-BASED ANOREXIA. E.Z. Stanley*, L.E. Doerries, T.S. Rieg and P.F. Aravich. College of William and Mary, Williamsburg, VA 23185; Christopher Newport University, Newport News, Va 23606; Eastern Virginia Medical School, Norfolk, VA 23501; & V.A. Med. Ctr., Hampton, VA 23667.

Suprachiasmatic hypothalamic nucleus (SCN) lesions eliminate a variety of circadian rhythms. Circadian rhythms are known to be perturbed in anorexia nervosa (AN). Because of interest in the relationship between exercise and AN we have been exploring activity-based anorexia (ABA) in the rat (1.5 h/day food; 22.5 h/day wheel access). We have previously found that constant bright illumination (LL) increases susceptibility to ABA. This experiment determined if SCN lesions have a similar effect. Circadian rhythms were disrupted in two ways, viz., LL and bilateral electrolytic lesions of the SCN, according to a 2 x 2 factorial design (SHAM vs SCN lesion x LL vs 12/12 hr light-dark illumination; LD). Following a postoperative recovery period, rats were subjected to ABA. Susceptibility to ABA was defined as the number of days to lose 25% of body weight. Analysis of ad lib food intake before and after surgery demonstrated that the circadian distribution of feeding was successfully altered by both the SCN lesion and LL treatments. When exposed to ABA, the SCN-lesioned groups required the least number of days to reach the weight-loss criterion, the SHAM LL group required an intermediate amount and the SHAM LD condition required the most days. There were no differences in terminal wheel revolutions or food intake across groups. These data indicate that a disruption of light-entrainable rhythms increases susceptibility to ABA. This raises the possibility that disrupted circadian rhythms are a novel risk factor for anorexia nervosa.

ABLATION AND PHARMACOLOGY STUDIES OF THE FOOD-ENTRAINABLE CIRCADIAN SYSTEM IN THE RAT. R.E. Mistlberger*[1], D.G. Mumby[2], T. Kippen[2] and I.Q. Whishaw[3]. Depts. Psychology, Simon Fraser U.[1], Burnaby, BC, U of British Columbia[2], Vancouver BC, and U. of Lethbridge[3], Lethbridge, Ab.

Rats anticipate a daily mealtime by entrainment of circadian oscillators outside of the suprachiasmatic nuclei (SCN). Neural mechanisms of this oscillator system are unknown. The present studies tested hypotheses concerning the possible role of sensory afferents and cortical, limbic and basal forebrain structures in the generation and entrainment of food-anticipatory rhythms. Food anticipation, measured by wheel-running and food-bin activity, was robust in rats sustaining (a) trigeminal nerve deafferentation, (b) complete ablations of the hippocampus and amygdala, their efferents and forebrain targets, (c) complete ablations of the nucleus accumbens, septum and adjacent medial forebrain and preoptic areas, or (d) complete removal of the neocortex. Intact rats receiving the dopamine antagonist haloperidol (IP, .3 or 2.0 mg/kg) 30 min prior to oral or intragastric feeding time showed some attenuation of anticipation and overall activity, but so did saline injected intragastric fed control rats. The results do not support previous suggestions that limbic or dopaminergic systems involved in memory and reinforcement processes have circadian functions necessary for food anticipation. EFFECTS OF THE PHOTOPERIOD ON WHITE ADIPOSE TISSUE CATECHOLAMINE CONTENT IN SIBERIAN HAMSTERS. T. G. Youngstrom* and T. J. Bartness. Depts. of Biology and of Psychology, Georgia State Univ., Atlanta, GA 30303.

We demonstrated previously that Siberian hamsters show impressive decreases in body weight, almost exclusively as body fat, during the first few weeks of short day (SD) exposure. This decrease in lipid stores is not accompanied by a significant decrease in food intake at this time. As an indication of sympathetic nervous system activity, and consequently lipid depletion, white adipose tissue (WAT) catecholamine (CA) content was measured in long day (LD)- and SD-housed hamsters. Male Siberian hamsters were killed 5 wk following transfer to SDs. Epididymal WAT (EWAT) and heart (control tissue) were harvested, and norepinephrine (NE), dopamine (DA) and epinephrine (EPI) content were measured by HPLC with EC detection. SD exposure increased NE content (ng/µg protein) in EWAT, but not in heart. DA content was not affected by the photoperiod for either tissue. For both photoperiods, the content of EPI was greater in EWAT than in heart. SD exposure increased EPI content in EWAT compared with that of the LD controls. Conversely, EPI content in heart was greater in LDs than in SDs. These results suggest that the rapid body weight (fat) decreases occurring during the first few wks of SD exposure may be due to an enhanced sympathetic nervous system drive on WAT. In addition, possible WAT *in situ* conversion of NE to EPI, or of EPI-containing neural input is suggested by the high EPI content in EWAT. Supported by NIMH RSDA MH 00841 and NIH DK 35254 to TJB.

PHOTOPERIODIC CONTROL OF BODY FAT REGULATION FOLLOWING LIPECTOMY IN SIBERIAN HAMSTERS. M. M. Mauer* and T. J. Bartness. Depts. of Biology and of Psychology, Georgia State Univ., Atlanta, GA 30303.

Siberian hamsters decrease body weight, primarily as body fat, when exposed to short, 'winter-like' days (SD). We were interested in testing whether the apparent ability to 'regulate' total body fat is photoperiod-dependent. In this experiment, male hamsters were housed in long days (light:dark 16:8) or transferred to SDs (light:dark 8:16) for 22 wks. SD-housed hamsters become photorefractory, showing gonadal recrudescence and body weight (fat) gain after ~20 wk of SD exposure. Therefore, we thought that surgical lipectomized (LIPX) hamsters undergoing naturally-occurring body weight (fat) increases would exhibit an enhanced ability to show seasonally-appropriate body fat levels. Paired epididymal white adipose tissue (EWAT) fat pads were removed (EWATx) or sham surgery was performed in LD hamsters and in SD hamsters exhibiting at least a 8% body weight loss across the 22wk SD period. Twelve weeks postsurgery some EWAT regrowth was seen in both LD and SD EWATx animals (47 & 23% of sham control values, respectively). Surprisingly, only LD EWATx animals returned to sham body weight and total carcass lipid levels. The LIPX-induced deficit in total body fat was compensated by retroperitoneal and dorsal WAT pad weight increases above sham values. These LD results suggest a seasonally-appropriate ability to regulate total body fat that is not seen in SD recrudescing hamsters. This inability of SD EWATx hamsters to regulate total body fat may reflect a permissive action of the gonadal steroids on fat accumulation, since their testes only were partially recrudesced (mean paired weight=~250mg). Testes of this size likely would be accompanied by relatively lower serum testosterone (T) concentrations. The possible role of T in the ability to regulate seasonally-appropriate body fat levels is currently being examined. Supported by NIMH RSDA MH 00841 and NIH DK 35254 to TJB.

BIOLOGICAL RHYTHMS AND SLEEP VI

HOST CLOCK RESETS PHASE OF METABOLIC ACTIVITY OF GRAFTED SCN. J. Servière[1], J. le Sauter[2] and R. Silver[2]. [1]Physiol. Sens. INRA, 78350 Jouy/Josas, France ; [2]Barnard College Columbia Univ., N.Y., N.Y. 10027.

In mammals, the suprachiasmatic nuclei (SCN) act as the dominant pacemaker controlling circadian rhythms (CR). In rodents, ^{14}C-deoxyglucose (2-DG) studies have demonstrated, both *in vivo* and *in vitro* that SCN energy consumption fluctuates with high levels of glucose utilisation during subjective day. In SCN lesionned animals, locomotor activity CR can be restored by transplantation of fetal whole tissue containing SCN. In intact animals, grafts can develop without altering period or phase of the host. To further explore interactions between host and donor SCNs, supernumerary SCN from neonates were implanted in intact adults male Syrian Hamsters ; the phase of the CR in host and donor SCNs were examined using 2-DG metabolic activity as an index.

Host and pregnant hamsters were housed in opposite light/dark cycles. On the day of birth, whole tissue containing SCN from neonates was implanted into the IIIrd ventricle of intact adults. Locomotor activity was recorded under constant darkness. 2-DG was injected during inactive (CT05) and active (CT14) periods. On the first day after grafting, the donor clock retained its phase indicating that isolation of the SCN from the fetal brain and implantation into the adult host animal did not disrupt circadian rhythmicity in the donor clock. From the 14th day after grafting, host and donor SCN were in synchrony, invariably with the phase of the host animal. The results indicate that the host SCN sends a signal which is effective in reseting the grafted SCN, and not vice versa. Further 2-DG injections at various delays after grafting will help to determine whether a diffusible signal is involved in synchronizing the two clocks. Supported by grants from INRA (J.S.) and AFOSR F49620 (R.S.).

SUPRACHIASMATIC NUCLEUS TRANSPLANTS NORMALIZE ENTRAINMENT IN AGED TAU MUTANT HAMSTERS. M. W. Hurd and M. R. Ralph*. Dept. of Psychology, Univ. of Toronto, Toronto, Ontario, Canada, M5S 1A1.

Fetal suprachiasmatic nucleus (SCN) transplants are able to restore circadian activity rhythms that have been eliminated by lesions. Using a period mutation in the golden hamster, tau, transplants between wild-type hamsters and mutant hamsters have demonstrated that period (24 vs. 20 or 22 hours) is an endogenous property of the tissue grafts. Expression of the donor rhythm requires at least a partial lesion of the host SCN and both donor and host rhythms may appear simultaneously if the host SCN is partially ablated. The partial SCN lesion causes reproducible changes in activity rhythms including shortened period, reduced amplitude and fragmentation. Similar changes accompany aging in animals which may reflect a progressive cellular and/or synaptic degeneration within the SCN. We have therefore investigated expression of fetal SCN grafts in intact, aged hosts and have found previously that grafts are capable of increasing total activity and altering the period of the host.

In these experiments, tau mutants that had received wild-type grafts were placed into a 14:10 light-dark (LD) cycle to assess entrainment patterns. Fetal tissue blocks from wild-type animals were harvested and transplanted into hosts of different tau genotypes using a standard protocol described elsewhere (Ralph et al., 1990). Preliminary results suggest that transplanted animals are able to entrain to a LD cycle. Normally, tau mutants are either unable to entrain to a LD cycle or they entrain with an abnormally advanced phase angle (Ralph & Menaker, 1988). However, mutant animals with wild-type implants exhibited entrainment patterns that are characteristic of the wild-type. These results suggest that the SCN graft is able to integrate functionally with the circadian system of the aged host.

CIRCADIAN RHYTHMICITY RESTORED BY RAT-TO-HAMSTER ANTERIOR HYPOTHALAMIC (AH) HETEROGRAFTS IS NOT ABOLISHED BY INDUCTION OF ANTIGENIC RESPONSE TO RAT. P.J. Sollars* and G.E. Pickard. Department of Psychiatry, Univ. of Penn., Philadelphia, PA 19104

We have reported that rat-to-hamster heterografts of fetal AH tissue containing the suprachiasmatic nucleus (SCN) are able to restore circadian rhythmicity to arhythmic, SCN-lesioned hosts. To determine the extent to which the rat implant is responsible for generating the restored rhythm, seven successful restorations of rhythmicity were followed after several weeks by application of rat skin grafts onto the dorsal surface of the hamster host to trigger an immunological rejection of the AH heterografts. In animals with the most robust restored circadian patterns of locomotor activity, this procedure failed to abolish or even to disrupt the rhythm. This suggests either that the skin grafts did not induce a rejection of the implanted neural tissue, or that the observed rhythmicity arose from an oscillatory capacity remnant in the brain of the SCN-lesioned hamster hosts. Histological evaluation of the damage to the host SCN and of the viability of the neural implant will be conducted to distinguish between these possibilities. Supported by MH47501 to GEP.

ALTERATIONS IN NEURONAL EXCITABILITY IN VENTROBASAL COMPLEX OF THE RAT ACCOMPANYING CHANGES IN STATE OF AROUSAL. G.A.Marks' and H.P.Roffwarg. Dept. of Psychiatry, Southwestern Med. Sch., Dallas, TX 75235.

Neurons of the thalamus are influenced by state of arousal. Transfer of information through the thalamus is subject to state-specific alterations related both to inhibition and excitation. The absence of inhibitory interneurons in many dorsal thalamic nuclei, including ventrobasal complex (VB), of rat provides a specialization for studying the consequences of altered inhibitory mechanisms. Spontaneous activity of VB neurons in the rat and in neurons in thalamic nuclei that contain interneurons is similar in that discharge rate is high in active waking and REM sleep and low in SW sleep. However, bursting discharge occurs in rat VB neurons during REM sleep rather than the single spike discharge that characterizes the REM sleep in other thalamic nuclei. Inasmuch as bursting activity is associated with inhibition in thalamic neurons, we attempted to uncover whether the pattern of excitability across states of arousal is different for VB neurons in rat.

Excitability of individual VB neurons was measured by the proportion of responses to near threshold level shocks (50% in SW) applied to the medial lemniscus during different states of arousal. In the majority of cases, we observed high levels of excitability in waking and REM sleep and relatively low levels in SW sleep. These are the same excitability changes observed in other thalamic nuclei. We conclude that the altered discharge pattern of VB neurons in rat does not make for a major functional change in state-dependent-information transfer through this thalamic nucleus.

511.5

A CONTROLLED WAVELET TRANSFORM FOR BIOLOGIC TIME-SERIES. S. J. Schiff*, Dept. of Neurosurgery, Children's Nat. Medical Center, Washington, D.C. 20010.

Fourier transforms have had wide application to detect periodic components in biologic time-series, and are most accurate when applied to long time-series with "stationary" mean values. When faced with non-stationary, erratic biological signals, wavelet transformations permit one to continuously explore along a signal for meaningful patterns at progressively smaller time scales. Recent use has been made of pseudo-random number controls to identify non-random clustering in 2 dimensional maps of galaxy and asteroid distribution using wavelet transformations. This same control technique is here applied to 1 dimensional time-series. The method is developed and verified with transient periodic functions, using sine functions contained within Gaussian envelopes contaminated with added noise. Noise can be effectively filtered out using pseudo-random number time series as controls, and non-random clustering of points and periodicity detected. The ability to detect fractal and chaotic behavior is explored. The method is then applied to a set of experimental time-series of spinal cord reflexes that has been previously characterized as a linearly correlated stochastic process. This method is widely applicable to experimental data from many biologic systems.

511.6

SPONTANEOUS PHASIC ACTIVITY IN TWO THALAMIC NUCLEI DIFFERS ACROSS BEHAVIORAL STATE. L.D. Sanford, A.R. Morrison*, W.A. Ball, R.J. Ross and G.L. Mann. Depts. of Anim. Biol., and Psychiatry, Univ. of Penn. and VAMC., Phila., PA 19104.

Ponto-geniculo-occipital waves (PGO) recorded from the lateral geniculate body mark the onset and course of rapid eye movement sleep (REM). PGO-like waves occur in many brain areas including the thalamic central lateral nucleus (CL). Both PGO and CL waves occur spontaneously and may be elicited by "alerting" stimuli in all behavioral states. Both nuclei receive cholinergic input from the mesopontine region thought to be responsible for PGO generation. To determine whether waves in CL and LGB could be produced by common generator mechanisms we compared rate/min of each wave in non-REM (NREM), transition from NREM into REM (T) and REM. The subjects were 5 cats with standard sleep recording electrodes (EEG, EOG, and EMG) and with depth electrodes in LGB and CL. Rate/min of both waves was consistent across episodes and within cats during each test state. PGO rate/min was greater in REM (58 $\pm$ 2.0) and T (36 $\pm$ 3.7) than in NREM (9 $\pm$ 0.71). CL wave rate/min was somewhat greater during NREM (10.7 $\pm$ 3.4) than T (2.8 $\pm$ 0.8) and REM (0.9 $\pm$ 0.5) although the difference did not reach significance ($p < .08$). PGO rate/min was higher than CL wave rate/min during T ($p < .01$) and during REM ($p < .001$). There was no significant difference between PGO and CL waves during NREM. Although similar rates/min of PGO and CL waves were found in NREM, waves in each nucleus occurred concurrently or independently. CL waves were infrequent in T and REM, when PGO were most frequent. The results indicate that macropotentials in CL and LGB are not the same waves propagated anteriorly from a common brainstem generator region, and that their mechanisms are differentially active across behavioral state. We suggest that phasic activity during REM, which may be recorded in many areas of the brain, is not a unitary phenomenon. Supported by MH-42903, MH-18825 and the D.V.A. Med. Res. Serv.

ONTOGENY OF THE CIRCADIAN LOCOMOTOR ACTIVITY RHYTHM IN CRAYFISH. M. L. Fanjul-Moles*, M. Miranda-Anaya and J. A. Prieto-Saqredo. Lab. de Neurofisiología Comparada, Fac. Ciencias, UNAM., México, D. F., 04510, MEXICO.

The aim of this work was to investigate the temporal organization of locomotor activity during ontogeny in crayfish. *Procambarus clarkii* juvenile instars, aged between 10 and 120 days after hatching, were individually housed in especially designed activity recording cages under constant temperature conditions. The animals were divided in two experimental groups (n=20). In a first group each crayfish was left in free running condition under darkness (DD) during 30 days. In a second group each crayfish was in DD free running for at least 10 days and afterwards changed to a light dark cycle (LD 12:12) during the next 20 days. In general the activity rhythms of juvenile instars were not nearly as robust as those expressed by adults[1], and activity onsets were not well defined. 58% of animals examined between 10 and 90 days exhibited a circadian activity rhythm in DD (τ=23.3 hrs). Only the 50% of this age animals showed the ability to synchronize to LD cycle (τ=24.1 hrs). The juvenile crayfish 120 days old displayed a free running clearer and shorter circadian activity rhythm (τ=21.7 hrs) and fully synchronized to the LD cycle (τ=23.7 hrs). This result , although preliminary seems to indicate that the expression of the overt activity rhythm in crayfish is related to the postembryonic development.

This work was partially supported by PADEP UNAM FC9120 and CONACyT CON 39 POS.

CIRCADIAN REGULATION OF EFFERENT OPTIC NERVE ACTIVITY IN *LIMULUS*

CL Passaglia, WW Weiner, M Raghavan and RB Barlow, Jr.*
Institute for Sensory Research, Syracuse University, 13244

A circadian clock in the brain modulates sensitivity of the *Limulus* lateral eye via efferent fibers traveling in the optic nerve. The rhythmic efferent signals regulate numerous structural and functional properties of the retina that combine to enhance nighttime sensitivity as much as 10^6 times (Barlow *et al., J Gen Physiol* 89: 353-378, 1987). We analyzed the temporal characteristics of the clock's output by recording for several days from efferent fibers of the lateral optic nerve in restrained animals partially submerged in a seawater aquarium placed in a light-proof Faraday cage.

No efferent activity is detected during the animal's subjective day, but a structured firing pattern is observed during the animal's subjective night. Throughout most of the night, efferent spikes are fired in highly synchronous bursts of about 10-12 spikes each. Clusters of 6-12 bursts are grouped into packets separated by long intervals of inactivity ("dead time"). The intervals between spikes, bursts, clusters, and packets are shortest in the early evening and lengthen throughout the night. The burst rate is highest following the onset of activity, decreases as the night progresses, and stops by dawn. Prior to dawn, the interspike interval can lengthen to the point that discrete bursts are no longer distinguishable suggesting a gradual uncoupling of efferent cell bodies in the brain. This complex temporal organization of activity may indicate the presence of nested oscillators that control the various periods of efferent activity: interspike (ms), interburst (1-7 sec), intercluster (>10 sec), interpacket (mins), and circadian (~24hr).

EXPRESSION OF PERIOD (*PER*) REPEAT SEQUENCE WHICH EXISTS IN *DROSOPHILA* CLOCK GENE IN THE RAT BRAIN. N.Shibata*[1], S.Noji[2], K.Ono[3], T.Nohno[5], N.Ishida[4], Y.Mitsui[4], A.Tokunaga[3], S.Taniguchi[2] and T.Ohmoto[1] Dept. of Neurological Surgery[1], Dept. of Third Anatomy[3], Okayama Univ. Med. Sch., Dept of Biochemistry[2], Okayama Univ. Dental Sch., Okayama, 700, Cell Science and Technology Division[4], Fermentation Research Institute, Agency of Industrial Science and Technology, Tsukuba Science City, 305, Dept. of Pharmacology[5], Kawasaki Medical College, Kurashiki, 701-01, Japan

This study aims to elucidate circadian rhythm in mammals. *Per* repeat sequence, which is a hexamer repeat sequence (ACNGGN)n, exists in the clock gene of *Drosophila*. A fragment of the genomic DNA containing *per* repeat was cloned from mouse liver DNA library, and was identified to be cp2.2. Eleven cDNA recombinants were cloned with cp2.2 from rat brain cDNA library. One of them was designated pRB15, which contained *per* repeat. The temporal and spatial expression of genes hybridized with pRB15 was examined in the adult rat brain by *in situ* hybridization. Hybridization signals were obserbed in almost all neurons. Fluctuation of the signals under the light-dark cycle was apparently observed in the suprachiasmatic nucleus; the hybridization signals was intense in the middle of the day, but became weak in the middle of the night. However, the signal stayed relatively constant in other brain regions. The signal was detected in some glial and ependymal cells in the day but few in the night. The present findings suggest that genes hybridized with the *per* repeat sequence may be involved in the circadian rhythm in the rat nervous system.

THE GENICULOHYPOTHALAMIC COMPONENT OF THE CIRCADIAN SYSTEM IN A MUTANT ANOPHTHALMIC MOUSE: CYTOARCHITECTURE AND IMMUNOCYTOCHEMISTRY FOR NEUROPEPTIDE Y (NPY). L. K. Laemle* and J.E. Ottenweller. Dept. of Anatomy, Cell Biology and Injury Sciences and Dept. of Neuroscience, New Jersey Medical School, Newark, NJ 07103.

Circadian rhythms generated by the suprachiasmatic nuclei (SCN) are entrained to environmental light. Light information normally reaches the SCN through two visual pathways: a direct pathway (RHT) from the retina and an indirect pathway (GHT) from the intergeniculate leaflet (IGL). The mutant anophthalmic mouse is characterized by the absence of the RHT.The development of the GHT in these animals has not been explored. In the normal mammalian system GHT terminals in the SCN are known to contain NPY. We have used light microscopic methods to examine the GHT in anophthalmic mice. Serial sections were stained with cresyl violet for study of cytoarchitecture or with immunocytochemical methods for localization of NPY. Our data demonstrate that the IGL is well developed in anophthalmic mice. Perikarya and fibers in the IGL are immunoreactive for NPY, and based on a robust plexus of NPY fibers and terminals in the SCN, we conclude that a GHT develops in the absence of visual input. (Supported by a grant from the Whitehall Foundation).

BIOCHEMICAL MODELING OF THE BULLA GOULDIANA OCULAR CIRCADIAN CLOCK, Michael H. Roberts*, Dept. of Biology, Clarkson University, Potsdam, NY, 13699

The eyes of several marine snails contain circadian pacemakers. Although these clocks have been extensively studied, no detailed model of the cellular mechanism regulating the circadian rhythm has been explicitly formulated. Based upon some recent inhibitor studies, we have proposed that the cellular mechanisms generating the circadian and cell division cycles may be similar (Roberts et al., 1992). In support of this proposal, a 29kDa homolog of the cell-cycle kinase, p34cdc2, is found in the Bulla eye (Leader and Roberts, in prep.).

In an attempt to further support our proposal, a mathematical simulation derived from a model of the cell cycle (Tyson, 1991) is used to model the molluscan circadian rhythm. Manipulation of rate constants in the model corresponding to protein synthesis and tyrosine kinase activity produces results which match the effects of protein synthesis and tyrosine kinase inhibitors on the phase and the period of the circadian rhythm. In addition, period stability in spite of rate constant manipulation can be observed, suggesting a mechanism for the temperature compensation of circadian rhythms. These simulations provide support for the hypothesis that circadian rhythms in the molluscan eye are generated by biochemical processes similar to those generating the cell division cycle. Supported by NS26272.

ANISOMYCIN BLOCKS PHASE SHIFTS OF THE *BULLA* CIRCADIAN PACEMAKER TO LOW EXTRACELLULAR CA^{2+} PULSES. S.B.S. Khalsa* & G.D. Block. Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22901.

Circadian studies have revealed 2 types of phase response curves (PRC's) which are shifted 12 hrs in time from each other. In *Bulla* and *Aplysia* pulses of light, depolarizing seawater, cGMP (*Aplysia*) and depolarizing current injection (*Bulla*) yield PRC's with phase shifts in the subjective night (depolarizing-type PRC). Pulses of cAMP, hyperpolarizing seawater, serotonin (*Aplysia*), hyperpolarizing current injection (*Bulla*), low extracellular Ca^{2+} (*Bulla*) and FMRFamide (*Bulla*) yield PRC's with phase shifts largely in the subjective day (hyperpolarizing-type PRC). It has been hypothesized that the membrane potential rhythm drives a transmembrane Ca^{2+} flux rhythm, and these agents all phase shift by perturbing Ca^{2+} flux. Depolarizing-type PRC agents phase shift by generating a Ca^{2+} influx during the subjective night when it is normally low; hyperpolarizing-type PRC agents phase shift by inhibiting Ca^{2+} influx during the subjective day when it is normally high.

Studies in *Aplysia* have shown that serotonin and cAMP-induced phase shifts are blocked with anisomycin. This study addresses whether a similar blockade can be observed in *Bulla* for hyperpolarizing-type PRC agents. Pulses of low Ca^{2+} seawater (with EGTA) were applied in the late subjective day from CT 8-14 to yield phase advances relative to controls. When this experiment was repeated with additional 0.75 uM anisomycin applied to both experimental and control eyes from CT 7-14, no phase shift was apparent. Anisomycin applied alone at this phase has little effect. Preliminary data suggest that FMRFamide-induced phase advances may also be blocked with anisomycin.

These data provide support for the hypothesis that agents generating a hyperpolarizing-type PRC act via a common mechanism: inhibition of transmembrane Ca^{2+} flux, which in turn generates a phase shift via a protein synthesis-dependent mechanism. *Supported by NS15264 to G.D.B.*

THE TRANSCRIPTION INHIBITOR, 5,6-DICHLORO-1-ß-D-RIBOFURANOSYLBENZIMIDAZOLE (DRB) BLOCKS THE PHASE-SHIFTING EFFECT OF cGMP ON THE CIRCADIAN RHYTHM OF NEURONAL ACTIVITY IN RAT SCN *IN VITRO*. C. Liu* and M.U. Gillette. Neuroscience Program and Dept. of Cell and Structural Biology, Univ. of Illinois, Urbana, IL 61801.

A phase advance of the circadian rhythm of neuronal activity in the SCN is induced with subjective night-time treatment with cGMP analogs. The phase-shifting effect of cGMP could be mediated by regulating transcription or changing post-transcriptional processes. To study the two possibilities, we have examined the effect of the reversible trancription inhibitor DRB on the SCN circadian rhythm and tested whether it could block the phase-shifting effect of cGMP.

Coronal hypothalamic slices containing the SCN were prepared from 8 wk old female Long Evans rats housed in a 12L:12D cycle. The medium in the brain slice chamber was replaced with fresh medium containing DRB, 8-Br-cGMP or both for designated periods. The neuronal activity rhythm in SCN was measured by monitoring firing rates the following day.

A two-hour pulse of DRB (100 μM) given at CT 13-15 had no detectable effect, however, when given at CT 1-3, CT 5-7, CT 9-11, CT 17-19 and CT 21-23, it produced either arrythmicity or multiple activity peaks. DRB (10 μM) had no effect at CT 13-15 and CT 17-19 but disordered the circadian rhythm when given at CT 5-7 and CT 9-11. Treatment with 1-hr 8-Br-cGMP(0.5 mM) at CT 17-18 caused 6-7 hr phase advance. This phase-advance effect was totally blocked in the presence of 10 μM DRB (CT 17-19). When a DRB pulse was given either before the 8-Br-cGMP pulse at CT 15-17 or 1 hr late at CT 18-19, the effect of the cGMP anolog was not blocked. These results demonstrate: 1) the SCN circadian rhythm is insensitive to DRB treatment during early to middle subjective night but interrupted by the treatment at other circadian times; 2) DRB blocks the resetting effect of cGMP. They suggest that transcriptional events are involved in maintaining the circadian oscillator and that immediate early gene transcription may mediate the phase-shifting effect of cGMP. CIRCADIAN VARIATION IN S100 PROTEIN IN HAMSTER CNS. U. Vaidya*, L. Morin and M. R. Wells. Nerve Regeneration Research Laboratory, Dept. of Veterans Affairs Med. Center, Northport, N.Y. 11768 and Depts. of Neurology and Psychiatry, SUNY, Stony Brook, N.Y. 11794.

Astrocytes participate in a variety of localized functions including the inactivation of neurotransmitters, extracellular ionic concentrations, and possibly the supply of trophic factors to neurons. A calcium binding, astrocyte-specific protein, S100b, has recently been reported to have neurotrophic activity in both the peripheral and central nervous systems. We now report preliminary evidence that S100b production varies during the circadian cycle in both the suprachiasmatic nucleus and in other areas of CNS. Adult, male hamsters (n=7 per group) were maintained on a (10:14) light /dark cycle. Tissue samples, consisting of spinal cord, visual cortex, somatomotor cortex, optic nerves, suprachiasmatic nucleus including a portion of the underlying chiasm, anterior hypothalamus, and hippocampus were taken at the midpoint of the light and dark cycles. Samples were homogenized, and the soluble fraction examined for content of S100b protein using an enzyme-linked immunoassay. Content of S100b protein was expressed as a function of total protein content in the soluble fraction. Significant light-dark (L>D)differences were observed in visual cortex and suprachiasmatic nucleus ($p<0.05$). Optic nerve also showed a similar trend which was not statistically significant. Spinal cord and anterior hypothalamus showed a significant D>L difference ($p<0.05$). These data provide evidence for a greater content of S100b protein in astrocytes at times of increased neuronal activity at different points in the circadian cycle. Supported by the Dept. of Veterans Affairs.

H8 BLOCKS QUIPAZINE-INDUCED PHASE ADVANCES OF THE MAMMALIAN CIRCADIAN CLOCK IN VITRO. R.A. Prosser*, H.C. Heller, and J.D. Miller. Dept. of Biological Sciences, Stanford University, Stanford CA 94305.

The mammalian circadian clock located in the suprachiasmatic nuclei (SCN) produces a 24 hr rhythm in spontaneous activity when isolated *in vitro*. This clock can be phase-shifted *in vitro* by a variety of agents, including cAMP analogs and the serotonin agonist quipazine. cAMP analogs induce phase advances in the subjective daytime, while quipazine induces daytime phase advances and nighttime phase delays. The daytime effects of quipazine are mimicked by the 5-HT_{1A} agonist 8-OH-DPAT and blocked by the 5-HT_{1A} antagonist NAN-190. Since 5-HT_{1A} receptors stimulate cAMP production in some systems, we investigated whether the effects of quipazine could be blocked by the protein kinase A inhibitor H8.

Coronal brain slices containing the SCN, prepared from male Wistar rats housed in a 12:12 LD cycle, were maintained in constant perifusion conditions. At a specified time during day 1 *in vitro* the tissue was treated for 1 hr with either quipazine (1 uM), H8 (5 uM), or quipazine + H8. The activity of single cells was recorded extracellularly on day 2 and their firing rates were averaged into 2 hr intervals to determine the pattern of SCN neuronal activity. This rhythm was then compared to that seen in untreated slices.

We find that, while H8 has no effect by itself at CT 6, it blocks the phase advance induced by quipazine at this time (2.88±0.13 hr advance with quip., N=2, vs 0.83±0.13 hr advance with quip+H8, N=3). In contrast, preliminary results suggest that H8 does not block quipazine-induced phase delays at CT 15. Other preliminary results suggest that H8 alone induces significant phase-delays when applied at CT 10. These results suggest that the chain of events through which quipazine phase-advances the SCN clock includes the following: bind to 5-HT_{1A} receptor -- incr. cAMP -- stimulate protein kinase A. ALTERATIONS IN CIRCADIAN CONTROL IN SPONTANEOUSLY HYPERTENSIVE RATS. R.V. Peters[1]*, E.G. Stopa[2], G. Anderson[3] and H.E. Albers[1]. [1]Lab. of Neuroendocrinol. & Beh., Depts. Biol. & Psych., GA State University, Atlanta GA 30303; [2]Dept. Path. & [3]Dept. Med., SUNY Health Science Center, Syracuse, NY 13210.

The suprachiasmatic nuclei (SCN) of spontaneously hypertensive rats (SHR) contain higher levels of vasoactive intestinal peptide (VIP) mRNA than do the SCN of normotensive Wistar-Kyoto (WKY) control rats. Since the SCN is the site of a putative circadian pacemaker, and VIP is hypothesized to play an important role in the control of circadian rhythms, we have investigated whether circadian control is altered in SHR rats. Previously, we have reported that the onset of activity occurs nearly 1.5 hrs earlier relative to lights off in SHR rats than in WKY controls. The present study examined whether the difference in the timing of activity onset might result from differences in the free-running period of the underlying circadian pacemaker. The free-running period of the circadian activity rhythm in constant darkness was significantly shorter in SHR rats than in WKY controls. The free-running period was lengthened by constant light in both groups but remained comparatively shorter in SHR rats. Following the experiments, the SHR rats were confirmed to have higher blood pressure than WKY controls. These data suggest that the circadian period may be related to the levels of VIP in the SCN. (Supported by AG09301).

DIURNAL RHYTHM OF GALANIN-LIKE IMMUNOREACTIVITY IN HYPOTHALAMIC NUCLEI OF THE RAT. A. Akabayashi[1], J.I. Koenig[2], J.T. Alexander[1], S.E. Kyrkouli*[1], and S.F. Leibowitz[1]. [1]The Rockefeller Univ., NY, NY 10021 and [2]Georgetown Univ. Sch. Med., Wash DC 20007

Galanin (GAL) is found to be abundant in the hypothalamus and has a range of functions in the physiological control of various endocrine and behavioral process. The purpose of this study is to examine the diurnal rhythm in hypothalamic GAL levels to explore possible new roles for this brain peptide. Male Sprague-Dawley rats, maintained on a 12:12 hr light/dark cycle, were sacrificed by decapitation at light (N=10) and dark (N=10) onset. Ten hypothalamic nuclei, and the anterior (AP) and posterior (PP) pituitary were microdissected. GAL was measured by RIA. Circulating serum corticosterone (CORT), aldosterone (ALDO), insulin, and glucose levels were also determined.

GAL levels were significantly higher at dark onset relative to light onset in the suprachiasmatic nucleus (24.5 ± 4.4 vs. 10.9 ± 1.8 ng/mg protein, in the light, $p<0.02$) and the supraoptic nucleus (30.7 ± 4.3 vs. 15.3 ± 2.0 ng/mg protein, $p<0.01$). While a reverse trend, higher GAL levels at light onset, was apparent in the magnocellular paraventricular nucleus (PVN; 25.0 ± 5.1 vs. 19.1 ± 4.6 ng/mg protein, $p>0.1$), other areas (parvocellular PVN, arcuate nucleus, AP, and PP) exhibited no diurnal rhythm of GAL levels. Measurement of circulating levels of hormones revealed strong diurnal light/dark rhythms for CORT and ALDO, with peak levels at dark onset. No significant relationship between these hormones and GAL levels was detected. These results indicate possible roles of GAL in biological circadian rhythm.

511.18

EARLY DESIPRAMINE EXPOSURE ALTERS CIRCADIAN RHYTHMS IN RATS. A. M. Rosenwasser* and M. J. Hayes, Dep't of Psychology., Univ. of Maine, Orono, ME 04469.

Rats exposed to desipramine during early postnatal development show neuro-behavioral alterations in adulthood that may model human depression. In the present study, we applied this model to the study of free-running circadian drinking rhythms. Neonatal rats were cross-fostered and culled into litters. Male pups were given daily desipramine (5.0 mg/kg, s.c.; N=6) or saline (N=6) injections on postnatal days 8 through 22. After weaning, animals were housed individually and drinking was continuously monitored during extended exposure to constant darkness (DD), constant light (LL), and re-exposure to DD. Desipramine-treated rats showed unusual instability of free-running period and generally longer periods than saline-treated rats under DD, but periods did not differ in LL. Desipramine-treated rats also showed increased intake of a 10% alcohol solution, consistent with a previous report. These results indicate that developmental perturbation of monoaminergic systems can alter circadian rhythmicity and behavior in adulthood.

512.1

A PARADOXICAL SLEEP WINDOW FOR PLACE LEARNING IN THE MORRIS WATER MAZE. G.M. Rose* and C. Smith, Medical Research VAMC, Denver, CO, U.S.A. and Dept. of Psychology, Trent University, Peterborough, Ontario, Canada

Paradoxical (PS) sleep, or REM sleep, deprivation is known to disrupt learning in both human beings and laboratory animals. Recently it has been shown that loss of PS during distinct periods, termed PS or REM windows, is as effective in inducing learning impairments as is total PS deprivation. In rats, PS is accompanied by rhythmical slow activity ("theta" rhythm) in the hippocampus. Electrical stimulation patterned to mimic this theta rhythm is very effective in inducing long-term potentiation (LTP), a lasting increase in synaptic strength which is thought to serve as a memory encoding device. Taken together, these observations suggest the possibility that endogenous plasticity mechanisms are engaged during the PS window. However, a necessary step in verifying this hypothesis involves demonstrating the existence of a PS window for a hippocampus-dependent learning task.

Long-Evans rats were given 4 trials/day in the place learning version of Morris water maze. The rats were then selectively deprived of PS for a specific 4-hour interval after training. It was found that PS deprivation during the window 5-8 hours after training, but not at other intervals, delayed the learning of the location of the hidden platform. Thus, PS during a particular period after training is necessary for normal acquisition of this hippocampus-dependent place learning task. Studies are currently in progress to evaluate whether NMDA-receptor antagonists, administered during the PS window, will also retard place learning in the water maze.

512.2

CORONARY FLOW SURGES ENHANCED DURING THE PHASIC MUSCLE TWITCHES OF REM SLEEP. **LW Dickerson, MM Thurnher, RL Verrier.* Georgetown University School of Medicine, Department of Pharmacology, Washington DC 20007**

Previous studies in dogs showed dramatic increases in coronary blood flow (CBF) coupled with episodes of sinus tachycardia during REM sleep. The present report found that 90% of these surges were concentrated in periods of phasic REM sleep and only 10% in tonic REM sleep. The incidence of these surges was related to the degree of phasic eye movement activity, in that the surges were three times more frequent during intensely phasic REM sleep than during moderately phasic REM sleep. However, the magnitudes of heart rate and CBF surges were unaffected by the particular substage of REM sleep in which the surge occurred.

An additional enhancement of the magnitude of CBF surges was associated with the presence of phasic muscle twitches and not with frequency of eye movements or PGO waves. The increase in CBF (29.3% ± 1.8%) was significantly greater ($p<0.006$, unpaired t-tests) in phasic REM sleep with muscle twitches (n=100 events) than in phasic REM sleep without twitches (21.6% ± 1.8%) (n=62 events). There were no changes in blood pressure in either group and no significant differences in the magnitudes of the increase in heart rate between these two groups. CONCLUSIONS: (1) A mechanism other than enhanced cardiac metabolic demand (HRxSBP) is implicated in the additional 8% increase in CBF concomitant with muscle twitches during REM sleep. (2) The tachycardia-associated surges in CBF represent part of the repertoire of autonomic responses intrinsic to the phasic periods of REM sleep in dogs. (3) The phasic events of REM sleep (eye movements vs. muscle twitches) affect the incidence and magnitude of CBF surges differentially.

512.3

SLEEP APNEA PATTERNS IN LEAN AND OBESE ZUCKER RATS. **S. De Mesquita*, K.A. Burgess and E. A. Schoene. Dept. of Physiology, Marshall University School of Medicine, Huntington, WV 25755-9340.**

Sleep apnea is strongly associated with obesity in humans. This study investigated the frequency and type of sleep apneas in obese and lean Zucker rats. Nine lean (475±6g) and six obese (743±20g) Zucker rats were implanted with EEG and EMG electrodes and allowed to recover. All rats were monitored for sleep-wake pattern for 4 hr on five consecutive days. Prior to each sleep recording each rat was fitted with a chest pneumograph.

Two types of apneas were identified: Quiet Apneas (QA) and Augmented Apneas (AA).

	Quiet Apnea		Augmented Apnea	
(sec)	NR	R	NR	R
lean	2.4±.3	1.7±.1	2.8±.2	2.3±.2
obese	1.5±.1	1.4±.1	1.9±.2	1.7±.1

Both types of apneas tended to be longer in the lean rat during NR (Non-Rapid Eye Movement) sleep. The frequency of apnea occurrence was not significantly different between the lean and obese rats, however there were significantly more apneas during REM than Non-REM sleep.

512.4

ABSENCE OF REBOUND AND INCREASE OF VIP WHEN CSF IS EXTRACTED AFTER SLEEP DEPRIVATION. A. Jiménez-Anguiano, A. Báez, R. Aguilar-Roblero* and R. Drucker-Colín. 1. Depto. de Neurociencias, Inst. de Fisiología Celular and 2.Inst. de Invest. Biomédicas, UNAM, México, D.F.,México.

Cerebrospinal fluid (CSF) from sleep-deprived (SD) animals and VIP has been shown to increase REM sleep periods in normal and insomniac animals. The aim of this study was to determine the effects of CSF extraction (EXT) from SD cats on REM sleep rebound and to quantify by RIA the concentration of the VIP-LS in the CSF from SD cats. 43 adult cats implanted with a cannula in 4th V were used. EXP I: 23 cats were additionally implanted with electrodes for standard sleep-wake cycle recordings and were studied under the following conditions: control (CC), under SD by the water tank method for 24, 48 and 72 h and under SD for 24, 48 and 72 h with EXT of 100 ul of CSF. They were recorded during 12 hours. EXP II: 20 cats were studied in the following conditions: CC, under SD for 24, 48 and 72 h and CC of SD with a large platform (LP), for 24, 48 and 72 h. After the SD or CC, CSF (200-400 ul) was withdrawn. Then, all samples were analyzed with VIP 125 I RIA. Results showed that SD produces an increase of REM sleep which was abolished by the EXT of CSF. Moreover, this rebound is related to an increase in the concentration of VIP in the CSF from SD cats and this effect was independent of stress. These results suggest that during SD, the VIP is accumulated in the CSF and this may be causally related to REM sleep rebound.

512.5

EFFECTS OF CHRONIC SLEEP DEPRIVATION ON CENTRAL ADRENOCEPTORS IN RAT BRAIN. *L.-L. Tsai, B.M. Bergmann, B.D. Perry* and A. Rechtschaffen. Depts. of Psychiatry and Psychology, The University of Chicago, Chicago IL 60637.*

We deprived rats of sleep (SD) for 10 days by the disk-over-water method (Bergmann et al. Sleep 12:5-12, 1989) and compared their regional adrenoceptor binding sites with those of yoked control (YC) and home cage control (CC) rats (n=7, each group). Relative to baseline, the SD rats lost 73±7% (Mean±SD) of total sleep and 90±7% of paradoxical sleep. As in previous studies (Everson et al., Bergmann et al. Sleep 12:13-21, 31-41, 1989), food intake and energy expenditure increased and waking body temperature eventually decreased more in the SD rats than in the YC rats. For 11 brain regions, six concentration saturation assays using ^{3}H-prazosin, ^{3}H-rauwolscine, and ^{125}I-iodocyanopindolol were used to determine B_{max} and K_D values for α_1, α_2, and ß receptor binding sites, respectively. Adrenoceptor binding site B_{max} and K_D values were significantly different among groups only for the cerebellum and the hypothalamus. In the cerebellum, higher α_2-binding site density (SD: 24.7±4.1, YC: 26.6±4.5, CC: 19.1±2.7 fmol/mg protein, $p < 0.05$) with lower affinity (SD: 0.47±0.12, YC: 0.59±0.2, CC: 0.25±0.08 nM, $p < 0.05$) and lower ß-binding density (SD: 70.0±19.7, YC: 75.0±8.5, CC: 97.8±25.1 fmol/mg protein, $p < 0.05$) were seen in the SD and YC rats than in the CC rats. This pattern is attributable to apparatus effects common to the SD and YC rats. In the hypothalamus, α_2-binding site density (SD: 133.7±68.9, YC: 70.2±19.9, CC: 75.0±20.3 fmol/mg protein, $p < 0.05$) was higher in the SD rats than in the YC and CC rats without differences in affinity. The hypothalamic binding site differences are attributable to sleep loss in the SD rats. Thus, the present results did not support a functional role of sleep in the upregulation of adrenoceptors as proposed by Siegel and Rogawski (Brain Res. Rev. 13:213-233, 1988). However, the upregulation of hypothalamic α_2 receptor binding sites after prolonged sleep loss suggests a possible role of hypothalamic adrenoceptors in sleep-related mechanisms and functions.

512.6

HUMAN AND RABBIT INTERFERONS INDUCE SLEEP IN RABBITS. M. Kimura-Takeuchi*, J. A. Majde, L. A. Toth, M. R. Opp and J. M. Krueger, Univ. of TN, Memphis, TN 38163, and Office of Naval Res., Arlington, VA 22217.

Interferon (IFN) is usually defined by its antiviral activity; it also has many other biological activities. Human recombinant (hu-r) IFNα2 enhances non-rapid-eye-movement sleep (NREMS) in rabbits and rats and reduces latency to REMS in monkeys. Patients undergoing IFN therapy complain of sleepiness. The somnogenic effects of IFNß have not heretofore been documented nor has a species-specific IFN been assayed for sleep promoting activity in the species of origin. Thus, hu-rIFNß and rabbit (rb) IFN were tested in male rabbits implanted with EEG electrodes, a brain thermistor and intracerebroventricular (ICV) cannula. Each received pyrogen-free saline solution on day 1, and one of 3 IFN preparations on day 2: Hu-rIFNß (Berlex Lab., Inc.; 300,000 or 1,125,000 U), rb-IFNα/ß (Lee Biomolecular Res. Inc.; 640 or 6,400 U) or rb-IFN (NIH standard; 25 or 250 IU). Sleep-waking activity was monitored for 6 h after each injection. The high dose of hu-rIFNß, but not the low dose, significantly increased NREMS and brain temperature (T_{br}); neither dose altered REMS. All doses of rb-IFN enhanced NREMS and elicited fever; none affected REMS. Further, in an antiviral assay using rabbit RK-13 cells, hu-rIFNß was much less potent than the rabbit IFNs. In conclusion, data suggest that the potencies of IFNs are relatively species-specific.
Supported partially by ONR N00014-90-J-1069, NS-26429.

512.7

REM SLEEP DEPRIVATION INCREASES CATECHOLAMINE TURNOVER AND TYROSINE HYDROXYLASE TRANSCRIPTION IN THE RAT. S.E.Smith, T.Porkka-Heiskanen†, T.Taira, J.Toppila and D.Stenberg*. Dept. of Physiology, Univ. of Helsinki, 00170 Helsinki, Finland, and †Dept. Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208-3520.

Adult male rats were deprived of REM sleep (REMs) for 8, 24, or 72 hours, or were allowed to sleep for 8 or 24 hours after 72 hours of deprivation. The deprivation group (DEP) was kept on small platforms (diameter 6.5 cm) in a water bath, while the control animals were kept on large platforms (diameter 11 cm, CON1) or in a dry cage (CON2). In some rats the hypothalamus was rapidly dissected and frozen for catecholamine measurement while in other rats the whole brain was removed for measurement of tyrosine hydroxylase (TH) mRNA. Catecholamines were measured from homogenized tissue using HPLC with EC-detection. The DOPAC/DA ratio was significantly higher in the posterior hypothalamus (PH) of DEP animals after 24 hours of deprivation ($p<0.05$) and significantly lower after 24 hours of recovery sleep ($p<0.05$). In addition, norepinephrine was significantly elevated in the PH after 72 hours of deprivation ($p<0.05$). TH mRNA was significantly elevated in the locus coeruleus in the DEP animals after 72 hours of deprivation ($p<0.05$). These findings suggest that catecholamine function is enhanced during REMs deprivation.

512.8

RELATIONS BETWEEN REM SLEEP AND THE PONTINE AUDITORY P1 EVOKED POTENTIAL INDUCED BY CHOLINERGIC AGONISTS INJECTED INTO THE PONS. **Z. Elazar* and Y. Navat, Dept. of Physiology and Pharmacology, Sackler School of Medicine, Tel-Aviv University, Tel-Aviv 69978, Israel.**

P1 potential, the 20-30 msec midlatency component of the vertex auditory evoked potential, was found to decrease in slow wave sleep and increase in wakefulness and REM sleep (Chen & Buchwald, 1986). We recorded this potential from the pons of cats chronically prepared with electrodes and cannulas for sleep studies. The pontine P1 potential was similar in shape but of shorter latency than that recorded from the vertex. Its amplitude varied with the behavioral state and was always higher in REM sleep than in slow wave sleep. Injections of carbachol or neostigmine (2-10 µg) in the vicinity of the electrode in pons induced REM sleep and an increase in the amplitude of the P1 potential up to twice that recorded during natural REM sleep. The amplitude of P1 decreased gradually to reach the level of the natural potential after 60 to 120 minutes, depending on the dose. The amplitude of potential P1 was dose dependent. The degree and time course of the amplitude change was correlated with the degree and time course of REM sleep enhancement. These results suggest that the amount of REM sleep is related with the intensity of cholinergic synchronous activation of pontine neuronal populations expressed by potential P1.

512.9

IL-1ß ANTIBODIES REDUCE SLEEP AND ATTENUATE IL-1ß-INDUCED ENHANCEMENT OF SLEEP IN THE RAT. Mark R. Opp* & James M. Krueger. Dept. Physiol. & Biophys., Univ. of TN, Memphis, TN 38163

Interleukin-1 (IL-1) is a cytokine with pleiotropic biologic actions (1). It is hypothesized that IL-1 is involved in the physiological regulation of sleep (2); if this is the case, then reduction of IL-1 levels at appropriate receptors should result in less sleep. To test this hypothesis, male Sprague Dawley rats were intracerebroventricularly (ICV) injected with 3 doses of anti-rat IL-1ß antibody (Cytokine Sciences; 5-, 10-, 20 µg) at light onset and sleep-wake activity determined for the next 12-hr. The amount of time spent in non-rapid-eye movement sleep (NREMS) or in REMS was not greatly affected by the two lowest doses of anti-IL-1ß. However, after the 20 µg dose of the antibody, the amount of time spent in NREMS was reduced by 61-min across the 12-h recording period, relative to control values; REMS was not greatly affected. To determine if anti-IL-1ß could antagonize the effects of exogenously administered hu-r-IL-1ß, another group of rats was pretreated with 20 µg of the antibody 1-h prior to "lights off" and injected just prior to "lights off" with 10 ng hu-r-IL-1ß. The characteristic enhancement by hu-r-IL-1ß of NREMS was completely abolished by this pretreatment. These data support the hypothesis of a role for IL-1 in sleep regulation. *Supported in part by: NS 25378 and MH 47103.* *1) Dinarello, CA. Blood 77:1627-1652, 1991. 2) Krueger, JM, et al., Yale J Biol Med 63:157-172, 1991.*

512.10

REM-ENHANCING EFFECTS OF ADRENERGIC ANTAGONIST IDAZOXAN INFUSED INTO THE MEDIAL PONTINE RETICULAR FORMATION IN THE FREELY MOVING CAT. M. Bier*and R.W. McCarley. Harvard Medical School/VAMC, Brockton, MA 02401

Adrenergic input to the medial pontine reticular formation (mPRF) has been postulated to play a role in the control of REM sleep and the sleep-wake cycle. We have previously reported (Soc. Neurosci. Abstr., 1991) the effects on sleep-wake states of adrenergic agonists norepinephrine (NE, mixed α_1,α_2 agonist), phenylephrine (PE, an α_1 agonist) and clonidine (CL, an α_2 agonist) microinjected into the mPRF. These data showed that CL is REM suppressive, presumably by action at α_2 receptors. The REM suppressive effect was localized to those regions of the mPRF which give short latency, long duration increases in REM following infusion of carbachol. Here we describe the effect of the α_2 antagonist idazoxan (IZ) on REM sleep. A series of microinjections into the mPRF of IZ (55 nmol and 550nmol in 0.5 µL/ 1 minute) were performed. In the first hour REM sleep was decreased following IZ (55nmol, -38.6% : 550nmol, -86.9%). In the second hour IZ at a dose of 55nmol decreased REM -56.9% while the higher dose of 550nmol increased REM by 44.1%. In the third hour REM sleep was increased at both doses of IZ (55nmol, 24.4% : 550nmol, 40.0%). In the fourth hour IZ increased REM at both doses (55nmol, 250% : 550nmol, 625%). Across the entire 4 hours of recording REM sleep was significantly increased by IZ at 55nmol (44.7%; n=12; $p<0.05$) while the higher dose also produced an increase (155%), but this effect was not significant with n=8. These data indicate a REM-enhancing role of IZ. This action is presumably mediated through antagonism of α_2 receptor activation but heterogeneity of this receptor and binding of IZ to imidazoline sites pharmacologically distinct from the α-adrenoceptors complicates interpretation of action in-vivo. EFFECTS OF A LOW DOSE OF 8-OH-DPAT ON SLEEP IN THE RAT. RH Pastel* and P Covington. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

8-OH-DPAT (8-hydroxy-2-(di-n-propylamino) tetralin hydrobromide) is a selective and potent 5-HT_{1A} agonist. One previous study demonstrated that 2.5 mg/kg of 8-OH-DPAT suppressed both rapid-eye movement (REM) and non-REM (NREM) sleep. However, that dose also induces the serotonin behavioral syndrome, hypothermia and increased feeding. We investigated the effects of 10 ug/kg of 8-OH-DPAT, a dose which does not produce these effects.

Three male rats were given saline (sc) and 24 hr later 8-OH-DPAT (10 ug/kg, sc). Treatments were administered at light onset and EEG was measured for 6 hr following injection. Administration of 8-OH-DPAT increased waking and decreased both NREM and REM sleep. The suppression of REM and NREM sleep, reported previously using a 2.5 mg/kg dose, could have been due to the induction of the serotonin behavioral syndrome, feeding behavior and/or hypothermia. The present results, using a smaller dose of 8-OH-DPAT, suggest that the effects of 8-OH-DPAT on sleep may be due to an effect on 5-HT_{1A} receptors.

DISRUPTION OF LIGHT-INDUCED C-FOS IMMUNOREACTIVITY IN THE SUPRACHIASMATIC NUCLEI (SCN) OF MIDDLE-AGED FEMALE RATS. J.M. Lloyd*, A. Cai and P.M. Wise. Department of Physiology, University of Maryland School of Medicine, Baltimore, MD 21201

Mammalian circadian rhythmicity of various biological functions is maintained by a light-entrained pacemaker in the hypothalamic suprachiasmatic nuclei (SCN). Recent evidence suggests that this light-entrainment may involve the induction of specific immediate early genes such as c-Fos. To determine if age-related deficits in SCN function involve altered levels of neuronal activation we compared c-Fos expression in the SCN of young and middle-aged animals. Regularly cycling or ovariectomized estradiol-treated young (3-4 month) and middle-aged (10-12 month) animals were administered an overdose of pentobarbital on proestrus or after 2 days of estradiol and perfused 75-90 min before and after lights on. Brains were processed for immunocytochemical localization of c-Fos (Cambridge Research, OA-11-823). In agreement with previous studies, in young animals c-Fos expression was evident only after lights on. However, in middle-aged animals, (a) in some instances, expression of c-Fos can be observed prior to lights on, (b) the intensity of light-induced c-Fos expression appears to decrease, and (c) the number of c-Fos containing neurons decreases. These data demonstrate that there is a disruption in light-induced c-Fos expression the SCN of middle-aged animals. Supported by NIH AGO2224 and NRSA AGO5525.

INDUCTION OF FOS IN THE SUPRACHIASMATIC NUCLEI IN VITRO. M.R. Dwyer*, E.L. Meyer, M.E. Harrington and E.L. Bittman. Dept. of Psychology, Smith College, Northampton, MA 01063 and Zoology Dept., University of Massachusetts, Amherst, MA 01003.

Light pulses which phase shift circadian rhythms also induce several immediate early genes, including c-fos, in the suprachiasmatic nuclei (SCN, Kornhauser et al, Science, 255, 1992). Both carbachol (an acetylcholine agonist) and forskolin (an adenylate cyclase activator) have been reported to phase-shift circadian rhythms. We used an in vitro slice preparation to determine if these pharmacological agents would also be associated with increased Fos-like immunoreactivity (Fos-lir) in the SCN.

Brain slices (600 μm) obtained from male golden hamsters housed under 14L:10D at either Zeitgeber time (ZT) 0-1 or ZT 8-9 (ZT 12 = lights off). The slices were maintained as described previously (Harrington et al, Soc. Res. Biol. Rhythms abs. 1992). Carbachol (10 mM) and forskolin (24.4 μM) were applied 6 h post-dissection. Control slices received no drug application. Thirty minutes later all slices were placed in cold 4% paraformaldehyde for 4 h. After storage in 30% sucrose, brain slices were sectioned (30-45 μm) into cryoprotectant (-20°C) and stored until staining with a rabbit polyclonal antibody (dch-1) raised against the N terminal (2-17) of rat Fos (D. Hancock and G. Evan, ICRF, London).

Control slices showed little Fos-lir in the SCN. Carbachol was able to induce Fos-lir at ZT 14. Forskolin was able to induce Fos-lir at both ZT 6 and ZT 14. Photic induction of Fos in vivo is only observed in the subjective night. Our results indicate that this may be due to a circadian fluctuation antecedent to or not involving adenylate cyclase activation. Supported by NIH NS26496 (MEH) and NIMH 44132 (ELB).

c-fos PROTO-ONCOGENE CHANGES AFTER REM SLEEP INDUCED BY VASOACTIVE INTESTINAL POLYPEPTIDE (VIP). H. Merchant-Nancy, A Jiménez-Anguiano and R. Drucker-Colín* Instituto de Fisiología Celular. Universidad Nacional Autónoma de México. México D.F. México.

Since it has been showed that intraventricular administration (IVA) of VIP induce a selective increase in REM sleep, we used Fos like inmunostaining (FLI) for constructing maps of the patttern of second messenger activity in the brain stem, after REM sleep induction by this manipulation. 12 male Wistar rats were implanted for conventional sleep recorgins. Aditionaly, a stainless steel cannula was implanted into the 4th ventricule. Two groups were used: a control, in wich an IVA of 5ul saline was applied, and a VIP group where 100 ng of VIP in 5 ul was inyected IVly. After 4 hr of sleep recording, the animals were anesthetised and perfused with 4% parafolmaldehyde. The brains were processed for inmunohistochemistry with the ABC technique of Hsu et al., 1982.We used a Fos antibody provided by Tom Curran. The results showed an increase in REM sleep frequency in VIP group. Moreover, this group showed a significant increase in FLI in several brain stem structures. These results suggest that VIP sleep inducing properties may depend on an increment in the number of active neurons in a withspread network in brain stem.

512.15

DEVELOPMENT OF FOS-LIKE IMMUNOREACTIVITY IN DORSOLATERAL PONTINE REGIONS ASSOCIATED WITH REM SLEEP. **Priyattam J. Shiromani*, Munazza Malik, Stuart Winston & Robert W. McCarley**, *VA Med Ctr & Harvard Med School, 940 Belmont St, Brockton, MA 02401*

We sought to determine the time course of activation of the immediate-early gene, *c-fos*, in conjunction with rapid-eye movement (REM) sleep. Carbachol, a mixed cholinergic agonist, was used to produce a sustained REM sleep episode. Fos-like immunoreactivity (Fos-LI) was assessed at various times after the end of REM sleep.

Cats were implanted (pentobarbital) with sleep recording electrodes and a guide cannula in the medial pontine reticular formation (medial PRF). Two weeks later, microinjections of vehicle (0.25ul;n=3) or carbachol (0.2-2.0 ug/0.25ul;n=9) were made. The animals were euthanized by overdose of pentobarbital at various intervals after end of REM sleep.

In vehicle controls, few Fos-LI cells were seen in the dorsolateral pons. Carbachol elicited 15 min to 70 min long REM sleep bouts. In carbachol animals examined immediately upon end of carbachol-REM sleep, counts of Fos-LI cells in the raphe, LC, LDT-PPT and the medial PRF were higher compared to vehicle controls. One carbachol animal with a 45 min long REM sleep bout showed few Fos-LI cells 24 hrs after end of REM sleep. A lower dose (0.2 ug/0.25 ul) of carbachol produced no REM sleep and no Fos-LI cells compared to vehicle controls. One carbachol animal had no REM sleep and no Fos-LI cells.

Fos-LI occurs in association with cholinergically-induced REM sleep in pontine regions implicated in REM sleep. A minimum duration of REM sleep appears to be necessary for Fos-induction. However, a plateau in number of Fos-LI cells is reached after about 45 minutes of continuous REM sleep. Some of the Fos-LI cells are cholinergic or noradrenergic.

BASAL AND PHOTIC-INDUCED EXPRESSION OF IMMEDIATE EARLY GENES IN YOUNG VS. AGED RAT BRAIN. E.L. Sutin*, B.F. O'Hara, F.L. Watson, and T.S. Kilduff, Sleep Res. Ctr, Stanford Univ., Stanford, CA 94305.

Many of the sleep disturbances of the elderly such as the fragmentation of the major sleep period and early morning insomnia may be due to a deterioration in the circadian system that underlies the timing of sleep and wakefulness. In an effort to address this issue at the molecular level, we have focused on circadian aspects of "immediate-early" gene (IEG) expression which may be involved in both input and output mechanisms of the circadian pacemaker. Two approaches have been utilized: 1) The photic-induction of IEGs in the suprachiasmatic nucleus (SCN) was examined in young vs. old rats. In a pilot study, young (4 months) and aged (22 months) male Fischer-344 rats were given either a 30 min light-pulse late in the subjective night at circadian time (CT) 22 or left in darkness. Message levels were identified by *in situ* hybridization using a [^{35}S] cRNA probe to c-*fos*. Aged rats that received photic stimulation at CT 22 demonstrated a blunted response of c-*fos* mRNA expression in the ventrolateral SCN relative to young rats. Neither young nor old rats remaining in darkness showed any detectable IEG expression. 2) IEG expression in extra-SCN regions was investigated across the circadian cycle using Northern blot analysis. Nocturnal rats have the highest levels of c-*fos* message during the night while maximal levels were observed in diurnal ground squirrels during the day, suggesting a correlation with activity. In contrast, c-*jun* mRNA was invariant in the rat but increased during the active phase in squirrels. Surprisingly, in older rats, which have weaker activity rhythms, a somewhat higher level of c-*fos* message was observed. In addition, two larger messages cross-hybridized with c-*fos* that were not apparent in the younger rats. Taken together, these results suggest alterations in circadian aspects of IEG regulation which may help elucidate mechanisms underlying the age-dependent decay of circadian organization.

NEURONAL GENE EXPRESSION DURING SLEEP DEPRIVATION. B.F. O'Hara*, K.A. Young, F.L. Watson, L. A. Roldan, W.C. Dement, and T.S. Kilduff. Sleep Research Center, Stanford University, Stanford, CA 94305.

The two-process model of sleep regulation posits that a homeostatic drive to sleep, referred to as Process S, increases with time spent awake. The purpose of this study was to evaluate whether immediate early gene expression is increased in brain in proportion to time spent awake, when Process S would be expected to increase. Rats were deprived of sleep by gentle handling beginning at light onset for 45 min, 3 hr or 6 hr. The duration of sleep deprivation in each of the three groups was chosen to correspond to the previously described response of EEG delta power to sleep deprivation. At the end of the deprivation period, animals were sacrificed by decapitation, the brain dissected into subregions and frozen. An equal number of control rats were sacrificed at each time point. To date, Northern blots have been prepared from cortex, thalamus, cerebellum and hypothalamus. c-*fos* expression was detectable in all brain regions from all animals, however, the sleep deprived animals showed higher expression than the control animals at all time points. Curiously, the highest levels of expression were observed in the 45 min as well as 6 hr deprived rats. The high c-*fos* mRNA expression in the 45 min animals may be attributable to the transient stress of movement to the deprivation room. The high c-*fos* mRNA in the 6 hr animals may reflect either (1) increased c-*fos* expression in parallel with build-up of Process S or (2) increased expression due to stress induced by increased handling of the deprived animals. Preliminary results indicate that c-*jun* does not undergo the same changes exhibited by c-*fos* whereas *jun*-B is more similar to c-*fos*. Further efforts will be directed towards (1) other modes of sleep deprivation in an effort to minimize stress, and (2) examination of other IEGs (Supported in part by the Upjohn Company).

NEURONAL GENE EXPRESSION ACROSS THE HIBERNATION CYCLE. T.S. Kilduff*, B.F. O'Hara, F.L. Watson, L. Bitting, E.L. Sutin, S.K. Welch, and H.C. Heller. Sleep Research Center, Stanford University, Stanford, CA 94305.

Changes in arousal state such as sleep and hibernation are likely to be accompanied by changes in gene expression, some of which may facilitate state transitions. The goal of this project is to evaluate whether gene expression is altered in specific brain regions across the hibernation cycle. Our initial focus is on immediate early gene (IEG) expression because IEGs are known to play a critical role in the regulation of long-term changes in gene expression. Golden-mantled ground squirrels (*Citellus lateralis*) were implanted with abdominal telemeters to monitor body temperature (T_b) continuously. Animals were placed in a constant temperature environment at 5°C under LD 12:12 photoperiod. Four animals were sacrificed between 1200-1600 P.S.T. during each of five phases of the hibernation cycle: euthermia (T_b=37°C); entrance to hibernation (T_b=20°C); day 1 of deep hibernation (T_b<8°C); days 4 or 5 of deep hibernation (T_b<8°C); and arousal (T_b=20°C). A sixth group of summer euthermic animals was also sampled. The brain was dissected into subregions, frozen on dry ice and RNA extracted. Northern blots were then prepared for subsequent hybridization with [^{32}P] c-*fos* and c-*jun* probes. Expression of c-*fos* and c-*jun* show clear changes throughout the hibernation cycle. For example, both genes exhibit a rapid increase of message in the hypothalamus during arousal from hibernation. This observation is of particular interest because previous work, including our 2-deoxyglucose studies, has shown this brain region to play a critical role in the arousal process. Preliminary results from *in situ* hybridization studies suggest that the suprachiasmatic nucleus is among the hypothalamic regions exhibiting this increase (Supported in part by the Upjohn Company).

512.19

LIGHT ACTIVATION OF IMMEDIATE EARLY GENE EXPRESSION OCCURS PREDOMINANTLY IN INTRINSIC NEURONS OF THE SUPRACHIASMATIC NUCLEUS. E. L. Bittman, M. H. Hastings, and F. J. P. Ebling*, Dept. of Anatomy, University of Cambridge, U.K.

Light exposure during the subjective night activates the expression of several immediate-early genes (IEGs) in the suprachiasmatic nucleus (SCN) of the Syrian hamster and causes phase shifts in circadian activity rhythms. The role of these light-responsive cells of the circadian pacemaker in the generation of behavioral and endocrine rhythms is not known. We have combined retrograde labelling of SCN neurons with photic induction and immunocytochemical detection of Fos and Egr-1 in an attempt to determine whether induction of IEGs occurs in cells which project to identified targets of this nucleus or to the contralateral SCN.

Hamsters (n=10) maintained on a 16L:8D cycle received unilateral stereotaxic injections (0.1-0.3µl) of fluorescent latex microspheres (Lumaflour, Inc.) aimed at the septum, preoptic area, hypothalamic paraventricular or ventromedial nuclei, subparaventricular area, intergeniculate leaflet (IGL), or SCN. After a survival period of 1.5-3 weeks, animals were exposed to light for 1h commencing 3 h after lights off and were then anesthetized and perfused with 4% paraformaldehyde. Frozen sections (40µm) were processed for Fos and Egr-1 immunoreactivity (-ir) and examined for fluorescent label.

Light exposure reliably induced Fos-ir and Egr-1-ir in the SCN and the IGL. As reported previously , the greatest concentration of IEG-ir neurons was seen in the ventrolateral SCN. Immunoreactive cells also occurred in the surrounding anterior hypothalamus. Retrograde labelling of SCN and subparaventricular neurons revealed projections to each of the areas targetted. Less than 1% of the Fos-ir or Egr-1-ir cells contained fluorescent microspheres. It is concluded that photic induction of these IEGs occurs principally in intrinsic cells of the SCN rather than its projection neurons. Supported by SERC (GR/H08716) and The Royal Society.

INGESTIVE BEHAVIOR: WATER AND SALT INTAKE

513.1

OSMOSENSITIVE VAGALLY-MEDIATED CONTROL OF DRINKING IN ADVANCE OF SYSTEMIC DEHYDRATION IN RATS. F. S. Kraly*, Y.-M. Kim and L. M. Dunham. Dept. of Psychology, Colgate Univ., Hamilton, NY 13346.

Intragastric infusions of hypertonic solutions activate splanchnic afferents to increase plasma vasopressin without changing plasma osmolality in rats (Choi-Kwon & Baertschi, Am. J. Physiol. 261: E18, 1991). We examined whether such infusions elicit drinking without systemic dehydration. Adult Sprague-Dawley male rats (n=32) were surgically prepared with a chronic gastric catheter. A test in rats not deprived of food or water was initiated by a 2 ml (in 1 min) infusion of 300, 600, 1200 or 1800 mOsm NaCl or sucrose, mannitol, LiCl or Na isethionate. The latency to initiate drinking was decreased ($p<.05$) and 60-min water intake was increased ($p<.05$) by 600, 1200 and 1800 mOsm NaCl compared to 300 mOsm NaCl. Plasma osmolality at initiation of drinking was not changed from baseline (300 mOsm NaCl) by 600 or 1200 mOsm ($p>.10$) but was increased by 1800 mOsm NaCl ($p<.05$). Equiosmotic solutions of sucrose, mannitol, Na isethionate and LiCl also elicited drinking. Drinking elicited by 600, 1200 or 1800 mOsm NaCl was abolished by total abdominal vagotomy ($p<.05$). Our results are consistent with the hypothesis of a vagally-mediated osmosensitive gastrointestinal and/or hepatic-portal mechanism for eliciting drinking in advance of systemic dehydration in the rat.

513.2

ROLES OF AT-1 AND AT-2 ANGIOTENSIN (ANG) II RECEPTOR SUBTYPES IN EXPERIMENTALLY-INDUCED WATER INTAKE IN RATS. M.J. Fregly, A. Rozelle, L. Han, K. Greenwood & N.E. Rowland*. Depts Psychol & Physiol., Univ of Florida, Gainesville, FL 32611.

Water intake induced by either central or peripheral injection of ANG II is blocked by the AT-1 receptor antagonist losartan potassium (DuP 753). We report the effects of acute cerebroventricular (ICV) injection of losartan (50 ug: 500x the dose that blocks water intake to ICV ANG II) on various types of thirst in rats. ICV losartan had no effect on water intake following either hypertonic NaCl, isoproterenol, carbachol (ICV), or on food intake in a dessert test. ICV losartan blocked drinking caused by either SC injection or IV infusion of ANG II. The antidipsogenic effect of central AT-1 blockade thus is selective for ANG II.

In contrast, ICV administration of the AT-2 receptor antagonist, PD 123319 (100 ug) blocked water intake following injection of hypertonic NaCl, isoproterenol, ICV carbachol and ANG II. ICV PD 123319 did not reduce food intake in a dessert test. Thus, the AT-2 antagonist may have a common action on the various mechanisms of water intake, but it does not nonselectively reduce food ingestion. We speculate that an AT-2 receptor may be on a "final common pathway" for the integrated thirst signal. **Supported by the American Heart Assoc., Florida affiliate.**

513.3

ANGIOTENSIN RECEPTORS IN SFO BUT NOT OVLT MEDIATE ISOPROTERENOL-INDUCED DRINKING. D.A. Fitts*. Dept. of Psychology, Univ. of Wash., Seattle, WA 98195.

Rats having lesions of the subfornical organ (SFO) drank an average of 0-2 ml water after isoproterenol, 10-50 mg/kg SC, compared with mean intakes of 5-7 ml in sham controls. The doses of isoproterenol were much lower than previously reported in SFO-lesioned rats (160 μg/kg, Simpson et al, JCPP, 1978), so this lesion-induced reduction in intake is not specific to high doses of isoproterenol.

Another experiment compared the effects of 90-min infusions of the angiotensin (ANG) receptor blocker [Sar^1,Thr^8]-ANG II (sarthran), 20 pmol/hr at 0.8 μl/hr, into SFO, organum vasculosum laminae terminalis (OVLT), or lateral ventricles after 20 mg/kg SC isoproterenol. A sarthran infusion into SFO significantly reduced drinking from 4.2 ± 0.4 ml in the saline vehicle control condition to 2.3 ± 0.6 ml (mean ± SE, $p < .01$); the same infusion into OVLT (4.6 ± 0.7 vs 5.0 ± 0.6 ml, respectively) or into the dorsal third ventricle caudal to the SFO (3.5 ± 0.9 vs 3.6 ± 0.4 ml) did not. Sarthran was ineffective at 20 (4.8 ± 0.5 vs 4.3 ± 1.0 ml) or 500 (3.3 ± 0.6 vs 4.4 ± 0.5 ml) pmol/hr in the lateral ventricles.

ANG accounts for at least 47% of the drinking observed after isoproterenol treatments in rats, and the receptors critical for this drinking are in SFO rather than OVLT. The study also confirms that blood-side ANG receptors in SFO are inaccessible to moderate doses of ventricularly applied blockers (Fitts & Masson, Behav. Neurosci., 1990). This explains some negative results in previous studies attempting to block peripheral ANG from the ventricles.

513.4

THE HYPERDIPSIA INDUCED BY INJECTION OF MUSCIMOL INTO THE MEDIAN RAPHE NUCLEUS (MR) IS ATTENUATED BY LESIONS OF THE SUBFORNICAL ORGAN (SFO) OR LATERAL HYPOTHALAMUS (LH). T.R. Stratford* and D. Wirtshafter, Department of Psychology, University of Illinois at Chicago, Chicago, IL 60680

We have previously reported intense hyperphagia and hyperdipsia in rats following injections of the GABA-A agonist muscimol into the MR. In the current study, we lesioned various forebrain structures which have been reported to play a role in the mediation of water intake and observed the effects on muscimol-elicited drinking. Electrolytic lesions of the SFO or ibotenic acid lesions of the rostral pole of the LH significantly attenuated the hyperdipsia. While control animals drank an average of 11.8 mls of water during the 60 min test period, the mean intake of SFO-lesioned rats was 2.1 mls and that of LH-lesioned rats was 3.0 mls. In contrast, electrolytic lesions of the precommissural median preoptic nucleus (MnPO) or excitotoxic lesions of the lateral preoptic area (LPO) significantly increased water intake during the test. Mean water intake was 20.8 mls for the MnPO-lesioned group and 21.4 mls for the LPO-lesioned group. Lesion effects on a series of regulatory challenges suggest that muscimol-induced drinking may be related to the renin-angiotensin system.

513.5

CHANGES OF DRINKING BEHAVIOR IN THE RAT AFTER SEPTAL LESIONS. R.-M. Liao*& C.-C. Yeh; Dept. of Psychology, National Cheng-Chi University, Taipei, Taiwan, R.O.C.

The septum has been suggested to play an inhibitory role in the drinking behavior. It is also known that the septum is heterogeneous in terms of neuroanatomical perspective. The present study examined the water intake and the locomotor activity of rats lesioned with kainic acid (0.5 ug/0.5 ul/ site) on three septal subregions: anterio-medial (MSa), posterio-medial (MSp), and lateral (LS) sites. There were significant differences between groups on both measurements in the postlesion tests. Drinking volume was enhanced mostly by the MSp lesion, so was the locomotor activity. Another experiment further determined the dipsogenic effects of polyethylene glycol (PEG; 20%, SC) and hypertonic saline (NaCl; 1M, IP) in the MSp lesioned rats. These cellular and extracellular thirst stimuli were given on the 18th postlesion day. Water intake was significantly increased by the hypertonic treatment, but not by the injection of PEG. In addition to showing the septal hyperdipsia, these data suggest that the septum can be functionally heterogeneous in drinking behavior.

513.6

SUPRACHIASMATIC LESIONS EFFECT UPON THE LATERALIZED PREFERENCE IN DRINKING BEHAVIOR OF RATS. R. Díaz-Pérez, P. Vergara-Aragón and B. Barrera-Mera*. Depto. de Fisiología. Fac. de Medicina. U.N.A.M. A. Postal 70250 México 04510 DF

Electrolytical lessions selectively applied on either left (L) or right (R) suprachiasmatic nuclei (SCN) have revealed direct SCN control on rodents locomotor circadian activity. Initial and final half-portions of the total amount of loco motor activity in a 24-h period of time, apparently receive a direct neural program from each L or R SCN. These evidences claim an evaluation of hypothalamic bilateral control upon volitive tasks drived by specific procencephalic nuclei, and upon SCN mutual bilateral interaction, judged by the lateralized preference. A preferential lateralization task was measured in 42 Wistar rats of either sex. These animals (60-190 g bw) were individually housed under a L-D 12-12 photoperiod. They obtained food ad libitum, and were furnished with a couple of water bottles for drinking. Each 24 h, we measured the amount of water drinked by the animals. The preference was 27% for R, 40% for L, and 33% for both bottles. Under ether anaesthesia all the R and L animals were lesioned at their contralateral SCN. Differing from the lesion effects upon other diencephalic nuclei, SCN lesions did not induce any modification on lateral preference in drinking for either side. These results suggest that rodent SCN activity does not control the lateral drinking preference.

513.7

ANGIOTENSIN II AT1 RECEPTOR BLOCKADE WITH DuP 753 ABOLISHES SODIUM INTAKE IN THE ADRENALECTOMIZED RAT. O. G. Galaverna*, C. Polidori, S. Y. Chow, D. H. Yi , A. N. Epstein, R. R. Sakai and S. J. Fluharty. Leidy Labs, Biology Dept., Univ. of Penn., Phila. PA 19104-6018.

In the intact sodium depleted rat, sodium intake is driven by the synergistic actions of angiotensin II (Ang II) and aldosterone on the brain. Removal of the adrenal glands results in a chronic loss of sodium and an increased sodium consumption. Our previous study has shown that central administration of Sarcosine^1-Isoleucine^8-angiotensin II (SARILE), a non-selective Ang II receptor antagonist, suppressed sodium intake in the adrenalectomized male rat. The suppression was dose dependent and the highest dose of SARILE resulted in a minimal intake, which was still present after aldosterone replacement, suggesting that the residual intake was need-free intake. In the present experiment we show that blockade of AT1 receptors inhibits the sodium intake of adrenalectomized rats. Adrenalectomized female (n=6) and male rats (n=6) were given a 3% NaCl solution 2 hours per day, and received daily injections of dexamethasone (20μg/day) to compensate for the lack of corticosterone, and a prophylactic treatment of gentamicin (4mg/day). On the day of the experiment, 15 minutes before the access to 3% NaCl, the animals were given a pulse intracerebroventricular injection of DuP 753, a selective AT1 receptor antagonist at doses of 30nM/2μl or 100nM/2μl (females), 50nM/2μl or 100nM/2μl (males), counterbalanced by an injection of 2μl of saline vehicle. The intake of salt was recorded thereafter at 15 min., 30 min., 1 hour and 2 hours. At all doses of DuP, sodium intake was significantly suppressed in both males and females. At the dose of 100nM, the intake was completely abolished in males, but a residual intake persisted in females which may be an expression of need-free sodium intake. It is concluded that in both female and male adrenalectomized rats, brain Ang activation is responsible for the increased sodium intake, and that AT1 receptors are involved in the natriorexigenic effect of the brain Ang activation.

513.8

EFFECT OF CENTRALLY ADMINISTERED MINERALOCORTICOID OR GLUCOCORTICOID RECEPTOR ANTAGONIST ON ALDOSTERONE-INDUCED SODIUM INTAKE IN RATS. L.Y. Ma, C. Polidori, J. Schulkin, A.N. Epstein, E. Stellar* B.S. McEwen and R.R. Sakai. Departments of Biology and Anatomy, University of Pennsylvania, Philadelphia PA 19104 and Lab. of Neuroendocrinology, The Rockefeller Univ., New York, NY 10021.

We have previously reported that intravenous (IV) infusion of aldosterone (ALDO) induces sodium intake in rats. Here we studied the role of central mineralocorticoid receptors (MR) and glucocorticoid receptors (GR) in mediating this ALDO-induced sodium intake. Male rats were fitted with an intracerebroventricular (ICV) cannula and an IV catheter. Water, 3% NaCl and Purina Chow were available ad libitum. Rats received a continuous ICV (cICV) infusion of the Type I, MR antagonist, RU-28318 (10μg/hr) combined with concurrent cIV infusion of ALDO (3.3μg/hr). Central administration of RU-28318 completely blocked ALDO-induced 3% NaCl intake (cIV ALDO = 9.5±3.1 mls, vs cIV ALDO + cICV RU-28318 = 0.4±0.2 mls 3% NaCl). The suppression of cIV ALDO-induced 3% NaCl intake was reversed once the cICV RU-28318 infusion was stopped. Continuous ICV infusion of the Type II, GR antagonist, RU-38486 (10μg/hr) was ineffective in suppressing ALDO-induced 3% NaCl intake. Together, the data provide evidence for a role of brain Type I MR involvement in ALDO-induced sodium intake in the rat. Supported by MH 43787 and NSO 3469.

BRAIN SODIUM AND SODIUM APPETITE IN THE RAT. S.Y. Chow,*A.N. Epstein, B.S. McEwen, S.J. Fluharty and R.R. Sakai. Univ. of Pennsylvania, Phila, PA. 19104 and The Rockefeller Univ., New York, NY. 10021.

We examined the effects of modifying brain cerebrospinal fluid (CSF) sodium concentration during sodium depletion on the expression of sodium appetite in the rat. Male rats fitted with intracerebroventricular cannula were sodium depleted by combining treatment with furosemide and removal of all ambient sodium. They received either 2M NaCl, 0.7M mannitol or isotonic saline (5µl/hr) by continuous infusion 2 hours prior to the beginning and throughout the depletion treatment. Sodium appetite, as measured by their ingestion of 3% NaCl, was recorded the following day. Infusion of 2M NaCl decreased 3% NaCl intake (5.7 ± 1.9 mls) and infusion of 0.7 M mannitol increased 3% NaCl intake (12.4 ±1.2 mls) as compared to infusion of isotonic saline (9.4 ± 1.7 mls). Infusions of either 2M NaCl or 0.7M mannitol had no effect on the rats' daily need-free sodium intake. In addition to the changes in sodium appetite, parallel changes in the expression of hypothalamic angiotensinogen mRNA were evident. Regulation of angiotensin II receptor binding in this brain area was also examined.

Together, the data show 1) that direct manipulation of CSF sodium concentration during sodium depletion affects the expression of sodium intake in the rat and 2) that the mechanism by which modification of CSF sodium affects sodium intake may be through its effects on the brain angiotensin system which can then act as a synergist with aldosterone to elicit sodium appetite in the rat.

AMYGDALA PATHWAYS INVOLVED IN SODIUM APPETITE IN THE RAT, ANATOMICAL CONSIDERATIONS. G.F. Alheid*,[1], J. Schulkin[2], and A.N. Epstein[3,†]. [1]Univ. Va. Health Sci. Ctr., Charlottesv. Va 22908, and Depts. [3]Biol. and [2]Anat. Univ. Penn, Phil. Pa. 19104. ([†]deceased).

It is known that destruction of the stria terminalis does not interfere with sodium appetite while large knife cuts in the ventral amygdalar association pathways do. In this study, we are reexamining the role of the ventral pathways with respect to DOCA and AII induced sodium appetite by placing small knife cuts in the trajectory of amygdalo-fugal and -petal pathways. In addition, behavioral testing is followed by the intracranial injection of fluorescent neuronal tracers for selected animals, in order to provide detailed information about the particular pathways spared by our knife cuts. We observed that small cuts medial to the central amygdaloid nucleus result in a decrease in sodium appetite after fluid volume depletion or repeated $Captopril_R$ injection, but normal responding to DOCA injections. Surprisingly, in all animals so far examined (n=8), these lesions did not block the projection of the central nucleus to the brainstem, since relatively complete retrograde labeling of the nucleus was possible in every case. Subsequently, we have also injected anterograde tracers into the central nucleus of knife-cut animals with the preliminary results (n=2) suggesting that these cuts might interrupt associative connections with the forebrain, and possibly central amygdalar afferents to the hypothalamus. SALT-TASTE RESPONSES OF FOREBRAIN NEURONS, WHICH ALSO RESPOND TO IONTOPHORETIC APPLICATION OF ANGIOTENSIN II, IN AWAKE RATS. S. Nicolaïdis*, M.-C. Mousseau and S.N. Thornton. CNRS URA 637, Neurobiologie des Régulations, Collège de France, 11 pl. Marcelin Berthelot, 75231 Paris CEDEX 05, France.

Pretreatment with deoxycorticosterone acetate (DOCA) for 3 days sensitises the rat anterior forebrain to a subsequent intracerebro-venticular injection of a below threshold dose of angiotensin (AII) such that a strong appetite for sodium is generated. We have investigated electrophysiologically the effects on neurons of the septum and preoptic area of iontophoretic application (Io) of AII and of giving salt solutions to awake rats before and after pretreating them with DOCA.

Male wistar rats were anaesthetised with ketamine (0.3 ml/100 g body weight) and a specially adapted cranioplastic prosthesis fixed to the skull after exposure of the dura. This prosthesis subsequently permits restraint of the rat in a stereotaxic apparatus while allowing the animal to move its body and limbs and to drink water or solutions of salt or glucose. A 7 barrelled microiontophoretic electrode sealed to an extracellular recording electrode was then advanced through the cortex into the septal then medial preoptic regions where unit activity was recorded at the same time as different solutions were offered to drink.

In the medial septal and medial preoptic areas, but not in other areas, neurons were recorded that differentially responded to salt and to water. Some of these salt vs water taste receiving neurons also responded to Io AII which elicited a "salt" type response. In these conscious rats DOCA pretreatment produced an enhancement of neuronal reponsiveness to AII as we have shown in anaesthetised preparations.

In these areas implicated in sodium regulation and appetite, specific gustatory projections onto AII responsive neurons that can be enhanced by DOCA pretreatment suggest a mechanism by which these hormones enhance preference for salty solutions.

THE EFFECT OF MINERALOCORTICOID (MC) TREATMENT ON SUBSEQUENT INDUCED SODIUM APPETITE. T.M. Nicholson * and N.E. Rowland. Dept. of Psych., U. of FL., Gainesville

Previous studies have shown that rats acutely depleted of sodium drink more NaCl on the second depletion than the first. It has been proposed that the high levels of hormones of sodium depletion (i.e. MC and angiotensin II {Ang II}) act synergistically to sensitize brain mechanisms for sodium appetite. In order to assess the generality of this behavioral sensitization as well as the relation of the two hormonal mechanisms, two groups of female Sprague-Dawley rats were treated for 1 week with either an MC (DOCA) or the Ang CEI, enalapril (which is thought to increase brain Ang II activity). Both groups showed the expected salt appetite as measured by 24 hour intakes of 0.2M NaCl and distilled water. After a 1 week rest, a second 1 week treatment was performed, with half of the rats receiving the same treatment, and the other half receiving the other (viz: DOCA-DOCA, DOCA-enalapril, enalapril-enalapril, enalapril-DOCA). After a further 2 week rest, the treatments in phase 2 were repeated. The rats that received DOCA on all 3 treatments showed a steady increase across the phases. The rats that received enalapril on all 3 treatments showed no change across the phases. The rats that were switched from DOCA to enalapril showed a paradoxical decrease in salt appetite compared with rats receiving enalapril without prior DOCA. Rats with prior DOCA treatment did not show an abnormal plasma renin (PRA) response to the acute enalapril treatment. The mechanism and time course of the paradoxical decrease in salt appetite will require further scrutiny because MC treatment and/or NaCl intake up-regulates Ang II receptors in many brain regions. FOURTH VENTRICLE MICROINJECTIONS OF DIAZEPAM ENHANCE HEDONIC REACTIONS TO TASTE. S. Peciña* and K.C. Berridge, Dept. of Psychology, University of Michigan, Ann Arbor, MI 48109.

Benzodiazepine administration (e.g. 5mg/kg diazepam, ip) enhances hedonic reactions to tastes (e.g. tongue protusions; Treit & Berridge, 1990). Benzodiazepines also enhance hedonic taste reactivity in decerebrate rats, which suggests that systems within the brainstem mediate this effect (Berridge, 1989). To test this hypothesis in normal animals, we compared the effects on hedonic taste reactivity of intracranial diazepam injections into the 3rd or 4th ventricles. Twenty rats were implanted with 3rd and/or 4th ventricle cannulae and with oral cannulae. Diazepam (0, 5, 15, 25, 40, 50, 75, and 100ug) was injected into either the 3rd ventricle or the 4th ventricle seven minutes before the rats were tested for taste reactivity to 0.3M sucrose (1ml/min).

Diazepam was more effective at enhancing hedonic reactions when injected into the 4th ventricle than when injected at the same dose into the 3rd ventricle: low diazepam doses (40ug) enhanced hedonic taste responses only when injected into the 4th ventricle and produced no hedonic enhancement when injected into the 3rd ventricle. Higher doses (50, 75ug) were effective in both ventricles. These results support the conclusion that benzodiazepine receptors in the brainstem mediate this enhancement of hedonic reactions to taste.

NEONATAL CHORDA TYMPANI TRANSECTION ALTERS ADULT PREFERENCE FOR NH_4Cl IN THE RAT. S.I. Sollars & I.L. Bernstein*. Dept. of Psychology, University of Washington, Seattle, WA 98195.

The chorda tympani nerve (CT) is considered the main gustatory pathway for NaCl taste stimulation. In the adult rat, bilateral transection of the CT does not affect preference for salts. The current study examined the effect of transection of CT in 10-day-old rats on adult preference for salts. This approach was based on anatomical evidence that primary gustatory nerves play an inductive role in taste bud development with the sensitive period for this effect spanning the first 10 days postnatal in the rat. Ten-day-old Wistar rats were given bilateral transection of the CT (CTX; N=13) or sham operations (SHAM; N=12). When 60-days-of-age the animals had two-bottle access to salt solutions (NaCl, NH_4Cl, KCl, $CaCl_2$) and water. CTX animals displayed a significantly higher preference for NH_4Cl at all concentrations tested (.05M, .1M, .15M, .2M) while their preference for other salts was not consistently altered. Following the series of two-bottle tests, animals were tested for generalization of conditioned taste aversions (CTA) to salts. LiCl was used to condition a significant CTA to .1M NaCl. Tests for generalization were performed by giving one-bottle access to NH_4Cl or KCl and a two-bottle test with NH_4Cl and NaCl. CTX and SHAM animals showed similar patterns of CTA generalization and the two-bottle test revealed that CTX animals were clearly able to discriminate between NaCl and NH_4Cl. The results suggest that neonatal transection of the CT significantly enhances adult preference for NH_4Cl and that this effect is not due to the animals' inability to distinguish between NH_4Cl and NaCl.

PSYCHOPHYSICAL EVIDENCE THAT SENSATIONS OF ASTRINGENCY ARE DUE TO DECREASES IN ORAL LUBRICATION. P.A.S. Breslin*, M.M. Gilmore, G.K. Beauchamp, and B.G. Green. Monell Chemical Senses Center, Phila., PA 19104

Aluminum potassium sulphate ($AlK(SO_4)_2$ - 'alum') was tested, in three experiments, for its ability to elicit sensations of oral astringency ('dryness') independently of its ability to elicit taste sensations. First, the perceived astringency of alum (10 g/l) was compared to water on a nongustatory surface by rubbing a cotton roll saturated with stimulus between the gum and upper lip. Astringent sensations were rated on a visual analog scale that ranged from 'no sensation' to 'extremely intense'. Alum elicited strong sensations of astringency when the lip was moved laterally against the gum to increase friction. Second, subjects were asked to identify which of two solutions elicited a sensation of astringency in a forced-choice, two-alternative paradigm by simply dipping the anterior of the tongue into two cups: one containing alum, the other a mixture of sucrose, citric acid, and caffeine that approximated the taste elicited by alum. Subjects were as likely to identify the mixture as astringent as they were the alum, when only the anterior of the tongue was stimulated. These two studies support the notion that friction is important in the identification of astringency, whereas taste cues are not. Third, after sensations of astringency had been elicited, several rinses were compared for their ability to decrease astringency. Water, cellulose, corn oil, and the subjects' own saliva were compared when rubbed between the gum and upper lip in a cotton roll. Water did not decrease oral astringency as effectively as the other lubricants. Together these three studies point to tactile sensations caused by increased friction between oral membranes as the primary basis of astringent sensations.

This research was supported by a grant to B.G.G. DC-00249 and training grant DC 00014-13.

INGESTIVE BEHAVIOR: NUTRIENTS, SEROTONIN AND INSULIN

514.1

EFFECT OF DILUTIONS OF CORN OIL ON INTAKE AND PREFERENCE IN LEAN AND OBESE MALE ZUCKER RATS. D. Greenberg*, D.R. Lewis, J.M. Philopena, and G.P. Smith. Bourne Laboratory, Dept. of Psychiatry, New York Hospital-Cornell Medical Center, White Plains, NY 10605.

In dietary selection studies obese Zucker rats choose a greater proportion of their diets as fats than do lean rats. To investigate the contribution of the orosensory effects of fats for the control of fat ingestion in these rats, we measured the sham fed intake of several dilutions of corn oil in one-bottle intake tests and two-bottle preference tests.

Male Zucker rats (n=11 obese, n=7 lean) were fitted with gastric cannulas for sham feeding. In 1-bottle sham feeding intake tests, eight concentrations of corn oil, decreasing in concentration by half and ranging from 100% to 0.78% were offered to rats in descending order. At the completion of this series of tests, 2-bottle preference tests were performed on two consecutive days comparing preference for 100% and 75% corn oil. There were no clear differences in 2-bottle preference. In 1-bottle tests, although intake was an inverted-U function of concentration for both genotypes, obese rats required a larger D_{50} to increase intake 50% of maximum (12.5% vs. 6.25%), and obese rats achieved maximal intakes at one-half the concentration required by lean rats (25% vs. 50%). The steeper intake response function for obese rats may be relevant to their increased fat intake.

Corn Oil Concentration		
	Obese	Lean
D_{50}	12.5%	6.25%
smallest dose for maximal intake	25%	50%
peak preference (2 bottle test)	n=5, 75%; n=6, 100%	n=7,75%

DOSE-DEPENDENT EFFECTS OF DUODENAL AND ILEAL INFUSION OF GLUCOSE AND OLEIC ACID ON MEAL PATTERNS IN RATS. T.A. Woltman and R.D. Reidelberger*. Veterans Administration Medical Center and Department of Biomedical Sciences, Creighton University School of Medicine, Omaha, NE 68105.

The mechanisms mediating the inhibition of feeding by luminal nutrients in the proximal and distal small intestine are not clearly understood. In the present study we determined the dose-dependent effects of duodenal and distal ileal infusion of glucose and oleic acid on meal patterns in ad libitum feeding rats. Animals (n=8-12) with chronic cannulas in both the duodenum and ileum (14 cm proximal to the cecum), received a 2-h infusion (0.13 ml/min) of glucose (0, 0.01, 0.02, 0.04, 0.08, and 0.16 kcal/min) or oleic acid (0, 0.003, 0.017, and 0.085 kcal/min) at the start of the dark period, and meal patterns were monitored for 19 h. ***Results***: Three-hour cumulative intake was inhibited dose-dependently by ileal as well as duodenal infusion of both glucose and oleic acid. Ileal glucose was more inhibitory than duodenal glucose, while duodenal fat was more inhibitory than ileal fat. Duodenal glucose and fat inhibited feeding by decreasing meal frequency; ileal fat decreased only meal size, while ileal glucose reduced both meal size and frequency. ***Conclusion***: It appears that distinctly different mechanisms mediate the inhibitory effects of duodenal and distal ileal glucose and fat on food intake.

INTESTINAL CAPSAICIN ATTENUATES OLEATE-INDUCED SUPPRESSION OF FOOD INTAKE WITHOUT CAUSING ANATOMICALLY DETECTABLE NEURONAL DAMAGE OR IMPAIRED OLEATE ABSORPTION. C.S. Tamura and R.C. Ritter.* Dept. of V.C.A.P.P. and Pharmacology/Toxicology Graduate Program, Washington State University, Pullman, WA 99164.

We have previously reported that intraintestinal infusion of capsaicin (5mg/rat) attenuates suppression of sham feeding by intraintestinal oleate infused 24h post-capsaicin (Soc. Neurosci. Abstr. 17:542, 1991). The attenuation is transient and oleate-induced suppression is reestablished by 48h post-capsaicin. To determine whether capsaicin's desensitization of oleate-induced suppression was due to destruction of vagal sensory neurons, we examined the dorsal hindbrain for evidence of neuronal degeneration following intestinal capsaicin infusion. Intestinal capsaicin (5mg) produced no histochemical evidence of sensory neuron degeneration in the dorsal hindbrain. In contrast intraperitoneal injection of capsaicin, 5mg/rat or 50mg/kg, produced degeneration of terminals and fibers in the nucleus of the solitary tract and the spinal trigeminal nucleus. To assess the possibility that intestinal capsaicin damages enteric neural fibers, we examined substance P-like immunoreactivity (SPLI) in whole mounts of intestinal myenteric and submucous plexes. Intestinal capsaicin caused no apparent loss of SPLI in either plexus one hour after intestinal capsaicin. Finally, we measured intestinal absorption of ^{14}C oleate in vehicle- and capsaicin-infused rats. Preliminary results indicate that intraintestinal capsaicin does not alter oleate absorption. We conclude that capsaicin attenuates oleate-induced suppression of sham feeding by a mechanism other than vagal sensory neuron destruction, substance P depletion or impairment of intestinal absorption. Supported by NIH NS20561 to R.C.R.

514.4

SUBSTRATE SPECIFIC REVERSAL OF GLUCOPRIVIC BUT NOT LIPOPRIVIC FEEDING. L.K. Singer* and S. Ritter. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

Food intake is stimulated by drugs which block glucose or fatty acid utilization (glucoprivic and lipoprivic feeding, respectively). The purpose of the present experiment was to identify the metabolic fuels capable of modulating glucoprivic and lipoprivic feeding and eventually, to determine the metabolic specificity of receptors which monitor glucose and fatty acid utilization for control of food intake. Glucose and fatty acid utilization were blocked with 2-deoxy-D-glucose (2DG, 200 mg/kg) and 2-mercaptoacetate (MA, 600 μmol/kg), respectively. Rats with intraatrial catheters were infused (0.1 ml/min) with 0.3M saline, glucose or lipids (Intralipid), beginning 15 min before injection of 2DG or MA and for the 2 h post drug period during which food intake was measured. We found that glucose infusion blocked the feeding response to 2DG, but that equicaloric lipid infusion did not (saline = 2.55g, glucose = 0.65g, lipid = 2.1g). Preliminary data indicate that glucose infusion also blocked the response to MA. These data may indicate that receptors controlling glucoprivic feeding have a high degree of metabolic specificity, while those controlling lipoprivic feeding may respond to a broader spectrum of metabolic fuels.

514.5

POSTMEAL FATTY ACID OXIDATION DEPENDS ON MEAL COMPOSITION. D.M. Surina*, W. Langhans, R.P. Reeves, C. Wenk. Institute of Animal Sciences, Swiss Federal Institute of Technology, 8092 Zurich, Switzerland.

The influence of macronutrient content of a meal on fatty acid oxidation was investigated in 13 Caucasian males after consumption of a high fat (HF) breakfast (33% CHO, 52% Fat, 15 % Pro), containing also short- and medium-chain fatty acids, and after a high carbohydrate (HC) breakfast (78% CHO, 6% Fat, 15% Pro). Respiratory quotient (RQ) and plasma beta-hydroxybutyrate (BHB) were measured during the three hours following the meal as indicators of whole body substrate oxidation and hepatic fatty acid oxidation, respectively. Plasma insulin, glucose, lactate, free fatty acids (FFA), and triglycerides were also determined. RQ was significantly lower and plasma BHB was higher after the HF meal than after the HC meal, implying that more fat is burned in general and in the liver after a HF meal. As expected, plasma FFA and triglycerides were higher following the HF meal, and insulin and lactate were higher after the HC meal. In sum, considerable fat oxidation occurred in response to a single high fat meal, without prior adaptation to a high fat diet. The short- and medium-chain fatty acid content of the HF meal may be the primary contributor to the observed increase in plasma BHB, which reflects elevated hepatic fatty acid oxidation. This is interesting in relation to previous studies which link changes in hepatic fatty acid oxidation to the control of food intake.

CELIAC GANGLIONECTOMY DECREASES THE HUNGER-STIMULATING EFFECT OF FAST HEPATIC PORTAL MONOSACCHARIDE INFUSIONS IN RABBITS. L. O'Farrell* and D. Novin. Neuroscience Program and Psychology Dept., UCLA, Los Angeles, CA 90024.

In previous experiments, fast (3 ml/min, 3.3 ml/kg, 0.3 *M*) hepatic portal vein glucose and fructose infusions increased subsequent chow intake in *ad libitum* fed rabbits. One mechanism responsible for this effect may be altered hepatic metabolism. Previous experiments showed that these hunger-stimulating infusions caused increased hepatic conversion of the monosaccharides into lipid, and decreased mitochondrial uptake of the sugars. Therefore, hunger may be associated with increased hepatic storage and decreased hepatic oxidation of nutrients. The present experiment tested whether these changes in hepatic metabolism might be causually related to the increased food intake. Because the hepatic branch of the vagus nerve could not be reliably located in rabbits, the celiac ganglion was removed. Like the vagus, this ganglion contains afferents arising in the liver. Celiac ganglionectomy decreased the hunger-stimulating effect of fast hepatic portal glucose and fructose infusions in rabbits relative to sham ganglionectomy. The results suggest that hepatic sensory innervation may be necessary for the increased chow intake following fast glucose and fructose infusions in rabbits.

514.7

ANORECTIC EFFECTS OF A NOVEL DOPAMINE-FATTY ACID BIOCONJUGATE. G.W. Hesse* and V.E. Shashoua. Ralph Lowell Laboratories, McLean Hospital, Harvard Medical School, Belmont, MA 02178.

A novel pharmacological agent consisting of a fatty acid amide linked to dopamine has been synthesized. This novel compound has been found to have anorectic effects. It inhibits food consumption by fasted mice in a dose dependent manner with an ED50 of about 15 umol/kg. The anorectic effects of this compound are antagonized by sulpiride, but not by domperidone, indicating that central nervous system dopaminergic receptors are involved. Chronic administration of this compound produces little or no tolerance. During daily administration of the compound for 21 days no loss of efficacy in appetite suppression in fasted mice was observed. At the end of the 21 day period, food consumption returned to the baseline level within 24 hours. Finally, the compound does not induce hyperactivity, stereotypy or catalepsy even at doses up to 100-fold above the ED50. This novel compound is an effective appetite suppressant which appears to lack the excitatory effects on behavior often associated with dopaminergic anorectics.

514.8

INFLUENCE OF INTRAVENOUS NUTRIENTS ON FOOD INTAKE AND ENERGY EXPENDITURE. E.K. Walls* & H.S. Koopmans. Department of Medical Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Metabolic theorists propose that satiety is produced by relative increases in the rate of oxidation of fuels. To determine if intravenous (iv) nutrient-induced satiety is dependent upon increased fuel oxidation, daily food intake (17 hr/day) and 24 hr energy expenditure (EE) via indirect calorimetry were measured during iv nutrient infusions in rats. Infusion of 52 kcal of glucose and amino acids (GAA) for 4 days immediately reduced food intake by 38.4 kcal or 74% of the nutrient calories infused. EE on day 1 of GAA (57.8 $\pm$ 1.2 kcal) was not greater than saline control (58.1 $\pm$ 1.3 kcal) but increased to 61.0 $\pm$ 1.3 kcal on day 4 ($p < .05$) whereas RQ values increased from .938 during saline to 1.07 and 1.08 on days 1 and 4 of GAA infusion ($p < .001$). Infusion of 40 kcal of iv lipid for 6 days reduced food intake by 21.9 kcal or 55% of the lipid calories infused. EEs on day 1 and 6 of the lipid infusion (62.7 $\pm$ 2.2 and 62.6 $\pm$ 2.4 kcal) were not greater than during saline control (62.6 $\pm$ 2.1 kcal), whereas RQ values were reduced from .904 to .848 and .811 on day 1 and 6 ($p < .001$). While the shifts in RQ indicate enhanced fat utilization in the lipid condition and increased carbohydrate utilization in the GAA condition, the fact that no changes in EE accompany large changes in food intake suggests that signals for iv nutrient-induced satiety are not generated by large increases in fuel oxidation.

514.9

PERIPHERAL CHRONIC CLONIDINE DOES NOT AFFECT SUSCEPTIBILITY TO ACTIVITY-BASED ANOREXIA. T.S. Rieg*, J. Choi, and P.F. Aravich. Department of Anatomy & Neurobiology, Eastern Virginia Medical School, Norfolk, VA 23501; Medical Research Service, VA Medical Center, Hampton, VA 23667.

Activity-based anorexia (ABA) is an animal model of anorexia nervosa (AN) with two characteristics of the disorder, decreased food intake and increased activity. We have previously shown that chronic stimulation of the paraventricular hypothalamus with the noradrenergic agonist clonidine exacerbates ABA rather than ameliorates it as predicted. This study determined if peripheral chronic administration of clonidine would affect ABA. Rats were implanted subcutaneously with osmotic minipumps infusing saline, 30, or 300 ug/kg/day. Following postsurgical recovery, all animals were exposed to ABA (1.5 hrs/day/ad lib food; 22.5 hrs/day ad lib wheel access). Susceptibility was defined as days to a 25% body weight-loss criterion. Results showed that clonidine did not affect susceptibility or food intake, but substantially increased wheel activity in a dose related fashion. These findings are perplexing in that susceptibility to ABA was not increased although the high dose animals were running more. This may be due to an inhibition of sympathetically mediated energy expenditure by clonidine in ABA.

514.10

CONCURRENT TAMOXIFEN AND FLUPHENAZINE: EFFECTS ON FOOD INTAKE, BODY WEIGHT AND ^{3}[H]-TAMOXIFEN BINDING IN BRAIN. J.M. Gray* and M. Bishop. Dept. Psych./Prog. Biopsych., Vassar College, Poughkeepsie, NY 12601

Ovariectomized (OVX) rats given daily injections of 50 ug fluphenazine (FLU) showed only slight decreases in food intake, although their body weights were significantly lowered by the end of the first week of treatment and the differences between drug-treated and control animals increased over the treatment period. OVX rats given daily injections of either 2 ug estradiol benzoate (EB) or 1 mg tamoxifen (TAM) showed transient, but highly significant, decreases in food intake and rate of body weight gain. The effects of TAM or EB on both food intake and body weight were additive with the effects of FLU in rats receiving concurrent administration of the drugs.

Prolonged treatment with FLU, TAM or a combination of the drugs had no effect on ^{3}[H]-TAM binding to 'anti-estrogen binding sites' (AEBS) in selected areas of the brain (hypothalamus-preoptic area and area postrema-nucleus of solitary tract region) and pituitary, although both unlabelled TAM and FLU compete for ^{3}[H]-TAM binding in the in vitro binding assay. (Supported by BNS-9011263).

514.11

OBESITY INDUCED BY MANIPULATIONS OF THE PARENTAL ENVIRONMENT RESULT IN ELEVATED MEDIAL HYPOTHALAMIC NOREPINEPHRINE, Alan Jones*, Emmanuel Pothos, Pedro Rada, Bartley G. Hoebel, and Deborah Olster. Pitzer College, Claremont, CA, Princeton Univ. Princeton, NJ, and University of California at Santa Barbara.

In previous work it has been shown that adult male offspring of rats that have either been injected with 6IU/Kg/day of Protamine Zinc insulin during days 15-20 of gestation (Jones & Dayries, 1990) or undernourished to 50% of baseline intake during the first two weeks of gestation only (Jones & Friedman, 1982) develop significant obesity commencing at about 50 days of age. The present experiment examined the question of whether rats with these two forms of obesity display abnormalities in neurochemical release in areas of the brain known to influence feeding and body weight. Twenty-one gauge stainless steel guide shafts, were chronically implanted using standard stereotaxic procedures. One week later 3mm 26 ga microdialysis probes were lowered into the medial hypothalamus. Dialysate collection began 12 hours later. Dialysates collected from both male and female animals in the two experimental conditions contained significantly higher Norepinephrine levels ($p<.05$) than did controls. It would appear that in addition to sharing a similar time course of onset and a sex dependent expression of obesity (only males become obese), both of these models of obesity are also characterized by elevated medial hypothalamic norepinephrine. Since expression of this obesity is sex dependent, we investigated whether sex steroids might be mediating the effect. Gonadal weights were measured and plasma estrogen and testosterone levels were measured. These data will be presented.

514.12

EFFECTS OF SYSTEMIC TRYPTOPHAN ON EXTRACELLULAR LEVELS OF NEUTRAL AMINO ACIDS IN PVN AND CAUDATE PUTAMEN. C.E. Greenwood[1]*, L.T. NG[1], P.J. Currie[2], D.V. Coscina[2], G.H. Anderson[1]. Dept Nutr Sci[1], Univ of Toronto & Clarke Inst of Psychiatry[2], Toronto, Canada.

Intraperitoneal (IP) injections of a variety of amino acids (AA), including tryptophan (TRP), increases brain AA levels and results in food intake suppression. While brain levels of AA remain elevated for up to 2 hrs after IP injections, the distribution of AA between the intra- and extra- cellular pools and possible regional differences in these responses are unknown. This study examined the effects of IP TRP (100 mg/kg) on extracellular levels of TRP and the large neutral amino acids (LNAA), which compete for the same brain uptake carrier, in separate brain regions known to regulate food intake. Microdialysis probes were simultaneously placed in the hypothalamic paraventricular nucleus (PVN) and caudate/putamen (CP) of anaesthetized rats and dialysates collected for 1 hr prior to and 2 hrs after IP TRP. Plasma TRP levels and TRP/LNAA ratio rose immediately ($p<0.05$) following TRP administration and remained elevated for 100 min. A similar time course was observed with extracelluar PVN and CP TRP levels increasing significantly within 40 min of injection and remaining elevated for 100 and 40 min ($p<0.05$), respectively. Consistent with the concept of competition for brain uptake carriers, extracelluar levels of the LNAAs were decreased following TRP administration. In all cases, no significant interaction was observed when comparing responses between the PVN and CP suggesting that these two regions responded similarly to systemic TRP administration. However, due to a larger variation in the PVN compared to the CP, a significant decline in individual LNAA was not observed. These results demonstrate that alterations in brain levels of AA following systemic AA administration is reflected in the extracelluar fluid and suggest that there is little or no difference in response between the PVN and CP. SEROTONIN IN THE PARAVENTRICULAR NUCLEUS (PVN) AND THE SEROTONIN ANTAGONIST METERGOLINE INJECTED PERIPHERALLY (I.P.) PRODUCE OPPOSITE EFFECTS ON MEAL PATTERNS IN RATS. J.T. Alexander, *G.B. Brennan, W.K. Cheung and S.F. Leibowitz, The Rockefeller University, New York, N.Y. 10021

Studies have shown that carbohydrate is the preferred macronutrient in the first meal of the nocturnal feeding cycle. It has been proposed that serotonin (5-HT) is involved in switching off this initial carbohydrate meal, acting through hypothalamic 5-HT_1 receptor mechanisms that control satiety. To provide a further test of this hypothesis, we have examined, in male albino rats, the impact of PVN injections of 5-HT (2.5 nmoles) and i.p. injections of the 5-HT antagonist, metergoline (MTG, 1.0 mg/kg), administered at dark onset, on the microstructure of feeding over the 12 hr nocturnal cycle. Serotonin in the PVN produced a selective decrease in carbohydrate intake. This effect, while still evident 8 hrs after injection, was exhibited primarily during the first meal of the feeding cycle. During this meal, there occurred a selective decrease in size, percent composition, feeding time and feeding rate for carbohydrate, as well as an increase in the satiety ratio (post-meal interval/meal size) for this nutrient. In contrast, i.p. MTG injection produced opposite effects, namely, a selective stimulation of carbohydrate ingestion, an increase in the rate of carbohydrate feeding, and a decrease in the satiety ratio for this nutrient. This effect was followed 3 hrs later by a potentiation of protein, but not fat, intake. These results indicate that 5-HT may be involved in switching off preference for the carbohydrate diet at the onset of the natural feeding cycle.

NEURAL SITES OF ACTION OF DEXFENFLURAMINE: c-Fos IMMUNOHISTOCHEMICAL STUDY IN RATS. B.-H.Li*, L. Han & N.E.Rowland. Dept Psych, Univ Florida, Gainesville FL 32611

The critical sites of anorectic action of the serotonin-ergic agent dexfenfluramine (DFEN) are unclear. We have examined rat brain for the presence of c-Fos following acute and chronic regimens of DFEN. C-Fos was localized in vibratome sections using antibodies (F.R. Sharp and Oncogene Ab2) to the N-terminus of Fos protein.

Saline-treated control rats showed minimal c-Fos product. Low doses of DFEN (2-3 mg/kg) increased c-Fos in several brain regions, with maximal responses after 2-6 hr; the signal was undetectable after 26 hr. Brain regions most strongly activated were: nucleus (N) of the solitary tract; lateral parabrachial N; paraventricular thalamic N; central N amygdala; bed N of stria terminalis; rostral striatum, and orbitofrontal cortex. Many of these regions receive visceral or gustatory input, suggesting a functional relationship to the anorectic action of DFEN. Anorectic tolerance occurs with repeated injection of DFEN and a parallel decrease in DFEN stimulation of c-Fos occurs after chronic low dose DFEN. Preliminary studies with C-Jun antibody (Oncogene Ab2) shows presence in the central N amygdala and rostral striatum after acute DFEN. Food deprivation induces c-Fos in several brain regions; that in the supramammilary area is reversed by acute DFEN. Supported by IRIS (Servier).

HYPOTHALAMIC 5-HT_{1A} RECEPTOR SUB-TYPES ARE INVOLVED IN CONTROL OF GLUCOSE RELATED FEEDING. B. Moorjani, P. Lacy *, and M. Jhanwar-Uniyal. The Rockefeller Univ. New York, NY 10021 and Osteopathic Med/Hlth Sci, Des Monies, IA.

The sulphonylurea tolbutamide (TOL), a hypoglycemic agent, and the 5-HT_{1A} agonist, 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT), cause hyperphagia. This study explored the mechanism common to these hyperphagic actions. The objective was to examine the effect of chronic and acute TOL, and glucose (GLU) replacement therapy, on the 5-HT_{1A} receptor density, in the medial hypothalamus (MH) and lateral hypothalamus (LH) of male Sprague-Dawley rats. Rats were given one of the following treatments: a) 5 chronic injections (i.p.) of either propylene glycol (vehicle), TOL (25mg/kg), or TOL + GLU (20%); b) acute injections (i.p.) of vehicle or TOL (50 mg/kg). Rats were sacrificed 30 mins post-injection, their brains were removed, and the MH and LH were dissected. The radioligand binding technique was used to estimate the binding of [3H] 8-OH-DPAT (2 nM) to 5-HT_{1A} receptor sites (in the presence or absence of 10μM 5-HT). Trunk blood was collected for estimation of plasma GLU. The results show: 1) TOL induced a significant decrease in GLU levels in both chronic (-57.8%) and acute (-52%) states; 2) TOL produced an increase in 5-HT_{1A} receptor density in the MH, under both chronic (234%;$p<0.01$) and acute (132%;$p<0.01$) conditions; 3) GLU replacement caused a partial restoration of receptor density (-45% from the TOL treated rats). These findings suggest that the medial hypothalamic 5-HT_{1A} receptor sub-types may interact with blood glucose in the control of feeding behavior, and TOL may induce hyperphagia via activation of 5-HT_{1A} receptors.

REDUCTION IN DARK ONSET FEEDING AND CARBOHYDRATE INTAKE IN GENETICALLY OBESE (ob/ob) AND LEAN (+/?) MICE INJECTED WITH 5-HYDROXYTRYPTAMINE. P.J.Currie[1]* and L.M. Wilson[2]. [1]Clarke Institute of Psychiatry, University of Toronto, Toronto ON M5T 1R8 and [2]Department of Psychology, University of Manitoba, Winnipeg MB R3T 2N2 Canada.

The genetically obese (ob/ob) mouse exhibits multiple disturbances in neural systems putatively involved in the control of feeding, including altered levels of brain 5-hydroxytryptamine (5-HT) and reduced 5-HT metabolism. 5-HT has also been implicated in the control of carbohydrate ingestion in nonobese rodents, specifically at the onset of the dark cycle. This study examined the effects of intraventricular injection of 5-hydroxytryptamine creatinine sulphate on food intake (lab chow diet) and macronutrient (carbohydrate, protein, and fat) selection in free-feeding obese mice ($n=7$) and lean controls ($n=7$). Mice were injected with 5-HT (35-140 nmol) or sterile physiological saline, in counterbalanced order, immediately prior to dark onset. 5-HT decreased feeding and carbohydrate ingestion dose-dependently ($p<.05$), and as a result, tended to enhance the proportional intake of protein and fat. Obese mice, however, showed a reduced sensitivity to the anorectic effect of exogenously administered 5-HT. Although these results are consistent with a role for serotonin in the control of feeding and carbohydrate ingestion in mice, the altered sensitivity of the ob/ob to 5-HT treatment may result, in part, from an impaired satiety control mechanism in this genetic strain. (Supported by NSERC of Canada to LMW and a MHRC predoctoral scholarship to PJC).

Insulin Receptor Binding is Altered in Artificially Reared Rats Overfed as Neonates. E. Taylor*, J. Diaz, G. Watkins, and D. Figlewicz Lattemann, Dept. of Psychology, Univ. of Washington, Seattle, WA 98195 and VA Med. Center, Seattle, WA 98108.

Freinkel (1980) proposed that the fuel rich environment experienced by a fetus of a gestational diabetic could result in an abnormal insulin system, causing the offspring to be obese throughout life and more likely to develop gestational diabetes. Critical events in neural and hormonal development during late gestation in humans occur in early postnatal life in rats. We have shown that overfeeding rats during this critical time produces adult rats that are frankly obese and either unable to carry pregnancies to term or producing significantly smaller pups.

The purpose of this study was to examine the immediate effects of overfeeding on insulin receptor binding in brain and liver. At postnatal day four, rats were assigned to one of 3 groups: (1) mother-reared (MR); (2) Gastrostomy-fed to weight match MR's (WM); (3) Gastrostomy-fed with excess formula (OF). On day 14 the animals were sacrificed and cerebral cortices and livers were assayed for insulin receptor binding.

At sacrifice OF animals were significantly larger than MR's or WM's. Insulin binding was greatest for MR's and least for OF's. A similar but not significant trend was seen in cortical binding.

Hyperinsulinemia is seen in babies of gestational diabetics. Our data suggest that: (1) overfeeding rats during the second postnatal week may induce hyperinsulinemia leading to a decrease in insulin binding in liver; (2) formula feeding in itself may cause a lesser degree of hyperinsulinemia.

DISCRIMINATION OF INSULIN-PRODUCED HYPOGLYCEMIA P.M.DUNCAN* and W.LICHTY. Psychology Dept Old Dominion University. Norfolk, Va. 23508.

Eight rats were trained to discriminate the normal state of euglycemia from the hypoglycemia produced by injection of 6 units/kg insulin. A "drug discrimination" procedure was used with two-lever Skinner boxes and a food-motivated operant. A 60-sec no-reinforcement was followed by 6 min during which either left, or right lever presses were reinforced on a VI 10-sec schedule. Insulin or water injected 25 min prior to the operant sessions determined whether left, or right lever presses were reinforced. During 40 training sessions, reliable discrimination of the insulin-produced cue developed, with a mean of 73% responses on the "insulin lever" after insulin injection, and only 18% after water injection. After insulin, or water injection mean blood glucose levels dropped to 75%, or rose to 127% pre-injection values. When injected with 800 mg/kg ethanol, most rats chose the non-insulin ("euglycemic") lever. These results show that insulin produces a specific interoceptive cue, presumably involving hypoglycemia.

PARAVENTRICULAR HYPOTHALAMIC INJECTION OF 7-CHLOROKYNURENIC ACID (7CK) STIMULATES FEEDING IN SATIATED RATS. *T.L. Sorrels and E. Bostock, Psychology Dept., Queens College, CUNY, Flushing, NY 11367.

7CK (3ug & 6ug) and 2-amino-5-phosphonovaleric acid (AP5; 5ug & 10ug) were injected into the following hypothalamic sites: anterior h.(AH), lateral h.(LH) ventromedial n.(VMN) dorsomedial n.(DMN), and the paraventricular nucleus (PVN) of satiated rats and 1 hour consumption of pelleted food was measured. Rats with cannulae in the third ventricle anterior or posterior to the PVN were also given 7CK. AP5 failed to increase feeding at any site at the doses tested. 7CK data

DRUGS OF ABUSE: ETHANOL AND GABA

515.1

THE EFFECTS OF ALCOHOL ON INHIBITORY MECHANISMS IN RAT HIPPOCAMPAL CA1 NEURONS IN VIVO. J.R. Criado* and R.Thies. Depts. Psychiatry & Behav. Sci. and Physiology & Biophysics, Univ. of Okla. HSC, Okla. City, OK 73190.

Alcohol typically inhibits neurons, which may be due to potentiation of inhibitory GABAergic systems. Alcohol also may excite neurons, which could be due to either direct facilitation or disinhibition of tonically-active inhibitory GABAergic interneurons. Potentiation of the effects of GABA by alcohol has been shown in neurochemical and behavioral but not in electrophysiological studies. This study examined the acute effects of various doses of i.v. alcohol on GABAergic inhibitory mechanisms in hippocampal CA1 neurons.

The paired pulse paradigm was used to test the effects of alcohol on the activity of local inhibitory circuits in the CA1 region. Local groups of neurons (recording population spikes) were activated by paired pulses from the same source (orthodromic-orthodromic) or from two different sources (antidromic-orthodromic). Local inhibitory circuits were characterized by manipulating the period of inhibition with GABAergic agonists and antagonists released from a multibarrel pipette.

Recurrent inhibition was unaffected by alcohol, but alcohol prolonged the inhibition in response to feedforward and recurrent inhibition together. Consequently, alcohol probably potentiates feedforward inhibition, possibly by affecting post- or pre-synaptic $GABA_B$ receptors (Supported by the Department of Psychiatry and Sigma Xi).

GABAERGIC AND NONGABAERGIC SYNAPSES IN THE DENTATE MOLECULAR LAYER ARE DIFFERENTIALLY AFFECTED BY CHRONIC ETHANOL ADMINISTRATION. E. Fifková*, H. Eason, J. Lanman and K. Bueltmann. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

The effect of chronic alcohol exposure and withdrawal on the GABAergic and nonGABAergic synapses of the dentate molecular layer (DML) has been studied in the alcohol-sensitive LS_{IBG} and alcohol-insensitive SS_{IBG} mice, respectively (28 animals total). Mice were fed for 4 mo either with a control isocaloric liquid diet or with an isocaloric liquid diet containing ethanol (23.5% ethanol derived calories). Half of the ethanol-treated mice were withdrawn from the diet for 1 mo. All animals were treated for GABA immunoelectron microscopy in the postembedding procedure.

Out of the total synaptic population in the middle and distal thirds of the DML, 91% and 87% of synapses are on dendritic spines and 9% and 13% on dendritic shafts, respectively. Within the population of axodendritic and axospinous synapses, the GABAergic contacts represent 60% and 3%, respectively. There are more synapses on dendrites in the distal than in the middle third, while on spines, the contacts are equally distributed across both thirds. During ethanol exposure, there was a significant loss (24%) of axospinous synapses in the distal third of the DML. This change was transient and returned to control values during withdrawal. However, in the GABAergic synapses there was a progressive loss of axodendritic contacts which peaked during the withdrawal period (41% and 37% in the middle and distal thirds of the DML, respectively). Given that in the DML the major synaptic input is on dendritic spines, the ethanol-induced loss of the excitatory axospinous synapses could affect the activity of dentate granule cells. The loss of the GABAergic inhibition could be secondary to the reduced excitation. The sequence in which these changes occur supports such a conclusion. Functional validation of these synaptic changes remains to be established in the dentate fascia. However, in chronic ethanol preparations, the CA1 pyramids display a reduced capacity to induce long-term potentiation which could result from a decreased excitatory synaptic input (Tremwel and Hunter, Alcoholism, 15:336A, 1991). Supported by #AA06196.

ETHANOL DIFFERENTIALLY MODULATES SYNAPTICALLY EVOKED $GABA_A$ RECEPTOR-MEDIATED RESPONSES FROM HIPPOCAMPAL, CORTICAL AND SEPTAL NEURONS IN RAT BRAIN SLICES. B.L. Soldo*, W.R. Proctor and T.V. Dunwiddie, and University of Colorado Health Sciences Center, and Veterans Admin. Medical Research Services, Denver, CO.

Previous electrophysiological studies have reported variable results concerning the effects of ethanol on $GABA_A$ receptor-mediated responses in the CNS. The present study was designed to determine whether ethanol modulation of GABA responses is brain region dependent, and to identify factors that might regulate ethanol sensitivity. We examined the effects of ethanol on synaptically evoked $GABA_A$ IPSCs, which were studied with whole-cell voltage clamp recordings from neurons in three brain regions (hippocampus, cerebral cortex, and septum) that have been reported to differ in their degree of ethanol modulation. Bicuculline-sensitive IPSCs elicited by local stimulation were isolated by pretreatment with the glutamate specific antagonists, DNQX and APV. Ethanol (20-160 mM), did not significantly modulate evoked $GABA_A$ IPSCs in CA1 pyramidal neurons. In contrast, ethanol potentiated these responses in cortical neurons (layer V), and in medial and lateral septal neurons. However, even in these areas, there were neurons whose IPSCs were unaffected by ethanol. These results suggest that ethanol modulates responses to endogenous GABA released during synaptic activation, that there are overall differences in $GABA_A$ receptors from various brain regions, and that there may be additional factors (such as heterogeneous subpopulations and local endogenous neuromodulators) that affect ethanol sensitivity within certain brain regions.

A SLICE PATCH ANALYSIS OF ETHANOL EFFECTS ON AMINO ACID-INDUCED SYNAPTIC CURRENTS. R. A. Morrisett,* Dept. Pharmacol., Univ. Nebraska Med. Ctr., Omaha, NE 68198-6260.

It is generally agreed that the physiologic expression of NMDA-receptor mediated synaptic currents is dependent upon a decrease in GABAergic inhibition (disinhibition). Priming stimulation paradigms (5 Hz) produce this loss of inhibition presumably through the activation of presynaptic $GABA_b$ receptors which subsequently inhibit the release of GABA. We have previously demonstrated that such NMDA receptor-mediated synaptic responses and the resultant synaptic plasticity (LTP) is blocked by ethanol in a dose-dependent manner. This inhibitory effect of ethanol could be due to a direct action of ethanol upon the NMDA receptor channel complex and/or ethanol could directly potentiate $GABA_a$ mediated synaptic currents. The present work utilized patch clamp recordings to determine the site of action of ethanol at both perforant path-dentate granule and Schaffer collateral-CA1 pyramidal synapses.

Synaptic currents were pharmacologically isolated to verify the identity of the glutaminergic and GABAergic components. Pairing of stimuli over the range of intervals of 150-1000 msec resulted in a profound depression of the outward (GABAergic) currents. The decrease in GABAergic currents was completely reversed by $GABA_b$ antagonists. Ethanol (25-100 mM) had no effect on the outward GABAergic currents or upon the fading the these currents when stimuli were paired at 200 msec. Conversely, in the presence of DNQX, pairing of stimuli revealed a slow inward current that was highly D-APV or ethanol sensitive. These data strongly suggest that the contribution of $GABA_a$ conductances to the acute effects of ethanol in the hippocampal formation is limited, and that the NMDA channel is the major ligand-gated ion channel affected by ethanol. (Supported by the State of Nebraska and the Alcoholic Beverage Medical Research Foundation)

515.5

ETHANOL ENHANCEMENT OF GABA-MEDIATED CHLORIDE CURRENTS IN ISOLATED CEREBELLAR PURKINJE CELLS IS EXERTED BY AN INCREASE IN BURST DURATION AND STEPS TO MULTIPLE LEVELS OF THE PREDOMINANT SINGLE CHANNEL CONDUCTANCE. M.F. Pacheco* and D.J. Woodward. CUIB-Univ. de Colima, COL., 28045 Mexico and Dept.of Physiol. and Pharmacol., Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27106.

This work was undertaken in order to characterize, under patch clamp conditions, the actions of ethanol on GABA-mediated chloride currents (I_{GABA}) in dissociated Purkinje cells from 1-8 days old rats. In the whole-cell configuration, short pulses (1 psi, 17 sec) of ethanol (10 to 50 mM) enhanced up to 127 % the currents elicited by GABA (10 μM, 2 psi, 100 msec). Repetitive (every 30 sec) ethanol pulses or continuous bath perfusion induced a gradual potentiation (dose-dependent) of I_{GABA}, up to 300 % above control after 20 min of alcohol (10-50 mM) application. In cell-attached (V_H=E_m) and inside-out (V_H=-40 mV) configurations, ethanol (10-50 mM) induced initially an increase in the burst duration of GABA-gated channels (GABA concentration in pipette: 0.5 μM), followed by steps to multiple levels of the predominant single channel conductance. We conclude that ethanol enhancement of I_{GABA} takes place by direct interaction of ethanol with the GABA receptor, which increases the frequency of occurrence of channel opening and/or a change in the gating properties, as well as by inducing recruitment of additional channels. 515.6

ETHANOL POTENTIATION OF GABA RESPONSES IN CEREBELLUM: INVOLVEMENT OF cAMP. **Ronald K. Freund*, Anya M. Y. Lin, Michael R. Palmer, Dept. of Pharmacology, Univ. of Colorado Health Sciences Center, Denver, CO 80262 and Institute of Biomedical Sciences Center Academia Sinica, Taiwan**

A number of studies have demonstrated the involvement of the $GABA_A$ receptor complex in the actions of ethanol (EtOH). While we have been able to antagonize EtOH-induced inhibition of Purkinje neuron firing in vivo with the $GABA_A$ receptor antagonist bicuculline, it has been difficult to consistently demonstrate an EtOH-induced potentiation of GABA inhibitions, unless those inhibitions are modulated by a β-adrenergic agonist. In the present study we investigated the potentiative effect of EtOH on modulated GABA responses to determine whether cyclic adenosine monophosphate (cAMP) might be involved. GABA, 8-bromo-cAMP (8-BrcAMP) and EtOH were applied locally from multibarrelled pipettes by iontophoresis or electroosmosis. Similar to the effects of norepinephrine or isoproterenol, continuous application of the membrane-permeable cAMP analog, 8-BrcAMP was able to sensitize the GABA mechanism of cerebellar Purkinje neurons to the potentiating effects of EtOH. Preliminary data indicated that 8-BrcAMP is not acting through an adenosine mechanism, since the modulation by 8-BrcAMP, as well as the EtOH-induced potentiation, were still observed after systemic injection of the adenosine antagonist theophylline. The present data suggest that the catecholaminergic sensitization of GABA receptors to EtOH involves a second messenger action of cAMP. (Supported by USPHS grants AA05915 and AA00102.)

515.7

PRE- AND POSTSYNAPTIC EFFECTS OF ETHANOL ON THE INTERACTION OF NOREPINEPHRINE WITH GABA RESPONSES IN THE CEREBELLUM OF YOUNG AND OLD F344 RATS: ELECTROPHYSIOLOGICAL AND IN VIVO ELECTROCHEMICAL STUDIES. **A.M.Y. Lin*, M.N. Friedemann, P.C. Bickford, G.A. Gerhardt, R.K. Freund and M.R. Palmer. Veterans Admin. Med. Ctr., and Depts. of Pharmacology and Psychiatry, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262, and Institute of Biomedical Sciences Center, Academia Sinica, Taiwan.**

In previous electrophysiological studies, we have shown that ethanol potentiates GABA-induced depressions of cerebellar Purkinje neurons when these responses were simultaneously augmented (modulated) by a β-adrenergic agonist, such as norepinephrine (NE) or isoproterenol (ISO). Aged F344 rats have been shown to have deficits in the postsynaptic function of β-adrenergic mechanisms in the cerebellum and, thus, might be expected to be less sensitive to the ethanol-induced potentiation of GABA effects in this brain area. In the present study, we found electrophysiological evidence which suggests that not only does the efficacy of locally-applied ISO for potentiating cerebellar GABA responses decrease with aging in F344 rats, but also that ISO frequently causes antagonism of GABA effects in the aged animals. In contrast, ethanol enhanced both the potentiating and inhibitory interactions of ISO with GABA responses in the young (6 months) and old (24 months) F344 rats, respectively. Similarly, our in vivo electrochemical data indicate that the clearance of locally applied NE was inhibited by ethanol applications in both young and aged F344 rats. These data suggest that ethanol inhibits NE uptake in the cerebellum, since the time-course of NE clearance was significantly lengthened by ethanol. Furthermore, this effect of ethanol appears to be preserved in the aged animals. (Supported by the VAMRS and by USPHS grants AG04418, AG06434, AG00441, AA05915 and AA00102)

515.8

EFFECTS OF MICROINJECTION OF EXCITANT AMINO ACID ANTAGONISTS OR GABA AGONISTS INTO THE BRAINSTEM RETICULAR FORMATION ON AUDIOGENIC SEIZURES DURING ETHANOL WITHDRAWAL A. Riaz*, D. N. Chakravarty and C.L. Faingold. Dept. Pharmacol. Southern Illinois Univ. Sch. Med. Springfield, IL 62794.

Ethanol is reported to alter the action of excitant amino acids (EAAs) and GABA in several brain sites. The brainstem reticular formation (RF) plays an important role in propagation of generalized seizures, including audiogenic seizures (AGS). Previous studies indicate that microinjection of an EAA antagonist, AP7, into the pontine RF blocks AGS in the GEPR. Effects of microinjection of GABA agonists into the RF of the GEPR have not been reported. In the present study, Sprague Dawley rats were implanted with guide cannulae bilaterally over the pontine RF (nucleus gigantocellularis) stereotaxically. Ethanol was administered intragastrically (9-15 g/kg/day). At the end of day 4, ethanol was withdrawn. Animals exhibiting AGS at 10h after ethanol withdrawal (ETX) received infusions of vehicle (phosphate buffer or dimethylsulfoxide) into the RF without effect. Vehicle infusion was followed by infusion of an NMDA antagonist (CPP), a non-NMDA antagonist (CNQX) or a GABA-A agonist (THIP). Both CPP (10nmol/side) and CNQX (30nmol/side) suppressed AGS during ETX. THIP (10nmol/side) also blocked AGS during ETX. These results support a vital role of enhanced EAA and reduced GABA neurotransmission in the RF in AGS susceptibility during ETX. These findings further support the importance of the RF in several forms of AGS and audiogenic-like seizures. (Support NIAAA AA08591).

EFFECT OF ALCOHOL DEPENDENCE AND WITHDRAWAL ON mRNA FOR $GABA_A$ RECEPTOR SUBUNITS AND CCK IN MICE.
H. Day, E. Pettersson, M. Field, J.A. Poat and J. Hughes*. Parke-Davis Neuroscience Research Centre, Addenbrookes Hospital Site, Hills Rd., Cambridge CB2 2QB.

A period of chronic ethanol treatment followed by withdrawal from the drug, results in profound behavioural symptoms and changes in $GABA_A$ receptor activity. Recently we have shown that the novel anxiolytic, CI-988, a selective CCK_B receptor antagonist, inhibits withdrawal induced behaviours. The present study extends these observations to examine the effect of ethanol at various time intervals, on levels of mRNA for CCK and $GABA_A$ receptor $\alpha 1$, $\alpha 6$ and $\gamma 2$ subunits in the brain. Mice were exposed to 8% ethanol, given as a liquid diet, for 1-7 days. After 7 days, animals were withdrawn for 16 hours and then slowly infused i.v. with N-methyl-DL-aspartate (NMDLA) until a clonic seizure was induced. CI-988 (0.1-1 mg/kg s.c.) was given at the start of the withdrawal period and 40 minutes prior to testing for spontaneous and NMDLA-induced seizure activity. mRNA for $GABA_A$ receptor subunits and CCK was measured by Northern blot analysis and *in situ* hybridisation using oligonucleotide probes labelled at the 3' end with [^{32}P] or [^{35}S]dATP respectively. Ethanol treatment and withdrawal produced a number of changes in the mRNA for $GABA_A$ receptor subunits although mRNA for CCK was unaffected at any phase of the experiment. During withdrawal, the mean convulsive dose (MCD) of NMDLA decreased from a control value of 143 ± 8.9 to 72 ± 8 mg/kg. CI-988 dose-dependently antagonised the proconvulsant actions of NMDLA, with a minimum effective dose of 0.3mg/kg s.c. (MCD of NMDLA = 112 ± 6.4 mg/kg), although the drug is without anticonvulsant activity *per se*. The results suggest that CCK_B receptor activation may play a role in alcohol withdrawal, although this does not appear to be via an increase in CCK mRNA. It is possible that CCK_B receptor activation is the more important function.

515.10

EFFECT OF ACUTE ETHANOL EXPOSURE ON GABA-ACTIVATED CHANNEL ACTIVITY IN GANGLION CELLS OF RAT RETINA.
H. H. Yeh*, Dept. Neurobiology & Anatomy, University of Rochester Medical Center, Rochester, NY 14642.

This laboratory has previously demonstrated that acute exposure to ethanol potentiates GABA-activated whole-cell current responses in ganglion cells isolated from the rat retina. Despite this and similar reports by others on select central nervous system neurons, issues related to the cellular and subcellular mechanisms underlying this effect of ethanol are outstanding. Here, results are presented on ongoing work aimed at testing the effect of ethanol on GABA-activated channel currents in membrane patches isolated from retinal ganglion cells.

Ganglion cells were isolated by treating postnatal or adult rat retina with either papain or pronase E and thermolysin. GABA-activated channel activity, elicited in cell-attached and inside-out patches by including 2-5 uM GABA in the recording pipet, was monitored continuously before, during and after bath application of 50 mM ethanol.

A reversible effect of ethanol could be detected in approximately 60% of the patches examined (14 of 24). Cell-attached and inside-out patches gave the same results. Generally, ethanol increased to varying degrees the probability of channel opening or burst duration. This occurred without alterations in the mean amplitude of GABA-activated channel current. The degree of change during exposure to ethanol was subtle except in two cases, where dramatic increases in channel activity were observed in the inside-out patch configuration. It is proposed that these changes may account for the modulation of GABA currents observed under whole-cell voltage clamp. Importantly, the finding that ethanol can exert effects on GABA-activated channel activity in inside-out patches leads to the postulate that ethanol could interact directly with the $GABA_A$ receptor complex independent of intracellular intermediaries which may contribute indirectly by priming the state of neuronal receptivity to GABA.

515.11

INTERACTION OF TEMPERATURE AND ETHANOL ON 5α-PREGNAN-3α-OL-20-ONE (3α,5α-P)-INDUCED ALTERATIONS OF GABA-STIMULATED CHLORIDE UPTAKE IN LS AND SS MICE: PRELIMINARY STUDIES.
M. Bejanian*, D.A. Finn, K.W. Gee and R.L. Alkana. Dept. Molecular Pharmacology and Toxicology, Univ. So. California, Los Angeles, CA 90033.

Offsetting hypothermia during intoxication increases sensitivity to ethanol-induced loss of righting reflex in SS mice and decreases sensitivity in LS mice. Recent studies suggest genotypic differences in the interaction of temperature and ethanol on the $GABA_A$ receptor complex (GBRC). The present study investigated the interactive effects of temperature and ethanol on 3α,5α-P-induced alterations of GABA-stimulated chloride uptake in LS and SS mice synaptoneurosomes. 3α,5α-P (10 μM) produced a significant increase in GABA-stimulated chloride uptake in LS mice and a non-significant increase in SS mice at 30, 34 and 38°C. Ethanol (100 mM) did not significantly alter the effects of 3α,5α-P on the GBRC at 30 and 34°C. At 38°C, ethanol significantly decreased the effects of 3α,5α-P on GABA-stimulated chloride uptake in LS mice and produced a non-significant increase in SS mice. In the absence of 3α,5α-P, ethanol (25-100 mM) produced a significant increase in GABA-stimulated chloride uptake at 30°C, but not 34 and 38°C in LS mice, and had no effect at any of the tested temperatures in SS mice. Although speculative, these preliminary results suggest that the effects of temperature on behavioral sensitivity to ethanol may involve temperature-induced alterations in the 3α,5α-P and GABA site in LS mice, and the 3α,5α-P site in SS mice (Supported by USPHS grants AA03972 AA05234, NS25986 and NS24645).

515.12

FAILURE TO "PRECIPITATE" SIGNS OF ETHANOL WITHDRAWAL WITH A GABA ANTAGONIST AND A BENZODIAZEPINE INVERSE AGONIST.
S. Rassnick*, J. Krechman and G. F. Koob. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Previous work has shown that spontaneous withdrawal from ethanol (E) and precipitated opiate withdrawal produce a decrease in responding for food reinforcement, suggesting that this effect reflects a disrupted motivational state during withdrawal from chronic drug administration. The present study was designed to test whether administration of bicuculline methiodide, a competitive GABA receptor antagonist, or RO 15-4513, a benzodiazepine inverse agonist, would "precipitate" signs of withdrawal during chronic E intoxication. It was hypothesized that an increased sensitivity to the response-disruptive effects of these drugs during E intoxication would provide evidence for a "precipitated" E withdrawal syndrome. Rats were trained to lever-press for food on a fixed ratio-15 schedule of reinforcement, then maintained E dependent for 2 weeks on a liquid diet containing 35% E-derived calories, or maintained on a control liquid diet. E-dependent rats displayed a decreased sensitivity, rather than an increased sensitivity to the response-disruptive effects of bicuculline methiodide (100 ng ICV) and RO 15-4513 (3 and 6 mg/kg). The inability of these drugs to "precipitate" E withdrawal is consistent with recent biochemical studies which show that chronic E intoxication produces a down-regulation or uncoupling of activity at the GABA/benzodiazepine receptor complex (Supported in part by NIAAA grants: AA 05297, AA 06420, and The Alcoholic Beverage Medical Research Foundation).

DRUGS OF ABUSE: COCAINE'S INTERACTION WITH NON-DOPAMINE SYSTEMS

516.1

BLOCKADE OF SENSITIZING EFFECTS OF AMPHETAMINE PREEXPOSURE ON COCAINE SELF-ADMINISTRATION BY THE NMDA ANTAGONIST MK-801.
S. Schenk*, A. Valadez, C. McNamara and B.A. Horger. Dept. Psychology, Texas A&M Univ., College Station, TX 77843.

Rats preexposed with amphetamine acquired cocaine self-administration (0.125, 0.25 or 0.5 mg/kg/infusion) at a faster rate than saline preexposed rats. This suggests that repeated exposure to this drug prior to self-administration testing sensitized the rats to the reinforcing effects of cocaine. Co-administration of MK-801 (0.25 mg/kg, IP), a non-competitive NMDA antagonist, blocked the ability for chronic exposure to amphetamine to sensitize rats to cocaine; these rats' rate of acquisition of cocaine self-administration did not differ from saline preexposed controls. Thus glutamatergic systems and the NMDA receptor in particular may play a critical role in the sensitization produced by intermittent exposures to amphetamine. The NMDA antagonist also effected the motor activating effect of an acute injection of amphetamine. A suppression of the activating effects during the first 30 min post-amphetamine and an enhancement of the activating effects during the last 30 min post-amphetamine was produced by MK-801. These data suggest that the behavioral expression of an acute exposure as well as chronic administration of this drug (ie., sensitization) may rely on an intact NMDA receptor system. In experienced self-administering rats, MK-801 also shifted the dose response curve for cocaine self-administration to the right, suggesting an antagonism of the reinforcing effects of cocaine even in rats that had already undergone a form of sensitization. These data are discussed in terms of similarities between pharmacological sensitization and long-term potentiation resulting from electrical stimulation of limbic sites.

BUPRENORPHINE MIMICS MORPHINE ACTIVATION OF DOPAMINE NEURONS, IN VIVO.
S.J. Grant*, G. Sonti, D.A. Highfield Dept. Psychology and Prog. in Neuroscience, Univ. Delaware, Newark, DE. 19716.

Buprenorphine (BUP) is a synthetic opioid proposed as a potential treatment for cocaine craving. BUP is commonly described as a partial opioid agonist, but little is known of its electrophysiological effects. We previously reported that BUP, like morphine, completely suppresses the spontaneous activity of noradrenergic neurons of the locus coeruleus. We now report that BUP also mimics the morphine-induced activation of dopamine cells.

Extracellular single unitactivity was recorded from dopaminergic (DA) neurons in the substantia nigra (SN) and Ventral Tegmental Area (VTA) of chloral hydrate anesthetized rats. Standard physiological and anatomical criteria were used to identify DA neurons. Like morphine, BUP (10-400 μg/kg, i.v.) activated DA neurons in the VTA, but not the SN. As previously seen in the LC, BUP had a long duration of action and could not be reversed by the opioid antagonists naloxone or naltrexone (up to 10 mg/kg).

These studies demonstrate that buprenorphine has morphine like effects in both the VTA and the LC. Since BUP does not exhibit limited efficacy, partial agonist, or mixed agonist-antagonist properties on neural activity, these results are consistent with the hypothesis that *in vivo* BUP acts acutely as an agonist. The effects of acute and chronic BUP pre-treatment on morphine actions in the VTA and LC are in progress.

SELECTIVE REGULATION OF MU AND KAPPA OPIOID RECEPTORS FOLLOWING REPEATED EXPOSURE OF GUINEA PIGS TO COCAINE. Y. Itzhak* and I. Stein, Dept. of Biochemistry & Molecular Biology, REPSCEND Labs, University of Miami School of Medicine, Miami, FL. 33101

The precise neurochemical mechanisms involving cocaine-induced psychological and neurophysiological addictions are not entirely clear. Since a few studies implied the involvement of the opioid system in the reinforcing effects of cocaine, we sought to investigate the regulation of opioid receptors following repeated exposure to the drug. Guinea pigs were treated with either saline or cocaine (40 mg/kg/day; i.p.) for 7 days, sacrificed 24 h after the treatment, and various brain regions were dissected and prepared for opioid receptor binding. The three subtypes of opioid receptors, mu, delta and kappa, were labeled with [^{3}H]DAGO, [^{3}H]DPDPE and [^{3}H]U69 593, respectively. A significant down-regulation of mu-opioid receptors (40-60% of control Bmax) was observed in the frontal cortex, amygdala, hippocampus and thalamus. No change in mu-opioid receptor binding was detected in caudate putamen, substantia nigra, neocortex and hypothalamus. Delta-opioid receptor binding in the various brain regions of cocaine-treated animals did not differ from control. Kappa-opioid receptor binding was significantly increased (135±5% of control) only in the cerebellum, a region that contains primarily kappa-opioid receptors in guinea pig brain. Taken together, these findings indicate that repeated cocaine administration induces distinct alterations in opioid receptors which may be associated with the neurochemistry of cocaine-addiction. Supported by NIDA DA07589.

516.4

SYSTEMIC ADMINISTRATION OF DYNORPHIN A(1-13) MARKEDLY INHIBITS DIFFERENT BEHAVIORS INDUCED BY COCAINE IN THE MOUSE. M. Ukai *, T. Kamiya, T. Toyoshi, M. Mizutani and T. Kameyama. Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, Meijo University, Nagoya 468, Japan.

The effects of systemic administration (i.p.) of dynorphin A(1-13) on the cocaine-induced behavioral alterations in the mouse were determined by using multi-dimensional behavioral analyses based upon a capacitance system. A 1.0 mg/kg dose of cocaine did not influence various behaviors, while increasing doses to 3-30 mg/kg produced a significant increment in the frequency of behaviors such as linear locomotion, circling, rearing and grooming. Although a 1.0 mg/kg dose of dynorphin A(1-13) alone produced a significant decrease in grooming behaviors, higher doses (3.0 and 10.0 mg/kg) of the peptide failed to affect different behaviors. The cocaine (3.0 mg/kg)-induced increases in linear locomotion, circling and rearing behaviors were significantly inhibited by dynorphin A(1-13) (10.0 mg/kg). The inhibitory effects of dynorphin A(1-13)(10.0 mg/kg) were antagonized by the opioid antagonist Mr2266 (5.6 mg/kg). It is thus possible that the systemic administration of dynorphin A(1-13) inhibits different behaviors induced by cocaine through the blood-brain barrier, although the instability of amino acids bonds or the relatively large molecular weight of dynorphin A(1-13) may result in the failure to demonstrate opioid activity by the peptide after systemic administration.

Behavioral Evidence for Changes in 5-HT$_{1A}$ Receptor Sensitivity During Withdrawal From Continous or Intermittent Cocaine. JOYNER, C. M., KING, G. R., SUNDAR, K. S.*, ELLINWOOD, E.H., JR. Changes in 5-HT neurotransmission may partially mediate the development of sensitization and tolerance to chronic cocaine administration. Rats were pre-treated with 40 mg/kg/day of cocaine for 14 days by either subcutaneous injections or continous infusion by osmotic minipumps. The rats were then withdrawn from the pretreatment regime for 7 days and behaviorally assessed. In Experiment 1, rats received 0, 0.5, 1.0, or 2.0 mg/kg i.p. injections of NAN-190, 1-(2-Methoxyphenyl)-4-[4-(2-phthalimido) butyl]piperazine, a putative 5-HT$_{1A}$ receptor antagonist. In Experiment 2, the rats received the same doses of NAN-190 in combination with a 15 mg/kg i.p. injection of cocaine. The results of Experiment 1 indicate that the continuous infusion group demonstrated a dose dependent supression of locomotor behavior by single doses of NAN-190. NAN-190 had no consistent dose dependent effect on the locomotor behavior of the subjects in the other pretreatment groups. The results of Experiment 2 indicate that NAN-190 generally had a greater suppressive effect on cocaine induced locomotion in the daily injection group, than the saline control group, which is consistent with 5-HT$_{1A}$ receptor supersensitivity. In contrast, NAN-190 had no suppressive effect on cocaine induced locomotion in the continuous infusion group, which is consistent with 5-HT$_{1A}$ receptor subsensitivity. Changes in 5-HT$_{1A}$ receptor sensitivity may mediate the withdrawal symptoms of anxiety and depression exhibited by human cocaine abusers thus providing a potential basis for treatment .This research was supported by NIDA grant SRCD-5P5D-DA05303-02.

CHRONIC COCAINE TREATMENT ENHANCES SEROTONIN-MEDIATED BEHAVIORS, BUT NOT NEUROENDOCRINE RESPONSES, IN THE RAT. M.H. Baumann* and R.B. Rothman, Lab. Clin. Psychopharmacol., NIDA Addiction Research Center, Baltimore, MD 21224.

There is compelling evidence that acute cocaine alters serotonin (5HT) neurotransmission, but the effects of chronic cocaine on 5HT neurons are not well characterized. In an attempt to assess 5HT function after repeated cocaine injections, we have employed the 5HT-releasing drug *d,l*-fenfluramine as a pharmacological probe *in vivo*. Male rats were fitted with indwelling jugular catheters under metofane anesthesia. Beginning 2 days after surgery, rats were treated twice daily with cocaine (15 mg/kg,ip) or saline for 7 consecutive days. At 42 hr and 8 days after the final chronic injection, rats were challenged with low dose (1.25 mg/kg, iv) or high dose (5.0 mg/kg, iv) fenfluramine. Specific aspects of the 5HT behavioral syndrome, including flat body posture and forepaw treading, were scored on a graded scale at 2, 10, 20 and 30 min post-fenfluramine; serial blood samples (0.5 ml) were removed immediately before and at 15, 30 and 60 min after drug. Plasma was assayed for prolactin (PRL) and corticosterone (CORT) by RIA. Cocaine-treated rats exhibited enhanced behavioral sensitivity to high ($P<0.01$) and low ($P<0.001$) doses of fenfluramine given 42 hr after cessation of chronic treatment. The potentiation of fenfluramine-induced behaviors was still observed at 8 days post-cocaine. PRL responses to fenfluramine were virtually identical in cocaine- and vehicle-treated groups at all times and doses tested. Interestingly, the plasma CORT response to low dose fenfluramine was significantly blunted ($P<0.01$) in cocaine-treated rats at the 42 hr time point, but this effect was normalized by 8 days of cocaine abstinence. These data suggest that chronic cocaine differentially affects 5HT function: 1) while 5HT-mediated behaviors are persistently enhanced, 2) 5HT activation of the HPA axis is transiently impaired. The relevance of these findings to clinical medicine is unclear at present, but the possibility of serotonergic dysfunction in human cocaine addicts should not be discounted.

516.7

5-HT$_3$ ANTAGONIST INHIBITION OF COCAINE-INDUCED BEHAVIOR AND SEROTONERGIC INNERVATION OF DISTINCT ANATOMICAL SITES. A. Svingos* and R. Hitzemann, Departments of Psychiatry and Psychology, SUNY at Stony Brook, NY 11794-8101 and VAMC, Northport, NY 11768.

We have previously reported that endogenous 5-HT is required for 5-HT$_3$ antagonists to attenuate cocaine-induced hyperactivity (Soc. Neurosci. Abs. 348.16, 1991). It has been suggested that both the caudate-putamen (Cp) and nucleus accumbens (Na) are anatomical sites of action for 5-HT$_3$ antagonism of dopamine (DA) mediated behaviors (Blandina et al. 1988, Carboni et al. 1989, Chen et al. 1990). In order 1) to further investigate the requirement of endogenous 5-HT in the 5-HT$_3$ antagonist inhibition of cocaine-induced behavior and 2) to localize possible anatomical sights of action, *p*-chlorophenylalanine (PCPA) treated animals were observed in a longitudinal-recovery study. Animals were pretreated with PCPA (100 mg x 3 days) and then either sacrificed on days 0, 7, 14, 28, and 56 or tested behaviorally for the 5-HT$_3$ antagonist-cocaine interaction. Recovery of 5-HT levels in the Na and Cp and the raphe nuclei was followed by immunohistochemical techniques. There was no apparent differential recovery of 5-HT in the Cp and Na; the rate of recovery was slow with 5-HT levels being only 30 to 50% of normal by day 14. As expected, recovery of 5-HT in the raphe nuclei occurred more rapidly. Data will be presented paralleling 5-HT recovery with 5-HT$_3$ antagonist behavioral efficacy.

COCAINE SENSITIZATION: RESPONSIVITY OF SEROTONIN (5-HT) NEURONS TO IONTOPHORETIC 5-HT. *K.A. Cunningham* and S.K. Bryan.* **Dept. Pharmacol. Toxicol., Univ Texas Med Branch, Galveston, TX 77550.**

With repeated exposure, rodents become sensitized to the motor-activating properties of cocaine. Cocaine is known to interact with the 5-HT systems in the brain, and cocaine sensitization appears to be associated with an enhanced sensitivity of 5-HT dorsal raphe (DR) neurons to systemic cocaine, fluoxetine and 8-OHDPAT. The present study is designed to compare the sensitivity of somato-dendritic autoreceptors to local application of 5-HT in cocaine-sensitized vs. control rats. Male rats were treated with IP saline (n=6) or cocaine (15 mg/kg; n=5) BID for 7 days. Comparisons of behavioral ratings (Kilbey-Ellinwood) between Day 1 and Day 7 indicated that sensitization developed with this cocaine regimen. Following a 24-hr withdrawal, rats were anesthetized with urethane (1.5 g/kg) and single-unit extracellular recording and iontophoretic studies of DR 5-HT neurons were conducted. Both *'fast'* (>1.2 Hz) and *'slow'* cells (<=1.2 Hz) in controls exhibited similar current-response curves to 5-HT (2.5-10 nA; 0.04 M, pH 4.0); an average inhibition of 52±8% was observed at 7.5 nA. In contrast, the responsiveness of 5-HT neurons from cocaine-sensitized rats appeared to be dependent upon basal firing rates. *Slow* cells in cocaine-sensitized rats were more responsive to 5-HT than *fast* cells from cocaine-sensitized rats as well as both *fast* and *slow* cells from saline-treated rats. For example, the mean suppression observed at 7.5 nA of 5-HT was 79.9 ± 5.7% in *slow* cells and 35.0 ± 6.0% in *fast* cells sampled from cocaine-treated rats. These preliminary studies suggest that at least a subpopulation of 5-HT DR neurons becomes supersensitive to local application of 5-HT after repeated cocaine exposure. Thus, the enhanced sensitivity observed in response to systemic cocaine, fluoxetine and 8-OHDPAT in cocaine-sensitized rats appears to occur in part at the level of the cell body. ***Supported by DA 05708, DA 06511 and NARSAD.***

SEROTONIN LESIONS AFFECT RESPONDING ON A PROGRESSIVE RATIO SCHEDULE REINFORCED BY EITHER INTRAVENOUS COCAINE OR FOOD. E.A. Loh[1*], G. Baker[2], G. Vickers[1] & D.C.S. Roberts[1]. [1]Dept. of Psychology, Carleton University, Ottawa, [2]Dept. of Psychiatry, University of Alberta, Edmonton, Canada.

We have shown that injections of the serotonergic neurotoxin 5,7-DHT into the amygdala or the medial forebrain bundle of rats will result in an apparent increase in motivation to self-administer cocaine (Psychopharm. 101 (1990) 262). In the present study we examined the effect of intraventricular (icv) injections of 5,7-DHT on cocaine self-administration reinforced under a progressive ratio (PR) schedule of reinforcement. On this schedule, the response ratios escalate following each reinforcement. Rats were implanted with chronically indwelling iv cannulas and trained to self-administer cocaine on a PR schedule. Rats then received icv infusions of either 5,7-DHT (10 μg; n=10) or ascorbic/saline vehicle (n=5) and were tested for an additional 7 days. Lesioned rats demonstrated substantial increases in final ratio attained and decreases in forebrain 5HT levels. In a second study, similar increases in final ratio were found in animals responding for food reward following identical 5,7-DHT lesions. The data indicate that 5,7-DHT lesions may produce a global influence on reinforcement rather than a specific effect on cocaine reinforcement. (Supported by the MRC)

NORADRENERGIC RESPONSIVITY DURING COCAINE ABSTINENCE. C. J. McDougle*, L. H. Price, T. R. Kosten, J. Black, R. T. Malison, R. C. Zimmermann, H. D. Kleber. Yale Univ. Dept. of Psychiatry, New Haven, CT 06519.

Preclinical and clinical evidence suggests involvement of noradrenergic systems in the neurobiology of cocaine abstinence. Pharmacological challenge with yohimbine hydrochloride, an alpha 2-adrenergic receptor antagonist, was used to investigate noradrenergic responsivity during early and late abstinence from cocaine in human cocaine addicts. METHOD: Ten inpatients (9 men, 1 woman) with DSM-III-R cocaine dependence received 2 mg/kg of intranasal cocaine 3X/day for three consecutive days. Each subject then received randomized, double-blind challenge tests of active or placebo yohimbine (0.4 mg/kg, I.V.) on the two days following cocaine administration (early abstinence) and again two weeks later (late abstinence). Plasma 3-methoxy-4-hydroxyphenethyleneglycol (MHPG) (ng/ml) and cortisol (ng/ml) responses, as well as behavioral and physiological (sitting and standing blood pressure and pulse) measurements were obtained following each challenge. RESULTS: 3-way ANOVA (drug X time X phase of abstinence) with Huynh-Feldt correction revealed a significant interaction for plasma MHPG ($F=2.7$, $df=5,45$, $p<0.05$) (greater during early abstinence), but not for plasma cortisol, behavioral, or physiological variables. Placebo-corrected peak change between abstinence phases showed a significant difference for a measure of "NERVOUS" (30.2±31.9 (early) vs. 5.2±19.9 (late), $df=9$, $t=-2.7$, $p<0.02$), and a trend toward significance for sitting systolic blood pressure. CONCLUSION: These data suggest that early abstinence from cocaine in humans may be associated with increased noradrenergic responsivity which normalizes over time.

UP-REGULATION OF SIGMA BINDING SITES FOLLOWING REPEATED EXPOSURE OF GUINEA PIGS TO COCAINE. I. Stein* and Y. Itzhak, Dept. of Biochemistry & Molecular Biology, REPSCEND Labs, University of Miami School of Medicine, Miami, FL. 33101

Although it is believed that blockade of the dopamine (DA) transporter by cocaine is primary for its psychotropic effects, the drug interacts with several transporters and CNS receptors. Cocaine, for instance, has similar affinities for the DA transporter and sigma binding sites (ca. 1 uM). The latter are postulated to be involved in the effects of various psychotropic agents, and are down-regulated following exposure to the antipsychotic agent, haloperidol (Itzhak & Stein, Brain Res. 566: 166, 1991), that has similar affinities for both D2 and sigma receptors (ca. 2 nM). Inasmuch as both cocaine and haloperidol interact with sigma binding sites, but affect DA neurotransmission in "opposite directions", we sought to investigate the effects of cocaine-exposure on sigma binding sites. Guinea pigs were treated with either saline or cocaine (40 mg/kg/day; i.p.) for 7 days, sacrificed 24 h following the treatment, and the brain was dissected and prepared for sigma-ligand-receptor binding assays. Binding of (+)[^{3}H]pentazocine and (+)[^{3}H]-3-PPP, two selective sigma ligands, in various brain regions indicated a significant up-regulation (142% of control) of sigma binding sites in the substantia nigra. In other brain regions no significant change in the binding parameters of the sigma-ligands was detected. The specific alteration in sigma binding sites observed in substantia nigra may be related to the behavioral sensitization that usually follows repeated exposure to cocaine. Supported by NIDA DA07589.

CHRONIC CONTINUOUS VS. INTERMITTENT COCAINE ADMINISTRATION: DIFFERENTIAL ALTERATIONS IN NEUROTENSIN CONCENTRATIONS FOLLOWING A CHALLENGE STIMULATION. S.T.Cain*D.Griff, C. Joyner, and E.H. Ellinwood. Dept. Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

We have previously reported that 14 days of either continuous or intermittent exposure to cocaine yields regimen-specific neuroanatomically-selective changes in basal NT-like immunoreactivity [NT-LI] (Cain et al., Soc. Neurosci. 1991). We have now evaluated residual alterations in NT responsivity in response to a challenge stimulation. Rats were treated with 40 mg/kg cocaine/day for 14 days using continuous or intermittent administration paradigms. After 7 days of withdrawal, the animals were given a 20 mg/kg ip. challenge dose of cocaine and sacrificed 24 hrs. later. In rats treated continuously with cocaine, NT-LI was significantly increased in the nucleus accumbens 24 hrs. following the challenge dose relative to animals treated for 14 days with saline vehicle or intermittent cocaine injection. In contrast, in animals treated with chronic intermittent injections of cocaine, NT-LI in the substantia nigra was significantly increased relative to animals treated for 14 days with saline vehicle or continuous cocaine. These results indicate that differential cocaine dosing protocols induce neuroanatomically-selective changes in the responsivity of CNS NT systems and thus, support the possibility that NT is an important modulator of the behavioral consequences of chronic cocaine exposure. INFLUENCE OF DIFFERENT TRAINING DOSES OF COCAINE ON GENERALIZATION TO NONCOMPETITIVE NMDA ANTAGONISTS. M.A. Napolitano, K.M. Kantak and R.D. Spealman*. Boston Univ. Boston, MA 02215 and New England Reg. Primate Res. Ctr., Southborough, MA 02215.

Generalization of the discriminative stimulus (DS) effects of cocaine to $MgCl_2$, dizocilpine, and PCP was studied in rats trained to discriminate cocaine (2, 5, or 10 mg/kg) from vehicle. In rats trained to discriminate 2 mg/kg cocaine, $MgCl_2$ (10-100 mg/kg) produced partial generalization (maximum 73%). With higher training doses of cocaine (5 and 10 mg/kg), there was no reliable generalization. There was also partial generalization of cocaine to dizocilpine (0.03-0.3 mg/kg; maximum 75%) and PCP (1.0-3.0 mg/kg; maximum 78%) in 2 mg/kg cocaine-trained rats. Additionally, at the 5 mg/kg training dose of cocaine, partial generalization of cocaine to dizocilpine (maximum 29%) and PCP (maximum 87%) was produced. After pretreatment with $MgCl_2$ (30 mg/kg) in rats trained to discriminate 5 mg/kg cocaine, the DS effects of a low dose of cocaine (1 mg/kg) were enhanced from 12% to 63% and the DS effects of higher doses of cocaine (5 and 10 mg/kg) were attenuated from 100% to 75% and 89%, respectively. Similarly, with pretreatment with dizocilpine (0.178 mg/kg) in rats trained to discriminate 5 mg/kg cocaine, the DS effects of a low dose of cocaine (1 mg/kg) were enhanced from 12% to 32% and the DS effects of higher doses of cocaine (5 and 10 mg/kg) were attenuated from 100% to 79% and 59%, respectively. Pretreatment with PCP (1.78 mg/kg) in rats trained to discriminate 5 mg/kg cocaine produced an enhancement of the DS effects at a low dose of cocaine (1 mg/kg) from 12% to 60%. Pretreatment with this dose of PCP did not alter the DS effects of higher doses of cocaine. These results suggest that noncompetitive NMDA antagonists have characteristics of partial cocaine mimetics, with the degree of generalization dependent upon the training dose of cocaine.

516.14

DISCRIMINATIVE STIMULUS EFFECTS OF MG^{2+} AND GENERALIZATION TO COCAINE AND NONCOMPETITIVE NMDA ANTAGONISTS. K.M. Kantak* and E.S. Kitchell. Lab. of Behav. Neurosci., Dept. Psychol., Boston Univ., Boston, MA 02215.

Six rats were trained to discriminate 100 or 135 mg/kg $MgCl_2$ from saline in a 2-lever FR 10 food-reinforced procedure. After 35 training sessions, rats made 99.9% of the total responses on the drug lever following injections of the training dose. There were dose-dependent decreases in % total drug lever responding following generalization testing with various doses of $MgCl_2$ (3.0-100 mg/kg). There was partial generalization of $MgCl_2$ to cocaine (1.0-10 mg/kg) with a maximum of 82% drug lever responding with 3.0 mg/kg. Partial generalization was also engendered to the noncompetitive NMDA antagonists dizocilpine (0.03-0.178 mg/kg) and PCP (1.0-3.0 mg/kg). There was a maximum of 75% drug lever responding with 0.1 mg/kg dizocilpine and a maximum of 82% drug lever responding with 3.0 mg/kg PCP. These data indicate that $MgCl_2$ can serve as a discriminative stimulus in rats which extends previous findings showing $MgCl_2$ to have reinforcing stimulus properties in a cocaine self-administration substitution procedure (Kantak et al., 1991). Furthermore, these discriminative stimulus effects of $MgCl_2$ partially generalize to cocaine, suggesting that these two compounds share some common effects. That these effects may be mediated through the NMDA receptor complex, which includes recognition sites for Mg^{2+}, PCP, and dizocilpine, is suggested by the findings showing partial generalization of $MgCl_2$ to other noncompetitive NMDA antagonists. Further characterization of the role of the NMDA receptor complex in cocaine pharmacology is warranted.

EFFECTS OF COCAINE, MORPHINE AND MK-801 ON STRIATAL ACETYLCHOLINE OVERFLOW. A. Zocchi* and A. Pert. Biological Psychiatry Branch, NIMH, Bethesda, MD 20892

Cocaine, morphine, and MK-801 all produce increases in locomotor behavior in rats through different initial receptor interactions. One common link through which these drugs may exert at least part of their behavioral effects is the cholinergic interneuron in the striatum. The purpose of this study was to evaluate the effects of these three compounds on striatal acetylcholine (ACh) following systemic injections. The effects of cocaine on ACh were examined in both anesthetized and awake preparations. For the latter, rats were implanted with CMA guide cannulae aimed for the striatum. One week following surgery, microdialysis probes were introduced into the striatum and perfused with artificial CSF containing 10 μM neostigmine at 0.5 μl/min. The animals in the anesthetized study were injected with chloral hydrate, placed in a stereotaxic frame and then had dialysis probes introduced into the striatum. Dialysates were analyzed for ACh and choline by a reverse phase HPLC system with electrochemical detection.

Cocaine (20 mg/kg i.p.) increased striatal ACh levels approximately 50% during the first three 20-min sampling periods. The increase in ACh was even more pronounced in anesthetized rats (peak effect of approximately 160% increase during the second sampling period). Systemic administration of MK-801 (0.5 mg/kg) or morphine (10 mg/kg) had little if any effect on striatal ACh in anesthetized rats. The effects of cocaine on ACh are unexpected since indirect and direct dopamine agonists have been reported to inhibit ACh function in vitro. Our findings are, however, compatible with those from a recent microdialysis study in which amphetamine was found to increase ACh through a D_1 dopaminergic mechanism. The negative findings with MK-801 and morphine suggest that the ACh interneurons may not have important glutamatergic or opioid inputs.

EPILEPTIFORM ACTIVITY ELICITED IN THE RAT DENTATE GYRUS IN VITRO IN SOLUTIONS WITH NORMAL $[Ca^{2+}]_o$ CONTAINING AMINO-ACID RECEPTOR ANTAGONISTS. P.R. Patrylo[1,3]*, J. Schweitzer[2], and F.E. Dudek[1,3]. Mental Retardation Res. Ctr.[1] and Div. of Neurosurgery[2], UCLA Sch. of Med., Los Angeles, CA 90024, and Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins CO 80523[3]

We have shown that the dentate gyrus can undergo ictal-like seizure activity *in vitro* in response to concurrently lowering $[Ca^{2+}]_o$ from 1.3 mM to "0" or 0.5 mM and elevating $[K^+]_o$ from 3 mM to 7-11 mM (Schweitzer et al., submitted). Addition of DL-AP-5 and DNQX, antagonists to the NMDA and non-NMDA receptors, did not block this seizure-like activity. In these experiments we examined whether seizure-like activity could be induced in the dentate gyrus in solutions containing "normal" $[Ca^{2+}]_o$ (i.e., 1.3 mM) or slightly decreased $[Ca^{2+}]_o$ (i.e., 0.9 mM). Such reduced Ca^{2+} concentrations are observed *in vivo* during high-frequency stimulation (15 Hz) of afferent input. In the presence of "normal" $[Ca^{2+}]_o$ (1.3 mM), $[K^+]_o$ as high as 12 mM failed to produce these epileptiform events (n=6). Epileptiform activity could be elicited in 1.3 mM $[Ca^{2+}]_o$ solutions, however, if the $GABA_A$ receptor antagonist bicuculline (30 μM) and elevated $[K^+]_o$ were used concurrently (n=4). The addition of DL-AP-5 (10-50 μM) and DNQX (10-50 μM) either before (n=6) or after (n=4) raising $[K^+]_o$ did not block this epileptiform activity. Bursts were also elicited in solutions without bicuculline, if the $[Ca^{2+}]_o$ was 0.9 mM and $[K^+]_o$ was 9-11 mM (n=2). These results suggest that dentate granule cells can generate epileptiform activity in normal or slightly reduced $[Ca^{2+}]_o$ when $[K^+]_o$ is elevated, particularly when synaptic inhibition is depressed. Furthermore, this form of seizure activity persists in the presence of antagonists for excitatory amino acid receptors. Supported by NIH grant NS16683 and NRSA fellowship NS08993.

SIMULATION AND EXPERIMENTAL ANALYSIS OF AN EPILEPTIC OSCILLATION IN THE *IN VITRO* HIPPOCAMPAL SLICE. R.D. Traub*, R. Miles and J.G.R. Jefferys. IBM Watson Res. Ctr., Yorktown Heights, NY 10598 USA, Institut Pasteur, Paris 15, France and St. Mary's Hospital Med. Sch., London W2 1PG, England.

The potent $GABA_A$ blocker picrotoxin, applied to guinea-pig hippocampal slices, induces in the CA3 region an epileptic event called an "afterdischarge" (AD). ADs consist of a long initial (1^e) burst, lasting up to several hundred ms, a number of briefer secondary (2^e) bursts at 50-65 ms intervals, and a long afterhyperpolarization (AHP). All AD components are synchronized between cell body, apical dendrites, different cells, and the local field potential.

We constructed a model of the disinhibited CA3 region with 100 19-compartment pyramidal cells, each with Na, K and Ca currents whose kinetics were determined (where possible) from whole cell patch records in isolated cells (Traub, Wong, Miles & Michelson, *J. Neurophysiol.* 1991, 66: 635-650). Cells were randomly connected by excitatory synapses with "AMPA" (fast, voltage-independent) and "NMDA" (slow, voltage-dependent) synapses. The model generates ADs as follows: AMPA synapses mediate the initial synchrony and depolarize the dendrites, unblocking NMDA receptors. The long 1^e burst results from the delayed onset of the AHP (Lancaster & Adams, *J. Neurophysiol.* 1986, 55: 1268-1282). A prolonged NMDA current generates repeating dendritic Ca spikes, producing the 2^e bursts. 2^e bursts are synchronized in turn by the AMPA synapses. Experimental results supporting this model include (1) effects of NMDA blockers (suppressing the 2^e bursts); (2) effects of dendritic current injection: a rhythmical series of brief bursts with slow action potentials (presumed Ca spikes).

In conclusion, in this type of experimental epilepsy, recurrent excitatory synapses engage intrinsic cellular oscillatory properties. Recurrent excitation also maintains synchrony of the oscillations.

EXCITATORY SYNAPTIC COUPLING BETWEEN GABAERGIC INTERNEURONS IN THE HIPPOCAMPUS. H.B. Michelson* and R.K.S. Wong, Department of Pharmacology, SUNY Health Science Center, Brooklyn, New York 11203.

We are interested in the interactions between interneurons in the hippocampus. Experiments were carried out using dual intracellular recordings in the guinea pig hippocampus slice preparation, where excitatory glutamate transmission is blocked by CPP and CNQX (both 10 uM). Synchronized discharge of interneurons is recorded in the presence of 4-aminopyridine. At least two glutamate-independent mechanisms exist for the synchronization of inhibiitory interneurons in the hippocampus. One process is mediated by an excitatory action of GABA via depolarizing $GABA_A$ receptors. This process is blocked by picrotoxin (PTX). Another synchronization process persists in the presence of PTX, producing large amplitude slow inhibitory postsynaptic potentials (IPSPs) in all principal cell populations. These events are 7-15 mV in amplitude; they reverse monophasically at -93 mV, and occur at a slower frequency than the $GABA_A$ synchronized event. Only a subpopulation of interneurons participate in the generation of the slow IPSP. Some interneurons which are synchronized by the $GABA_A$ mechanism become silent after PTX; others show the slow IPSP after PTX. In a third group of interneurons, PTX abolishes the depolarizing envelope, but the interneurons continue to fire bursts of action potentials during the slow IPSP. These bursts show properties suggesting that they are sustained by electrotonic transmission. Thus, interneurons can be coupled by depolarizing $GABA_A$ receptors or by electrotonic junctions. (Supported in part by grants from the N.I.H and American Epilepsy Foundation)

SYNAPTIC MODIFICATION UNDERLYING IN VITRO EPILEPTOGENESIS. L.R. Merlin* and R.K.S. Wong. Depts. of Neurology and Pharmacology, SUNY/Health Science Center, Brooklyn, NY 11203

We are interested in the modification of synaptic events leading to electrically induced epileptiform discharges. Intracellular recordings were obtained from CA3 pyramidal cells in guinea pig hippocampal slices; stimuli (bipolar, .35-3mA, 140μs) were applied to the stratum radiatum at the border between CA1 and CA2. These stimuli presumably activated the recurrent synapses between the CA3 pyramidal cells. The typical response to a single (test) shock consisted of an EPSP followed by a compound IPSP. Successive tetanization (60Hz, 2s, intensity 2x test stim) progressively altered these synaptic events, ultimately resulting in evoked burst discharges. Specifically, we noted that tetanization induced long-lasting depression of the early IPSP. This could result from either a reduction in the IPSP conductance (g) or an increase in the concomitant gEPSP, or both. To determine whether gIPSP is reduced, we examined the test response at different membrane potentials. The IPSP amplitude varied linearly with the membrane potential. Following tetanization of adequate intensity, the slope of this relationship decreased, suggesting a decrease in IPSP conductance (cf. Stelzer et al, *Nature* 1987). This decrease was cumulative with successive tetani. With sufficient suppression of inhibition, delayed EPSPs first emerged most typically between the peaks of the early and late IPSPs. Additional tetani often induced evoked (and occasionally spontaneous) synchronized bursting consisting of an initial component lasting up to 110ms, followed by phasic bursting at approximately 15Hz. These results suggest that the reduction of inhibitory conductance following tetanization allowed recurrent excitatory synapses to sustain epileptiform activity in the CA3 region.

HIGH POTASSIUM INDUCED SEIZURES IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS DEPEND UPON TEMPERATURE DURING GROWTH. Y. Tamaki*, J. Wilson, and C. Shin. Epilepsy Research Laboratory, Duke and VA Med. Ctr., Durham, N.C.27705

We had reported that modest elevation of extracellular K^+ (8.3 mM) induced seizures (SZs) in organotypic hippocampal(HPC) cultures more reliably than in acute adult HPC slices. The literature suggests that HPC organotypic cultures grown in higher temperature show more spontaneous epileptiform discharges. We examined the effect of temperature during the culture period on high K^+ induced SZs in organotypic HPC cultures.

Organotypic cultures were prepared from 6-day-old rat HPC according to the methods of Gähwiler (1988, TINS). Cultures were maintained in a 35°C or a 37°C incubator. At 9-14 DIV, extracellular field recordings were made from CA1 pyramidal layer in standard aCSF (95/5, O_2/CO_2) at 36°C.

Only 6 of 24 cultures grown at 35°C displayed SZs in high K^+ (8.3 mM) media, while 38 of 43 grown at 37°C exhibited SZs ($p < 0.0001$, Fisher's Exact). The SZ frequency and duration were not significantly different between these two groups (35°C [n=5] vs 37°C [n=33]; 1.7 ± 0.6 vs 2.9 ± 0.3 SZs/10min; 30.6 ± 6.1 vs 34.4 ± 3.2 sec/SZ)

Cultures grown at higher temperature were more likely to develop SZs in high K^+ medium. This suggests that temperature may play an important role during growth and maturation of pyramidal neurons in the organotypic culture in determining the intrinsic properties and/or the synaptic responses of the neurons.

Chronic Epileptogenesis *in vitro*. S.N. Hoffman, P.A. Salin, K.L. Chow*, D.A. Prince, Department of Neurology & Neurological Sciences, Stanford University School of Medicine, Stanford, CA 94305.

We used an *in vitro* model of chronic epileptogenesis in partially isolated neocortical slabs (Prince and Tseng Neurosci. Abstr. 1991) to explore critical aspects of the epileptogenic lesion. Guinea pig neocortical slices were prepared from areas of previous *in vivo* lesions. Recordings from sensorimotor and lateral cingulate cortex were made using extracellular arrays and patch electrodes. Lesions consisting of a white matter undercut and /or surrounding multiple transcortical linear incisions were made at P7-P34 and examined *in vitro* 18-103 days later (N=16). Long latency "interictal" or "ictal" cellular and field potential activities occurred most prominently in layers II-III within 1-2 mm of the transcortical lesion. Normal field potentials were evoked in homotopic cortex and >2-3 mm from the transcortical injury. Transcortical lesions alone induced abnormal activities, however a contiguous white matter lesion resulted in the most hyperexcitable tissue which had spontaneous interictal discharges. Conduction velocities of evoked epileptiform events in layer II-III ranged from 37mm/sec near the transcortical injury to 6-7mm/sec away from this site. APV (100 μM, bath) abolished all epileptiform activity. Epileptiform responses were also blocked by increasing stimulus intensities, suggesting that inhibition was present and recruitable. Spontaneous and evoked IPSCs were present in identified filled layer III and V pyramidal cells in slices showing abnormal discharges. Intracellular events during "ictal" field potentials consisted of complex prolonged (5-10 sec) depolarizations which triggered high frequency spikes. Undercut lesions in white matter or layer VI, without surrounding transcortical incisions, did not result in development of hyperexcitability. This model will allow a detailed assessment of factors contributing to the development of epileptogenesis following cortical injury. 4-AMINOPYRIDINE-INDUCED SPONTANEOUS ACTIVITY IN THE IMMATURE RAT HIPPOCAMPUS: DEVELOPMENTAL AND PHARMACOLOGICAL CHARACTERISTICS. C. Psarropoulou* and M. Avoli. MNI, McGill University, Montreal, QC, Canada H3A 2B4.

Perfusion with 4-aminopyridine (4-AP, 50μM) induced the appearance of spontaneous activity in the CA3 and CA1 areas of immature (2-30 days postnatally) rat hippocampal slices. These potentials were ictal-like and interictal-like epileptiform discharges, a GABA-mediated depolarizing potential and spreading depression (SD) episodes (in 30% of the slices). The overall pattern of activity and the characteristics of each type of potential changed with maturation (their frequency increased, their duration decreased), and in addition the changes took place at different stage of development for each potential. SDs and ictal discharges were rarely seen after 30 days postnatally. In CA1 area, interictal discharges had significantly smaller amplitude than in CA3 and SDs had larger amplitude and duration and also, occurred more frequently.

The NMDA receptor antagonist CPP (1-5μM) blocked SD (n = 15 slices), but had no effect on the other types of activity (n = 16). The non-NMDA receptor antagonist CNQX (2-5μM) did not block SD (n = 11), but blocked the ictal and interictal discharges (n = 20). Sensitivity to CNQX application was greater in the first 10 days postnatally. The $GABA_A$ receptor antagonist bicuculline (3-10μM) blocked SD (11/14 slices) and the GABA-mediated depolarization and increased the frequency of epileptiform discharges (n = 13). The non-uniform temporal profile of the maturational changes of the various 4-AP-induced spontaneous potentials and their pharmacological profiles suggest different mechanisms of generation and possibly different impact on the overall neuronal activity.

TETRAETHYLAMMONIUM-INDUCED EPILEPTIFORM ACTIVITY IN YOUNG AND ADULT RAT HIPPOCAMPUS. Y. Fueta* and M. Avoli. MNI and McGill University, Montreal, QC, Canada H3A 2B4

Extracellular field potential recordings were used to study in vitro the epileptiform activity evoked by tetraethylammonium (TEA, 3-10mM) in the CA3 subfield of hippocampal slices obtained from young (12-18 day-old) and adult (>60 day-old) rats. TEA induced ictal- and interictal-like activity in young slices. By contrast, in adult slices only interictal-like discharges were observed. Both the N-methyl-D-aspartate (NMDA) receptor antagonist CPP (5-10μm) and the non-NMDA receptor antagonist CNQX (5-10μM) were necessary to suppress ictal- and interictal-like discharges in young slices. As opposed to this, interictal-like activity in adult slices was reduced and eventually blocked by CNQX (0.5-3μM) only. Furthermore, epileptiform activity recorded in young slices was modified by CPP (i.e. decrease in the rate of occurrence of ictal-like events and reduction in duration of interictal-like discharges) while that observed in adult slices was resistant to this NMDA antagonist.

Our data indicate that the epileptiform discharges induced by TEA in the CA3 subfield of the rat hippocampal slice display patterns of activity that are dependent upon age. Furthermore, the participation of non-NMDA and NMDA receptors in the TEA-induced activity undergoes age-dependent changes.

GABA INCREASES CA1 NEURONAL SYNCHRONY DURING ZERO CA^{2+}-INDUCED BURSTING IN THE HIPPOCAMPAL SLICE. P.L. Watson* and R.D. Andrew. Anatomy Department, Queen's University, Kingston, Ontario K7L 3N6.

Hippocampal slices (400 μm) superfused with ≤ 0.2 mM $CaCl_2$ saline exhibit spontaneous epileptiform bursts which can be recorded extracellularly across the CA1 region despite the loss of synaptic transmission. Application of 100-500 μM GABA in "low" Ca^{2+} saline (0.2 mM $CaCl_2$) reversibly arrested bursting (n=13). The effect was blocked by co-application of 50-100 μM bicuculline methiodide (BMI), a GABAa receptor antagonist (n=3). GABA in "zero" Ca^{2+} saline (ϕ $CaCl_2$, 1 mM EGTA) increased the interburst interval, but paradoxically also increased burst duration and enhanced population spike amplitude and frequency during each burst (n=11). This dramatic increase in neuronal synchronization was also eliminated by co-application of 50-100 μM BMI (n=3).

The results suggest that in the absence of extracellular Ca^{2+}, activation of the GABAa receptor promotes non-synaptic synchronization of neuronal firing. One possible mechanism is an enhancement of a Ca^{2+} channel-mediated Na^+ conductance which only operates at less than micromolar concentrations of extracellular Ca^{2+} (Almers and McCleskey, 1984, J. Physiol. 353, 585). The data also suggest that the "low" and "zero" calcium models are more physiologically distinct than previously suggested.

OPTICAL REAL-TIME MAPPING OF SPONTANEOUS EPILEPTIFORM ACTIVITY IN HIPPOCAMPAL BRAIN SLICES. L.V. Colom* and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The site of origin and propagation pathways of spontaneous epileptiform discharges have not been clearly demonstrated for the different *in vitro* models of epilepsy. The sites of generation and their correlation to local circuits are critical for the understanding of the phenomena of epilepsy. While multichannel electrical recording techniques harm the tissue, optical techniques are non-invasive and thus well suited for this study. Voltage-sensitive dyes were used to monitor spatio-temporal pattern of epileptiform activity in transverse hippocampal slices of both guinea pigs and mice. Two *in vitro* models of epilepsy have been established in hippocampal slices, employing increased recurrent excitation or decreased synaptic inhibition. These conditions were reproduced in our experiments by either raising the bath potassium concentration to 8-10 mM or adding $GABA_A$ antagonists to the bath (bicuculline and picrotoxine, 20 μM and 50 μM respectively). Neural activity was optically monitored from a region including *cornu ammonis* (CA) and *gyrus dentatus*. Changes in extrinsic fluorescence from an area up to 2 x 2 mm were recorded by a photodiode matrix with 100 detectors, connected to a specially designed multichannel amplifier. Individual signals, each proportional to local neural activity, were topographically monitored in real-time by using a video camera and superimposing them on a videomicrograph of the preparation in use. A latency analysis of the spontaneous discharges resulted in two major findings. In both models of epilepsy the site of origin remained the same within each of the studied species. However, in the mouse the epileptiform activity was originated in the CA3c region, while in the guinea pig the site of origin was in the CA2-CA3a region. These results suggest that CA2-CA3a and CA3c are the areas with the lowest threshold for the generation of epileptiform activity in guinea pig and mouse respectively.

CNQX-INSENSITIVE SPONTANEOUS EPSPS AND EPILEPTIC BURSTS IN LOW Mg^{2+} IN RAT HIPPOCAMPAL SLICES

M.A. Whittington & J.G.R. Jefferys*, Dept. Physiology & Biophysics, St.Mary's Hosp. Med. Sch., Imperial College, London W2 1PG, UK.

Low concentrations of Mg^{2+} in cerebrospinal fluid have been shown to elicit spontaneous epileptic burst discharges. Here we examined the relationship between spontaneous epsps and epileptic bursts in this model.

Hippocampal slices in vitro were prepared from adult male Sprague-Dawley rats. Intra- and extracellular recordings were made of spontaneous activity in area CA3 in the presence of 1 mM or 0 mM Mg^{2+}. The slow, APV-sensitive component of glutamatergic excitation was isolated from the fast component by bath application of 20 μM 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). In the presence of CNQX no fast epsp could be evoked at either 0 or 1 mM Mg^{2+}. Spontaneous epileptic bursts occurred in 0 mM Mg^{2+} (mean ± SEM frequency 7.1 ± 1.0 Hz, n=7) and persisted in the presence of CNQX at a reduced rate (0.2 ± 0.1 Hz, n=5). In the absence of Mg^{2+} two distinct populations of spontaneous epsps were seen with modal half-widths of 6 ms and 14 ms. The short duration epsps were seen alone in the presence of 1 mM Mg^{2+} and were blocked by CNQX. The longer epsps persisted in the presence of CNQX at a reduced frequency.

These observations show that APV-sensitive glutamatergic excitation alone was sufficient to generate epileptic bursts. The occurrence of bursting correlated with long-duration spontaneous epsps suggesting that the initial trigger for these epileptiform events was synaptic activation of the NMDA-subtype of glutamate receptor. *Supported by the Wellcome Trust*

CHOLERA TOXIN MODEL OF EPILEPSY IN RAT HIPPOCAMPAL SLICES EX VIVO: POSTSYNAPTIC POTENTIALS

A.E. Watts & J.G.R. Jefferys (SPON: European Neuroscience Association) Dept Physiology & Biophysics, St.Mary's Hosp.Med.Sch., Imperial Coll., London W2 1PG, UK

Injecting cholera toxin into rat hippocampus induces an epileptic syndrome lasting 7-10 days. Epileptic activity is preserved in the hippocampal slice in vitro. We have attributed the epileptogenesis to a depression of intrinsic potassium currents responsible for accommodation and for AHPs. Here we measure both spontaneous and evoked postsynaptic potentials (psp's) to assess synaptic excitation and inhibition.

Cholera toxin (0.5-1.0 μg) was injected bilaterally into dorsal hippocampus of anaesthetised adult male Wistar rats, which were then allowed to recover. Transverse hippocampal slices prepared 3-4 days later, at the peak of the syndrome, exhibited both evoked and spontaneous epileptic discharges. When these all-or-none bursts were blocked by raising Ca^{2+} in the bathing medium from 2 to 6 or 8 mM we were able to evoke epsp - ipsp sequences. These consisted of a fast epsp followed by both a fast and a slow ipsp. The times to peak of the epsp and slow ipsp did not differ from controls ($p>0.05$), although the fast ipsp peaked slightly later ($p=0.02$). Reversal potentials did not differ significantly from controls. No changes were apparent in the conductance underlying the evoked psp's. Initial analysis of spontaneous epsp's indicated a slight increase in epsp amplitude but no change in half-width.

Models of epilepsy where inhibition is intact, such as that induced by cholera toxin, may provide new insights into mechanisms of the epilepsies. *Supported by the Wellcome Trust.*

EPILEPTIFORM ACTIVITY INDUCED BY VERATRIDINE IN CA1 NEURONS IN RAT HIPPOCAMPAL SLICES.

L. M. Tian* and K. A. Alkadhi, Department of Pharmacology, University of Houston, Houston, TX 77204-5515.

Epileptiform activity can be generated in individual neurons without synaptic involvement. The intrinsic mechanism for this is unclear. Using conventional intracellular recording techniques, we report here results showing that abnormality of Na^+ channels may lead to epileptiform discharges or even seizure-like events in rat hippocampal CA1 pyramidal neurons *in vitro*. Veratridine-induced Na^+ channel abnormality is utilized as a model.

In the presence of veratridine (30-100 nM) the action potential induced by a brief depolarizing current pulse is followed by a slow depolarizing plateau (SDP, 6 neurons). Tetrodotoxin (TTX, 10 nM) markedly blocks the SDP amplitude with no significant effects on the amplitude and duration of the initial action potentials (4 neurons). When Ca^{2+} concentration is doubled in the superfusate, the SDP amplitude decreases. The amplitude and duration of SDP decrease when the membrane is hyperpolarized and increase when depolarized.

A burst of action potentials riding on the SDP appears when concentrations of veratridine over 100 nM are used (20 neurons). This burst is paroxysmal and can be blocked by TTX (30 nM) as well as by high Ca^{2+} concentrations, apparently, by decreasing the SDP. These results suggest that an abnormality of Na^+ channels could be an intrinsic mechanism for epileptogenesis.

TRANSPUTER MODELLING OF EPILEPTIFORM ACTIVITY IN THE CA1 REGION OF THE HIPPOCAMPUS

Y.C. Ge, C. Bernard, J.B. Willis and H.V. Wheal* Dept of Physiology & Pharmacology and Dept of Mathematics, University of Southampton, Southampton, SO9 3TU, U.K.

The activity of individual cells in the hippocampus has been modelled using a similar approach to that of Traub (1991, *J. Neurophy.*, 66, 635-650). This model includes a description of the cellular channel currents I_{Na}, $I_{K(DR)}$, $I_{K(C)}$, $I_{K(A)}$, I_{Ca} and I_{AHP}. However, the kinetics of the processes were empirically tuned to fit bursting behaviour of CA3 and CA1 pyramidal cells.

The pyramidal cells together with two populations of interneurons in CA1 have been incorporated into a 3D model of the synaptic connectivity of the CA3 and CA1 areas. Mechanisms of non-NMDA and NMDA EPSCs, as well as IPSCs mediated by $GABA_A$ and $GABA_B$ receptors, are included. Bursting in CA1 driven by CA3, or bursting in CA1 following the synaptic plasticity reported following KA lesion (Wheal, 1989, *Comp. Biochem. Physiol.*, 93A, 211-220) has been investigated.

The simulations of the hippocampal network are performed on transputers using software that is both fast and interactive. A general purpose numerical integration routine and an efficient communication scheme have been developed to allow the model to be run on toroidally connected transputer arrays of different sizes. For example, 100ms of activity on a network of 6400 neurones can be simulated in 8 minutes using a Parsytec Multicluster with 19 Inmos T800 transputers.

Preliminary studies indicate that this anatomically based model can be used to study the dynamic properties of neurones in the hippocampus, including monitoring the behaviour of subpopulation of cells that contribute to epileptiform activity.

This project is funded by the M.R.C. and Wellcome Trust.

EFFECTS OF ESTRONE-3-SULFATE ON SYNAPTIC CURRENTS IN CA1 PYRAMIDAL CELLS IN THE RAT HIPPOCAMPUS.

R. Raman, D. Crockett, A. McCartin, and S. Veregge*. Dept. of Biological Sciences, San Jose State University, San Jose, CA 95192-0100.

Previous work has demonstrated the convulsant nature of the estradiol metabolite, Estrone-3-Sulfate (ES). In this study, we used whole-cell, thick slice, patch clamp techniques to observe the action of Estrone-3-Sulfate on synaptic currents in hippocampal CA1 neurons of 18-25 day old male rats. Synaptic currents were evoked orthodromically by stimulating the Schaffer Collateral pathway. Patch clamp recordings were made using 3-6 MΩ electrodes filled with 125 mM potassium gluconate. Evoked currents were observed at holding potentials ranging from -70 to -55 mV. Stimulation of the Schaffer Collaterals elicited the typical EPSC (inward current)/IPSC (outward current) response. Perfusion of Estrone-3-Sulfate, at a pharmacological dose (450 μM), produced an increase in the amplitude of the inward current and a decrease in the outward current. In some cases, however, there was a more sudden transition to a prolonged, multiphasic inward current (EPSCs) that was not preceded by a decline of the IPSC. In addition, pyramidal cells exposed to ES exhibited both evoked and spontaneous bursting activity. Bursts were associated with a large amplitude inward current similar to currents associated with other models of epilepsy. These data suggest that Estrone-3-Sulfate may either facilitate excitatory synaptic transmission or depress inhibitory transmission. However, further experiments need to be performed to clarify the mechanism by which Estrone-3-Sulfate produces epileptic activity.

EXCITABILITY OF CA1 REGION OF RAT HIPPOCAMPUS CHANGES POSTNATALLY TO ELEVATION OF $[K^+]_o$.

M.L. Smith, N.R. Kreisman*, J.L. Scripter, and L.L. Rihn. Dept. of Physiology and Neuroscience Program, Tulane Univ. Sch. of Med., New Orleans, LA 70112.

Seizure susceptibility in rats peaks during the second postnatal week and declines thereafter toward adult levels. We hypothesized that this may be due to age-related differences in hippocampal sensitivity to elevations in $[K^+]_o$. Hippocampal slices (400-500 μm thick) were prepared from rats of four different age groups; 9-12, 18-22, 28-32, and 60-80 days old (d.o.) and maintained in vitro at 31-33°C. Field potentials were recorded in the CA1 pyramidal cell layer in response to stimulation of the Schaffer collaterals with constant current pulses (10 msec; 50-250 μA). $[K^+]_o$ was increased stepwise from 3.5 mM to 6 mM, 8.5 mM, and 11 mM. Both the amplitude and number of evoked population spikes increased in rats ≥18 d.o. as $[K^+]_o$ increased, with a peak response at 8.5 mM K^+. In contrast, spike amplitude decreased in 9-12 d.o. rats, or was blocked completely in association with a large negative extracellular potential. However, evoked responses recovered more readily in slices from younger rats upon washing with 3.5 mM $[K^+]_o$. Spontaneous epileptiform activity occurred in elevated $[K^+]_o$ in 50-83% of slices from rats ≥18 d.o. but not in 9-12 d.o. rats. Our results show that regulation of $[K^+]_o$ is less effective in the hippocampal CA1 region of 9-12 d.o. rats than in adults, probably because of poorly developed mechanisms for transporting and buffering K^+. However, 18-22 d.o. rats appear to be most susceptible to develop epileptiform activity in response to rises in $[K^+]_o$.

THE METABOTROPIC GLUTAMATE RECEPTOR CONTRIBUTES TO THE KINDLING OF EPILEPTIFORM EVENTS IN RAT HIPPOCAMPAL SLICES. S. M. Bawin*, W. M. Satmary, A. R. Sheppard and W. R. Adey. Loma Linda University and VA Medical Center, Loma Linda, CA 92357.

We previously demonstrated that repeated sine wave stimulation (SW, 60 Hz, 100-600 μA_{p-p}, 2-4s, every 5 min) in the CA2/3 stratum radiatum kindled afterdischarges (ADs) and electrographic seizures (EGSs) in CA1 and CA2/3. Spontaneous interictal bursts (ISs) developed 2-4 min following SW (induction phase). SW-induced ADs and EGSs required activation of the NMDA receptor, while the expression of kindled ISs required activation of non-NMDA ionotropic glutamate receptors.

We used the same kindling techniques to study the role of the metabotropic receptor (mGluR) in SW-induced epileptiform events. We compared kindling in control medium (ACSF) with kindling during bath applications of the mGluR agonist t-ACPD (50-100 μM), the antagonist DL-AP3 (100 μM), and a Ca^{2+}-dependent K^+ current blocker (TEA, 50-100 μM).

T-ACPD slightly facilitated ADs and EGSs. However, the initial IS frequency, measured during the first 10 min of spontaneous bursting, was twice as high as in ACSF (0.08-0.12 Hz), stabilized at about 0.1 Hz, and persisted for hours following the last SW. TEA also facilitated SW-induced ADs and EGSs. The initial frequency of ISs was 20% higher than in ACSF and remained unchanged for 120-180 min. Addition of AP3 to ACSF or TEA prior to kindling did not alter ADs and EGSs. However, AP3 reduced the initial frequency of ISs by about 40% and the bursts disappeared in 60-70 min. By contrast, addition of AP3 following kindling did not alter the IS frequency.

These results suggest that mGluR 1) does not significantly contribute to the short term effects of SW (depolarizations, ADs, EGSs), 2) is not required for the maintenance of established bursts, but 3) activates long-lasting bursting mechanisms during the induction phase of the ISs.

DIFFERENTIAL SENSITIVITY OF HIPPOCAMPAL CA1 REGION IN THE SPRAGUE-DAWLEY AND WISTAR RATS TO EVOKED EPILEPTIFORM ACTIVITY IN HIGH POTASSIUM MEDIUM. T.E.Nelson, D.L. Quinn*, R.A. Anderson. Biology Department, Muskingum College, New Concord, OH 43762.

Brain slices from Sprague-Dawley rats were found to be more prone to electrically-induced epileptiform activity in the hippocampal CA1 region than in Wistar rats. The stimulating electrode was placed in the afferent pathway to the CA1 (including Schaffer collateral and commissural fibers) in hippocampal slices bathed in high potassium medium (8.0 mM) in a static pool system. Morphological classification of evoked extracellular field potentials was similar to the methods described by Gilbert et al (Brain Res 361:389-391, 1985). Evoked interictal discharges, patterns of repetitive discharge, in the CA1 and CA3 (mossy fibers were stimulated to activate the CA3) regions of the hippocampal slices were collected. Frequencies of spontaneous bursting were also noted in these regions. In the CA1 only, Sprague-Dawley rats showed a significantly higher number of spikes (Chi square, $p<.01$) following electrical stimulation of the afferent pathways. The CA3 evoked spike patterns were similar in both Sprague-Dawley and Wistar rats. There were no significant differences between the two rat strains with regard to spontaneous burst frequency.

517.19

A GABA-WITHDRAWAL SYNDROME IN HIPPOCAMPAL SLICES. García-Ugalde G. , Galarraga E.*, Bargas J. and Brailowsky S. Instituto de Fisiología Celular. UNAM. México 04510, D. F.

The interruption of intracortical infusion of GABA induces electrographic seizures in rats (Brain Res. 442:175, 1988). This phenomenon was named "GABA withdrawal syndrome" (GWS). We now describe this phenomenon *in vitro*. Field potentials were taken from the CA_1 subfield of the rat hippocampal slice to study the effects induced by the interruption of GABA superfusion. Also, GABAergic inhibition was examined using the paired-pulse paradigm. Saggital hippocampal slices were incubated in GABA (1-5 mM) for 1 or 2 hours. In the washing period, the "intensity vs response amplitude" relationship was analyzed. In some experiments the whole procedure was performed in the recording chamber, that is, the same slice was used before, during and after GABA superfusion (1-5 mM).
With the stimulation parameters used (0.2 Hz, 200 µsec), activation of the Schaffer afferents produced one population spike in control conditions (n=9). In contrast, multiple population spikes were observed in 70% of the slices previously incubated in GABA (5mM). Also, we recorded an increase (210 %) in the amplitude of the population spike with respect to its control value (n=3). This effect was even more evident after 1 hour of GABA washout. A marked reduction of the paired-pulse inhibition was recorded in the slices previously incubated in GABA (1 mM) for 2 hours (n=4).
The results indicated that the interruption of GABA superfusion induces hypersynchronic activity in hippocampal slices. This effect may be due to a dysfunction in GABAergic neurotransmission.

Evidence of Epileptiform Activity in Slices of Piriform Cortex in Response to Stimulation of the Putative Focal Seizure Generation Region, Area Tempestas (AT). J. Doherty* and D.A. Eagles. Department of Biology, Georgetown University, Washington, D.C. 20057.

Generalized, bilateral focal motor seizures can be evoked in rats in response to injection of picomolar amounts of the GABAa receptor antagonist, bicuculline, in a highly discrete region in the anterior extent of the deep endopiriform nucleus (Piredda and Gale, 1985). This region has been termed the area tempestas (AT). This work has prompted the hypothesis that the area tempestas may be a critical site that is somehow involved in the generation of limbic seizures. Using the patch slice technique, we have generated a model system in which the neuronal circuitry which underlies this AT mediated epileptogenicity can be examined. We have focally stimulated area tempestas with bicuculline methiodide and have evoked epileptiform-like activity in the pyramidal cells of the overlying piriform cortex. This model system should allow characterization of the processes which underlie the epileptogenicity of area AT.

Using both single cell whole-cell patch and field potential recordings, we have shown evidence for AT mediated activation of the overlying piriform cortex. Bicuculline methiodide, focally delivered over AT through a pressure driven micropipette potentiates the response of afferent input into the piriform cortex in single cell recordings and generates epileptiform-like responses in populations of layer II pyramidal cells. This epileptiform-like activity is characterized in single cell recordings by paroxysmal depolarizing shifts (PDSs) and long latency depolarizing potentials and in field potential recordings with rhythmic, oscillatory depolarizing waves.

DEGENERATIVE DISEASE: ALZHEIMER'S—NEUROPHARMACOLOGY AND NEUROTRANSMITTERS III

518.1

CORRELATIONS BETWEEN COGNITIVE IMPROVEMENTS AND PHARMACOKINETICS DURING TREATMENT WITH BMY-21502 IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE (DAT). A. Berardi*, S. Asthana, K.C. Raffaele, J.V. Haxby, R. Shrotriya, K. Dandekar, T.T. Soncrant. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892 and Bristol-Myers Squibb Pharm. Res. Inst., Wallingford, CT 06492-7660.

We have reported that treatment with BMY-21502 in DAT leads to significant improvements on visuomotor and attentional tasks, namely on a simple reaction time task ($p < .05$), on the Symbol Digit ($p < .05$), Digit Span ($p < .05$), Stroop Naming ($p < .01$), and Stroop Interference ($p < .005$) tests. The objective of the present study was to determine the relation of significant cognitive improvements after treatment with BMY-21502 in DAT patients to plasma concentrations of BMY-21502 and its two major active metabolites, BMY-42191 and BMY-40440. Nine DAT patients (mean MMS = 21.4 ± 4.03, range = 15-26; 5 probable and 4 possible DAT) underwent psychometrics at various doses of BMY-21502 (200-900 mg/day); all doses were combined for correlation analyses. One subject with kinetic values > 3SD over the group mean was excluded. Improvement on simple reaction time was significantly correlated with BMY-21502 ($r = -.39$, $p < .05$); improvements on the Symbol Digit and Stroop Color tests were significantly correlated with both BMY-21502 (Symbol Digit: $r = .43$, $p < .05$; Stroop Color: $r = .42$, $p < .05$), and BMY-40440 (Symbol Digit: $r = .42$, $p < .05$; Stroop Color: $r = .45$, $p < .05$). Because high positive correlations were found between levels of BMY-21502 and both major metabolites (all $p = .0001$), second order partial correlations were used to determine whether significant cognitive improvements could be accounted for by BMY-21502 or one of its metabolites separately, after the contribution of the other two had been partialled out. Significant positive partial correlations were found between improvement on the Symbol Digit test and the plasma concentrations of both BMY-21502 ($r = .38$, $p < .05$) and BMY-40440 ($r = .48$, $p < .01$). A significant negative partial correlation was found between improvement on the Symbol Digit test and the plasma concentration of BMY-42191 ($r = -.56$, $p < .005$). These results suggest that cognitive improvement during treatment with BMY-21502 in DAT patients correlates with kinetic measures and that it may result from the combined effect of BMY-21502 and its two major metabolites.

518.2

TOXICITY DURING CONTINUOUS INTRAVENOUS ADMINISTRATION OF PHYSOSTIGMINE IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE
S. Asthana*, K.C. Raffaele, A. Berardi, M.B. Schapiro, T.T. Soncrant. Unit on Pharmacology and Pharmacokinetics, Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda, MD.

Alzheimer's disease (AD) is accompanied by a depletion of presynaptic cholinergic markers in the neocortex that has been implicated in cognitive impairments. In an attempt to improve cognition in AD, physostigmine, a reversible cholinesterase inhibitor, was administered by continuous intravenous infusion to 9 patients with possible or probable Alzheimer's disease. Escalating doses (0.5-25 mg/day) were administered over a 2-week period. A dose was identified that optimized cognition and then was administered in a randomized, double-blind, placebo-controlled, cross-over design . Five subjects developed nausea, vomiting, headache, nightmares, sweating, generalized malaise or dizziness during the escalating or double-blind phase. Two of these patients could not tolerate the higher range of doses and the other three developed toxicity when their optimum dose was administered during the double-blind phase. These results suggest that steady-state administration of physostigmine is associated in some subjects with toxicity that may limit its use as a potential therapeutic agent.

518.3

COMPARISON OF MEMORY PERFORMANCE DURING PHYSOSTIGMINE AND ARECOLINE TREATMENT IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE. K.C. Raffaele,* A. Berardi, S. Asthana, M.B. Schapiro, J.V. Haxby, and T.T. Soncrant. Laboratory of Neurosciences, National Institute on Aging, Bethesda, MD 20892.

Since the cholinergic system is compromised in Alzheimer's disease, we have compared the responses of 6 patients with mild or moderate dementia of the Alzheimer type (DAT) during treatment with continuous intravenous infusions of physostigmine (a cholinesterase inhibitor) or arecoline (a direct cholinergic agonist). During separate inpatient stays, patients received infusions of escalating doses of arecoline or physostigmine. Response was tested during infusions of 2, 6, 12, 18, and 25 mg/day of physostigmine or at 1, 4, 16, 28, and 40 mg/day of arecoline. As measured by changes in verbal memory (Buschke selective reminding test), patients' responses to the two drugs were not always consistent. Two subjects improved their performance with at least one dose of arecoline but not with any dose of physostigmine; two subjects improved with at least one dose of physostigmine but not with any dose of arecoline; one subject improved with both drugs; one subject did not improve with either drug. Verbal memory improvement following arecoline tended to occur at low doses (4 or 16 mg/day), while improvement following physostigmine was more likely to occur at high doses (25 mg) which also were likely to cause adverse side effects. Differences in the therapeutic/toxic dose ratio may account for some differences in response to the two drugs.

518.4

DIHYDROPYRIDINE AND PHENYLALKYLAMINE BINDING TO Ca^{++} CHANNELS IN HUMAN NEUROLOGICAL DISORDERS AND AGE-IMPAIRED ANIMALS. A. Sen, T. V. Dam*, D. Cécyre, W. Rowe, P. Boksa and R. Quirion. Douglas Hospital Research Centre, and Dept. of Psychiatry, Faculty of Medicine, McGill University, Montréal, Québec, Canada H4H 1R3.

Alterations in Ca^{++} availability and metabolism have been suggested as possible mechanisms of cellular aging. Particularly pertinent to brain Ca^{++} availability is the recent demonstration that L-type Ca^{++} channel blockers, such as nimodipine, can facilitate learning and memory in animals. We have investigated the status of this class of Ca^{++} channels in human neurodegenerative disorders associated with memory deficits, including Alzheimer's (AD), Parkinson's (PD) and Huntington's (HD) diseases. Additionally, comparison was made with data obtained in age-impaired and unimpaired (Morris-maze tested) 24 month old rats. [^{3}H]PN200-110, (dihydropyridine) and [^{3}H]D-888 (phenylalkylamine) were used as radioligands to evaluate binding parameters to L-type Ca^{++} channels using either membrane binding homogenate (human) or quantitative receptor autoradiography (rat). Rather surprisingly, and despite neuronal cell losses, it appears that both [^{3}H]PN200-110 and [^{3}H]D-888 binding are well preserved in AD, PD and HD brain tissues, except for a significant decrement in B_{max} values in the basal ganglia of HD patients. Specific [^{3}H]PN200-110 binding parameters are also rather similar in various regions of the age-impaired and unimpaired rat brain. Taken together, these results suggest that the L-type Ca^{++} channel binding protein is well preserved in various neurodegenerative disorders. This also indicates that clinical trials with related drugs should not be hampered by losses of the relevant Ca^{++} channel receptor protein. Sponsored by Miles/Bayer.

SUT-8701, CCK8 ANALOG, HAS POTENTIAL AS AN ANTIDEMENTIA DRUG FOR ALZHEIMER'S DISEASE. K. Sugaya*, M. Takahashi, K. Kojima, T. Katoh[2], M. Ueki[2] and K. Kubota[3] Aging and Intractable Diseases Area, Res. Inst. for Biosciences, [2]Dept. of Applied Chem., Faculty of Science and [3]Dept. of Pharmacol., Faculty of Pharmaceutical Sciences, Science Univ. of Tokyo, 2669 Noda, Chiba 278, JAPAN.

Alzheimer's disease (AD) patients have severe degenerations of cholinergic systems in their cerebral corticies. We reported that cholecystokinin octapeptide (CCK8) prevented the decline of cerebral cholinergic markers in the basal forebrain (BF) lesion rat as a model animal of AD. In this study, we compared the action of CCK8 and SUT-8701 in the several experiments. Continuously s.c. administered SUT-8701 dose dependently preserved the K^+ stimulated ACh release and choline acetyltransferase (ChAT) activity in the rat cerebral cortex micro punches 2 weeks after BF lesion. These effects were more potent than those of CCK8 and they could be seen even when SUT-8701 was administerd with a few days interval after the lesion. Learning and memory experiments were performed with using Morris water maze. We used young and aged rats. Several days after the pre-training (3 trial/day for 5 days), half of the young rats were lesioned. After 2 weeks drug treatment, we examined the each group again in the same paradigm. The goal latency of aged or lesioned rats was longer than the young control rats. With the SUT-8701 treatment, the goal latency of aged or lesioned rats was decreased as the young control rat level. The affinity to the CCK receptor of SUT-8701 compared to that of CCK8 was 80 times less in the guinea-pig puncreus, but only half in the mouse cerebral cortex. SUT-8701 had about 100 times less effect on the suppression of liquid food intake, which supposed to be a maijer peripheral type side effect, than CCK8. These results suggest that SUT-8701 has more potent and selective preventing effect of the degenerations of cholinergic systems compared to CCK8 and potential as an antidementia drug for AD.

518.6

ENHANCED HYPOTHALAMIC-PITUITARY-ADRENAL AXIS RESPONSE TO PHYSOSTIGMINE IN AGING AND ALZHEIMER'S DISEASE. M.A. Raskind*, E.R. Peskind, D. Wingerson, M. Pascualy, D.J. Dobie, R.C. Veith, D.M. Dorsa, and C.W. Wilkinson. Dept. of Psychiatry and Behavioral Sciences, University of Washington School of Medicine, and Seattle and American Lake VA GRECC, Seattle, WA 98195.

Increased hypothalamic-pituitary-adrenocortical (HPA) axis responsivity has been documented in aged rodents and glucocorticoids have been implicated in age-associated neuronal degeneration. We asked if enhanced HPA axis responsivity occurs in normal human aging and in Alzheimer's disease (AD). The plasma ACTH, beta-endorphin (βE), and cortisol responses to the cholinesterase inhibitor physostigmine were determined in older normals (n=10, age 71 ± 2 yrs.), AD patients (n=11, age 72 ± 2 yrs.), and young normals (n=7, age 27 ± 2 yrs.). Expressed as area under the curve, older normals and AD patients had significantly higher ACTH, βE, and cortisol responses ($p<0.01$) than did young normals. Plasma physostigmine concentrations were similar among groups. Unexpectedly, at peak response, the ratio of βE to ACTH was significantly lower in the AD subjects (.39 ± .03) than in the older normal (1.24 ± .73) or young normal (1.09 ±.36) subjects. These results suggest that the age-associated enhanced HPA axis responsivity observed in rodents also occurs in humans and that processing, secretion, or metabolism of POMC products may be altered in AD. Supported by AGO5136, AGO8419, and the Dept. of Veterans Affairs.

CHRONIC INFUSION OF MUSCARINIC AGONISTS MAY BE NECESSARY TO ATTENUATE AF64A COGNITIVE IMPAIRMENTS IN RATS. H. Morris*, S. A. Maurer, F. E. Storch, and C. A. Boast. Wyeth-Ayerst Research, Princeton, NJ 08543-8000.

In rats, AF64A selectively and irreversibly reduces cholinergic markers resulting in cognitive deficits (Walsh et al., Br. Res., p. 91, 1984), which are considered a useful model of SDAT. Replication of reductions of AF64A-induced cognitive deficits in rats after acute administration of cholinomimetics (Nakahara et al., Soc. Neuro. Abs., p. 837, 1987) has not been reported. Acute administration of arecoline is ineffective on SDAT memory impairments (Raffaele et al., Psychopharm Bull., p. 315, 1991). Chronic administration of cholinomimetics in animals (Nakahara ibid) and humans (Raffaele ibid) was of greater benefit. We now report that acute administration of various cholinomimetics to AF64A-treated rats did not improve performance deficits on an 8-arm radial maze task. Five daily treatments with oxotremorine (0.1 mg/kg, i.p.) also did not improve maze performance; however, two-week infusion of arecoline (10 mg/kg/day) or oxotremorine (1 mg/kg/day) via osmotic mini-pumps produced significant transient improvements. Two-week infusion of AF102B or pilocarpine did not improve performance. Thus, in the AF64A model, as in SDAT, acute administration of cholinomimetics may be inadequate to reduce cognitive impairments. Chronic treatment with cholinomimetics in this model, as in SDAT, appears to be of greater benefit in attenuating cognitive deficits.

518.8

ANIMAL MODEL OF WANDERING IN ALZHEIMER'S DISEASE: DOPAMINERGIC-CHOLINERGIC INVOLVEMENT, ACTIVITY, AND LONG TERM CHANGES. J.P. Ryan*, M. Markham, A. Woods, & K. Metroka. Department of Psychology, State University of New York at Plattsburgh, Plattsburgh, New York 12901.

Ryan and colleagues (1990, 1991) have developed an animal model of wandering using bilateral injections of 15 ug/uL colchicine into the rat dentate gryus. The present set of experiments elaborated on the model by investigating neurotransmitter changes, activity levels and duration of lesion effects. Experiment I examined cholinergic and dopaminergic interactions through the use of several agonists and antagonists: Mecamylamine, Pimozide, Spiperone, SCH 23390, SKF 38393, and Quinpirole. The results indicate that the D1 and D2 receptor antagonists administered simultaneously ameliorate spatial learning and memory deficits. The beneficial effects are significantly enhanced by the additional administration of the nicotinic antagonist. The nicotinic antagonists administered alone worsened circumference swimming. Dopamine receptor agonists have no effect on observed behavior. Experiment II investigated the differential affect of administering 7, 15 and 25 ug/uL colchicine on activity and spatial learning. The results indicate that the highest dose of colchicine consistently induces circumference swimming and this appears to be associated with an increase in activity in the Wahmann wheel. Experiment III examined behavior 60 and 120 days postlesion. The results indicated that behavioral deficits are stable by 60 days. By 120 day nonlesioned animals exhibit age related behavioral deficits. The studies confirm the viability of the animal model and have implications for treatment.

518.9

Neuropathological and Behavioral Effects of Intraventricular Immunotoxin to the Nerve Growth Factor Receptor. R.G. Wiley*, T. Berbos, M. Ward and D.A. Lappi. Neurology Service, DVAMC, Nashville, TN 37212-2637.

Cholinergic neurons of the basal forebrain have been implicated in learning and memory. In Alzheimer's disease degeneration of these neurons may cause some of the behavioral manifestations of the disease. These are the only neurons in the forebrain that normally express the low affinity nerve growth factor receptor ($p75^{NGFr}$) abundantly. In the present study, we sought to determine the histopathological and behavioral consequences of intraventricular injection of immunotoxin directed at $p75^{NGFr}$. The immunotoxin consisted of the monoclonal antibody, 192 IgG, disulfide coupled to a ribosome inactivating protein, saporin. 192 IgG binds to rat $p75^{NGFr}$. Anesthetized, adult male Sprague-Dawley rats were stereotactically microinjected with either 4 μg of 192 IgG-saporin or 7 μg of OKT1-saporin into the lateral ventricle. After 4 weeks, they were tested on a step-down passive avoidance task. On the first and ninth trials, footshock was administered when the animal stepped down off a platform. 192 IgG-saporin rats were clumsy, more reactive to being handled but less reactive to the footshock than either OKT1-saporin, sham-operated or naive control rats. Also, the 192 IgG-saporin rats continued to step down more rapidly than the other three groups ($p<0.001$). These doses of 192 IgG-saporin produce major cell loss in the medial septum, diagonal band of Broca and nucleus basalis as shown by immunocytochemical staining for choline acetyltransferase and $p75^{NGFr}$. Purkinje cells of the cerebellum are also damaged. We conclude that immunotoxin-mediated destruction of the cholinergic forebrain caused behavioral changes consistent with impaired new memory formation. However, diminished pain sensitivity, decreased ability to inhibit the punished behavior, hyperactivity or damage to other neural systems are alternatives that require consideration.

518.10

CHRONIC CYTOCHROME OXIDASE INHIBITION BY SODIUM AZIDE INFUSION ALTERS HIPPOCAMPAL PROTEIN KINASE C ACTIVITY M. Catherine Bennett[1]*, Lea Waltrip[2], David M. Diamond[1,3], Gregory M. Rose[1,3] and Jeanne Wehner[2]. [1]Dept. of Pharmacology, UCHSC, [2]Inst. Behav. Genetics, UC Boulder and [3]Medical Research, VAMC, Denver, CO 80220

Several investigators report that PKC activity is decreased in the particulate fraction and increased in the cytosolic fraction of brain tissue from Alzheimer's disease (AD) patients (*Brain Res., 453*, 165-169, 1988; *J. Neur. Trans., 30*, 69-78). We investigated PKC activity in rats with chronic cytochrome oxidase inhibition induced by azide infusion. A dysfunction of the mitochondrial enzyme cytochrome oxidase is a concomitant of AD (*Neurol., 40*, 1302-1303). In previous work, we reported that azide treatment causes deficits of learning and hippocampal plasticity (*JGPN, 5*, 93-101, 1992). We now report that chronic azide treatment alters PKC activity.

Adult male S-D rats (350-425g) were implanted (SC) each with an Alzet osmotic minipump (2ML4) containing 0.9% saline or sodium azide (160 mg/ml, in saline). Two weeks later, rats were sacrificed and the hippocampi were assayed for PKC activity (*Brain Res., 523*, 181-187, 1990). PKC activity was decreased in the particulate fraction, which includes mitochondria, and increased in the cytosolic fraction. Thus, the alterations in PKC activity induced by azide treatment parallel those found in AD. These data support the hypothesis that a defect in mitochondrial metabolism may be pathogenic in AD.

518.11

EFFECTS OF AMIRIDIN ON ACETYLCHOLINE RECEPTOR-GATED ION CHANNELS. J. F. Roper*, W.-C. Chau and R. J. Bradley. Dept. of Psychiatry and Behav. Neurobiol., Univ. of Ala. at Birmingham, Birmingham AL 35294.

Amiridin (9-amino-2,3,5,6,7,8-hexahydro-1H-cyclopenta(b)quinoline monohydrate hydrochloride) (NIK-247) has been patented as a learning-stimulation and memory-improvement drug (U.S. Pat. No. 4,735,953, Lavretskaya *et al.*,1988). It was developed in the former USSR, where it is prescribed for symptomatic treatment of senile dementia of Alzheimer type. Its mechanism of action may include regulation of cell membrane lipid content (Burov *et al.*,1991) or modulation of neuronal K^+ channels (Y. Burov, pers. comm.). Amiridin is structurally similar to tacrine (9-amino-1,2,3,4-tetrahydroacridine), which is thought to improve cholinergic transmission by inhibiting brain acetylcholinesterase (AChE) (Summers *et al.*,1986, 89). AChE inhibitors can interact directly with acetylcholine receptors (AChR) (Wachtel, 1990). The objective of this study was to investigate the effects of amiridin on AChR single channel kinetics. Nicotinic AChR-gated ion channels in clonal BC_3H1 mouse tumor cells were studied using the cell-attached patch clamp technique. 200 nM acetylcholine (ACh) and .1 to 40 μM amiridin were applied at transmembrane potentials of -70 to -140 mV. Amiridin reversibly blocked open AChR-gated ion channels in a concentration-dependent manner. In the presence of drug, brief closed periods, or gaps, appeared in ACh-activated single channel currents, transforming them into a burst configuration (Neher and Steinbach, 1978). The mean channel open time decreased with increasing drug concentration. The mean burst duration and mean gap duration increased with increasing drug concentration. The amplitude of single-channel currents did not appear to be altered by the drug. Channel blocking may antagonize the cholinergic activating effects of AChE inhibition or of K^+ channel-mediated restoration of a more normal resting membrane potential in pathologically depolarized neurons. The physiological significance of this antagonism would depend on the relative efficacies of the drug at its various sites of action.

518.12

Effects of Linopirdine (DuP 996) on KCl and $CaCl_2$ Dose Response of Potassium Evoked Release of [^{3}H]Acetylcholine from Superfused Hippocampal Slices. W. J.Tinker, C. Maciag, S. W. Tam and R. Zaczek*. The DuPont Merck Pharmaceutical Co., Wilmington, Delaware.

Linopirdine, a drug which improves the performance of rodents in several learning paradigms, has been shown to enhance the K^+-stimulated release of [^{3}H]acetylcholine ([[^{3}H]ACh), [^{3}H]dopamine and [^{3}H]serotonin from rat brain slices without affecting their basal efflux. To futher elucidate the mechanism of action of linopridine we examined K^+ and Ca^{++} dose response curves for [^{3}H]ACh release from superfused rat hippocamal slices in the presence and absence of the drug. We found that linopirdine shifted the K^+ dose response curve of [^{3}H]ACh release to the left suggesting that the drug lowers the depolarization threshold for release. However, maximal release realized at saturating concentrations of K^+ (60 mM) was not increased in the presence of the drug. Linopirdine also affected the alterations in K^+ evoked [^{3}H]ACh release brought about by changes in Ca^{++} concentrations . There was substantial release of [^{3}H]ACh in the presence of very low (0.1 mM) extracellular calcium when linopirdine was present in the superfusion medium, indicating a shift in the dose response curve of this ion to the left . In addition, the maximal release of [^{3}H]ACh reached at saturating concnetrations of Ca^{++} was increased in the presence of the drug. The present study suggests that linopirdine exerts its effects by increasing the sensivity of neuronal membranes to K^+, Ca^{++} or to both ions. The complexity of linopirdine actions will require futher study in order to fully understand the mechanism through which the drug enhances neurotransmitter release as well as cognitive performance.

DEXAMETHASONE AND INTERLEUKIN-1 INDUCE THE EXPRESSION OF ALPHA-1-ANTICHYMOTRYPSIN IN HUMAN CORTICAL, BUT NOT CEREBELLAR OR BRAIN STEM ASTROCYTES: IMPLICATIONS FOR ALZHEIMER'S DISEASE. S. Das and H. Potter*. Department of Neurobiology, Harvard Medical School, Boston, MA.

The acute phase protein α_1-antichymotrypsin (ACT) is a primary component of the mature senile plaques characteristic of Alzheimer's disease (AD), where it is found bound to β/A4 protein, a proteolytic fragment of the amyloid precursor protein (APP). Immunocytochemistry and *in situ* hybridization indicates that astrocytes are a source of the increased amounts of ACT in the AD brain. We have previously shown that dexamethasone, and perhaps some other unknown cytokines, can induce the expression of ACT mRNA in cultured rat astrocytes. Since the acute phase mediators IL-1α and dexamethasone have been shown to induce ACT in HepG-2 cultures in vitro, we asked whether these factors could induce ACT expression in human astrocyte cultures from different brain regions. We found that dexamethasone and IL-1 could cooperatively induce ACT message 20-fold in subconfluent astrocytes from the frontal cortex. Confluent cortical astocytes expressed a high level of ACT message constitutively and no further induction could be detected after addition of dexamethasone and IL-1. However, astrocyte cultures from the brain stem and cerebellum had a negligible baseline expression of ACT message (even in the confluent stage), and the induction by dexamethasone and IL-1 in these cultures was minor compared to the induction seen in the cortical subconfluent cultures. These preliminary results indicate that the differential response of astrocytes from distinct brain regions may underlie the localization of pathology seen in AD: mature plaques are seen in cortical regions where the response of the astrocytes to acute phase mediators is more robust, whereas in the cerebellum, where diffuse plaques never progress to mature ones, the astrocytes are only weakly induced by the same factors. We postulate that the pathogenesis of AD involves an initial insult—the deposition of β/A4 and formation of diffuse plaques—followed by progression to mature plaques and neuronal cell death in those regions of the brain where the local glial environment is more likely to develop an inflammatory response.

518.14

'IN VIVO' PHARMACOLOGY OF PD 142676, A NOVEL CHOLINESTERASE INHIBITOR. M. J. Callahan*, W. J. Lipinski, C. J. Moore, M. R. Emmerling, V. E. Gregor and R. E. Davis. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

PD 142676, a chemically novel cholinesterase inhibitor, was assessed for effects on gastrointestinal motility, core body temperature, quantitative electroencephalography (EEG), brain acetylcholine (Ach) levels measured by microdialysis, performance in a water maze task, and short-term memory in a delayed match-to-sample test. Gastrointestinal motility in rats was decreased when PD 142676 was administered acutely or chronically. PD 142676 decreased core body temperature and produced a pattern of EEG activity characterized by a predominance of low voltage, desynchronized activity. These changes in EEG activity are consistent with an increase in electrophysiological arousal in rats and rhesus monkeys. In rats this electrophysiological arousal was maintained over 14 days of repeated administration. In anesthetized rats, PD 142676 increased Ach overflow in dialysates from frontal cortex to a level equivalent to that produced by other cholinesterase inhibitors. Water maze performance was improved on day 1 and day 2 when tested in the C57/B10j mouse. In aged rhesus monkeys, match-to-sample performance was improved on long delay trials (5-15 sec) to a level equivalent to performance on short delay trials (1 sec). These data suggest that PD 142676 is a potent, orally active cholinesterase inhibitor that improves cognitive performance in rodents and aged rhesus monkeys.

"IN VITRO" PHARMACOLOGY OF PD 142676, A NOVEL CHOLINESTERASE INHIBITOR. M.R. Emmerling, R.D. Schwarz, V.E. Gregor, C. Lee, C. Raby*, J.D. Scholten, T.A. Pugsley, and R.E. Davis. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48106.

Acetylcholinesterase (AChE) inhibitors are potential palliative therapies for the treatment of Alzheimer's disease (AD). The present report describes the *in vitro* properties of a "*second generation* " inhibitor, PD 142676. The new compound is equipotent with tacrine in inhibiting human AChE (IC50 of 40 nM) and similar in potency to other AChE inhibitors being considered for the treatment of AD. The new compound is a poor inhibitor of butyrylcholinesterase (IC50 of 20 μM compared to 5 nM for tacrine). PD 142676, like tacrine, is a reversible, mixed inhibitor of AChE (Kis=45 nM, Kii=81nM) that binds in the active site of the enzyme, as determined by protection from irreversible inhibitors. PD 142676 binds to all subtypes of muscarinic receptors with nanomolar affinity and may act as an antagonist based on its ability to reverse arecoline-induced decreases in the release of 3H-ACh from rat cortical slices. The compound also blocks high affinity choline uptake by rat hippocampal synaptosomes with an IC50 of 2.5 μM compared to 9.59 μM for tacrine. These results show that PD 142676 possesses *in vitro* pharmacological properties similar to tacrine despite its novel chemical structure. The accompanying abstract shows that PD 142676 also has *in vivo* central cholinomimetic activity.

518.16

INHIBITION OF ACETYLCHOLINESTERASE (AChE) BY CHLORO-SUBSTITUTED TACRINE ANALOGUES. C.J. Moore*, V.E. Gregor, C. Lee, and M.R. Emmerling. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48106.

Tacrine is an anticholinesterase that is a potential palliative treatment for Alzheimer's disease. The IC50 of tacrine against human AChE is 30 nM, making it one of the more potent compounds under investigation. The presence of side effects limits the dose of tacrine that can be given without affecting the patient's well being. Thus, it is desirable to obtain improved forms of tacrine with fewer side effects. In an effort to obtain such compounds, we evaluated a number of substituted 4-aminoquinoline and 9-aminoacridine compounds from the company files. We noted that compounds having chlorosubstituents on the benzene ring, in particular in the 6-position of tacrine, were more potent than other analogues. Based on these findings, we synthesized and characterized a group of benzene-ring chlorosubstituted tacrine derivatives. Of these, PD 142012 is the most potent (IC50 = 1.8 nM). It is equipotent with the benzylpiperidine derivative E2020 and 34 times more potent than physostigmine. PD 142012, like tacrine, is a mixed inhibitor of AChE that binds reversibly to the active site of the enzyme. These results indicate that it is possible to make an analogue that is more potent than tacrine itself and that still retains the mechanism of tacrine's inhibition of AChE.

518.17

PURIFICATION OF ACETYLCHOLINESTERASE USING A TACRINE-SEPHAROSE AFFINITY COLUMN. J.L. Grimm, T.W. Hepburn, R.T. Carroll*, and M.R. Emmerling. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48106.

Tacrine is currently under consideration for the palliative treatment of Alzheimer's disease. A method has been established to search for proteins with which tacrine may interact in an effort to understand fully its mechanism of action. A tacrine-sepharose affinity gel was synthesized in a single step by coupling it to epoxy activated sepharose through its primary amine. This affinity gel was tested for its ability to isolate acetylcholinesterase (AChE) from both bovine serum and Torpedo electric organ. AChE is purified to near homogeneity in a single step from these sources. In addition, several other proteins are purified from these sources and are currently under investigation. In summary, other methods used in the purification of AChE are often complicated by lengthy isolation protocols and/or by multiple organic synthetic steps needed to produce the affinity gels. The tacrine affinity gel provides a simple method for creating an affinity column for AChE purification and holds the potential to identify other proteins with which tacrine interacts.

518.18

TRYPSIN ACTIVITY IS NOT INTRINSIC TO ACETYLCHOLINESTERASE (AChE). R.T. Carroll and M.R. Emmerling*. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48106.

Our previous results (BBRC, 1991, 181, 858-862) indicate that the trypsin-like activity associated with purified eel AChE may result from contamination with bovine pancreatic trypsin. In the present study, we tested purified *Torpedo Californica* AChE solubilized by trypsin or collagenase for protease activity. Purified AChE solubilized by trypsinization has a trypsin-like activity that digests BAM-22P but not Substance P. However, velocity sedimentation centrifugation reveals that the trypsin activity, detected by digestion of S-2288, fails to cosediment with the AChE activity. We also observed that the peak of trypsin activity in Sigma (type V-S) electric eel AChE also failed to co-sediment with the peak of AChE activity before or after AChE purification. Purified, collagenase-solubilized Torpedo AChE digests neither Substance P, BAM-22P nor S-2288, even though collagenase itself digested BAM-22P. The sedimentation value and the molecular weight of the AChE solubilized by collagenase were the same as AChE solubilized by trypsinization. Finally, AChE purified from fetal bovine serum has neither trypsin-like nor Substance P degrading activity. These results suggest that the trypsin activity detected in purified AChE results from protease contamination and is not intrinsic to AChE.

ESTROGEN DEPRIVATION AND REPLACEMENT AFFECTS ACTIVE AVOIDANCE LEARNING IN FEMALE SPRAGUE-DAWLEY RATS. M. Singh*, F.S. Huang, E.M. Meyer and J.W. Simpkins Departments of Pharmacodynamics and Pharmacology, Univ. of Florida, 32610.

The combined endocrine and neurotransmitter deficit hypotheses for the etiology of AD, serve as the basis of our study. The central hypothesis is that ovarian steroids, specifically estradiol (E2), serve a neurotrophomodulatory role in the function of the basal forebrain cholinergic system. We studied the effects of ovarian steroid deprivation (by ovariectomy) and estrogen replacement on learning, using the 2-way active avoidance paradigm, at two separate time points. The short term ovariectomized (OVX) and steroid-replaced (E2) groups were ovariectomized for 3 weeks. The E2 group received estradiol replacement for 2 weeks prior to behavioral testing. These same animals were tested for learning 21 weeks later, with estrogen replacement maintained both during the testing period and between short and long term testing points. Our data show that the short term OVX group were learning-impaired and maintained their inability to learn 21 weeks later. At the long term testing stage, a significant effect of ovariectomy was observed on total avoidances (or correct responses) made over the testing period when compared to intact controls (34 ± 7.8 vs. 88 ± 24.8). Estrogen replacement prevented this deficit. Furthermore, the short term E2 group learned the task by reaching a desired criteria in 9.5 ± 2.1 days. Maintenance on estradiol replacement and subsequent retesting 21 weeks later showed that the animals reached criteria in a much shorter time (in 1.3 ± 0.3 days), suggesting a significant retention of the previously learned task. In contrast, OVX animals never attained the desired criteria. The method employed in restoring estrogen produced plasma levels that were in the physiological range (26 - 43 pg/ml, with one exception (137 pg/ml)). Our interpretation of the results is that physiological levels of estradiol play an important role in cognition and memory. This research may provide a novel animal model for the study of AD and supports a role for estrogens in memory and cognition (Supported by NIH AG 10485).

518.20

COMPARISON OF INTRACRANIAL INFUSIONS OF COLCHICINE AND IBOTENIC ACID AS MODELS OF NEURODEGENERATION IN THE BASAL FOREBRAIN. L. W. Shaughnessy*[1], S. Barone Jr.[2], W. R. Mundy[3] & H. A. Tilson[3]. [1]Curriculum in Neurobiology, UNC, Chapel Hill [2] METI & [3] NTD, U.S. EPA, RTP, NC 27711.

Intracranial infusion of various toxicants has been used to experimentally produce an animal model of neuro-degeneration. The goal of the present experiment was to make direct comparisons of ibotenic acid and colchicine in terms of damage to basal forebrain cholinergic neurons. Bilateral infusions of either colchicine (3.0μg/0.5μl/site), ibotenic acid (6.0μg/0.5μl/site) or vehicle (0.5μl/site) were made in the nucleus basalis magnocellularis (NBM) of male Long Evans rats (n=10/group). Four weeks post-lesion, behavioral assessments were made. The toxicants produced equivalent decreases in step-through latencies in passive avoidance behavior without causing any change in locomotor activity. Five weeks post-lesion, rats were sacrificed for neurochemistry or histochemistry. ChAT and AChE activity were measured in several brain regions of half of the rats. Within the frontal and parietal cortices, a significant decrease in activity (25%) was seen in the lesioned rats. The brains of the remaining rats in each group were sectioned and stained using ChAT immunohistochemistry and AChE histochemistry. Analysis of the number of ChAT-immunoreactive cells in the NBM showed a significant decrease (70%) following infusion of either toxicant. Qualitative examination of the AChE histo-chemical staining in the NBM and cortex showed a similar decrease following infusion of either toxicant. In summary, similar levels of cholinergic hypofunction were achieved for both toxicants and further comparisons of "extracholinergic" markers are planned.

519.1

POTENTIAL BIOACTIVATED NEUROTOXINS, N-METHYLATED ß-CARBOLINIUM IONS, ARE PRESENT IN HUMAN BRAIN. K. Matsubara*, M.A. Collins[2], S. Fukushima, J. Ikebuchi[1], A. Akane, S. Takahashi, E.J. Neafsey[2], and H. Shiono, Dept. of Legal Med., Shimane Med. Univ., Izumo 693, [1]Tottori Univ. Med. Sch., Yonago 683, Japan and [2]Biochem. & Anatomy Depts., Loyola Univ. Med. Center, Maywood, IL 60153.

Potential bioactivated neurotoxins, 2-N-methyl-ß-carbolines and 2, 9-N,N'-dimethyl-ß-carbolines, were analyzed in the parietal association cortex of human brain using GC/MS. The brains (n=9) were taken from fresh corpses with no history of abnormal neuropathology, during forensic autopsies. 2-Methyl-norharman existed in all samples (0.16 ± 0.05 pmol/g, mean ± SD) and 2,9-dimethyl-norharman was detected in 8 out of 9 samples (0.10 ± 0.04 pmol/g). 2-Methyl-harman and 2,9-dimethyl-harman were detectable in only two samples (0.03 ± 0.07 and 0.05 ± 0.10 pmol/g, respectively). Norharman and harman were also measured using HPLC/fluorescence detection. Norharman was present in all samples (0.59 ± 0.45 pmol/g), whereas harman was detected in 7 out of 9 samples (0.21 ± 0.07 pmol/g). Generally, the levels of N-methylated ß-carbolines in the brain were lower than those of their non-methylated forms. Recent studies show that N-methylated ß-carbolines resemble the synthetic parkinsonian toxicant, MPP+, with respect to structure and neurotoxic activity (Brain Res. 570, 154, 1992). Such "bioactivated" carbolinium ions could be endogenous causative factors in Parkinson's disease. Supported by the Japanese Ministry of Education, Science and Culture.

IDENTIFICATION OF C3 ADRENALINE NEURONS IN HUMAN MEDULLA; LOSS OF C1 AND C3 NEURONS IN THE MEDULLA OBLONGATA IN PARKINSON'S DISEASE

W.-P. Gai*, L.B. Geffen@, L. Denoroy# and W.W. Blessing. Dept. of Med., FlindersUniv.,Australia.@Dept.of Psychiat., Queensland Univ. Australia. #Dépt. de Méd. Expériment., Univ. Claude Bernard, Lyon, France.

Phenylethanolamine N-methyltransferase (PNMT) neurons were mapped in the medulla oblongata from 7 patients with idiopathic Parkinson's disease (PD) and 8 age-matched controls. Brains were removed and fixed by perfusing aldehyde through carotid and vertebral arteries. Serial transverse sections (50µm) through the brainstem were divided into 15 series. Neuropathological examination of the substantia nigra and locus coeruleus were performed to confirm PD, using conventional criteria. One series of sections was incubated with a rabbit antibody to bovine PNMT, diluted 1 in 10000, and processed using the avidin-biotin-peroxidase procedure. PNMT cells in each section were counted using the Magellan program and a Macintosh IIcx computer. The total number of cells was estimated by multiplying the number per section by 15. In the ventrolateral medulla, from the level of the obex to 11 mm rostral to the obex, there were 7631±844 C1 neurons in normals. This number was significantly reduced in PD (3604±1051, P<0.01, 53% loss) and many PNMT neurons contained Lewy bodies. We observed a midline C3 group of PNMT neurons in normal brains and this group was also severely affected (88% loss) in PD. Neither the C2 group nor the small PNMT neurons in the nucleus tractus solitarius was significantly reduced. Our results demonstrate a selective loss of C1 and C3 cells in PD, providing the first quantitative evidence for damage to brainstem sympathetic premotor neurons. These changes may underlie some of the autonomic symptoms of PD.

519.3

EXPRESSION OF CORTICAL NICOTINIC CHOLINOCEPTORS IN PARKINSON'S DEMENTIA COMPARED TO ALZHEIMER'S DISEASE H. Schröder*¶,♦, E. Giacobini¶, R.G. Struble+ A. Maelicke♦ Depts. Pharmacology¶ and Psychiatry+, Southern Illinois Univ. Sch. of Med., Springfield, IL 62794, ♦Dept. Physiological Chemistry and Pathobiochemistry, Univ. of Mainz, F.R.G.

In Alzheimer's disease (AD) as well as in Parkinson's dementia (PD) cerebrocortical nicotinic binding sites are markedly reduced. In AD frontal cortex the neuronal expression of nicotinic cholinoceptors (nAChR) is significantly decreased (Schröder et al., *Neurobiol. Aging*, 12:259, 1991) whereas no data are available on nAChR expression in PD cortices. Using the monoclonal nAChR-antibody WF 6 (Fels et al., *J. Biol. Chem.*, 261: 15746, 1986) autopsy samples of human frontal cortex were studied immunohistochemically in: (1) PD patients [n=6; 78±4yrs] and (2) age-matched controls [n=4; 75±9yrs]. Densities of WF6-immunoreactive [(1) 2677±697 neurons/mm^3 (mean±s.e.m) (2) 5605±1357] and of cresylviolet-stained neurons did not show statistically significant differences (p>0.05). Although ranges of nicotinic binding site reductions in homogenate binding studies are similar in AD and PD (Whitehouse et al., *Arch. Neurol.*, 45:722, 1988), in contrast to AD, neuronal nAChR expression appears to be only slightly reduced in PD. This speaks in favour of a qualitative alteration of nAChR binding sites in PD rather than for a shortage of nAChR protein supply. Supported by the Deutsche Forschungsgemeinschaft (Schr 283/8-1, 11-1), Southern Ill. Univ. Central Res. Committee award and R.J. Reynolds Tobacco Co..

STRIATAL DOPAMINE, TYROSINE HYDROXYLASE, AND DOPAMINE TRANSPORTER ARE MARKEDLY REDUCED IN A PATIENT WITH DOPA-RESPONSIVE DYSTONIA. X.H. Zhong*, A.H. Rajput, O. Hornykiewicz, and S.J. Kish. Clarke Institute of Psychiatry, Toronto, and Univ. of Saskatchewan, Saskatoon, Canada

Dopa-responsive dystonia (DRD) is a variant of childhood-onset idiopathic torsion dystonia which shows a therapeutic response to L-dopa. To date, little is known regarding the biochemical changes underlying the disease.

We have measured the striatal dopamine (DA) level, tyrosine hydroxylase (TH) activity and protein level, and DA uptake sites (by specific GBR 12935-binding) in the caudate and putamen of one DRD patient (aged 19, first described by Rajput et al., 2nd Intl. Cong. Movement Disorders, Munich, June 24-26, 1992) and four controls matched with respect to age and postmortem time. A marked DA loss (-97%) accompanied by reduction of TH activity (-88%) and TH protein concentration (-79%), and reduction of DA uptake sites (-68) in putamen was found in our patient, with somewhat less severe changes in caudate (-83%, -45%, -42% and -9% respectively). The extent of reduction was in the pre-parkinsonian range, being less severe than that in Parkinson's disease (PD). However, the subregional pattern of the reduction was similar to that in idiopathic PD. Our findings are consistent with the excellent clinical response of DRD patients to L-dopa therapy and suggest a cause-effect relationship between the striatal DA loss and the DRD syndrome.

519.5

SUPEROXIDE DISMUTASE EXPRESSION IN THE NIGRO-STRIATAL PATHWAY OF PATIENTS WITH PARKINSON'S DISEASE. A. Baccichet*, C. Thiffault, N. Aumont, D. Dea and J. Poirier. Douglas Hospital Research Centre, Department of Psychiatry and Centre for Studies in Aging, McGill University, Montreal, Quebec, Canada.

Several recent animal and human studies have provided evidences suggesting a role for the excessive formation of destructive hydrogen peroxide and/or the lack of antioxidant protection in the progressive loss of dopaminergic neurons of the substantia nigra of parkinsonian patients. The most interesting and consistent finding related to the antioxidant status in idiopathic parkinson's disease (IPD) has come recently from different laboratories showing a significant increase in the activity of the superoxide dismutase (SOD) in the striatum and substantia nigra. While SOD activity has been widely associated with superoxide detoxification, the end product of the reaction, namely the hydrogen peroxide, has received little attention. Accordingly, we have begun a systematic analysis of the two main forms of superoxide dismutase (cupper/zinc and manganese) in term of activity, protein levels and mRNA prevalence in the substantia nigra and striatum of control and IPD individuals. Results obtained so far indicate that the major portion of the cupper-zinc SOD mRNA and protein is restricted to neuromelanin-containing neurons of the substantia nigra. In the striatum, the distribution of the cupper/zinc SOD is more homogenous and appears to be mostly restricted to neuronal population. A significant increase in the activity of the manganese form of SOD (but not of the cupper/zinc form) was found in the striatum of parkinsonian patients. Supported by the Parkinson Foundation of Canada and by a Scholarship from the Medical Research Council of Canada.

519.6

THE EFFECT OF L-DEPRENYL AND MPTP ON SUPEROXIDE DISMUTASE ACTIVITY IN THE STRIATUM OF C57BL/6 MICE

C. Thiffault*, R. Quirion, N. Aumont, and J. Poirier.
Douglas Hospital Research Centre, Department of Pharmacology and Therapeutics, Department of Psychiatry and Centre for Studies in Aging, McGill University. Montreal, Quebec, Canada, H4H 1R3.

L-deprenyl, a potent monoamine oxidase B inhibitor is currently used in the treatment of Parkinson's disease (PD). L-deprenyl appears to delay the necessity of l-dopa therapy in the early stages of the disease although it does not halt the progression of PD. The beneficial effect of deprenyl in PD seems to be of short duration (6-12 months). Recently, it has been demonstrated that administration of l-deprenyl to rats in vivo increases the superoxide dismutase (SOD) activity in the striatum. SOD is a key enzyme involved in the detoxification of superoxide radicals and is principally expressed in neurons. Results obtained in our laboratory indicate that acute administration of l-deprenyl (10 mg/kg, every 2 days) and deprenyl/1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP; 3 X 20mg/kg, every 2 hrs) over 15 days period induces an increase in the activity of SOD in the striatum of C57BL/6 mice by more than 2 fold. It is not clear at this time whether the induction of SOD is beneficial to dopaminergic neurons. The MPTP regimen which destroyed 40-60% of tyrosine hydroxylase immunopositive neurons causes a marked decrease in the striatal SOD activity in C57BL/6 mice. These latest results contrast with the increase of the SOD activity as observed in the striatum of PD patients.

LOSS OF BASIC FIBROBLAST GROWTH FACTOR IN SUBSTANTIA NIGRA NEURONS IN PARKINSON DISEASE. P.L. McGeer*, I. Tooyama, T. Kawamata, D. Walker, T. Yamada, K. Hanai[1], H. Kimura[1], M. Iwane[2], K. Igarashi[2], and E. G. McGeer. Kinsmen Lab. of Neurol. Res. and the Neurodegenerative Disorders Centre, U. of British Columbia, Vancouver, Canada, V6T1Z3; [1]Institute of Mol. Neurobiology, Shiga U. of Med. Sci., Otsu, Shiga, Japan; and [2]Takeda Biology Res. Lab., Takeda Chem. Ind., Osaka, Japan

Basic fibroblast growth factor (bFGF) has been shown to occur in mesencephalic dopaminergic neurons and to have a neurotrophic effect on these neurons in vitro and in vivo. We examined the substantia nigra (SN) of 6 cases of Parkinson's disease (PD) and 8 controls immunohistochemically using a monoclonal antibody to bFGF. The mean number of melanin-positive neurons in sections of PD SN was 30.3% of the control mean, but the number of bFGF-immunopositive neurons was only 4.7% of the control mean. BFGF-immunoreactivity was observed in only 8.2% of PD, but in 93.7% of control melanin-positive neurons. These results suggest a profound depletion of bFGF in surviving dopaminergic neurons of the SN in PD. This depletion may be related to the disease process. CSF STUDIES IN UNMEDICATED PARKINSON DISEASE: DOPAMINE METABOLISM AND XANTHINE. P. LeWitt[1], M. Galloway[1], W. Matson[2], P. Milbury[2], M. McDermott[3], D. Oakes[3], I. Shoulson[4], and The Parkinson Study Group (DATATOP Study)[4]. [1]Clin. Cell. Neurosci. Progr., Detroit, MI 48207, [2]ESA, Inc., Bedford, MA 01730, [3]Div. Biostat. and [4]Dept. Neurology, Univ. Rochester Sch. Med., Rochester NY 14642.

Striatal HVA is a major component of CSF HVA. Despite this, its CSF concentration did not correlate with a variety of Parkinson Disease (PD) indices such as bradykinesia and disability scores. Our studies also found sub-stantial overlap of CSF HVA concentration between PD and control subjects. In PD, concentrations of CSF dopamine, DOPAC, dopamine-3-sulfate, 3-methoxytyramine, homovanillol, levodopa, and 3-O-methyldopa were 12.6% of HVA. None of these substances correlated to Parkinsonian severity or differentiated PD from controls.

CSF xanthine and HVA concentrations were highly correlated ($r = 0.82$, $p < 0.0001$). PD and control subjects differed when CSF xanthine concentrations were indexed against HVA: PD xanthine/HVA: 15.44 ± 6.50; controls: 10.91 ± 4.48 ($p < 0.002$). Though dopaminergic neurotransmission interacts with purines, the basis for the relationship is unknown.

519.9

EFFECT OF PHENYLALANINE CHALLENGE ON LEVODOPA TRANSPORT INTO CSF IN PARKINSONIAN PATIENTS. R.M.Beckner, W.R.Woodward, C.W.Olanow, J.G.Nutt*. Depts. of Neurology, Oregon Health Sci. Univ., Portland, OR and Univ. of S. Florida, Tampa, FL.

Levodopa crosses the blood-brain barrier via the large neutral amino acid (LNAA) transporter. LNAA's have been shown to reduce the clinical efficacy of levodopa in fluctuating parkinsonian patients, possibly by competitive inhibition of levodopa transport into brain. To determine whether CSF levodopa is an accurate index of brain levels, we administered phenylalanine challenges during two-hour, constant-rate levodopa infusions and monitored plasma and CSF drug levels in two parkinsonian patients with Omaya reservoir implants in their lateral ventricles. CSF levodopa levels were not reduced by phenylalanine when compared to levels achieved during infusions without an amino acid challenge. In contrast, the duration of the clinical response to levodopa was markedly reduced from over 100 minutes in the absence of a challenge to less than 20 minutes in the presence of phenylalanine. Phenylalanine levels rose 16-fold in plasma and 10-fold in CSF in one patient, while DOPAC and HVA levels in CSF were not appreciably altered. The plasma and CSF levodopa kinetics with and without phenylalanine were similar to those observed in monkeys, with levodopa entry into CSF lagging behind that of plasma. These results suggest that CSF levodopa is not in equilibrium with brain extracellular or neuronal concentrations and that CSF levodopa levels are not an accurate indicator of clinical response. Levodopa is probably transported into CSF at the choroid plexus, and this transport must differ from that at the capillary endothelium. Supported by NIH Grant NS21062.

519.10

EFFECT OF INHIBITION OF CATECHOL-O-METHYLTRANSFERASE IN LEVODOPA-TREATED PARKINSONIAN PATIENTS. J.G.Nutt, R.M.Beckner, W.R.Woodward, J.H.Carter, S.T.Gancher, J.P.Hammerstad*, A.Gordin. Dept. of Neurology, Oregon Health Sci. Univ., Portland, OR 97201, and Orion Pharmaceutica, Finland.

A major route for disposition of levodopa (L-DOPA) in the presence of carbidopa is O-methylation by catechol-O-methyltransferase (COMT). Inhibition of COMT could augment the clinical effects of L-DOPA by decreasing elimination and increasing bioavailability of L-DOPA, and by reducing accumulation of 3-O-methyldopa (3OMD). The acute effects of Entacapone (OR-611), a competitive inhibitor of systemic, and to a lesser extent, brain COMT, on the pharmacokinetics and pharmacodynamics of levodopa has been examined in 7 parkinsonian patients with fluctuating motor responses to levodopa.

OR-611 did not affect maximum concentrations of plasma L-DOPA achieved after oral or intravenous administration, nor did it affect the time to maximum concentrations after oral administration. The area under the time-concentration curve was increased by 58% ($p<0.04$, $n=6$) after oral administration and by 45% ($p<0.01$, $n=7$) after intravenous administration. The elimination constants were reduced by 44% and 34% respectively. The duration of clinical response to L-DOPA was increased by 50% ($p<0.06$, $n=6$) with oral doses and 47% ($p<0.02$, $n=7$) with intravenous infusions. These results indicate that OR-611 may help in the treatment of parkinsonism by prolonging the clinical response to L-DOPA. This effect is achieved without increasing maximum plasma drug concentrations, which may reduce adverse effects. Supported by NIH Grants NS21062 and RR00334, and Orion Pharmaceutica.

CHANGES IN DOPAMINERGIC RESPONSE TO ACUTE AND CHRONIC APOMORPHINE IN PARKINSONISM. S.T. Gancher, J.G. Nutt, W.R. Woodward, E.A. Zimmerman*, Department of Neurology, Oregon Health Sciences University, Portland, OR 97201.

The dopaminergic agonist, apomorphine (APO), is effective in the treatment of parkinsonism. We sought to determine whether tolerance develops to the antiparkinsonian effects of APO, and if so, what temporal factors influence its development. In an acute study, 7 patients with motor fluctuations received test doses of APO (50 μg/kg), preceding and following 6 and 22-31 hour APO infusions. The responses to both preinfusion test doses were similar. The duration of response to test APO doses that followed either infusion were reduced, by 35% following the short infusion and by 68% following the long infusion. In addition, the duration of effect after discontinuing the long infusion was briefer than after discontinuing the short infusion. In a chronic study, 7 patients received test APO doses (12.5-100 μg/kg) before and after a 3 month period of subcutaneous APO infusions administered during waking hours. No overall change in APO dose-response or in APO kinetics was observed over the 3 month period. However, 3 patients were able to lower their APO infusion rate, and these patients achieved higher plasma APO levels and AUCs following APO test doses at the end of the 3 month period. Our data suggest that tolerance develops rapidly to APO (hours), the magnitude of which is duration-dependent. This tolerance, however, disappears after an overnight period without medications, and cumulative tolerance to chronic diurnal APO infusion does not occur. Supported by NIH Grants NSO1539 and NS21062, and the American Parkinson's Disease Association.

CHARACTERIZATION OF THE ROTENONE BINDING SITE OF MITOCHONDRIAL COMPLEX I IN AN AUTORADIOGRAPHIC ASSAY. JT Greenamyre, DS Higgins and RV Eller, University of Rochester, Rochester, NY 14642.

Complex I (NADH dehydrogenase) is the proximal enzyme of the mitochondrial electron transport chain and is inhibited with high affinity by rotenone. Defective complex I activity has been implicated in the pathogenesis of Parkinson's disease, but little is known of the characteristics or distribution of this enzyme in brain. We have custom-synthesized and radiolabeled a rotenone analog, [^{3}H]dihydrorotenone (DHR), and have used it to develop a quantitative autoradiographic assay for complex I in brain. Using 100 μM rotenone to define nonspecific binding, DHR binding to rat brain is saturable with a K_D of about 10 nM; the B_{Max} varies more than 20-fold across brain regions. At DHR concentrations below 10 nM, virtually all binding is specific. Scatchard analysis suggests that DHR binds to a single class of sites. The specificity of DHR binding for complex I is indicated by *(i)* displacement of binding by rotenone and MPP^+, *(ii)* loss of binding after lipid extraction, and *(iii)* marked enhancement of binding by NADH. We conclude that DHR binding provides a quantitative method to assess the biochemical characteristics of the rotenone binding site of complex I with a high degree of anatomical resolution. *(Supported by the Hope Geoghegan Fund, the American Academy of Neurology, the United Parkinson Foundation, and USPHS Grant NS01487)*

QUANTIFICATION OF TYROSINE HYDROXYLASE IN THE DOPAMINERGIC MESENCEPHALIC NEURONS OF CONTROL SUBJECTS AND PATIENTS WITH PARKINSON'S DISEASE AND ALZHEIMER'S DISEASE. A. KASTNER, E.C. HIRSCH*, F. JAVOY-AGID and Y. AGID. INSERM U289, Hôp. de la Salpêtrière, 75013 PARIS.

Parkinson's disease (PD) is characterized by massive degeneration of the dopaminergic neurons in the substantia nigra (SN). Moreover, the functional capacity of the surviving nigral neurons is affected, as indicated by a reduction in tyrosine hydroxylase (TH) mRNA in these neurons. Thus, to test the ability of the remaining neurons to express TH protein, a semi-quantitative immunocytochemical method was developed and was used to determine the relative amount of TH per neuron on mesencephalic sections of 9 control subjects, 6 patients with PD and 3 with Alzheimer's disease (AD). A second set of experiments was performed on 5 other controls and 5 PD patients for which the neuronal content of TH mRNA has been analysed previously. Proportionality between the densitometric values obtained in the operative conditions and the tissular concentrations of TH was established using bovine adrenal medulla homogenates as standards. Variable amounts of TH were detected in the dopaminergic neurons from one subject to another, and between the different cell groups of the mesencephalon in the same subjects. Reduced content of TH protein was found in the neurons of the parkinsonian SN, but not in those of the central grey substance, which are spared by the disease. Similarly, in patients with AD, the amount of TH per cell was specifically reduced in the ventral tegmental area, a region in which catecholaminergic neurons degenerate during the disease. Besides, in the SN of PD patients, a correlation was observed between the reduction of the cellular content of TH protein and that of TH mRNA, suggesting that the efficiency of TH gene expression is altered in the remaining dopaminergic neurons.

GABAERGIC LOCAL CIRCUIT NEURONS DEGENERATE IN THE MOTOR CORTEX OF AMYOTROPHIC LATERAL SCLEROSIS PATIENTS. Kuninobu Nihei , Ann C. McKee and Neil W. Kowall*. Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

Recent evidence suggests that neuronal degeneration in amyotrophic lateral sclerosis (ALS) may be mediated by excessive glutamate receptor activation. In the cerebral cortex, GABAergic local circuit neurons resist NMDA-type glutamate receptor mediated excitotoxicity but are disproportionately sensitive to non-NMDA receptor agonists. In Huntington's disease, a distinctive subset of GABAergic local circuit neurons containing parvalbumin are relatively spared, consistent with NMDA receptor-mediated toxicity. We evaluated GABAergic parvalbumin positive cortical interneurons in the rolandic cortex of six patients with sporadic ALS and six age-matched controls to determine if the pattern of neuronal loss in ALS is consistent with glutamate receptor mediated neuronal injury. In ALS motor cortex, the density of parvalbumin immunoreactive neurons (per mm^2) was significantly decreased compared to control values (31.4±3 vs. 52.2±4, p=0.003, unpaired t-test). The depletion of parvalbumin immunoreactive neurons in ALS motor cortex contrasts with the pattern of sparing found in Huntington's disease and is consistent with non-NMDA glutamate receptor mediated neurotoxicity.

RODENT BRAIN METABOLISM OF CYCASIN AND DNA ALKYLATION BY METHYLAZOXYMETHANOL (MAM). J.F. Kabel, G.E. Kisby*, †S.C. Mako, †R.H. Glew, P.S. Spencer. Center for Research on Occupational and Environmental Toxicology, Oregon Health Sci. Univ., Portland, OR. 97201 and †Dept. of Biochem., Univ. of New Mexico, School of Medicine, Albuquerque, NM 87131.

Cycasin, the β-D-glucoside of methylazoxymethanol (MAM), is a toxic agent in cycad seed which is under study as a possible etiological factor for western Pacific amyotrophic lateral sclerosis (ALS). Presently, there are 3 mammalian β-glucosidases: a lysosomal (β-glucocerebroside, **I**), membrane (TX-100 soluble, **II**) and cytosolic (broad specificity, **III**). Studies with guinea pigs demonstrated that whole-brain tissue cytosolic β-glucosidase activity is 500 x higher than activity in peripheral organs (e.g. liver, kidney). Cycasin hydrolysis by guinea pig liver β-glucosidase (**II**) was 50% of total *p*-nitrophenylglucopyranoside activity. Sprague-Dawley (SD) rat brain tissue enzyme activity differed among the β-glucosidases (**II** >> **I** > **III**). Approximately 5% of a single intracarotid bolus injection of cycasin (6 mg/kg; 100 µl over 60 sec) was detected in the CNS of a SD rat, predominately in the form of MAM. MAM reacts *in vitro* with calf thymus DNA to produce 7-methylguanine and O^6-methylguanine. Taken together, these studies demonstrate that brain tissue is able to rapidly hydrolyze cycasin to MAM, an agent known to alkylate DNA. Cycasin, which is neuronotoxic at low (1 µM) concentrations (Kisby *et al.*, 1992), may be acting as a 'slow protoxin' by permanently altering post-mitotic neural tissue DNA. Further study is needed to characterize the role of cycasin in western Pacific ALS. [Supported by a grant from NS19611]

520.3

ASTROGLIOSIS IN GUAM AMYOTROPHIC LATERAL SCLEROSIS (ALS) D. Munoz-O'Regan, C. Bergeron, R.M. Garruto, D.P. Perl, S. Wright* and P.D. Kushner, ALS Research Foundation, California Pacific Medical Center, San Francisco, CA 94115

Guam amyotrophic lateral sclerosis (GALS) has three salient features which distinguish it from ALS, (1) high incidence rate, (2) dementia, and (3) particular histopathological features common to Alzheimer's disease and Parkinsonism-dementia complex (PDC). Nineteen cases (mid-frontal and temporal cortices), eight GALS, two GALS presenting with PDC (GALS/PDC), five Guam PDC (GPDC) and four neurologically normal Guam cases comprised of persons of Chamorro descent (because of the incidence of neurofibrillary tangles within the population even amongst non-ALS, non-PDC cases), were examined as cryosections stained with immunoperoxidase technique for glial fibrillary acidic protein (GFAP).

Astrogliosis in GALS reveals itself in similar fashion to ALS within the subcortical white matter. Results indicate the morphological parameters of an on-going, "reactive" astrogliotic process within the superficial subcortical white matter in GALS in which stained astrocytes have two distinct morphologies; these profiles are located in different areas. The astrocytes of the gray/white matter junction display very numerous, elongated processes; in contrast, regressive astrocytes are evident just deep to this junction. Gray matter astrocytes have smaller cell bodies, shorter processes, and staining is not prominent. Peculiar to GALS is the presence of gliosomes, bead-like structures found on many linear processes of astrocytes, descending from the glial limitans. GALS/PDC cases show more consistency in gliotic response and similarity to GALS cases; conversely, GPDC cases display either numerous intensely stained astrocytes (4 cases) or no gliosis (3 cases). GALS has clinical and pathological differences from ALS and yet the parallel of superficial subcortical white matter astrogliosis implicates a special region of involvement in the pathology of all forms of ALS.

520.4

GFAP AND BETA AMYLOID STAINING IN THE CORTICAL GRAY MATTER IN AMYOTROPHIC LATERAL SCLEROSIS (ALS) D. Nagy, T. Kato, D. T. Stephenson, P. D. Kushner* ALS Research Foundation, California Pacific Medical Center, San Francisco, CA 94115

We examined cryosections of the midfrontal, inferior parietal, cingulate, temporal, and occipital cortices, as well as the primary motor cortex from 15 cases of adult-onset amyotrophic lateral sclerosis (ALS) with immunocytochemistry using anti-glial fibrillary acidic protein (GFAP) and anti-beta amyloid protein.

By GFAP staining there was found an increased subpial gliosis, "patchy" astrocytosis in LII-III, occasionally a few patches in the LIV, and a "finger-like" astrocytosis in LV-VI. The patchy astrocytosis was characterized by multiple clusters of astrocytes, each containing 2-8 glial cells, and it occured in 9 out of 15 cases. The "finger-formation" of the gray/white matter interface seemed to be an extension of the previously described widespread subcortical astrogliosis (J Neuropath Exp Neurol 50:263-277, 1991) and was found in 11 out of 15 cases.

By beta amyloid immunostaining we observed primitive plaques in 5 out of 15 cases. There were no classic plaques. Total number of ALS cases with both astrocyte-patches and amyloid-plaques was 3 out of 15. Our study demonstrates a ubiquitous patchy astrocytosis in widespread cortical brain regions, suggesting a potential involvement of the whole brain in the pathomechanism of the ALS. We cannot account for these patches as classic or primitive plaques, although they may indicate imminent future beta amyloid production. (Supported by M.D.A.)

PROCESSING OF TAU PROTEIN IN PICK'S DISEASE. S. Murayama*, Y. Higashi+ and H. Mori. Department of Neuropathology, University of Tokyo, Tokyo, 113 and +Kawasaki Medical School, Kurashiki, 701-01, Japan

In Alzheimer's neurofibrillary tangles (ADNFT), tau protein is cleaved in the N-terminus and only its carboxyl third is left (Kondo et al, Neuron 1988;1:827). We adopted an immunocytochemical approach whether similar process is observed in Pick bodies (PB) that share immunocytochemical properties with ADNFT. Formalin-fixed, paraffin-embedded hippocampi that were abundant with PB from four cases of Pick's disease (PD) were employed for this study. Ultrastructurally, PB in these cases contained 15nm straight filaments with occasional twisted profiles. PB-type filaments were also observed in ballooned neurons (BN) and neuropil around PB. Immuno-electron microscopically, phosphorylated epitope of the carboxyl third of tau protein was localized on these filaments (Murayama et al, Ann Neurol 1991;27:394). Employed antibodies and recognized sequence of tau protein were as follows: Alz 50 (2-16); anti-human tau (45-61); tau 1 (191-204); P2 (299-385); tau 0 (354-369); and tau 6 (420-429). Antibodies against both N- and C-termini of tau protein visualized PB, BN and neuritic change around PB. However, the staining pattern with anti-N or anti-C-terminus was different in: 1) anti-C-terminus stained PB more intensely than anti-N-terminus; 2) C-terminus-positive neurites were thicker and more curled than N-terminus-positive neurites; and 3) C-terminus-positive area in BN was smaller in size and more crisp than N-terminus-positive area. The most intense staining was obtained by P2 that recognized a sequence that was tightly bound to the core of paired helical filaments (PHF). These data suggest: 1) first abnormal deposition of tau protein and then cleavage in N-terminus occur in PD as well as in Alzheimer's disease; and 2) the core of PB-type filament and PHF may share the same sequence of tau protein.

PHF POSITIVE NEURITES IN A SEVERE CASE OF PICK'S DISEASE. E.J. Cochran, R.P. Zimmerman*, E.J. Mufson. Department of Neurological Sciences and Pathology, Rush Alzheimer's Disease Center, Rush-Presbyterian St. Luke's Medical Center, Chicago, IL 60612.

Pick's disease (PD) may present with a clinical picture which is indistinguishable from Alzheimer's disease (AD), although the neuropathological characteristics are significantly different. We report a case of PD with classic pathology, as well as extensive paired helical filament (PHF) containing neurites, without the AD-like senile plaques or neurofibrillary tangles. Gross evaluation of the brain of this 69 year old woman with a 11 year history of progressive dementia revealed severe atrophy involving the frontal, temporal, parasagittal parietal and occipital lobes. Paraformaldehyde (4%) immersion fixed tissue was either paraffin-embedded or cut on a freezing microtome. Numerous argyrophilic Pick Bodies (PB), predominantly located in neocortical and limbic cortical layers 2,3, and 5, were immunoreactive to ALZ 50, and antibodies against PHF and ubiquitin. In addition, numerous ALZ-50 positive neurons were seen in the hippocampus. Double immunostaining with ALZ 50 and anti-PHF showed colocalization in many PB. Strikingly, PHF immunostaining revealed extensive neuritic degeneration in neocortex and hippocampal complex similar to that observed primarily in AD. Within the hippocampus, not only were numerous PHF positive PB seen in the dentate granule cell layer, but also extensive neuritic PHF staining was found within the hilar region of the dentate gyrus. An occasional neurofibrillary tangle-like structure similar to that seen in AD was observed in the outer layers of the inferior temporal cortex. No senile plaques were identified with any of these cytoskeletal markers or A4 antibodies. The neuritic abnormalities described in this Pick's case suggests that neuritic degeneration primarily associated with AD occurs in a subpopulation of Pick's Disease. AUTOIMMUNITY TO GLUTAMATE DECARBOXYLASES GAD65 AND GAD67. D.L. Kaufman*, M. A. Atkinson, G. Ting, P. Robinson, J.D. Tian, D. Newman, M.G. Erlander, N. Kim, T. Phan, N. K. Maclaren, A.J. Tobin and M. Clare-Salzler. University of California, Los Angeles and University of Florida, Gainesville.

Immune responses to the GABA synthetic enzyme glutamate decarboxylase (GAD) may play an important role in the development of insulin-dependent diabetes mellitus (IDDM), Stiff-man syndrome, and IDDM-associated neuropathy. Years before the clinical onset of IDDM, we can detect autoantibodies to one or both forms of GAD (GAD65 and GAD67), synthesized from their respective cDNAs in recombinant expression systems. Although autoantibodies to GAD generally decline after IDDM onset (with the loss of the antigen containing β-cells), IDDM patients who develop acute neuropathies have high levels of GAD antibodies. These autoantibodies may reflect the continued stimulation of the immune system by GAD released from damaged peripheral nerves.

To study the role of GAD in the pathogenesis of IDDM, we have examined the ontogeny of T-cell responses to known IDDM autoantigens in a murine model of IDDM, the NOD mouse. Of the autoantigens tested (GAD, HSP65, CPH and insulin), the T-cell response to GAD is the earliest, suggesting that GAD may be a primary autoantigen in IDDM. CHANGES IN BRAIN LEVELS OF CARNITINES IN THE DIABETIC RAT: EFFECT OF ACETYL-L-CARNITINE. F. Maccari, P. Chiodi, M.T. Ramacci, M. Calvani*, L. Angelucci[1]. Sigma-Tau, Institute for Research on Senescence and Dept. of Neurol. Res., Pomezia, Rome; [1]Institute of Pharmacology II, La Sapienza Univ. of Rome, Italy.

Many biochemical and functional alterations have been observed in a number of diabetic rat organs, such as, among others, the variations in the content of carnitines related to the metabolism of glucose alternative substrates. However, the brain as the only one organ that maintains a normal glucose metabolism in diabetes seems to contradict this relation: in fact, in diabetic rats brain carnitine levels are dramatically reduced (-32%). Recently, acetyl-L-carnitine (ALCAR) has shown to be beneficial in modifying biochemical, electrophysiological and motor alterations in the diabetic rat. Thence, an experiment was set on to verify whether ALCAR was able to compensate for the loss of brain carnitines. Male Sprague-Dawley rats, weighing 300 g, either normal or diabetic (diabetes was induced with 50mg/kg i.v. streptozotocine) were used. Diabetic rats were treated daily for 14 weeks with i.p. 10 ml/kg vehicle or 50mg/10ml/kg ALCAR. At the end of treatment, 24 h after the last administration and 48 h of fasting, carnitine levels were determined. In diabetic rats, statistically significant decreases in the brain levels of free carnitine (-25%), acetylcarnitine (-26%) and long-chain acylcarnitines (-25%) were found. Treatment with ALCAR totally impeded the loss of brain carnitines due to diabetes. Besides confirming the loss of brain carnitines in diabetes, these results indicate that such a loss occurs in all three main classes of carnitines. They also indicate that ALCAR corrects both qualitatively and quantitatively the reduction in brain carnitines and are in accordance with the beneficial effects exerted by ALCAR in diabetes-induced neuropathies.

DECREASED NA PUMP ALPHA-1 ISOFORM IN SCIATIC NERVE OF SPONTANEOUSLY DIABETIC BB/WOR RATS. S.C. Specht* and Rosa Figueroa-Nieves. Institute of Neurobiology and Department of Pharmacology, Univ. P. R. Sch. Med., San Juan, P.R. 00901.

Sciatic nerves of diabetic and control female BB/Wor rats were analyzed by immunoprecipitation to determine their content of the α1 and α2 isoforms of the catalytic subunit of Na,K-ATPase. Immunobeads were prepared with the McK1 and McB2 antibodies developed by Sweadner and associates (JBC **264**:8271, 1989) and employed according to the protocol of Fambrough and Bayne (JBC **258**: 3923, 1983) with modifications. The eluted antigens were separated by SDS-PAGE, silver-stained, scanned and quantified with the 2D-ANALST program. Only α1 was found in detectable quantities. The average amount in control nerves was 1.6 pmol per mg protein (microsomal pellet) vs 1.12 in nerves of age-matched rats after 16 weeks of insulin-dependent diabetes, corresponding to a 30% reduction. The generally higher levels of Na pump in axons as compared to glia, suggests a neuronal deficit. [Supported by JDF grant 190919 and NIGMS grant SS RR 08224].

SHORT AND LONG TERM EFFECTS OF STREPTOZOTOCIN-INDUCED DIABETES ON THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS OF THE RAT. S.T. Dheen, S.S.W. Tay* and W.C. Wong. Department of Anatomy, National University of Singapore, Singapore 0511.

Streptozotocin-induced diabetic and age-matched saline-injected control rats were perfused at 3 and 7 days, 1,3,6,9 and 12 months post-induction. At 3-7 days, degenerating axon terminals showed a vacuolated electron lucent cytoplasm and clustering of small spherical agranular vesicles. The affected dendrites were characterised by a vacuolated electron lucent cytoplasm containing swollen mitochondria and disoriented neurofilaments. At 1-6 months, degenerating dendrites were hypertrophied and contained numerous vacuoles, tubulovesicular elements and unidentifiable electron dense residua. These degenerating dendrites were postsynaptic to either normal or affected axon terminals. Some myelinated axons showed vacuolation and displacement of their axoplasm. Degenerating somata contained a condensed nucleus and numerous vacuoles of various sizes, probably formed from dilated rER. At 9-12 months, degenerating dendrites showed an electron dense cytoplasm containing swollen mitochondria and dilated rER. Degenerating axon terminals were characterised by an electron dense or lucent cytoplasm containing swollen mitochondria and small spherical agranular vesicles. These degenerating axon terminals were presynaptic to either normal or affected dendrites. A few myelinated axons also showed electron dense degeneration. However, the somata appeared to be normal. We suggest that various metabolic disorders in the experimentally-induced diabetic rats may have contributed to these structural changes which may affect the synthesis of neurohormones in the paraventricular nucleus of the rat.

520.11

TREATMENT OF EXPERIMENTAL DIABETIC NEUROPATHY WITH ACETYL-l-CARNITINE. A.M.Di Giulio*, B.Tenconi, A.Bertelli, P.Mantegazza, +S.De Biasi, M.T.Ramacci and A.Gorio. Dept. of Medical Pharmacol., +Dept. of Physiol. and Biochem., Univ. of Milano; *Inst. for Res. on Senescence, Pomezia, Italy.

We have previously shown that acetyl-l-carnitine (ALCAR) treatment prevents the decline of nerve conduction velocity as well as the establishment of autonomic neuropathy in diabetic rats. We now report that in the sciatic nerve of alloxan treated rats a 50% reduction of substance P (SP) accumulation occurs at a ligature point, indicating a marked impairment of both anterograde and retrograde peptide transport. In the same animals we have also examined at the electron microscope the basal lamina of blood vessels and axons of the sciatic nerve. In diabetic animals the basal lamina is thicker than normal and made up of multiple layers. In ALCAR treated diabetic rats the basal lamina is normal and the SP axonal transport is at control values as well. These data further support the potential value of ALCAR treatment in diabetic neuropathy.

THREE-DIMENSIONAL MODELS DEMONSTRATE THE CHANGES IN CRF- AND VP-IMMUNOSTAINED NEURONS IN 139H-INFECTED HAMSTERS. X. Ye, R.I. Carp, Y. Yu, R. Kozielski, P. Kozlowski. NYS Institute for Basic Research in Developmental Disabilities, 1050 Forest Hill Road, Staten Island, New York, 10314.

Scrapie is a neurodegenerative disease of sheep and goats. Previous studies have shown that the 139H-infected hamsters causes marked lesions in the cells of the islets of Langerhans, and pituitaries. In the current studies, we used three-dimensional modeling to demonstrate the changes of hypothalamic immunostained corticotropin-releasing factor(ir-CRF) and vasopressin(ir-VP) neurons in 139H-infected hamsters. By using the immunostained technique, we observed the following: 1) A significantly higher number of ir-CRF neurons in hypothalamus in 139H-infected hamsters than in control hamsters. 2) A significantly lower number of ir-VP neurons in the lateral hypothalamus in 139H-infected hamsters than in control hamsters. 3) No significant difference between the number of ir-VP neurons in the dorsalmedial hypothalamus(DMH) or the supraoptic nuclei in 139H-infected hamsters and the number in control hamsters. However, the population of ir-VP neurons in DMH shifted to the anterior hypothalamus in 139H-infected hamsters.

520.13

AMYLOID-LIKE FIBRILS FORMED IN VITRO FROM PRION PROTEIN SEGMENTS. F Tagliavini F Prelli, L Verga, G Giaccone, M Salmona, F Passerini, T Wisniewski, B Ghetti, O Bugiani, B Frangione* Ist Neurol Besta, Milan, NYU Med Ctr, New York, Ist Farmacol Negri, Milan, Indiana U Sch Med, Indianapolis

Brain amyloid deposition is a pathologic hallmark of Gerstmann-Sträussler-Scheinker disease (GSS). The major component of amyloid fibrils isolated from patients of the Indiana family with GSS is an 11 kDa fragment of PrP spanning residues 58 to ~150. This family carries a missense mutation of PRNP gene, causing Ser for Phe substitution at codon 198. We studied fibrillogenesis *in vitro* using synthetic peptides homologous to residues 57-64, 106-126, 127-147, 181-205 wild-type and 181-205 with mutant Ser 198. Peptide 57-64, corresponding to the repetitive octopeptide of the PrP molecule, did not produce fibrils. Peptides 106-126 and 127-147 readily formed 8 nm fibrils; the latter also aggregated into paired helical-like filaments. Peptide 181-205 showed only a moderate tendency to produce fibrils, which was not influenced by the 198 mutation. These findings suggest that fragment 106-147 plays a major role in fibrillogenesis, whereas octopeptide repeats in the 11 kDa amyloid protein do not. Finding low fibrillogenic properties of peptide 181-205 agrees with the absence of this PrP segment in amyloid fractions extracted from patients of the Indiana kindred with GSS. Thus it appears that PrP codon 198 mutation does not directly influence amyloid fibril formation.

NORMAL NUMBER OF LOCUS COERULEUS CELLS IN FRONTAL LOBE DEMENTIA. K.F. Manaye*, D.D. McIntire, W.K. Smith, D.M.A. Mann, K. Woodward and D.C. German. Dept. of Psychiatry and Academic Computing Service, UT Southwestern Med. Cntr., Dallas, TX 75235, and Dept. of Pathology, Univ. of Manchester, UK.

In several neurodegenerative diseases, which have an accompanying dementia, including Alzheimer's disease (AD), Down's syndrome (DS), Pick's disease and Parkinson's disease (PD), there is a significant loss of locus coeruleus (LC) noradrenergic neurons. In AD, DS and PD we have shown disease-specific patterns of LC cell loss across the rostral-caudal extent of the nucleus. The present study sought to determine whether there are changes in the distribution of LC cells across the rostral-caudal extent of the nucleus in cases of frontal lobe dementia (FLD). Six FLD cases (mean age - 65 years; disease duration 1-17 years), were compared with seven normal controls (mean age - 67 years). The normal LC spans a rostral-caudal distance of 11-14 mm, and contains 16,773 ± 1,133 cells (mean ± SEM) on one side of the brain. There was no significant difference in the length or number of LC cells in the FLD cases. These data indicate that FLD is like multi-infarct dementia in that there is no degeneration of the LC neurons. Supported by AG-08013.

EARLY PATHOLOGICAL LESIONS IN THE PERIAQUEDUCTAL GRAY IN CHRONIC RECURRENT EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS P.O.Gerrits[1]*, E.J.'s-Gravenmade[2], D.H.Croon[1], and G.Holstege[1]. Dept. Anatomy[1], and Neurology[2], University of Groningen, The Netherlands.

Multiple Sclerosis (MS) is characterized by demyelination and plaque formation in the brain and spinal cord. Early stages of MS are often associated with changes of emotional behaviour and visuomotor complaints. The area of the mesencephalic periaqueductal gray (PAG) seems to play an important role in mediating responses to emotional stimuli. The question arises whether histopathological changes in the PAG play a role in the development of MS. Chronic recurrent experimental allergic encephalomyelitis (Cr-EAE) represents a well established animal model for MS. To determine the occurrence and the development of histo-pathological changes in the PAG, Cr-EAE-rats were investigated.

Using a new GMA-resin embedding technique for high resolution light microscopy, a cytoarchitectonic map of the normal rat PAG was made, which precisely defines myelin division patterns. Histopathological changes within these myelinated areas were studied histochemically using Sudan Black B, Cresyl Fast Violet and PAS and precisely mapped. Results clearly show that in Cr-EAE in rats, early histopathological changes such as inflammation, demyelination and gliosis are abundantly present within these areas. Pathology occurs predominantly around the small and larger blood vessels in the ventro- and ventrolateral areas of the caudal, and to a lesser extent of the rostral PAG.

A preliminary studie in human MS material revealed complete demyelination of the PAG, medial longitudinal fasciculus and parts of the tegmentum adjacent to the PAG, indicating that the PAG may be associated with changes of emotional behaviour.

520.17

BEHAVIORAL DEFICITS OBSERVED IN THE VARIOUS STAGES OF THIOACETAMIDE INDUCED HEPATIC ENCEPHALOPATHY IN MALE RATS. N.S. Norton[1]*, J.R. McConnell[2], and J.F. Rodriguez-Sierra[1]. Depts. of Cell Biology and Anatomy[1] and Radiology[2], University of Nebraska Medical Center, Omaha, NE 68198.

Hepatic Encephalopathy (HE) can be described as a collection of neuropsychiatric disturbances that occur following significant liver dysfunction in patients. HE is clearly associated with progressive complications in motor function such as rigidity, ataxia, and in the terminal phases, coma, eventually leading to death. To further elucidate the various stages of acute HE in an animal model, we examined the effects of acute HE using a series of behavioral tests. Male Sprague-Dawley rats were habituated to test conditions for 5-7 days prior to any treatment. Rats were treated with thioacetamide (600 mg/kg) dissolved in normal saline or in a saline control series. The HE syndrome was classified into 4 stages based on behavioral alterations. To assess the progression of HE, the animals were monitored every hour until reaching the appropriate stage of HE upon which they were euthanized. Blood (1 ml) was removed for liver enzyme function tests. Our results demonstrate a decrease in behavioral responses of thioacetamide-treated rats as compared to saline treated controls. In stages I and II, the rats exhibit decreased behavioral abilities and a gradual increase in liver enzymes. Upon reaching stage III, the behavioral impairments and the elevated liver enzymes are greatly augmented. This difference continued until the animals reached coma during stage IV. Our results provide an objective behavioral model for the study of acute HE in animals. This model could provide a source for uncovering factors responsible for the behavioral deficits in HE (Supported in part by the Department of Radiology, UNMC).

MITOCHONDRIAL mRNAs ENCODING FOR CYTOCHROME OXIDASE SUBUNITS CHANGE IN RESPONSE TO DISRUPTION OF DOPAMINE. A. C. Grobin*, P. S. Dannies, and A. Y. Deutch. Departments of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06508, and VA Medical Center, West Haven, CT 06516.

Recent data have indicated that there is a decrease in mitochondrial complex I activity in tissue from Parkinson's Disease (PD) patients. This appears to result from a change in mitochondrial DNA in PD. We have therefore examined changes in mitochondrial specific cytochrome oxidase (CO) subunit gene expression.

Administration of 3-acetylpyridine (3-AP) to rats results in a slowly progressive loss of the dopamine (DA) innervation of the dorsolateral striatal (CP_{dl}); the DA innervations of the medial striatum (CP_m) and nucleus accumbens (NAS) are spared. 3-AP rapidly and completely lesions the climbing fiber innervation of the cerebellum. Both CO I and II mRNAs increased in the CP_{dl} of 3-AP-treated rats. The changes in CO mRNAs progressively increased up to eight days after 3-AP treatment. The mitochondrial specific 16S ribosomal RNA also increased in the CP_{dl}. No changes in CO I or II mRNAs in the CP_m or NAS were observed. In contrast, 3-AP treatment resulted in a decrease in CO gene expression in the cerebellar vermis. Haloperidol treatment for 21 days did not alter CO I and II. The present data suggest that DA neurons undergoing degeneration exhibit a compensatory increase in CO gene expression, consistent with the increased physiological activity of these neurons, while neurons that have degenerated (cerebellar climbing fibers) exhibit decreased mitochondrial gene expression. Supported by the National Parkinson Foundation Center, MH-45124, and TG GM-07324.

ISCHEMIA: DRUG TREATMENT I

521.1

Effects of the 21-Aminosteroid Tirilazad Mesylate (U-74006F) on the Eicosanoid Levels in the Gerbil Brain Following Ischemia and Reperfusion. P.K. Andrus*, E.D. Hall, B.M. Taylor,[1] L.M. Sam[1] and F.F. Sun[1]. CNS Dis. Res. and Hypersens. Dis. Res.[1], The Upjohn Co., Kalamazoo, MI 49001.

The present study measured the early production of eicosanoids in the gerbil brain during early reperfusion, following either a 3 hr unilateral carotid occlusion (UCO - model of focal ischemia) or a 10 min bilateral carotid occlusion (BCO - model of global ischemia). Arachidonic acid (AA) metabolites were examined to determine if pretreatment with U-74006F could influence brain synthesis of eicosanoids. In the severe UCO ischemia model, there was an early (5 min) post-reperfusion elevation in brain levels of $PGF_{2\alpha}$, TxB_2 and LTC_4. In contrast, PGE_2 and 6-keto-$PGF_{1\alpha}$ were decreased. Pretreatment with known neuroprotective doses of U-74006F did not affect the increase in $PGF_{2\alpha}$ or TxB_2, but blunted the rise in LTC_4. The decreases in PGE_2 and 6-keto-$PGF_{1\alpha}$ were also attenuated. In the less severe BCO model, there was a post-ischemic increase in all of the measured eicosanoids. U-74006F decreased the rise in TxB_2 and LTC_4, but did not affect the other eicosanoids. The results of these studies suggest U-74006F can selectively decrease TxB_2 levels in the less severe model and it selectively inhibits leukotriene synthesis in both models. The inhibition of leukotriene formation is believed to be a manifestation of the lipid antioxidant properties of U-74006F, as lipid peroxides are potent activators of 5-lipoxygenase.

521.2

LAZAROID PROTECTION AGAINST NEUROTOXICITY IN CEREBELLAR GRANULE CELL MODELS. G.J. Fici, J.S. Althaus, D.E. Decker, S.E. Buxser and P.F. VonVoigtlander.* The Upjohn Company, Kalamazoo, MI 49001.

Novel *in vitro* methods for testing lipid peroxidation inhibitors (lazaroids) as protectants of neurotoxic insults in cerebellar granule cells were developed. We showed that these cells are susceptible to injury induced by buthionine sulfoximine (BSO), an inhibitor of γ-glutamylcystein synthetase, and ferrous ammonium sulfate (FAS), an initiator of lipid peroxidation. This study revealed that 30-1000 μM BSO after 24 hrs produced significant reduction (~15-60% of control) in cell viability, which corresponded to a decrease in glutathione (GSH) levels of 80% or greater. A FAS toxicity model was established as well and it produced 95-98% cell death relative to control.

The 21-aminosteroids, U-74006 and U-74500E, that were delivered to cells in a microemulsion demonstrated differing effects. U-74006 (0.1-100 μM) was unable to protect in either toxicity model. U-74500E (10 μM) significantly protected across the entire toxic range of BSO. In addition, it was completely protective in the FAS toxicity model at 1 μM. At this concentration, amount of actual drug delivered to cells was ~0.5 mole%. Measurements of GSH in the BSO-treated cells showed no sparing or protection of GSH with drug and GSH declined 35%-90% across the BSO dose range of 1-1000 μM. The ability of U-74500E to protect in these models may be a function of greater antioxidant activity (measured by cyclic voltammetry). It is hoped that these cell models of neurotoxicity will further reveal mechanisms of lazaroid mediated neuronal protection.

521.3

NBQX DOES NOT ALTER THE ISCHEMIA-INDUCED REDUCTION OF KAINATE/AMPA RECEPTOR GENE EXPRESSION IN RATS

W.A. Pulsinelli*, D.E. Pellegrini-Giampietro[1], and R.S. Zukin[1], Cornell University Medical Center, New York, NY 10021, and [1]A. Einstein Coll. Med., Bronx, NY 10461

We reported (see Pellegrini et al, these proceedings) that transient forebrain ischemia in rats selectively reduces expression of the GluR2 subunit that controls Ca^{++} permeability in CA1 hippocampal neurons. This reduction of GluR2 message may be causally related to Ca^{++} mediated injury to CA1 neurons. NBQX, a selective AMPA receptor antagonist, protects CA1 neurons against ischemia. In this study we examined whether NBQX altered the ischemia-induced changes in kainate/AMPA receptor message. Sham-operated rats and rats subjected to 10 min of forebrain ischemia were treated immediately after reperfusion with either vehicle, NBQX (30 mg/kg i.p. x 3), or MK-801 (2.5 mg/kg i.p.). Twenty-four hrs later glutamate receptor gene expression in CA1 hippocampus was examined by in situ hybridization. The results confirmed that GluR2 message in CA1, but not in CA3 or dentate gyrus, was markedly reduced. Message for GluR1 and NMDAR1 were little affected. However, neither NBQX nor MK-801 altered the ischemia-induced changes in glutamate receptor expression. The neuroprotective response of NBQX may be due to blockade of kainate/AMPA receptors, rather than blockade of the mechanism causing the downregulation of GluR2 expression.

521.4

GUANIDINOETHANE SULFATE IS NEUROPROTECTIVE TOWARD DELAYED CA1 NEURONAL DEATH IN THE GERBIL MODEL OF FOREBRAIN ISCHEMIA. H. Igarashi, I. L. Kwee, and T. Nakada*. Neurochem Res Lab, VA Res Service, Martinez, CA 94553 and Dept of Neurology, Univ of Calif, Davis, CA 95616.

Guanidinoethane sulfate (GES) is a taurine analogue originally introduced as a competitive transport inhibitor of taurine. Recent studies indicated that GES in brain cytosol may function as additional alkali which in turn protects brain pH against intracellular lactic acidosis. Indeed, GES has been shown to enhance the survival rate of mice exposed to anoxia. In this study, we investigated the protective effects of GES on delayed CA1 neuronal death using a gerbil model of forebrain ischemia. Pretreatment with GES (675 mg/kg/day IP for 2 weeks) showed significant neuroprotection on CA1 neurons studied 7 days after 5 minutes bilateral carotid occlusion. The result indicates that intracellular acidosis likely plays a role in mediating the harmful effects of ischemia, perhaps in the early steps of a deleterious cascade leading to excitatory amino-acid excess.

521.5

VOLTAGE SENSITIVE AND RECEPTOR OPERATED CALCIUM CHANNEL DENSITIES IN FOCAL CEREBRAL ISCHEMIA. M.J.Hogan, S.Takizawa, A.Gjedde*, A.M.Hakim. Cerebrovascular Research Unit, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada H3A 2B4

We have measured the number of L-type voltage sensitive calcium channels (VSCC) and *N*-methyl-D-aspartate (NMDA) receptors in acutely ischemic rat brain using in-vitro binding of the L-type VSCC antagonist [^{3}H]nimodipine and the competitive NMDA receptor antagonist [^{3}H]CGS-19755. Focal cerebral ischemia was produced in male Sprague Dawley rats under halothane anesthesia. After four hours of ischemia the rats were decapitated, the brains removed, frozen and sectioned at 20 μm onto glass slides. These were then dipped in incubation baths containing either [^{3}H]nimodipine or [^{3}H]CGS-19755. Washed and dried sections were then exposed to tritium sensitive photographic film and regional ligand binding determined autoradiographically. The maximal number of binding sites (B_{MAX}) for nimodipine in ischemic and contralateral non-ischemic frontal cortex were 16.3 ± 1.6 and 24.4 ± 1.1 pmol/g respectively. For the CGS-19755 these values were 217 ± 5 and 228 ± 14 pmol/g. In-vitro [^{3}H]nimodipine binding is comparable to in-vivo binding in ischemic tissue only and does not demonstrate focal VSCC activation. This can only be demonstrated in-vivo. Similarly, focal increases in NMDA receptors are not observed in-vitro after 4 hours of ischemia. Since NMDA receptor sites are 10 fold more common than VSCC's they may be more important to calcium influx during ischemia.

521.6

LACK OF PROTECTION BY THE ALPHA-2 ADRENORECEPTOR AGONIST DEXMEDETOMIDINE IN A FOCAL MODEL OF CEREBRAL ISCHEMIA C. M. Maier, D. M. Kunis*, G.H. Sun, T. Z. Guo, M. Maze, and G. K. Steinberg. Depts. of Neurosurgery and Anesthesia, Stanford University Medical Center, Stanford, CA 94305.

Dexmedetomidine, a highly selective alpha-2 adrenoreceptor agonist, decreases central sympathetic activity and reduces the anesthetic requirement of halothane. Preliminary studies show that dexmedetomidine improves the outcome from ischemic injury and thus may have potential therapeutic value. We studied eleven rabbits that underwent two hour occlusion of the left internal carotid, anterior cerebral, and middle cerebral arteries followed by four hours of reperfusion. Ten minutes after occlusion the animals were treated with either normal saline (n=5) or dexmedetomidine (n=6) using a computer controlled infusion rate set to maintain a steady state plasma concentration. Halothane concentration was reduced by 50% for drug treated rabbits in order to maintain a comparable level of anesthesia. Somatosensory evoked potentials were used to confirm adequate ischemia and injury was assesed with histopathology. There were no significant differences in the area of ischemic neuronal damage between the groups in either cortex (control 45.8 ± 8.8 % vs drug 41.4 ± 11.5 %) or striatum (control 72.1 ± 18.4 % vs drug 57.5 ± 18.6 %), or in physiological parameters. Drug plasma levels obtained every 90 minutes showed a mean of 4.0 ± .15 ng/ml. Our study demonstrates that dexmedetomidine, in the dose given, does not have a neuroprotective effect in this model of focal cerebral ischemia.

521.7

DELAYED TREATMENT WITH A SELECTIVE NEURONAL CALCIUM CHANNEL ANTAGONIST PROTECTS AGAINST NEURONAL DEATH AFTER GLOBAL CEREBRAL ISCHEMIA. K. Valentino*, S. Bowersox, M.L. Smith, B.K. Siesjo, T. Singh, T. Gadbois, A. Justice, J. Ramachandran and B.B. Hoffman. NEUREX Corporation, Menlo Park, CA, USA and University of Lund, Lund, Sweden

We previously reported that the synthetic omega-conopeptide SNX-111, a blocker of calcium flux through voltage-sensitive neuronal calcium channels, protected hippocampal CA1 pyramidal cells from ischemic damage in the rat 4-vessel occlusion model of reversible forebrain ischemia when administered by IV bolus injection either immediately or 1 hour post-occlusion [1]. We now report that (1) 5mg/kg SNX-111 infused IV over 15 minutes at 6 hours post-occlusion significantly decreases neocortical damage ($p<0.008$) in rats subjected to either 10 or 15 minutes of forebrain ischemia produced by common carotid occlusion (2-VO) plus hypotension, and (2) neuroprotection is provided when a single IV bolus injection of 5mg/kg SNX-111 is administered up to 24 hours after the ischemic insult in 4-VO (CA1 damage relative to untreated controls: 6 hr = 19%, 12 hr = 26%, 24 hr = 19%). Animals receiving SNX-111 under the latter conditions show comparable levels of neuroprotection when sacrificed at 5 or 12 days post-treatment, indicating that SNX-111 prevents, and not simply delays, cell loss after the ischemic insult. These findings (1) provide the first demonstration of neuroprotection in the rat 4-VO model by delayed treatment with a neuronal calcium channel blocker and (2) confirm that SNX-111 is neuroprotective in two different rat models of global forebrain ischemia.

521.8

EFFECTS OF DISTINCT ω-CONOPEPTIDES ON THE RELEASE OF GLUTAMATE AND GABA IN-VIVO. R. Newcomb* and A. Palma. NEUREX Corporation, Menlo Park, CA 94025.

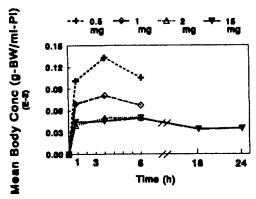
Two synthetic ω-conopeptides, SNX-111 and SNX-183, originally isolated from the cone snails, *C. magus* and *C. striatus*, respectively, have revealed a diversity of voltage sensitive calcium channels (Miljanich, et al., Soc. Neurosci. Abstr., 17, 1161, 1991). We used in-vivo dialysis to define the actions of these conopeptides on the release of amino acid transmitters in the dorsal hippocampus of the rat. The release evoked by potassium perfusion was suitable for quantitative comparison across experiments, and release of glu and GABA could be blocked with 10mM magnesium. SNX-183 and the structurally similar peptide SNX-230 (M-VIIC from *C. magus*; see abstracts by Hillyard, et al. and Gaur, et al.) blocked the release of glu and GABA at much lower concentrations than those required for SNX-111: The probe concentration of SNX-230 giving 50% of maximal inhibition was 0.2 uM, as compared to 200uM for SNX-111. Dose response curves for glu and GABA were similar in the hippocampus, while GABA release in the thalamus was comparatively resistant to the conopeptides. Chromatographic analysis showed that differences in potency were not due to differential degradation.

521.9

EARLY AND CONSTANT RELEASE OF NIMODIPINE FROM IMPLANTED PELLETS IN CONSCIOUS RATS FOR 24 HOURS A.D. Perez-Trepichio* and S.C. Jones Cerebrovascular Research Laboratory, Cleveland Clinic Foundation, Cleveland OH 44195

Experimental and clinical studies have shown potential benefit of nimodipine (NP) in cerebral ischemia. Therefore, it is important to evaluate methodologies for continuous administration of NP that may reduce the complexity of experimental therapy.

Sprague-Dawley rats were briefly (5 min) anesthetized during pellet implantation and assigned into two groups: Pellet (PE) and Placebo (PL). PE rats (n=14) received either 0.5, 1, 2 or 15 mg pellets and PL rats (n = 5) received placebo. Pellets were implanted in the nape of the neck. Plasma levels of NP were measured at 1, 3, 6, 18, and 24 h.



The plasma levels obtained with the 15 mg pellets are known to have a therapeutic effect on brain ischemia and can be rapidly achieved within one hour and maintained for 24 h. As shown in the figure, NP levels resulting from 2 and 15 mg pellets did not achieve the same mean body concentration (plasma concentration normalized to body weight and administered dose) as did lower doses.

These results indicate that pellets may be suitable for further evaluation of NP in experimental cerebral ischemia. Also it is important to emphasize that there was not a significant drop in mean arterial pressure ($p > 0.05$). (Supported by AHA-NEO F244, National AHA 91013150 and Miles, Inc.)

521.10

EFFECTS OF BERAPROST Na (BPS), A PROSTACYCLIN ANALOGUE, ON PROGRESSIVE CEREBRAL ATROPHY IN GERBILS.

S.UENO*, Y.MIYAUCHI, N.IZUMIMOTO, S.MATSUDA and T.ENDO. Basic Research Laboratories, Toray Industries Inc., Kamakura 248, Japan.

We have already reported that BPS, a new prostacyclin derivative, has protective effects against various ischemic models. In the present study, we investigated the effects of BPS on progressive cerebral atrophy in gerbils. The unilateral carotid artery of gerbil was repeatedly occluded. At the first ischemic procedure, we selected the symptomatic animals according to their stroke index score (K.Ohno, Brain Res, 297: 151, 1984), its score greater than 10. The selected animals were administered BPS at a dose of 1 to 100 μg/kg, p.o. twice a day for 4 weeks. We measured area ratio of ischemic hemisphere to opposite one with image processing system (Olympus, Japan). In the cerebral cortex of ischemic hemisphere, neuronal loss, acidophilic neurons and progressive atrophy were observed with increasing time of reperfusion after ischemic insult. On 4 weeks after the first ischemic episode, area ratio was approximately 90% in the control animals. BPS was found to inhibit the atrophy of ischemic hemisphere dose-dependently. Our results suggest that prostacyclin has a protective effect on the ischemia induced progressive atrophy.

522.1

INHIBITION OF NITRIC OXIDE SYNTHASE DOES NOT PROTECT AGAINST ISCHAEMIA-INDUCED HIPPOCAMPAL DAMAGE. E.M. McGowan* and P.C. Emson. MRC Group, Dept. of Neurobiology., A.F.R.C., I.A.P.G.R. Babraham, Cambridge, U.K.

Activation of NMDA receptors results in a Ca^{++} dependent release of Nitric Oxide (NO). Thus a role for NO has been postulated in NMDA receptor mediated excitotoxicity. Sustained NMDA receptor activation after an ischaemic insult and the subsequent accumulation of intracellular Ca^{++} is thought to be responsible for the selective pattern of delayed neuronal death seen in the CA1 region of the gerbil hippocampus. In an attempt to attenuate hippocampal ischaemic damage gerbils were treated twice daily with Nω-nitro-L-arginine (NArg, 5 or 10 mg/kg, i.p.), a competitive inhibitor of NO synthase (NOS). NArg was administered for 4 days prior to a single 5 min. period of global forebrain ischaemia, induced by occlusion of both common carotid arteries. NArg was also given throughout the survival period. Four days after reperfusion animals were sacrificed and the extent of neuronal damage determined histologically. No protection against ischaemic damage was observed at either dose used. To verify the degree of enzyme inhibition caused by NArg, NOS activity was assayed in crude enzyme extracts of forebrain by measuring the conversion of (^{3}H)-L-Arginine to (^{3}H)-citrulline. At the doses used NArg inhibited NOS activity by more than 85% when compared to saline treated animals. Contrary to *in vitro* studies on hippocampal slice preparations our data suggest that inhibition of NOS activity does not have a neuroprotective role in ischaemia.

522.2

BLOCKADE OF NITRIC OXIDE SYNTHETASE BY NITRO-ARGININE FAILED TO PROTECT THE BRAIN AGAINST TRANSIENT FOCAL ISCHEMIA IN TWO RAT MCA MODELS. D. Xue*, Z.G. Huang, S.Z. Gertler and A.M. Buchan. Neuroscience Unit, Ottawa Civic Hospital, Ottawa, Canada, K1Y 4E9.

NMDA and AMPA antagonists have been shown to reduce cortical injury following focal ischemia. A positive link between nitric oxide (NO) production and glutamate receptor activation on cyclic GMP has been proposed through in vitro culture studies. The possible effectiveness of NO synthetase inhibition by nitro-arginine in treating ischemic brain injury associated with an over-stimulation of glutamate receptors has been suggested. We studied this by using two focal stroke models. Transient focal ischemia was achieved by temporary clamping of the right middle cerebral artery for 2 hrs followed by 22 hrs of recovery in both Wistar (n=14) and SHR (n=21). Treatment with either saline (1 mL) or nitro-arginine (2 or 10 mg/kg) was given IV 40 minutes prior to ischemia. Regional cerebral blood flow was monitored at the time of drug infusion, the onset of ischemia, arterial reperfusion, and sacrifice (24 hrs). The volume of cortical infarction was then quantimented with frozen-sectioned brain slices. One-way analysis of variance was used.

Groups (n=7)		Cortical Infarction (mm^3 ± SE)	Reduction (%)
Wistar:	Saline	198±25	
	Drug (10 mg/kg)	199±35	
SHR:	Saline	164±9	
	Drug (2 mg/kg)	151±20	8 NS
	Drug (10 mg/kg)	145±11	12 NS

Pre-treatment with nitro-arginine, unlike glutamate antagonists, failed to protect the brain against transient focal ischemia.

522.3

FAILURE TO PROTECT HIPPOCAMPAL CA1 NEURONS BY NITRIC OXIDASE SYNTHETASE. H. Li*, S.Z. Gertler and A.M. Buchan. Neuroscience Unit, Ottawa Civic Hospital, Ottawa, Canada, K1Y 4E9.

Nitric oxide, a free radical, has recently been postulated to play an important role in a number of biological processes. Its proposed role as a mediator of ischemia-induced neuronal cytotoxicity was studied in a 4-vessel occlusion (4-VO) rat model which induces selective neuronal death. We have previously shown that this process is linked to AMPA, but not NMDA, glutamate receptors.

Adult male Wistar rats were subjected to 10 min. of severe transient forebrain ischemia using a modified 4-VO model. Nitro-arginine (10 mg/kg), a potent nitric oxide synthetase inhibitor, was infused intravenously 1 hour prior to ischemia. Saline-injected animals served as controls. Criteria rats were sacrificed 7 days later. The number of damaged hippocampal CA1 neurons were counted and calculated as a percentage. A Mann-Whitney U test was employed.

	% of Hippocampal CA1 Injury
Group (n)	Mean ± SD
Saline (8)	77.6 ± 10.4
N-arginine(8)	78.4 ± 11.3 NS

In this experiment, inhibition of nitric oxide synthetase failed to change the outcome of hippocampal CA1 neurons from ischemic injury.

522.4

BRAIN NITRIC OXIDE PRODUCTION IN FOCAL ISCHEMIA. Rosario R. Trifiletti *,Abraham Kader and Robert A. Solomon. Departments of Neurology and Neurosurgery,The Neurological Institute of New York, Columbia University College of Physicians and Surgeons.New York, NY 10032.

Nitric oxide (NO) has recently been implicated as a key mediator of N-methyl-D-aspartate (NMDA) receptor-associated glutamate neurotoxicity in primary neuronal cell culture (V.Dawson et al., PNAS 88: 6368-71(1991)) NMDA antagonists are potently neuroprotective in several adult rat models of focal ischemia . We sought to obtain evidence for NO production in cerebral ischemia by examining brain levels of "markers" of NO production (NO_2^- and cGMP) following varying periods of focal ischemia. Adult Wistar rats were subjected to bilateral common carotid ligation followed by cauterization of the (R) middle cerebral artery (MCA). Such treatment reliably produces a (R) cerebral infarct with no histologic damage to the contralateral hemisphere.

We find a marked transient increase (ipsi- vs. contralateral) in brain nitrite of 194 ± 112 % (n=6), 136 ± 102 % (n=7) and 91 ± 32 % (n=4) after 5,10 and 20 min of ischemia, respectively, but -6 ± 8% (n=4) after 60 min of ischemia. Less marked, but more sustained, increases in cGMP are observed as early as 5 min of ischemia. On a rat by rat basis, increases in NO_2^- are closely correlated those in cGMP (r^2 = 0.957 at 20min of ischemia) and can be abolished by pre-treatment with the NO synthase inhibitor N^G-nitro-L-arginine.

We propose that there is a transient activation of NO synthase in focal ischemia which leads to an increase in NO production, activation of guanylate cylcase, and cGMP production. These data support the hypothesis that NO may be a key mediator of focal ischemic damage *in vivo*.

522.5

POST-TREATMENT WITH THE KAPPA OPIOID PD117302 ATTENUATES ISCHEMIC DAMAGE TO CA1 NEURONS. F. Tortella*, L. Robles, M. DeCoster, J. Petras, C. Wingfield and +J. Moreton. Walter Reed Army Inst. Res., Washington, DC 20307 and +U. of Maryland, Sch. of Pharmacy, Baltimore, MD 21201.

Treatment of cultured rat neurons with novel kappa opioids derived from the arylacetamide series, including PD117302 (PD) and CI-977, provides significant protection from glutamate-induced cell injury. Systemic treatment with these compounds has also been reported to provide neuroprotection from focal ischemia and to improve functional outcome following global cerebral ischemia in rats. We now report neuroprotection with PD to rats subjected to 15 minutes of severe forebrain ischemia (4-vessel occlusion). PD (0.2, 1 and 5 mg/kg, i.v.) was given at reperfusion and at 2, 4, and 6 h post occlusion. Animals were perfusion fixed 72 h later. Ischemic injury was quantified in the CA1 of the hippocampus. In saline-treated rats ischemia caused extensive and consistent loss of pyramidal CA1 neurons. PD produced significant protection of CA1 neurons which was dose-dependent and nearly complete at the 5 mg/kg dose. Thus, kappa opioids from this series may be therapeutically effective in the treatment of ischemic neuronal injury.

522.6

EFFECT OF CI-977 ON ISCHEMIC BRAIN DAMAGE AND CEREBRAL BLOOD FLOW AFTER MIDDLE CEREBRAL ARTERY (MCA) OCCLUSION IN THE RAT. K.B. Mackay, K. Kusumoto, D.I. Graham & J. McCulloch*, Wellcome Neuroscience Group, University of Glasgow, G61 1QH, U.K.

Selective kappa agonists (such as CI-977) are putatively beneficial in some animal models of cerebral ischemia. The mechanistic basis for such neuroprotective effects is unknown. We have investigated the effect of CI-977 on ischemic brain damage and cerebral blood flow (CBF) in a rat model of focal cerebral ischemia. The left MCA was permanently occluded under halothane anesthesia in male Sprague-Dawley rats. Four hr later, animals were sacrificed by FAM fixation for histological examination. Local CBF was determined 30 min post-occlusion using [^{14}C]-iodoantipyrine autoradiography. Pre-administration of CI-977 (0.3mg/kg, s.c.) significantly reduced the volume of ischemic brain damage in cerebral hemisphere (by 27%) and cerebral cortex (by 32%) when compared to controls. CI-977 had no significant effect on either local CBF in any of the 24 regions examined or on the cumulative CBF volume in the hemispheres ipsilateral and contralateral to the occluded MCA when compared to controls. These results indicate that the neuroprotective effects of CI-977 following permanent MCA occlusion in the rat cannot be attributed to improved blood flow to ischemic tissue.

522.7

U50488 REDUCES THE SEVERITY OF TISSUE DAMAGE IN A RABBIT MODEL OF FOCAL CEREBRAL ISCHEMIA.

M.A. Widmayer, J.L. Browning and D.S. Baskin*. Dept. of Neurosurgery, Baylor College of Medicine and Research Service, Houston VAMC, Houston, TX 77030.

Following successful investigation of kappa agonist treatment of focal cerebral ischemia in the cat, we have broadened our research to include a more readily available and less costly species. Fourteen male, NZ white rabbits underwent occlusion of the right middle cerebral, anterior cerebral, and internal carotid arteries, beginning at their trifurcation and extending 1mm distally along each vessel. Six hours later half of the rabbits received an injection of 0.5 mg/kg U50488 (U50) and s.c. osmotic pump infusion of 0.4 mg/hr U50, and half received saline (SAL). Rabbits were sacrificed on the eighth post-op day and their brains stained with TTC. Abnormally stained tissue was categorized into infarct (colorless) and ischemic (lightly stained). Generally, abnormally stained tissue comprised 45% of brain tissue regardless of treatment. However, compared to saline treated rabbits, rabbits treated with the kappa agonist U50 had smaller infarcts (mean ± sem = 35.3 ± 5.9% vs 18.1 ± 4.5%; $p < 0.05$) and larger areas of ischemic tissue (12.4 ± 3.8% vs 24.1 ± 3.7%; $p < 0.05$) than SAL treated rabbits.

Corroborating research in cats, the kappa selective compound U50 reduced the severity of tissue damage secondary to focal cerebral ischemia in the rabbit. This research lends further support for clinical use of kappa agonists in the treatment of stroke. Additionally, the three vessel occlusion model shows promise in a species less costly and more available than cats.

522.8

EFFECT OF OPIATE ANTAGONISTS ON HYPOXIA AND CEREBRAL ISCHEMIA.

G. Delbarre*, B. Delbarre and F. Calinon, Faculté de Médecine, 37000, Tours, France.

In human and animal, the opiates have been shown to have significant physiologic effects on respiratory system and to be implicated in hypoxia and cerebral ischemia.

To determine the role of opiate in these mechanisms, we have studied opiate antagonists : on hypoxia (tail flick method on rat), and on cerebral ischemia by unilateral carotid ligation in gerbil (Delbarre, G., Stroke, 19:126, 1988).

Naloxone (0.5 mg.kg^{-1}, Per Os) significantly antagonizes the increase of reaction time of tail flick test induced by hypoxia ($p < 0.001$). Naltrexone (2.5 mg.kg^{-1}, Per Os) and WIN 44.441, a kappa antagonist (5 mg.kg^{-1}, Per Os), significantly improve the Stroke Index in gerbil cerebral ischemia ($p < 0.05$).

	Percentage of protection
Tail Flick after hypoxia	
(Naloxone 0.5 mg.kg^{-1})	54.93 ***
Ischemia	
- WIN 44.441 (5 mg.kg^{-1})	51.68 *
- Naltrexone (2.5 mg.kg^{-1})	39.71 *

Unpaired Student t test versus control -p < 0.05 * -p < 0.001 ***

These results demonstrate that opiate antagonists might play a therapeutic role in hypoxia and cerebral ischemia.

522.9

THE SELECTIVE GLYCINE ANTAGONIST 7-CHLORO-THIO-KYNURENIC ACID ATTENUATES FOCAL ISCHEMIA INJURY IN RATS.

J. Chen, S.H. Graham, F. Moroni and R.P. Simon*. Department of Neurology, U. California San Francisco, CA 94121.

Ischemic brain injury is mediated, at least in part, by the release of glutamate and other endogenous excitatory amino acid neurotransmitters activating a receptor gated Ca channel. Occupation of the strychnine insensitive glycine potentiation site is required for opening of the NMDA receptor gated Ca channel. Blockade of glycine binding might therefore be expected to attenuate ischemic neuronal injury in the brain.

We examined the effect of the selective glycine antagonist 7-chloro-thio-kynurenic acid (20mg/kg iv) given either 5min prior to or 15min or 60min after permanent middle cerebral artery occlusion in rats (n=6 in each drug treated group with n=9 saline controls). Stroke size was measured by computerized image analysis on serial 20μm cresyl violet stained sections 24 hrs following MCA occlusion. Infarct volume was smaller ($p<0.05$) in the 5 min pretreatment (114.2±13.5mm3) and 15 min posttreatment groups (148.1±21.2 mm3), but not in the 60 min posttreatment group (195.9±15.2 mm3) compared to controls (215.6±10.2 mm3). 5-chloro-thio-kynurenic acid (20mg/kg 5 min pretreatment), which does not bind to the glycine site but has similar antioxidant effects as 7-chloro-thio-kynurenic acid, was not effective (183.0±16.2 mm3).

These data support a potential role for glycine site antagonists in the treatment of stroke.

522.10

THIOKYNURENATES ANTAGONIZE L-GLUTAMATE-INDUCED NEURONAL DEATH BY ACTING AS GLYCINE ANTAGONISTS AND AS RADICAL SCAVENGERS.

M. Alesiani, M. Ciuffi, R. Pellicciari* and F. Moroni*. Department of Pharmacology, University of Florence, 50134 Florence, Department of Medicinal Chemistry, University of Perugia, 06100 Perugia, Italy.

Previous experiments have shown that a series of thioderivatives of kynurenic acid (KYNA) displaced ^{3}H-glycine (GLY) from its strychnine insensitive binding sites in cortical membranes (Eur. J. Pharmacol.199; 227, 1991) and antagonized L-GLU-induced neuronal death in cerebellar granule cells in culture (Eur. J. Pharmacol. in press). Among the thio-KYNA derivatives the most potent were 7-Cl-thioKYNA (its IC50 in displacing ^{3}H-GLY was 0.4 μM) and 5,7-diClthioKYNA (its IC50 was 0.6 μM). Other compounds of the series were less potent and none of the tested molecules (up to 100 μM) displaced ^{3}H-CPP, ^{3}H-KA or ^{3}H-AMPA from the respective recognition sites in cortical membranes, suggesting that these kynurenate derivatives were selective GLY antagonists. When 7-ClthioKYNA or 5,7-diClthioKYNA were compared with the corresponding oxoderivatives it was observed that they had similar potency in displacing ^{3}H-GLY from cortical membranes, but were 5 to 10 times more potent in preventing L-GLU-induced neuronal death. In an attempt to explain this particular effectiveness against L-GLU-toxicity we studied 7Cl-KYNA, 5,7diClKYNA and the corresponding oxoKYNA derivatives as lipid peroxidation inhibitors in a simple "in vitro" model (Neurochem. Res. 16, 43, 1991). 7-ClthioKYNA and 5,7-diClthioKYNA (1-50 uM)inhibited in a dose dependent manner the formation of thiobarbituric acid reacting substances in brain homogenates and their potency was significantly higher than that of vitamin E. Thus 7-ClthioKYNA and 5,7diClthioKYNA may reduce excitotoxic neuronal death by acting both as GLY antagonists and as radical "scavengers".

GM1 TREATMENT PROTECTS MEMBRANE INTEGRITY AND REDUCES LDH RELEASE FROM NEURONS EXPOSED TO GLUTAMATE; GM1 MEMBRANE SURFACE DISTRIBUTION IS MAINTAINED.

H. Laev*, S.E. Karpiak, J. Bonheur, and S.P. Mahadik[1], Div. Neuroscience NYSPI, & Dept. of Psychiatry, Columbia U. (Physicians & Surgeons). NY,NY.

As an *in vitro* model of ischemic damage, cortical neurons were challenged with glutamate (0.5 and 10mM), and the levels of released LDH [*lactate dehydrogenase*] were monitored at 1hr, 1,2, 4 and 7days. Analysis of neuronal plasma membrane disorganization (damage) was determined by the distribution of endogenous GM1 ganglioside using cholera toxin anti-toxin immunohistochemistry. The effects of GM1 ganglioside on LDH release due to membrane damage were also studied to further elucidate the mechanisms underlying this lipid's neuroprotective effects. Neuronal cortical cultures derived from 15 day fetuses and/or 0-1 day pups were subjected to glutamate (0.5 or 10mM) for 30min. Parallel cultures were treated with GM1: either a 90min pre- or I hr, 1, 2, 4,7 day post-treatment with 80uM of GM1. Exposure to 10mM glutamate caused over a 70-90% increase in LDH release at 1-48hrs. Pre-treatment with GM1 reduced the release to 50-60% while post treatment reduced the LDH release to 45%. The membrane structure changes observed by the GM1 immunohistochemistry paralleled the LDH release data. At 7 days only post-GM1 treated cultures showed significant structural integrity as evidenced by continuous staining of GM1 along the perykariya and processes. These data further support our hypothesis that GM1 treatment (both pre- and post) reduces plasma membrane damage.

GENETIC MODEL FOR ISCHEMIA - FEMALE STROKE PRONE SPONTANEOUSLY HYPERTENSIVE RATS [SHRSP]: GM1 TREATMENT EFFECTS

N. Hernandez*, C. Stier, J. MacDonall, R. Fernandez, and S.E. Karpiak. Div. Neuroscience NYSPI, & Dept. of Psychiatry, Columbia U. (Physicians and Surgeons), New York, NY 10032.

Stroke Prone Spontaneously Hypertensive Rats [SHRSP] may provide an advantageous model to study CNS ischemia. This genetic strain of rat develops pathological conditions that are associated with stroke. These include hypertension, arterial thickening, fibrinoid necrosis, infarcts, hemorrhage and hemorrhagic infarcts. The focus of this study was to detail mortality rates and occurrences of related stroke symptoms using the **female SHRSP**, and, to assess the neuroprotective effects of GM1 ganglioside treatment. Forty-six female SHRSP rats were randomly assigned to GM1 or saline treatment. Blood pressure was measured weekly beginning at 7wks. At 7.5 weeks all rats were fed Japanese Stroke-Prone Rodent Diet (Zeigler Bros., Gardner, PA) and their drinking water was replaced with 1% NaCl. Chronic GM1 treatment (10mg/kg i.m. daily: FIDIA Research Labs) began at 8.5wks. Spontaneous activity, sensorimotor and neurological performance on a tail-hang task was assessed 3 times weekly beginning at 10wks. At this time the rats were observed daily for *overt* stroke symptoms (>10% weight loss, limb paralysis, stereotypic movement). The female SHRSP rats exhibited 100% mortality within 92 days of being placed on the diet. GM1 reduced hyperactivity observed 1-2wks prior to the onset of overt stroke symptoms (supra) in control (saline) rats. There was no marked effect on functional measures, weight loss and increased blood pressure. GM1 did not alter the underlying pathologies, but did ameliorate the initial indications of CNS damage. The use and inclusion of female SHRSP in ischemia research may be helpful to better detail the pathology and treatment of stroke in patients with similar underlying pathologies.

GANGLIOSIDE TREATMENT FAILS TO ATTENUATE COGNITIVE DEFICIT FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA. R.L. Port*, P.W. Parsons, J.L. Briggs, R.N. Gandee and K.S. Seybold. Department of Psychology and Gerontology Program, Slippery Rock University, Slippery Rock, PA 16057 and Grove City College, Grove City, PA 16127.

Systemic administration of gangliosides has been shown to have significant beneficial effects on the central nervous system following various forms of insult. In the present study, adult male rats underwent bilateral carotid occlusion for ten minutes while anesthetized with sodium pentobarbital. Animals were treated at 10 min after occlusion and again at 24 hrs post-surgery with either GM_1 gangliosides (20 mg/kg i.p.) or vehicle-alone (control). A third group of nonoperated controls was included in the behavioral analyses. Animals were permitted two weeks to recover and trained daily in an eight-arm radial maze for four weeks. Analysis of behavioral data revealed that ganglioside- and vehicle-treated occluded animals made significantly more reference errors over the last week of training than did unoperated control animals. Differences in working memory errors were not statistically significant.

522.14

DELAY OF ANOXIC DEPOLARIZATION BY CREATINE, SPHINGOSINE DERIVATIVES, OR MANNITOL. M. Balestrino*[1], I. Cogliolo[1], G. Lunardi[1], A. Leon[2], S. Mazzari[2]. [1]Dept. of Neurology, University of Genoa, Italy, and [2]Fidia Research Labs, Abano Terme, Italy.

Delay of anoxic depolarization (AD) protects neurons from subsequent death (Stroke 21-SIII, 179-183, 1990). In the region of CA1 of rat hippocampal slices the following AD latencies were found (seconds, means±SD): control, 51±9 (N=9); creatine (25mM), 152±40 (N=4, $p<0.01$); Liga4 or PKS3 (sphingosine derivatives from Fidia; 5uM), 67±15 (N=7) and 85±27 (N=5), respectively ($p<0.03$ and $p<0.01$). Additional experiments with a "cross-over" design using mannitol (100mM) increased AD latency (25±9%), compared to paired controls (N=3, $p<0.05$). The effect of creatine (which delays ATP depletion during hypoxia: J. Physiol. 325: 51-65, 1982) supports the hypothesis (Soc. Neurosci. Abstr. 16: 277, 1990) that block of (Na^+, K^+)ATPase is the determining factor in AD. The efficacy of Liga4, PKS3 and mannitol suggests a role for both protein kinase C translocation and cell swelling in the delay of AD, and, possibly, in neuronal protection.

522.15

MK801 FAILED TO REDUCE INFARCT SIZE IN THROMBOTIC MIDDLE CEREBRAL ARTERY OCCLUSION IN RATS. H.Yao, M.D.Ginsberg*, B.D.Watson, R.Prado, W.D.Dietrich, S.Kraydieh and R.Busto. Cerebral Vascular Disease Research Center, University of Miami School of Medicine, Miami, FL 33101.

In animal models of focal cerebral ischemia, almost all studies have demonstrated significant reductions of infarct volume by the noncompetitive NMDA antagonist MK801.However, this drug failed to attenuate focal infarct in our present study.Male Sprague-Dawley rats were randomly assigned to receive either MK801 (1mg/kg) or saline ip 30 min before distal middle cerebral artery occlusion (dMCA-O).Irradiation with argon laser-activated 562nm dye laser after rose bengal (20mg/kg) iv was used to cause thrombotic dMCA-O. The ipsilateral common carotid artery was permanently occluded and contralateral carotid artery for one hour.In exp. 1, head temperature was controlled at 36°C.Three days after dMCA-O, brains were perfused and stained with H-E.Cortical infarct volume was 89±29 (mean±SD) mm3 in treated group, which was not different from 84±40 in control group.In exp. 2, head temperature was monitored but not controlled.Mean head temperature before ischemia was 34.4°C and decreased by 1-2°C after dMCA-O while rectal temperature was maintained at 37°C.Head temperature was not different between treated and untreated groups, thus excluding the confounding factor of temperature change.Further results of exp.2 will be presented.It is suggested from results of exp.1 that MK801 may be ineffective in head temperature controlled, thrombotic focal ischemia.

522.16

MK-801 PROTECTS IN A MODEL OF REPEATED EPISODES OF BRIEF NORMOTHERMIC FOREBRAIN ISCHEMIA IN RATS. B. Lin, W.D. Dietrich, S. Kraydieh, R. Busto, M.Y.-T. Globus and M.D. Ginsberg. Cerebral Vascular Disease Research Center, Dept. Neurology, Univ. of Miami School of Medicine, Miami, Florida, 33101.

We determined whether the non-competitive NMDA receptor antagonist, MK-801 (2mg/kg), would protect the brain if treatment was initiated after the first of three ischemic insults. Anesthetized rats were subjected to three 5-min periods of global forebrain ischemia by bilateral carotid occlusion plus hypotension (50 mmHg), separated by 1-hr periods. Ischemic brain temperature was maintained at 37°C. MK-801 (n=5) or water (n=6) was injected i.p. 45 min following the end of the first ischemic insult. Rats were perfusion-fixed at 7 days and regional ischemic cell change (ICC) assessed using a 3-point scale. Severe ICC was documented throughout the CA1 hippocampus, dorsolateral striatum, cerebral cortex and ventrolateral thalamus of nontreated rats. In treated rats, significant protection was documented in all brain regions ($p<0.01$, Kruskal-Wallis 1-way analysis by ranks). For example, in the ventrolateral thalamus, MK-801 treatment dramatically reduced damage from 2.6 ± 0.4 (mean ± SD) to 0.10 ± 0.1. These findings indicate that excitotoxic mechanisms are involved in ischemic damage produced by repeated ischemic insults and that significant protection can be demonstrated with MK-801 even when treatment is initiated after the first insult.

522.17

CGS-19755 IS NEUROPROTECTIVE DURING REPETITIVE ISCHEMIA. THIS EFFECT IS SIGNIFICANTLY ENHANCED WHEN COMBINED WITH HYPOTHERMIA. A. Shuaib*, S. Ijaz, W. Howlett, R. Mazagri. Dept. of Medicine, Div. of Neurology, Royal University Hospital, Saskatoon, Sask. S7N 0X0

In small animals the damaging effects of repetitive ischemia are cumulative and exceed that of a single similar duration insult. The more severe damage may be the result of prolonged release of glutamate. We looked at the protective effects of CGS-19755 (NMDA receptor blocker) or CGS-19755 in combination with mild hypothermia in a gerbil model of repetitive ischemia. We used 3 minutes of forebrain ischemia and repeated it 3 times at one hour intervals. Damage scores were assessed 2 days and 7 days after the insult. At 2 days, CGS-19755 treated animals showed significant protection in the cerebral cortex and hippocampus (CA1 and CA4), medial geniculate and the thalamus. At 7 days, milder protection was seen in the CA1 region of the hippocampus and cerebral cortex. The protective effects of CGS-19755 were better when the medication was started after the first ischemic insult as compared to animals where the medication was started prior to the initial insult. When CGS-19755 was combined with mild hypothermia, the effects of repetitive ischemia were completely abolished in all but one gerbil.

The use of NMDA receptor blockers may protect the brain in repetitive ischemia and this effect is significantly enhanced when combined with mild hypothermia.

522.18

THE NEUROBEHAVIORAL AND MORPHOLOGICAL PROTECTIVE EFFECTS OF CGS-19755 (AN NMDA RECEPTOR BLOCKER) IN AN ANIMAL MODEL OF ISCHEMIA. T.B. Wishart*, S. Ijaz, A. Shuaib, R. Mazagri, J. Kalra, W. Howlett. Depts. of Psychology, Medicine (Neurology) and Pathology, University of Saskatchewan, Saskatoon, Sask. Canada S7N 0W0.

CGS-19755 alone or in combination with mild hypothermia results in significant neuronal protection in an animal model of repetitive cerebral ischemia. This study was designed to examine sparing of behavioral function.

Groups consisted of sham-operated gerbils, gerbils with repetitive ischemia of 2 minutes with a reperfusion period of one hour, gerbils with ischemia + CGS, and gerbils with ischemia + CGS + hypothermia. Neural damage was assessed by examination of silver-stained sections.

Animals received 5 trials/day for 7 days in a Morris water maze. Gerbils subjected to repetitive ischemia had widespread neural damage and were significantly slower to learn the required response than were animals in all other groups. CGS or CGS + hypothermia had neuroprotective effects in thalamus, striatum, and substantia nigra. There were no behavioral differences between these groups and normal controls. CGS appears to be able to functionally protect animals from the behaviorally disruptive effects of cerebral ischemia.

522.19

ATTENUATION OF ISCHEMIC BRAIN INJURY BY THE NOVEL COMPETITIVE NMDA ANTAGONIST MDL 100,453.

[1]RH Zobrist*, [2]BM Baron, [2]JP Whitten. Marion Merrell Dow Research Institute, [1]Kansas City, MO, 64134, [2]Cincinnati, OH, 45215.

The excitatory amino acids glutamate and aspartate have been implicated in the delayed injury to brain tissue after cerebral ischemia through actions mediated by the N-methyl-D-aspartate (NMDA) receptor. The ability of the competitive NMDA antagonist MDL 100,453 to attenuate ischemic injury in a model of focal cerebral ischemia when administered either prior to, or after ischemia induction in spontaneously hypertensive rats was investigated. MDL 100,453 was administered via continuous intravenous infusion with Alza osmotic minipumps over a 24 hour time period starting either 30 minutes prior to (30 mg/kg/24 hr) or 30 minutes after (100 mg/kg/24 hr) tandem permanent occlusion of the right common carotid and middle cerebral arteries. MDL 100,453 was found to significantly reduce the volume of the resultant brain injury. The volume (mean ± sd) of infarcted brain was 174 ± 27 and 172 ± 15 mm^3, in saline treated control animals after pre- or post-occlusion administration, respectively, compared to 110 ± 21 and 124 ± 25 mm^3, respectively, in MDL 100,453 treated animals. The amount of protection seen was equivalent to that afforded by the prototype competitive NMDA antagonist CPP (91 ±11 and 119 ± 15 mm^3 after pre- and post-MCAO administration, respectively). These experiments therefore suggest that MDL 100,453 reduces ischemic damage and may be useful in the treatment of human strokes.

ISCHEMIA: GLUCOSE

523.1

HYPOGLYCEMIA OR INHIBITION OF GLUCOSE UPTAKE RESULTS IN A LACTATE PREVENTABLE INCREASE IN ADENOSINE AND DEPRESSION OF SYNAPTIC TRANSMISSION IN RAT HIPPOCAMPAL SLICES.

J. C. Fowler*. Department of Physiology, Texas Tech Health Sciences Center, Lubbock, TX 79430.

The effect of glucose deprivation on adenosine levels and on synaptic transmission was investigated in rat hippocampal slices. Adenosine levels were measured, using absorbance HPLC, in aliquots taken from static chambers of 2 ml volume each containing 4 hippocampal slices. Slices were kept on a net at an interface between the physiologic medium and the humidified atmosphere at a temp of 33-34°C. Electrophysiological measurements were made from slices under identical conditions.

Incubation of hippocampal slices in either glucose-free medium or in the presence of the glucose transport inhibitor cytochalasin B (50 μM) increased bath adenosine levels and depressed the extracellularly recorded synaptic potential or population spike. The addition of lactate (10 mM), a precursor for mitochondrial ATP generation, prevented the elevation in adenosine and the depression of the population spike. These results indicate that the neuroinhibitory modulator adenosine is elevated during glucose deprivation and contributes to the hypoglycemic depression of synaptic transmission. The rise in adenosine during glucose deprivation can be prevented by providing substrate for mitochondrial ATP generation. It is hypothesized that glucose transport inhibition may be a relevant neuroprotective strategy during cerebral ischemia as it may reduce lactic acid accumulation and help maintain elevated levels of the endogenous neuroprotectant adenosine.

523.2

HYPERGLYCEMIC HYPOXIA AND INTRACELLULAR ACIDOSIS ENHANCE THE DEPOLARIZING AFTERPOTENTIAL OF RAT MYELINATED AXONS.

P. Grafe, U. Schneider, and A.K.E. Horn*. Deptm. of Physiology, Univ. of Munich, W-8000 München 2, Germany.

The mechanism(s) underlying functional abnormalities of peripheral axons in diabetic neuropathy are not well understood. Here we report that the combination of hyperglycemia and hypoxia, two factors possibly involved in the pathogenesis of diabetic neuropathy, enhances the depolarizing afterpotential (DAP) of myelinated axons. Experiments were performed on isolated rat spinal roots maintained at 36°C in a HEPES-buffered solution containing 2.5 or 25 mM glucose. Electrical stimulation and d.c.-stable recordings of compound action potentials were performed in a three-chambered organ bath. Hypoxia was induced by replacing oxygen for 30 min by ultrapure argon (P_{O2} <2 mmHg).

Under normoxic conditions, a single action potential was followed by a DAP (duration about 10 ms). During hypoxia in a solution with 2.5 mM glucose, the DAP disappeared. In contrast, hypoxia in 25 mM glucose strongly enhanced the DAP and increased its duration by up to 40 ms. A similar enhancement in amplitude and duration of the DAP was observed after the axons had been acid-loaded by addition of propionate (20 mM) to the bathing solution (at constant interstitial pH). These results indicate that hyperglycemic hypoxia may change the DAP and, consequently, functional parameters of myelinated axons by an acidosis-induced decrease in internodal membrane conductance. *Supported by the DFG (SFB 220).*

523.3

MODERATE HYPERGLYCEMIA WORSENS ACUTE BLOOD-BRAIN BARRIER DAMAGE FOLLOWING BRAIN ISCHEMIA.

W.D. Dietrich*, O. Alonso, M. Halley, and R. Busto. Cerebral Vascular Disease Research Center, Dept. Neurology, Univ. of Miami School of Medicine, Miami, Florida, 33101.

We examined the effects of moderate hyperglycemia on the response of the blood-brain barrier (BBB) to normothermic (37°C) cerebral ischemia. Rats underwent 20 min of 4-vessel occlusion followed by 30 min of postischemic recirculation. Hyperglycemic rats received an i.p. injection of 50% dextrose 15 min prior to the ischemic insult. Horseradish peroxidase was used as an indicator of BBB dysfunction. Following normoglycemic brain ischemia (plasma glucose 115±4 mg/dl, n=5) extravasated protein was mainly restricted to the cerebral cortex. In contrast, hyperglycemic ischemia (plasma glucose 372±21, n=6) led to severe and widespread BBB disruption throughout the neuroaxis. Sites of protein leakage included the cerebral cortex, striatum, hippocampus, thalamus and cerebellum. Parenchymal damage, including dark shrunken neurons and swollen astrocytes, was detected at sites of BBB damage. Intraischemic hypothermia (30°C, n=4) significantly attenuated the vascular and neuronal consequences of hyperglycemic ischemia. Under normothermic ischemic conditions, hyperglycemia worsens the degree of BBB disruption compared to normoglycemia. Increased vascular permeability represents an important pathomechanism by which systemic hyperglycemia may aggravate ischemic outcome.

523.4

DURATION OF ISCHEMIA: EFFECTS ON OUTCOME IN NORMOGLYCEMIC (N) AND HYPERGLYCEMIC (H) RATS.

DS Warner*, MM Todd, Paula Ludwig Neuroanesthesia Research Group, Department of Anesthesia, University of Iowa, Iowa City, IA 52242

Acute hyperglycemia, prior to global ischemia, often results in seizures and death. The duration of ischemia necessary to elicit such effects was determined in this experiment. Fasted male Sprague-Dawley rats were anesthetized and prepared for forebrain ischemia (FBI). Prior to FBI, rats received either saline (plasma glucose=112±18 mg/dL) or glucose (PG=343±50 mg/dL). After 4, 8, 12, or 15 mins of FBI (bilateral carotid occlusion; MAP=30±5 mmHg), rats (n=12) were recovered and observed for seizures, motor function, and survival. Rats surviving 7 days underwent perfusion fixation for neurohistologic analysis. Seizure and mortality rates were compared between N and H groups for each ischemic duration. Significant differences were observed for both variables at ≥8 mins of FBI. Seizure rates continued to increase with increased ischemic durations (p<.01) while mortality rates stabilized at 8 mins (p=.42). Motor scores amongst survivors (7d postischemia) were different with ≥12 mins of FBI. The glycemic state of the rat becomes relevant to neurobehavioral outcome between 4 and 8 mins of global ischemia.

EXTRACELLULAR DOPAMINE IN HYPERGLYCEMIC ISCHEMIA.
WA Kofke*, RH Garman, RL Stiller, ME Rose, Dept. of Anes/CCM, Neurologic Anes. and Supp. Care Progr., Univ. of Pittsburgh, Pittsburgh, PA 15261

We tested the hypothesis that hyperglycemic (HG) exacerbation of ischemic striatal damage is associated with an increased elevation of extracellular dopamine (DA). **METHODS:** 16 fed male rats were used. Each rat underwent insertion of a striatal microdialysis (MD) probe and recovered overnight in soundproof isolation. On d2 vascular cannulae temp probe and EEG elec were inserted. GLC 40% or 5% 4 ml/kg/h was started in 8 rats/grp. After 1h of O_2/N_2O; 100% O_2, 0.5 mg Arfonad was given iv, blood removed to MAP 50mmHg, and both carotids occluded for 12m. Life support continued for 6h. MD pump speed was 2 ul/m. Dialysate samples were assayed for dopamine by HPLC. Path in the striatum was graded from 0-5 (0=norm). **RESULTS:** Five 40% glc and 2 5% glc rats had severe (grade 4 or 5) striatal damage ($p<.05$). Baseline (BL) DA was nondetectable. N_2O and ischemia both increased DA vs. BL ($p<.05$). DA was increased at 30m PI compared to BL and N_2O ($p<.05$). No between group DA differences occurred. **CONCLUSIONS:** 1) N_2O after minor surgery increases striatal DA. 2) HG exacerbation of ischemic striatal damage in rats is not due to increased extracellular DA.

523.6

PHYSIOLOGIC AND HISTOLOGIC EFFECTS OF PHENYTOIN IN A RAT GLOBAL ISCHEMIA MODEL. H. Qi, M. Maletic-Savatic, F. Hospod, G. Newman*. SUNY at Stony Brook, NY and VAMC at Northport, NY, 11794.

Phenytoin is frequently studied in rat models of ischemia and epilepsy. Despite this, the physiologic effects of phenytoin in the rat have not been studied in detail. Experiments testing phenytoin in a brain slice model of global ischemia revealed a profound concentration-dependent hyperglycemia up to 25 mM glucose as well as hypothermia to 34°C.

Male Sprague-Dawley rats (175 -275g) were injected with 50 to 200 mg/kg *i.p.* and sacrificed after 30 min in most experiments. Some rats were initially anesthetized with halothane - NO_2 for arterial catheterization and then given phenytoin *i.v.* 2 hours later with BP and arterial blood gas monitoring. Several Fischer-344 and Wistar Kyoto (WKY) strain males (175g) were also studied. Histology was assessed by counting the percentage of normal appearing CA1 neurons remaining in 500μ thick hippocampal slices after 5 hours *in vitro*.

Phenytoin, at serum concentrations from 6 to 60 μg/ml, causes a linear increase in serum glucose from 8.5 mM in saline controls to over 25 mM. The hyperglycemia is reversed by co-administration of insulin *i.m.*, is present to at least the same degree in Fischer-344 and WKY strains and is independent of animal temperature. Fos-phenytoin also induces hyperglycemia while propylene glycol vehicle does not. There is a concentration-dependent hypothermia produced by phenytoin. BP and blood gasses are not significantly affected by phenytoin. Phenytoin produces only inconsistent benefit in CA1 neuronal survival whether phenytoin is continued *in vitro* or not.

Phenytoin-induced hyperglycemia may affect results with rat models of cerebral injury. The present histologic results, along with our prior results in our thick slice model of ischemia, suggest that phenytoin will be more useful in treating focal than global ischemia.

ISCHEMIA: GENE OR PROTEIN INDUCTION

524.1

THE STRESS RESPONSE IS DEPENDENT ON HYPERTHERMIA AFTER BRIEF ISCHEMIA IN THE GERBIL. T. S. Nowak, Jr.* and S. Suga. Stroke Branch, NINDS, NIH, Bethesda, MD 20892.

Previous studies established 2 min ischemia as a threshold insult for producing several changes in gene expression in gerbil brain. Brief periods of ischemia, associated with accumulation of the heat shock / stress protein, hsp70, in vulnerable CA1 neurons, are also reported to induce tolerance to subsequent more severe insults. In our hands both hsp70 expression and induction of tolerance after brief ischemia have been variable. We now show that increases in hsp70 mRNA correlate with the presence of hyperthermia during early recirculation after 2 min insults. Gerbils were subjected to bilateral carotid artery occlusion under halothane/N_2O anesthesia. Hsp70 mRNA levels were evaluated by in situ hybridization and quantitative densitometry at 3 h or 24 h. Rectal temperature (T_R) was monitored during recirculation and release of anesthesia (Experiment 1) or anesthesia was continued and T_R was either maintained at 37 °C or elevated to 39-40 °C during 30-90 min recirculation (Experiment 2). In Experiment 1, pronounced hsp70 expression was observed only in gerbils with spontaneous $T_R \geq$ 39 °C. Hsp70 hybridization in all hippocampal fields was several-fold higher in hyperthermic animals at 3 h, and lasting hsp70 hybridization at 24 h was only detected in the hyperthermic group (Experiment 2). Earlier work identified temperature during early recirculation as an potential variable influencing the course of pathology in CA1 neurons after damaging insults. The present results implicate postischemic temperature as a factor affecting the reproducibility of transcriptional responses to threshold ischemia that may be of particular relevance to the expression of tolerance after brief challenges.

524.2

INDUCTION OF HEAT SHOCK PROTEINS IN ASTROCYTES AND NEURONS AFTER EXPOSURE TO PROSTAGLANDIN A1. R.N. Nishimura, B.E. Dwyer* and T. Yoshida. In Vitro Remyelination Laboratory and Molecular Neurobiology Laboratory, Sepulveda VAMC, Sepulveda, CA 91343.

The induction of heat shock proteins was investigated in cultured rat forebrain astrocytes and cortical neurons after exposure to prostaglandin A1 (PGA1) at doses of 0.05 to 4ug/ml of medium. Accumulation of the major inducible 68 kilodalton heat shock protein was undetectable by Western blotting at 3, 6, and 24 hours in neurons and minimally detectable in astrocytes. In contrast, the induction of a 32-34 kilodalton stress protein previously identified as heme oxygenase (Dwyer et al, Glia 5:300-305,1992) was detected in neurons after 6 hours of PGA1 exposure. Heme oxygenase induction in astrocytes was noted at 3 and 6 hours of exposure to PGA1 and was profoundly increased at 24 hours of PGA1 exposure. The results suggest that inflammatory cytokines are capable of inducing heat shock proteins in neurons and astrocyes and that they may be important in the induction of the acute phase protective response of CNS cells to injury.
Supported by the research service of the Department of Veterans Affairs.

524.3

DISTINCT PATTERNS OF HEAT SHOCK PROTEIN INDUCTION FOLLOWING FOREBRAIN ISCHEMIA IN RATS. H. Gaspary, S. Graham, S. Sagar, P. Weinstein*, and F.Sharp. Dept. of Neurology and Neurosurgery, UCSF Sch. of Med. SF, Ca. 94143.

During global ischemia, the synthesis of various heat shock proteins (HSP's), including HSP72, is induced in selectively vulnerable neurons, and occasionally in glial and endothelial cells, of the cortex, hippocampus, and striatum. The significance of HSP72 induction in these cells, however, is unclear.

The present study employs the model of simultaneous carotid occlusion and hypotension in rats for either 30 (n=6) or 15 (n=2) minutes. After 24 hours, immunohistochemistry was performed using a monoclonal antibody for HSP72. Sections were also stained with H&E or acid fuscin. In addition, sections from one brain were double-labeled for either HSP72 and glial fibrillary acidic protein (GFAP), or for HSP72 and isolectin B4, markers for astrocytes and microglia, respectively.

Mild ischemic injury was characterized by patchy HSP72 induction in neurons in the cortex and striatum, small columns of HSP72 positive neurons in Ca1 hippocampus, and no apparent abnormalities with H&E or acid fuscin. Moderate injury resulted in diffuse HSP72 induction in neurons throughout the entire forebrain, with occasional glial cell induction. On H&E stained sections, scattered necrotic neurons were evident in the cortex and hippocampus; Ca1-4 hippocampal neurons were acid fuscin-positive while the dentate gyrus appeared spared. HSP72 was not found in necrotic neurons when slides were counterstained with H&E. In severe injury, HSP72 induction was marked in glial and endothelial cells, with almost no neural expression, except in resistant regions (i.e. dentate gyrus). Areas with prominent glial induction corresponded to regions with widespread ischemic necrosis and pale staining on H&E, and acid fuscin positive cells throughout the hippocampus. Double-labeled sections revealed that both microglia and astrocytes (type I and II) express HSP72 in these severely injured brains.

These results confirm previous observations that HSP72 is expressed in injured neurons that survive ischemia. In addition, severe ischemic injury results in both microglial and astrocyte HSP72 expression in the absence of neuronal expression. Thus HSP72 is a valuable early marker to quantify ischemic injury.

FOCAL HSP-70 mRNA INDUCTION WITH LITTLE TO NO HISTOLOGIC INJURY IN RAT BRAIN. D.M.O'Rourke*, S.S. Glazier, F.A. Welsh, Div. of Neurosurg, Univ. of Penn., Phila., PA. 19104.

A variety of cell stresses including ischemia have been shown to induce heat shock proteins which may help defend cells against injury. The 70 k-Da protein, HSP-70, is one of the major proteins induced in ischemia. Although HSP-70 is a marker of regional metabolic compromise in brain ischemia, the relationship of HSP-70 production to neuronal cell injury or recovery is not well defined. We sought to determine whether HSP-70 could be induced by focal ischemia without producing neuronal injury in rat brain. Focal ischemia was induced in Wistar rats by transient, distal MCA occlusion for 20,30,or 60 minutes. After 24 h reperfusion, all animals undergoing 30 (n=5) or 60 (n=3) min of reversible ischemia exhibited micro-infarcts in the outer MCA neocortex with occasional extension to inner neocortex and limited selective neuronal necrosis in the peri-infarct zones. Brains undergoing 20 min (n=3) of ischemia exhibited either no histologic injury or occasional focal infarction nearly indistinguishable from that observed after occlusion for 30 or 60 min. Mean area of neocortical HSP-70 mRNA production (assessed by in situ hybridization after 2 h reperfusion) was larger than the core of infarction and was 3.4mm^2 at 20 min (n=3) and 9.4mm^2 at 30 min (n=3) at the level of the striatum predominantly in the outer layers of neocortex. Thus, distal, reversible MCA occlusion for 20-60 min results in focal HSP-70 mRNA production in neocortex with minimal histologic injury. Reversible ischemia for 20 min in this model may represent a window where HSP-70 mRNA is induced in cells which recover completely from metabolic stress.

NEURONAL PROTECTION FROM ISCHEMIC NECROSIS BY FOCAL INDUCTION OF HEAT-SHOCK PROTEINS. S.S.Glazier, D.M.O'Rourke, D.I.Graham, F.A.Welsh*. Div of Neurosurg, U of Penn, Phila, PA 19104.

Ischemic stresses inflict numerous changes on neural cellular elements. One such consequence is the production of several classes of stress-response proteins, or heat-shock proteins (HSPs). Both in-vitro and in-vivo models have correlated the induction of HSPs with a decrease in the expected injury from a subsequent stress. We have developed a model of cortical neuronal protection that allows direct comparison of a protected hemisphere with the contralateral, unprotected hemisphere. We used a distal middle cerebral artery occlusion in the rat as a priming insult to stimulate a stress response in the cerebral cortex without causing neuronal necrosis. Twenty-four hours later the animal was subjected to a ten minute period of bilateral common carotid artery occlusion with hypotension in a temperature and humidity controlled environment. This global ischemic insult has been characterized to result in symmetrical, selective cortical and subcortical neuronal necrosis in unprimed animals. In a preliminary set of three rats, we found a decrease in the number of necrotic neurons in the primed cortex compared to the unprimed side in two animals. In the third animal there was insufficient cortical injury on either side to detect protection. Subcortical structures were symmetrically affected in all three animals. This model suggests a correlation exists between the in-vivo induction of HSPs and resistance to ischemic cell death. The presence of a side-to-side control (opposing cortical regions), and a unilateral control (adjacent cortical and subcortical regions), makes this an attractive model for the further characterization and enhancement of neuronal protection during stress.

524.6

HEMEOXYGENASE mRNA AND PROTEIN LEVELS INCREASE IN NEURONAL CELLS IN RESPONSE TO HYPOXIA AND HYPOXIA-REOXYGENATION. C.M. Bitler, B.J. Murphy and L. Toll*, Department of Neuroscience, SRI International, Menlo Park, CA 94025

The presence of increased amounts of oxidized proteins in aged animals, particularly in the brains of such animals, have led to the discovery that compounds which react and stabilize free radicals generated during such oxidations can reverse degenerated behavioral parameters in older gerbils to levels comparable to those of young gerbils. In aerobic animals, a number of natural antioxidants exist which include superoxide dismutase, catalase, and the bile pigment, bilirubin. We have found that during a hypoxic episode in immortalized neuronal cells, hemeoxygenase (HO), the enzyme responsible for the generation of bilirubin, and the mRNA which encodes it, increase several-fold. Since free radicals are most prevalent in the brain following an ischemia-reperfusion episode, we mimicked this situation by reoxygenating the cells following hypoxia and found that the increased levels of HO mRNA are maintained. Interestingly, the regions of the brain most vulnerable to hypoxia-reperfusion are areas in which HO mRNA is most abundant. We propose that the generation of the antioxidants biliverdin and bilirubin protects the brain from the assault of free radicals generated during ischemia-reperfusion, and the extent to which hemeoxygenase is induced contributes to the resiliency or vulnerability of the brain (particularly, the hippocampus) to ischemia.

524.7

REGION-SPECIFIC CHANGES IN EXPRESSION OF SULFATED GLYCOPROTEIN-2 (SGP-2) FOLLOWING TRANSIENT GLOBAL ISCHEMIA AND INHIBITION BY LY231617. K.S.Fuson *, J.A.Clemens, J.A.Panetta, E.B.Smalstig, and P.C.May. Lilly Research Laboratories, CNS and Diabetes Divisions, Eli Lilly and Company, Indianapolis, IN 46285.

SGP-2 is emerging as an important marker for neurodegeneration. In this study, we examined SGP-2 RNA expression in rat hippocampus (HC), caudate nucleus (CN), and cortex (CX) 24 hours after transient global ischemia induced by four vessel occlusion (4VO). At 72 hours post-4VO, SGP-2 RNA is elevated in HC, CN, and CX (May et al, Mol. Brain Res., in press). However, at 24 hours post-4VO, SGP-2 RNA is increased only in CN and CX (1.5- and 1.7-fold, respectively); there is no change in SGP-2 RNA in HC. Induction of SGP-2 RNA at this early timepoint is limited to regions (CN and CX) where rapid neurodegeneration post-4VO takes place; this induction has not yet occurred in HC, where neurodegeneration is delayed. To further study the relationship between SGP-2 and neurodegeneration, we tested the effectiveness of LY231617, an antioxidant compound that is protective against ischemic damage in HC and CN, in preventing SGP-2 RNA expression following 4VO. LY231617 (50 mg/kg) or vehicle was administered orally before and after 30 minutes of 4VO, and the rats were sacrificed 72 hours later. Treatment with LY231617 prevented the induction of SGP-2 RNA in HC but not in CN, although 4VO-damage in both regions was markedly attenuated by the compound. These data suggest that ongoing neurodegeneration is not an absolute requirement for the induction of SGP-2 RNA in the brain.

524.8

CO-INDUCTION OF FOS AND JUN EXPRESSION FOLLOWING FOCAL CEREBRAL ISCHEMIA-REPERFUSION INJURY. G. An, T.N.Lin, J.J. Xue, Y.Y.He, C.Y.Hsu*. Division of Restorative Neurology, Baylor College of Medicine, Houston, TX 77030.

Alterations of immediate early gene expression have been observed during central nervous system ischemia. In the present study, the expression of the proto-oncogenes, c-fos, c-jun, jun B and jun D were investigated in a rat focal cerebral ischemia-reperfusion model. Northern blot analysis indicated that the expression of c-fos and jun B in control brains were very low and both were co-induced immediately following focal cerebral ischemia-reperfusion and peaked at 30 and 60 min after reperfusion respectively. c-jun was expressed constitutively in a significant level in all time intervals examined and was also enhanced in a similar pattern as c-fos and jun B but with a much lower magnitude. In contrast, no change in jun D expression was observed. The increases of c-fos, jun B and c-jun mRNAs were localized to the cortex and hippocampus, as shown by in situ hybridization. Nuclear run-on assays indicated that the increased mRNA levels of c-fos, jun B and c-jun are due to the increases of transcription rate in these genes. Mobility shift assays were used to determine the DNA binding activity of transcriptional factor AP1 (Fos-Jun heterodimer). Nuclear extract from control cortex showed a basal binding activity to the AP1 DNA sequence; however, 90 min ischemia followed by 4 hr reperfusion resulted in a 4 to 6-fold increase of AP1 binding activity, and the enhanced DNA binding activity persisted for at least 24 hr. These results suggest that, as general transcriptional factors, the changed expression of fos and jun may play a central role in post-ischemic alteration of genetic process.

524.9

LOCATION OF C-FOS AND C-JUN mRNA EXPRESSION AFTER NEONATAL HYPOXIA-ISCHEMIA. F. Munell, R.M. Gubits, R. E. Burke, A. Bandele, and D.C. DeVivo*. Dept. of Neurology and Dvsn. of Pediatric Neurology, Columbia Univ. Coll. of Phys. and Surg., NY, NY 10032.

The expression of c-fos and c-jun mRNAs was localized by in situ hybridization in a neonatal model of hypoxic-ischemic (H-I) brain injury (Rice et al.,1981). Rat pups (PND7) were exposed to unilateral common carotid ligation, followed by 3 h of hypoxia (8%O2/92%N2). Adjacent coronal brain sections were hybridized to 3'-end labeled oligomeric probes for c-fos and c-jun mRNAs. At 2 h post-hypoxia, c-fos and c-jun expression was observed in ipsilateral (I) striatum and hippocampus, as well as both vulnerable and spared regions of the cortex. A columnar pattern of expression was observed in the ipsilateral MCA cortex, which is similar to the pattern of permanent morphological damage observed in this area in neonatal, but not adult, models of unilateral H-I. Emulsion autoradiography of hybridized sections revealed cell-specific expression in these areas. In some animals, expression in the contralateral hemisphere occurred in sites that represented a partial mirror image of those on the I side. The ipsilateral striatum, MCA cortex, and hippocampus exhibit selective vulnerability to damage in the neonatal model. Since fos and jun mRNA expression occurs in both vulnerable and spared regions, AP1 transcriptional activity could mediate region-specific responses to H-I in the immature brain. Sup. by Colleen Giblin Fndtn. and NS26836.

524.10

IEG INDUCTION AFTER NEONATAL HYPOXIA-ISCHEMIA. R.M. Gubits*, R. E. Burke, H. Yu, G. Casey, A. Bandele,and F. Munell. Dept. of Neurology and Dvsn. of Pediatric Neurology, Columbia Univ. Coll. of Phys. and Surg., NY, NY 10032.

Immediate early gene (IEG) products, such as FOS and JUN, may partially mediate the longterm transcriptional response of CNS cells to specific changes in thier environment. To determine whether IEG products might play a role in the immature brain's response to hypoxia-ischemia (H-I), rat pups (PND7) were subjected to unilateral common carotid artery ligation followed by 3h of hypoxia (8%O2/92%N2) at 37°C, which results in pathological changes only in the ipsilateral hemisphere (Rice et al.,1981) . Following H-I, 3 animals were euthanized at each of 4 time points (1, 2, 18, and 24 hr). RNAs from 4 brain regions were analyzed by northern blot hybridization for their relative concentrations of 9 IEG mRNAs (c-fos, c-jun, junB, and TIS 1 (nur77), TIS7, TIS8 (zif268), TIS10, TIS11, and TIS21). Induction of all of the IEGs, except TIS7 and TIS10, was observed in ipsilateral forebrain, and less frequently in contralateral forebrain, at 1 and 2 hr post-hypoxia. In some animals, lower levels of expression were also detected at 18 and 24 hr. With minor exceptions, co-induction of all 7 IEGs was observed in a given RNA sample. In summary, exposure of neonatal rats to H-I produces a dramatic induction of 7 IEG mRNAs in their brains. Several convulsant drugs induce seizures, but not fos expression, before PND20 (Sakurai-Yamashita et al., (1991)). Thus, the extensive IEG response to H-I represents one of the few reported thus far in which IEG-encoded proteins could mediate longterm cellular responses in neonatal brain. Sup. by Colleen Giblin Fndtn. and NS26836.

524.11

ALTERATION OF NEUTROPHIN mRNA EXPRESSION AFTER FOCAL CEREBRAL ISCHEMIA-REPERFUSION. J.S.Liu, T.N.Lin*, J.J.Xue, Y.Y.He, G.An, C.Y.Hsu. Division of Restorative Neurology, Baylor College of Medicine, Houston, TX 77030.

Neurotrophins (NTs) have been shown to promote the differentiation and survival of certain types of neurons and may play a role in plasticity and regeneration after CNS injury. In this study, the influence of focal cerebral ischemia on NT family mRNA expression was examined using Northern blot analysis and in situ hybridization. Transient focal cerebral ischemia for 30 minutes with reperfusion of 30 minutes or 4 hours induced a transient increase in NGF and BDNF expression in ischemic cortex. A second peak was found two to four weeks after ischemic insult. The biphasic expression of NT mRNA was also observed to a lesser extent in the contralateral cortex which sustained only very mild ischemia. Similar biphasic NT mRNA expression was also noted if ischemia lasted for 90 minutes leading to a permanent infarct. Interestingly, in hippocampus, a monophasic peak happened between four hours to 1 week after reperfusion, which corresponded to a period of depressed NGF and BDNF expression in the ischemic cerebral cortex. There was no obvious increase in NT-3 expression. We also failed to detect CNTF mRNA signals in brain with or without ischemia. Results from this study suggest time-dependent expression of selected NTs.

524.12

THE EFFECT OF POST-OCCLUSION SURVIVAL TIME ON LESION VOLUME AND THE IMMUNOHISTOCHEMICAL LOCALIZATION OF MAP2 AND GFAP AFTER PERMANENT MIDDLE CEREBRAL ARTERY OCCLUSION IN THE MOUSE. C. Gonzales*, T.L. Sailer and J.A. Moyer. CNS Division, Wyeth-Ayerst Research, CN 8000, Princeton, N.J. 08543-8000.

Permanent middle cerebral artery occlusion in the mouse causes severe neuronal cell loss in the ipsilateral cortex presumably due to massive release of excitatory amino acids in the area of the lesion. Because this type of injury and the resulting cellular response is a dynamic process that occurs over days, the effect of time on infarct volume and the presence of neurons and glial cells in the area of an ischemic lesion were examined. Mice were anesthesized with 2% isofluorane and temperature was maintained at 37°C while the right middle cerebral artery was occluded by electrocautery. Animals were sacrificed 2, 4, and 6 days post surgery. Mean infarct volumes were determined at each timepoint using a Nissl stain and sections through the lesion were processed for immunohistochemistry using a polyclonal antibody against microtubule-associated proteins (MAP2) or a monoclonal antibody against glial fibrillary acidic protein (GFAP). The results showed that infarct volume decreased 50% from 2 days to 6 days post occlusion. GFAP staining was intense and localized throughout most of the ipsilateral hemisphere at 2 days post-occlusion and became more concentrated in the area of the lesion over time. In the perimeter of the lesion, there were surviving neurons that express MAP2, particularly at 4 and 6 days. These studies suggest that some neurons that appear abnormal 2 days after ischemia may show a recovery process over time.

524.13

INCREASES IN GAP 43 IMMUNOREACTIVITY AFTER CORTICAL INFARCTION. R.P. Stroemer *, T.A. Kent and C.E. Hulsebosch. Depts. of Anat. and Neurosci., Marine Biomed. Inst., Neurol., Univ. of Texas Med. Br., Galveston, TX 77550.

The denervation in the cortex following damage from ischemia should provide a stimulus for sprouting. Earlier work supported the existence of synaptogenesis after cortical infarction using antibodies to synaptophysin. The present study demonstrates the distribution of immunoreaction against GAP 43, a growth cone associated protein, as an indicator of neurite growth following cortical infarction. Hypertensive rats were subjected to permanent tandem occlusion of the right common carotid and right distal middle cerebral arteries. This procedure produces ischemia in the cortex with little damage to subcortical structures. After recovery times of three days to two months, the animals were perfused with paraformaldehyde and processed for conventional immunohistochemistry using monoclonal antibodies to GAP 43. These slices were evaluated on a Quantex image analyzer to determine the optical density of the reaction product. Preliminary optical density data is shown below (* P<.01 Student's T test):

Time Post-Op	O.D. ipsi. to Infarct	O.D. contra. to infarct
3 days *	17.0±5.5	-8.0±2.3
7 days *	47.0±6.1	30.1±6.6
14 days *	41.0±7	28.3±4.5
1 month	17.1±10.6	19.0±7.3
2 months	40.4±9.1	49.0±4.7

These results suggest that neurite sprouting occurs shortly after ischemia in the cortex, but is diminished by one month when synaptogenesis occurs.This supports the hypothesis of neurite growth and synaptogenesis in the cortex following ischemia. Supported by NS 11255, NS 01217, and Bristol Myers-Squibb.

TRANSIENT FOREBRAIN ISCHEMIA CAUSES AN IMMEDIATE INCREASE IN bFGF mRNA, AND A DELAYED DECREASE IN FGF RECEPTOR mRNA IN THE CA1 REGION OF THE HIPPOCAMPUS M. Endoh and J. A. Wagner*: Cornell University Medical College, 1300 York Ave., New York, N.Y., 10021

Using both in situ hybridization and RNAase protection assays we have studied the change in mRNA expression of both bFGF and FGF receptor in the rat hippocampus after a ten minute period of transient ischemia induced by the four vessel occlusion model. There was an increase in the expression of bFGF message at six hours and one day after ischemia with a subsequent decrease, possibly because of the presence of high concentrations of excitatory amino acids or increased metabolism in the injured tissue. At one week, bFGF message expression was again increased. This increase occurred after the period of neuron death and was associated with gliosis. Although no immediate change in message for the FGF receptor (flg) was observed, there was a decrease in this message that was temporally correlated with neuron death, suggesting either that the receptor was expressed on neurons or that its expression was dependent on the presence of viable neurons. These changes in the expression of FGF and FGF receptor are presumably a part of a coordinated response to ischemic injury that may be designed to minimize the severity of the effects of neuron cell loss.

524.15

EFFECTS OF INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) TREATMENT TWO HOURS AFTER HYPOXIC-ISCHEMIC INJURY. C E Williams, J Guan, M Dragunow*, and P Gluckman. Dept. Ped., Univ. Auckland, Private Bag, Auckland, New Zealand.

We have shown that following hypoxic-ischemic (HI) injury to the rat brain, there is marked induction of mRNA for IGF-1, IGF binding proteins BP2-4 and TGFβ in the areas of neuronal loss within 5 days. Induction of NGF-β, BDNF or neurotropin-3 was not detected. IGF-1 is known to be a potent non-selective neurotrophic agent. We examined the possibility that IGF-1 may be neuroprotective. Rats were subject to a unilateral HI injury by ligating one carotid artery then subjecting the animals to 10 min of 6% inspired O_2. This induces considerable neuronal loss and infarction in the middle cerebral artery territory of the ligated hemisphere. Growth factor or vehicle were administered as bolus injections into the lateral ventricles.

IGF-1 given 2 hours *after* the insult reduced the infarction rate. In controls the infarction rate was 86%: this reduced to 36% with 5μg IGF-1 (n=14) and to 27% with 50 μg IGF-1 ($p<0.05$, n=15). Similarly within each neuronal region IGF-1 caused dose dependent neuroprotection particularly in the striatum and cortex. IGF-1 treatment did not alter cortical temperature. Equimolar doses of insulin did not improve outcome. Indicating the protective effects of IGF-1 do not act via the insulin receptor or hypothermic mechanisms. This peptide may have therapeutic use in the rescue of the injured brain.

IDENTIFICATION OF CHANGES IN NUCLEOTIDE INTERACTING PROTEINS IN CONTROL VS ISCHEMIC RAT BRAINS Banumathi Sankaran, Boyd Haley* and James Clemens. Eli Lilly & Co., Indianapolis and College of Pharmacy, University of Kentucky, Lexington, KY, 40536.

The effects of ischemia on the phosphorylation and nucleotide binding properties of rat brain proteins were examined. Tissue homogenates were from the corpus striatum, dorsal hippocampus and paramedian cortex regions. Samples from both control rats and rats subjected to 30 minutes of 4VO followed by no reperfusion, 1hr or 24hrs reperfusion were phosphorylated or photolabeled. Either α or γ^{32}P labeled $8N_3ATP$ or $8N_3GTP$ were used. Major changes in phosphorylation and nucleotide binding of specific proteins in ischemic rat brains were observed. Most changes were observed in the striatum, a few in the hippocampus and almost none in the cortex. This agrees with the fact that after the ischemic insult, striatum degenerates in 24hrs, hippocampus dies after 3 days and cortex shows minimal degenerative changes. $8N_3ATP$ photoinsertion increases in ischemic brain proteins of 55-57 (CaM kinase), 42-43 (creatine kinase), 31 (unknown, but also a GTP binding protein that shows an increase in photoinsertion of $8N_3GTP$ in ischemic samples) and 14 (unidentified) kDa Mr values. Phosphorylation of a 110 kDa protein (CaATPase) is observed in controls but not in ischemic samples. Supported by Eli Lilly and Co. & NIH grant GM-35766-07.

GLOBAL CEREBRAL ISCHEMIA EFFECTS ON HIGH MOLECULAR WEIGHT PEPTIDES AND CA1 PYRAMIDAL NEURONS IN THE RAT HIPPOCAMPUS. T.M. Wengenack*[1], R. Slemmon[1], J.M. Ordy[2], P. Bialobok[2], W.P. Dunlap[3], and P.D. Coleman[1]. [1]Dept. of Neurobiol. and Anat., Univ. of Roch., and [2]Fisons Pharm., Rochester, NY and [3]Tulane Univ., New Orleans, LA.

The four-vessel occlusion (4-VO) rat model of global cerebral ischemia has been used widely to study selective hippocampal cell vulnerability, gliosis, and viability or plasticity of surviving cells. Intense interest exists on the molecular events of selective CA1 vulnerability and the plasticity of surviving neurons in response to injury. The specific aim of this study was to correlate the post-ischemic progression of CA1 cell death and the molecular events which may play a critical role in neuronal vulnerability and plasticity in response to injury.

Reverse phase HPLC was used to profile hippocampal peptide changes following 4-VO. Rats were sacrificed 1, 3, or 7 days after 30 min of 4-VO or sham surgery. Supernatants of denatured hippocampal homogenates were passed through G50 Sephadex columns and the high molecular weight fraction separated by HPLC. Peaks which exhibited a 25% or greater change after 4-VO were isolated for identification. Trypsinized peptides were sequenced and identified by homology match to GenBank. In two rats from each group, CA1 pyramidal neurons were counted in three anatomically-defined regions of CA1, in two sections of the dorsal hippocampus.

The number of CA1 pyramidal neurons was not decreased significantly on day 1 after 4-VO, but was on days 3 and 7. Peptides that exhibited a relative change of 25% or greater were: zinc binding protein (-26, -23, -24%; days 1, 3, 7), myelin basic protein (-7, -38, -28%), serum albumin (31, 58, 7%), calmodulin (8, -33, -19%), alpha hemoglobin (26, 50, 1%), and beta hemoglobin (62, -11, -21%). The correlation of post-ischemic CA1 cell death with specific peptide changes provided evidence on the critical role of specific molecular events in neuronal vulnerability and plasticity. Supported by NIH AG 00107 and LEAD Award AG 09016 to PDC.

ISCHEMIA: FREE RADICALS

525.1

DIFFERENTIAL VULNERABILITY OF HIPPOCAMPAL AND CORTICAL GLUTAMINE SYNTHETASE TO OXIDATIVE INACTIVATION. M.E. Harris,* T. Tatsuno, J.M. Carney, M.P. Mattson, and R.A. Floyd. Dept. of Pharmacology, Univ. of Kentucky Medical Center, Lexington, KY 40536.

Specific regions of the central nervous system are susceptible to age-related and degenerative changes. Oxygen free radicals may play a significant role. These oxygen radicals have been shown to oxidize membrane lipids and proteins such as glutamine synthetase (GS). GS plays a critical role in the metabolism of the excitotoxic neurotransmitter glutamate. Both hippocampal and cortical neuron/glia cultures were established from E18 rat fetuses. The cultures were exposed to the Fe^{2+} or Fe^{2+}/Ascorbate oxygen radical generating systems. Hippocampal GS exhibited a transient increase in activity at 2 uM Fe^{2+} (2 hr treatment) but was progressively inactivated at 10-100 uM Fe^{2+}. Cortical GS increased in activity at 2-100 uM Fe^{2+} and was inactivated only after longer exposure times to 100 uM Fe^{2+} (4-8 hrs). Hippocampal GS was also inactivated at 2-10 uM Fe^{2+} + 1mM Asc. whereas cortical GS was not inactivated until 200 uM Fe^{2+} + 1 mM Asc. or longer exposure times to 10 uM Fe^{2+} + 1mM Asc. This differential inactivation of GS was not seen in cell-free extracts of hippocampal and cortical cells. This data suggests that, in mammalian cells, there may be differences in cellular organization that render cells more or less vulnerable to oxidative damage. Supported in part by AG09690 and a gift from the Glenn Foundation.

525.2

OXIDATIVE INACTIVATION OF GLUTAMINE SYNTHETASE IN GERBIL BRAIN. T. Tatsuno*, J.M. Carney and R.A. Floyd. Dept. of Pharmacology, Univ. of Kentucky Medical Center, Lexington, KY 40536.

Glutamine synthetase (GS) plays an important role in the metabolism of the excitotoxic neurotransmitter glutamate. We have found the loss of forebrain GS activity associated with protein oxidation following transient ischemia and aging. We exposed the cytosolic fraction of gerbil brain to the ascorbate/Fe^{2+} oxygen radical generating system. Cytosolic GS activity was easily inactivated by ascorbate (3-30mM), Fe^{2+} (1-100μM) and ascorbate + Fe^{2+}. GS activity was protected by iron chelators, ATP and Mn^{2+} but not by GTP or spin-trap agents (PBN, POBN). Ascorbate-induced production of $\cdot$OH detected by the conversion of salicylate to dihydroxybenzoate was inhibited by deferoxamine, Mn^{2+} and partially by spin-trap agents but not by ATP, GTP or EDTA. We also detected Fe^{2+}-induced cytosolic protein oxidation (protein carbonyl formation), which was prevented by chelators. The loss of GS activity by ascorbate appeared to be due to a site selective oxidation. However, the ATP binding site on GS was unaffected as demonstrated by [^{32}P]8N_3-ATP photoinsertion. Oxidative inactivation of GS could be a potential marker for Fe-mediated damage within the tissue. Supported in part by NS23307 and AG09690.

525.3

THE EFFECT OF N-ACETYLCYSTEINE ON CHOROID PLEXUS TISSUE VIABILITY FOLLOWING TRANSIENT CEREBRAL ISCHEMIA. D. Palm*, P. Watson, N. Knuckey and C. Johanson. Dept. Clin. Neurosci., Program in Neurosurg., Brown Univ. & RI Hospital, Providence, RI 02902

Recent studies have revealed maximum ionic and ultrastructural changes in choroid plexus (CP) tissue 6 hr following 10 min of transient ischemia. The following studies evaluated CP tissue viability from rats pre-treated with, the free radical scavenger, n-acetylcysteine. Male, Sprague-Dawley rats (250-375g) were fasted overnight and anesthetized with a mixture of 2% halothane (HA), 70% NO_2, and 28% O_2. N-acetylcysteine (163 mg/kg i.p.) was administered 30 min and again 5 min prior to the ischemic insult. Ten min of ischemia was induced by bilateral common carotid artery occlusion with hypotension (50 mmHg). MABP, PCO_2, PO_2, and EEG were monitored and brain and body temperature were maintained at 37°C. CPs were dissected from lateral ventricles at 6 hr post ischemia and measured for tissue [Na] and [K]. The tissue [K]/[Na] ratio was used as an index of tissue viability. CP morphology was analyzed by electron microscopy (E.M.). The CP tissue [K]/[Na] ratio was reduced by 46% and 56% in halothane anesthetized rats (n=6) and animals pre-treated with n-acetylcysteine (n=6) respectively compared to control (n=6) values (2.01 ± 0.06). However, CP tissue [K]/[Na] ratio of HA animals (1.08 ± 0.13) did not differ from animals pretreated with n-acetylcysteine (0.88 ± 0.06). In reference to previous studies, the [K]/[Na] of HA rats was reduced by 30% compared to unventilated pentobarbital anesthetized (PA) rat (n=6) values (1.55 ± 0.16). Furthermore, E.M. of CP from HA animals demonstrated greater ultrastructural damage compared to PA animals. In conclusion, pentobarbital demonstrates a protective effect on CP tissue viability. However, no effect on CP tissue [K]/[Na], 6 hr post-ischemia, was observed with pretreatment of n-acetylcysteine. Further studies with pre- and post-treatment of n-acetylcysteine at various doses are indicated to characterize its possible protective effect on CP tissue viability.

SUPEROXIDE DISMUTASE AMELIORATES NEURONAL DEATH FROM HYPOXIA IN CULTURE. D. M. Rosenbaum*, J. Kalberg, J. A. Kessler. Albert Einstein College of Medicine, Bronx, New York 10461.

Biochemical changes that accompany cerebral ischemia include formation of free radicals such as the superoxide anion O_2, and these highly reactive substances may be an important cause of neuronal damage. The purpose of this study was to test the hypotheses that free radical formation does play a role in the ischemic cascade, occurs intracellularly and that free radical scavengers, if taken up intracellularly, will protect from hypoxic damage. A tissue culture model of hypoxia was employed using both PNS (superior cervical ganglia) and CNS (hippocampal) cells. Pretreatment with free superoxide dismutase (SOD) had little effect on neuronal survival after hypoxia as measured by trypan blue exclusion. However, when SOD was taken up intracellularly under depolarizing conditions (55 mMK$^+$ in the medium) survival was increased significantly. During hypoxia, neurons reduced nitroblue tetrazolium to form the blue precipitate formazan, and the color change was blocked in neurons pretreated with SOD in depolarizing medium. Similar findings occurred in both SCG, as well as hippocampal neurons. Free radical formation appears to play a role in cell death caused by hypoxia and free radical scavengers, if taken up intracellularly, may ameliorate their effect.

PATTERN OF CELLULAR LOCALIZATION OF LIPID PEROXIDATION DURING RAT FOREBRAIN REPERFUSION FOLLOWING CARDIAC ARREST. A. Daya, B.C. White, and J.A. Rafols*, Departments of Anatomy and Cell Biology and Emergency Medicine, Wayne St. Univ. Sch. of Med., Detroit, MI 48201.

Following cardiac arrest and resuscitation an in situ reaction of thiobarbituric acid (TBA) and fluorescent microscopy were used to localize post-ischemic peroxidative damage in the rat forebrain. After reperfusion (90 or 240 mins.) the brains were fixed transcardially with 50% aldehyde-free methanol, 10% acetic acid, 2mM EDTA and 0.375% TBA. Formation of TBA-malondialdehyde (fluorescence peak of TBA-MDA adduct = 515 nm) was assessed in serial 40 µm frontal sections. Brains of normal and ischemic-only groups provided the controls. Intense granular fluorescence was found within the cell body of neurons in many of the selectively vulnerable zones (SVZ) after either reperfusion time. Fluorescent granules were disposed primarily in the perinuclear region coincident with the Golgi apparatus, and were absent in glial cells. The dorsolateral sector of the cerebral cortex at rostral levels contained the largest numbers of fluorescent neurons (FNs) which were distributed heterogeneously throughout the layers. Numerous FNs were also found in the pyramidal layer of Cornu Ammonis (CA_1, CA_3 and hilar region) but only a few FNs were detected in the dorsolateral striatum and septal nuclei. The present data indicates that neurons in the SVZ are targets of peroxidation during reperfusion. It further suggests that, within a zone, a time dependent vulnerability during reperfusion may exist among neurons of different morphological and chemical phenotypes. (Supported by NIH grants NS-24819 and GM08167).

Expression of glutathione reductase in ischemia sensitive brain regions.

S.Knollema, H.Hom, J.Korf, M. Ruiters# and G.TerHorst*
Dept. Biological Psychiatry/# Biomedical technology Center, Univ of Groningen, The Netherlands.

Damage as result of hypoxia and/or ischaemia affects the substantia nigra, the hippocampus, striatum and cortex more than other brain regions. The cause of this cell death is unknown but it is likely that free radical generation plays an important role. And although defense mechanisms against these radicals are present in the brain, these may be insufficient to counteract with the large radical generation during ischaemia or other radical generating circumstances as an MPTP injection.

In vitro studies of scavenger enzyme activities in homogenized samples of different brain regions are controversial.In vivo studies, describing expression of these enzymes in the rat brain are also not available. We studied the localization of glutathione reductase which reduces Oxidized glutathione (GSSG) to glutathione (GSH).

The hypoxia sensitive CA1 region in the hippocampus shows a high glutathione reductase appearance compared to the CA2/CA3. Furthermore cells in the zona compacta of the substantia nigra, probably dopaminergic, were labelled. In the SN pars reticulata a strong extracellular labeling was found with only few positive neurons. In the dorsolateral striatum many neurons expressed this enzyme whereas the medial part and the globus pallidus showed faint cellular staining.

This distribution might explain some features found after ischaemia.

ATRIAL NATRIURETIC PEPTIDE BLOCKS PROTEOLYSIS OF THE BLOOD-BRAIN BARRIER BY BACTERIAL COLLAGENASE IN RAT.

G. A. Rosenberg* and E. Estrada. Neurology Service, Veterans Affairs Medical Center, and Departments of Neurology and Physiology, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131

Atrial natriuretic peptide (ANP) is important in regulating brain fluid balance and in the control of brain edema. We have shown in collagenase-induced hemorrhages that brain edema is present by 4 hours and worsens over 24 to 48 hrs before recovery begins; the BBB is opened by 30 min. Therefore, we studied the effect of intravenous or intraperitoneal injection of ANP on edema formation and on the BBB. Adult rats (n=6) had lesions produced in the caudate/putamen by the stereotactic injection of 0.4U of bacterial collagenase in 2µl of saline. Other rats (n=7) had similar collagenase lesions, but had 5µg/kg/hr ANP infused for 24 hrs with an osmotic pump; 24 hrs after the lesions the brains were removed and water and electrolyte contents determined. Another group of rats (n=5) had ANP (50µg/kg/hr) infused intravenously for 90 min beginning 1 hr prior to the lesion; the permeability of the BBB was studied by the intravenous infusion of ^{14}C-sucrose given 10 min before the end of the experiment. Five control rats were similarly studied but without ANP. ANP significantly reduced the percent water at the injection site from 82.39±.24 to 80.55±.35 and the sodium from 402±17 to 309±15 mEq/mg dry wt (p<0.002). The percent uptake of ^{14}C-sucrose from blood into the brain was reduced from 17.3±2. in rats with lesions to 5.1±.4 in rats with ANP (p>0.0004). We conclude that intravenous ANP is effective in reducing brain edema in a hemorrhagic lesion by protecting the capillary from proteolytic damage by bacterial collagenase. ANP may be useful in treatment of brain edema.

526.2

FASTIGIAL STIMULATION ENHANCES EEG RECOVERY AND REDUCES TISSUE DAMAGE AFTER FOCAL ISCHEMIA. F. Zhang and C. Iadecola, Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Stimulation of the cerebellar fastigial nucleus (FN) increases cerebral blood flow (CBF) but not metabolism and reduces the brain damage resulting from focal ischemia (JCBF&M 10:810, 1991). The FN may exert this effect by enhancing CBF to the ischemic tissue without increasing local metabolic demands. To test this hypothesis we studied whether the protective effect is restricted to the neocortex, a region in which the CBF increase is independent of metabolism, and whether stimulation of the dorsal medullary reticular formation (DMRF), a treatment that increases CBF and metabolism, also reduces the brain damage resulting from ischemia. In halothane anesthetized rats (1-3%) the middle cerebral artery (MCA) was occluded proximally or distally to the lenticulostriate branches. FN or DMRF were stimulated (50-100µA; 50Hz; 1 s on/1 s off) for 1 hr. Infarct volume was determined one day later. In unstimulated rats, proximal MCA occlusion (n=7) produced infarcts involving cortex (250±45mm^3) and striatum (57±8) (Mean±SD). Distal MCA occlusion (n=6) produced infarcts restricted to the neocortex (223±28). FN stimulation substantially reduced stroke size (p<0.001). The reduction was greater after distal (-69±8%) than proximal (-38±8%) MCA occlusions (p<0.001) and occurred in neocortex (-43±9; p<0.001) and not in striatum (-16±21; p>0.05). MCA occlusion reduced EEG amplitude in the ischemic cortex by 73±8%. One hr later the EEG recovered by 13% in unstimulated rat and by 48% with FN stimulation (p<0.003). DMRF stimulation (n=7) did not affect stroke size or EEG recovery (p>0.05). Thus stimulation of the FN, but not DMRF, attenuates the functional impairment and tissue damage resulting from cerebral ischemia. The finding that the protection is limited to the neocortex and that the amount of tissue salvaged is greater after distal MCA occlusion suggests that the FN may protect ischemic tissue from infarction by enhancing collateral flow without increasing local metabolic demands. Activation of selected neural networks protects the brain from the consequences of focal cerebral ischemia. (Supported by the American Heart Association of Minnesota).

SPINAL CORD BLOOD FLOW IN RESPONSE TO $PaCO_2$ WITH LASER DOPPLER FLOWMETRY. L. J. Mouw, P. W. Hitchon, R.K. Osenbach, J.C. Torner, and C.M. Loftus* Division of Neurosurgery, Univ. of IA Hosp. and Clinics, Iowa City, IA 52242.

Spinal cord blood flow (SCBF) is affected by numerous physiologic parameters including $PaCO_2$. The authors describe a new technique of measuring SCBF in a rat model using laser doppler flowmetry. Male Wistar rats underwent induction of anesthesia followed by tracheostomy and femoral vessel cannulation. A C7 bilateral laminectomy was performed to expose the dorsal spinal cord. Using a stereotactic frame with intraoperative magnification, a needle-tip fiberoptic probe was placed over the dorsal horn of the cord. Ventilation was adjusted to maintain the $PaCO_2$ ± 3 mmHg at one of three predetermined levels (30, 40, 50). SCBF was averaged over two minutes of continuous monitoring. Segmental SCBF at $PaCO_2$ levels of 30, 40, and 40 mmHg were 58.8, 96.2, and 106.4 cc/100gm/min respectively (P=0.0001). Linear regression revealed that the slope was 2.74 when the $PaCO_2$ changed from 30 mmHg to 50 Hg (P=0.0002). Laser doppler flowmetry is a useful tool in measuring relative changes as well as continuous on-line dynamic monitoring of segmental SCBF in the rat.

LEUKOCYTE BEHAVIOR DURING ACUTE REPERFUSION AFTER GLOBAL CEREBRAL ISCHEMIA IN THE RAT BRAIN CORTEX MICRO-CIRCULATION. G.Sixt, A.Villringer*, U.Dirnagl. Dept. of Neurology, University of Munich, 8000 Munich 70, F.R.G.

We tested the hypothesis that leukocytes (WBCs) are activated within the brain microcirculation by global ischemia, and that obstruction by WBC is responsible for postischemic hypoperfusion. Wistar rats were anesthetized with Inactin, tracheotomized, ventilated, and a closed cranial window was implanted (dura removed). Arterial blood pressure, endexspiratory pCO_2, body temperature, and cortical rCBF (Laser-Doppler flowmetry) were measured continuously. Global cerebral ischemia was induced for 10 min by reversible bilateral common carotid occlusion combined with hypotension. WBCs were labelled intravitally with Rhodamine 6G. WBCs within the microcirculation of the outer 100 µm of the cortex were imaged with confocal laser scanning microscopy. Over the 3 h observation period, in controls (n=5) there was no significant increase of stickers (WBCs adherent to the vessel wall) and rollers (WBCs rolling allong the vessel wall), and no extravasation of WBCs occured. Ischemia induced an increase of venular stickers, in capillaries only few occluding WBCs were seen. No changes were observed in arteries. Extravasation of WBCs was observed in all animals beginning 1.5 hours post ischemia. We conclude that WBCs are activated within the first hours after global cerebral ischemia, however, mechanical obstruction by WBCs may not cause postischemic hypoperfusion.

	Baseline n=5	Hyper n=5	Hypo (20min) n=5	Hypo (1h) n=5	Hypo (2h) n=3	Hypo (3h) n=2

ADHESION AND INFILTRATION OF MONOCYTE/MACROPHAGES IN BLOOD VESSELS OF HYPERTENSIVE RATS Y. Liu, A.-L. Sirén, F. Barone, G. Feuerstein, and J.M. Hallenbeck*. Dept. of Neurology, USUHS, Bethesda, MD 20814, Stroke Branch, NINDS, Bethesda, MD 20892, and Dept. of Pharmacology, SmithKline Beecham, King of Prussia, PA 19406.

The endothelial adhesion of monocytes and expression of the intercellular adhesion molecule-1 (ICAM-1) in the carotid arteries of rats with and without the stroke-risk factor hypertension were demonstrated using the immunohistofluorescence technique. Perfusion-fixed frozen sections (16 μ) of carotid arteries of spontaneously hypertensive rats (SHR), stroke-prone SHR (SHR-SP) and normotensive Wistar-Kyoto (WKY) rats were exposed to specific monoclonal antibodies against rat monocyte/macrophages (ED-1) or rat ICAM-1. All slides were double stained with anti-Factor VIII antibodies for the identification of endothelial cells which showed no ED-1 staining. In SHR and SHR-SP, single monocytes or clusters of monocyte/macrophages were found adhering to the endothelium. In SHR-SP, ED-1 positive cells were present also in a subendothelial location. The number of endothelium-attached monocyte/macrophages per millimeter of internal elastic lamina was significantly greater in SHR-SP than in SHR (5.1 ± 0.7 and 3.2 ± 0.4, $p<0.05$, $n=4$). No ED-1 staining was found around the endothelium in WKY rats. Patchy expression of ICAM-1 on endothelial cells was found in carotid arteries of SHR and SHR-SP, but not in WKY rats. The results suggest that the increased accumulation of monocyte/macrophages and activation of endothelial cells are associated with the stroke-risk factor hypertension increasing the tendency for the endothelium to convert from an anticoagulant to a procoagulant surface.

ATP-SENSITIVE POTASSIUM CHANNELS IN RAT BRAIN MICROVASCULAR ENDOTHELIAL CELLS

Damir Janigro, Ellen L. Gordon & H. Richard Winn*
Dept. of Neurological Surgery, University of Washington, Seattle, WA 98104

The endothelium plays an important role in the modulation of vascular tone and blood cell activation. Extensive work has demonstrated that the release of EDRF from the endothelium is evoked by a number of physical and chemical stimuli requiring Ca^{+2}. Since endothelial cells do not express voltage-dependent calcium channels, calcium influxes following receptor activation may be facilitated by cell hyperpolarizations mediated by the activation of potassium conductances. We have investigated the electrophysiological properties of an ATP-sensitive K^+ conductance in whole cell and membrane patches from rat aorta and brain microvascular endothelial cells. Whole cell as well as patch currents were increased by either intracellular dialysis of ATP or by application of glucose-free/NaCN (2 mM) solutions. Both currents were reversibly blocked by glibenclamide (1-100 μM). The $K_{(ATP)}$ channel opener pinacidil (30 μM) caused activation of an outward current in the presence of physiological $[ATP]_i$. In inside-out patches, ATP (10 μM-1 mM) invariably caused a dramatic decrease in channel activity. We conclude that both rat aorta and brain microvascular endothelial cells express $K_{(ATP)}$ channels. $K_{(ATP)}$ may play a role in the regulation of endothelial cell resting potential during impaired energy supply and therefore modulate EDRF release.

526.7

RESPONSE OF CEREBRAL CAPILLARY ENDOTHELIAL CELLS TO HYPOXIA AND RADIATION. G. T. Gobbel, T. Y. Y. Chan, J. R. Fike, P. H. Chan*. CNS Injury & Brain Edema Res. Center, Dept. Neurol., & Brain Tumor Res. Center, Dept. Neurosurg., Univ. of Calif., San Francisco, CA 94143.

Nitric oxide synthesis inhibitors, such as nitro-L-arginine, and polyamine inhibitors, such as alpha-difluoromethylornithine (DFMO), can inhibit ischemic and/or radiation-induced brain injury. The cellular basis of these effects may be related to inhibition of NMDA receptor activation. We have examined the effect of both radiation and hypoxia on cerebral capillary endothelial cells and modification of that effect by nitro-L-arginine (0.5 mM) and DFMO (1 mM). Cells were isolated from 14 day old Sprague-Dawley rats. At 4-7 days after plating, cells were treated with 24, 48, or 62 hrs of complete hypoxia or a 16, 32, or 64 Gy radiation dose. There was an initial increase in cell injury, as detected by an increase in lactate dehydrogenase (LDH) within the media, at 48 hrs of hypoxia, and the release of lactate dehydrogenase (LDH) intensified with increasing time of hypoxia or increasing radiation dose. The hypoxia-induced LDH release correlated with an increase in the ratio of dead to viable cells (ethidium bromide and fluorescein diacetate staining). While DFMO did not reduce release of LDH due to radiation, it did appear to reduce radiation-induced shedding of endothelial cells from the substrate. Neither DFMO nor nitro-L-arginine seemed to alter hypoxic injury under our experimental conditions. DFMO inhibited a hypoxia-induced increase in total LDH measured within cells attached to the substrate, suggesting that hypoxia either induces an increase in intracellular LDH or stimulates cellular proliferation. These results suggest that activation of NMDA receptors are not involved in hypoxia-induced injury to cultured cerebral endothelial cells. In addition, the modification of radiation-injury by DFMO may be related to a reduced rate of release of damaged endothelial cells and thus maintenance of the endothelial cell layer. Supported by NIH Grants AG 08938, NS-14543, NS-25372, and National Brain Tumor Foundation.

Hypoxia-induced changes in endothelial layer permeability with cultured cells from the middle cerebral artery. K. Takenaka, N.F. Kassell, J.A. Jane*, K.S. Lee Dept. of Neurological Surgery, Univ. of Virginia, Charlottesville, VA 22908.

The effect of hypoxia on endothelial layer permeability was examined in cells cultured from the middle cerebral artery. Permeability was assessed by measuring the passage of [^{14}C] labeled sucrose or albumin across a cellular monolayer seeded onto semipermeable polycarbonate filters. Cultures were placed in an hypoxic chamber for 1 to 18 h. During this time, no gross morphological changes were observed using phase-contrast microscopy. In addition, no increases in lactate dehydrogenase activity were observed in the medium. Permeability of sucrose increased gradually in a time-dependent manner with hypoxia; the rate of sucrose passage after 18 h of hypoxia was 120% of control levels ($p<0.05$). Re-oxygenation after hypoxia enhanced this effect to 200% of control levels. No significant change in the passage of albumin across the cellular monolayer was observed during 18 h of hypoxia. However, after re-oxygenation, albumin permeability was increased to 136% of the control level ($p<0.05$). In contrast, endothelial cells derived from the carotid artery were resistant to such permeability changes after hypoxia. These results suggest that re-oxygenation is an important factor in changing permeability of the intracranial, endothelial layer after hypoxia.

526.9

EFFECTS OF THE CYTOPROTECTIVE AGENT TIRILAZAD MESYLATE (U-74006F) ON THE TIME COURSE OF NEUTROPHIL INFILTRATION IN CEREBRAL ISCHEMIA. J.A. Oostveen* and L.R. Williams, CNS Diseases Res., The Upjohn Co., Kalamazoo, MI.

Using the gerbil unilateral carotid occlusion (UCO) model of transient cerebral ischemia, initial experiments identified a substantial accumulation of cytochrome oxidase (CO) - positive neutrophils (NLs) in the ischemic hemisphere after 24 hrs of reperfusion. The NL accumulation correlated with a severe neuronal death in the CA1 region of the hippocampus (H). Treatment with tirilazad at 10 mg/kg i.p. both immediately before and after the UCO resulted in a significant 64% reduction in NL accumulation, and a significant 25% reduction in the incidence of neuronal death. In the present experiments, animals were collected after 0 to 24 hrs of reperfusion, and frozen coronal sections were stained with CO and cresyl violet histochemistry. The incidence of neuronal death was scored semiquantitatively with a Viability Index (VI) of 0 (no damage) to 4 (complete neuronal loss). After 3 hrs UCO and 2 hrs reperfusion, beginning neuronal death was apparent ($VI = 0.36 \pm 0.10$, $n=11$), but NLs were not observed. After 4 hrs reperfusion, neuronal death was the same ($VI = 0.28 \pm 0.12$, $n=14$), and NLs were observed adherent to the endothelium. At 6 hrs reperfusion, migration of NLs into the parenchyma was extensive, and neuronal death was more advanced ($VI = 0.78 \pm 0.20$, $n=9$). After 6 hrs of reperfusion, tirilazad treatment resulted in an 80% reduction in NL accumulation, and an 85% improvement in the VI ($n=9$). Thus, tirilazad may act directly on the endothelial cell layer to limit peroxidative membrane damage and to limit chemotactic signaling, and may have a direct action on NLs to limit their activation, adhesion, diapedesis, or migration, thus limiting consequent NL-mediated oxidative neuronal destruction.

527.1

EARLY ISCHEMIC INJURY IN THE BASAL GANGLIA: AN IMAGING AND NEUROPATHOLOGICAL STUDY.
R.N. Bryan[1]*, C.A. Pardo[2], L. Monsein[1], V. Mathews[1] and P. Barker[1]. Neuroradiology Div.[1] and Neuropathology Lab[2]. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205.

Early magnetic resonance imaging (MRI) and neuropathological changes were evaluated in a model of regional ischemia in baboons. Models included complete ischemia (CI) and incomplete ischemia with reperfusion (IIR). The earliest changes in basal ganglia (BG) appeared in IIR as detected by MRI (three hours postischemia). Immunocytochemical studies included the analysis of neurofilaments, microtubule-associated protein-2 (MAP2), and calcium-binding proteins (calbindin and parvalbumin). The external portion of the striatum appeared to be the initial focus of necrosis. Loss of patch and matrix organization of striatum was one of the earliest changes, as demonstrated by a disappearance of compartmental distribution of MAP2. The magnitude of ischemic injury in IIR appeared to be more severe than CI. These findings suggest that disruption of neurocytoskeletal organization is an early change during ischemic injury and that reperfusion enhances ischemic damage.

527.2

DIFFUSION/PERFUSION MAGNETIC RESONANCE IMAGING OF CEREBRAL EMBOLISM IN RATS.
M. Tsuura, A.J. de Crespigny and J. Kucharczyk* Department of Radiology, UCSF, San Francisco, CA 94143.

To determine whether an intracerebral distribution of emboli can induce perfusion deficits and ischemic brain injury, diffusion/perfusion magnetic resonance(MR) imaging techniques were employed using a General Electric 4.7 Tesla imager before and after cerebral embolism in rats. Clot emboli made from venous blood which had been drawn 48hours earlier were injected into the right internal carotid arteries of male Sprague-Dawley rats(n=5). Diffusion-weighted spin echo imaging was used to detect early ischemic injuries. Sequential echo planar imaging(EPI)or gradient echo imaging(GRE) was carried out following bolus i.v. injection of the magnetic susceptibility contrast agent, DyDTPA-BMA(0.25mmol/kg), or after one minute apnea during which deoxyhemoglobin provided endogenous contrast. Images were also acquired during clot embolization to localize the intravascular distribution of the emboli.

Images acquired during blood clot injection showed signal loss in the right cerebral hemisphere which corresponded to the distribution of the emboli due to the magnetic susceptibility effect of deoxyhemoglobin. The spatial distribution of signal loss corresponded to perfusion deficits and hyperintense areas on diffusion-weighted images. On perfusion images, images acquired during one minute apnea demonstrated no signal changes in ischemic tissue. In normally perfused tissue there was less signal decrease during apnea in white matter than gray matter. Signal overshoot following rebreathing is also greater in gray matter as apnea-induced hypercapnea produces a greater increase of blood flow. Perfusion deficits in cerebral white matter were more visible on DyDTPA-BMA enhanced EPI or GRE.

MR imaging thus provided excellent in vivo mapping of the distribution of emboli in relation to cerebral perfusion deficits and acute ischemic injury.

527.3

EARLY DETECTION OF EMBOLIC STROKE BY CONTRAST ENHANCED MAGNETIC RESONANCE IMAGING.
K.H.Taber*, S.R. Northrup, J. Kirkpatrick and L.A. Hayman. Departments of Radiology and Pathology, Baylor College of Medicine, Houston, TX 77030.

Sequential magnetic resonance (MR) images were acquired at 2.35 Tesla in rabbits 30 minutes to 6 hours after induction of embolic stroke. The normal evolution on T2 weighted images was a gradual appearance of bright signal, with the area(s) of stroke moderately well delineated by 2-4 hours after onset. Contrast-enhancement with Gd-DTPA resulted in development of extremely bright signal on both T1 and T2 weighted images by 30-60 minutes after administration. This delayed enhancement indicates that the contrast agent is gradually pooling in the stroked tissue. Comparison of the bright areas on the MR images with the areas of stroke as determined by TTC staining indicated that the stroke was accurately portrayed. Thus, contrast administration can be used in this model of stroke to allow earlier identification of the affected area than is possible on non-enhanced MR images.

DIFFUSION MR IMAGING: CORRELATION WITH HISTOPATHOLOGICAL FINDINGS IN EVOLVING STROKE.
C.Pierpaoli, A.Righini, C.Ferrarese, I.Linfante, R.Miletich* and J.R.Alger, G.Di Chiro,
Neuroimaging Branch,(NINDS, NIH) Bethesda MD 20892

Conventional T2 weighted magnetic resonance imaging (T2WI) is able to detect the vasogenic edema developing during cerebral ischemia but is inadequate for the evaluation of the size, severity and location of the lesion within the edematous area. In this study we investigated the ability of diffusion-weighted MRI (DWI), a technique sensitive to the Brownian motion of water molecules, to offer more specific information about the histopathological changes encountered in the evolving and complete stroke.

Focal cortical infarction was induced in rats by transcranial photoactivation of I.V. injected Rose Bengal . Axial T2-weighted and diffusion-weighted spin-echo images were acquired at various times for five days. The images obtained were matched with histological sections stained with Cresyl violet, H&E and triphenyltetrazolium chloride.

DWI was able to identify changes in the injured area as soon as 20 minutes after the induction of the ischemia. Moreover a clear discrimination among the necrotic core, a surrounding rim in which the tissue architecture was still preserved and the peripheral edematous gray matter was observed at 24 hours.

Our data suggest that DWI may be suitable for improving diagnostic capabilities as well as for testing "in vivo" the effectiveness of stroke therapies.

SYMPOSIUM. MOLECULAR BIOLOGY OF OLFACTION.
G.M. Shepherd, Yale (Chairperson); R.R. Reed, Johns Hopkins; L. Buck, Harvard; R. Axel, Columbia; D. Lancet, Weizmann Institute.

The molecular mechanism of odor discrimination has long been a central unsolved problem in sensory neurobiology. The last decade has seen enormous progress, from audacious hypotheses to a profound molecular understanding. These developments have culminated recently in the molecular cloning of candidate olfactory receptor genes. The purpose of this symposium is to convey the excitement generated by this breakthrough, summarize current understanding of the molecular basis of olfaction, and delineate the areas where this new knowledge impacts on the neurosciences.

G.M. Shepherd will provide an overview, correlating the molecular physiology and pharmacology of olfactory transduction with the molecular components of the transduction pathways, and delineating implications of the new studies for neural mechanisms of odor processing. **R.R. Reed** will summarize his studies in cloning and sequencing the G protein, adenylate cyclase, and membrane conductance channel in the sensory transduction pathway in the olfactory sensory neuron. He will describe his current work in identifying new members of the receptor gene family. **L. Buck** will describe the innovative strategy and methodology used in cloning and sequencing the large gene family for the candidate receptor proteins belonging to the 7 transmembrane domain receptor superfamily. She will discuss the complexities of the olfactory receptor repertoire in mammals. **R. Axel** will summarize the extension of his collaboration with Buck to a comprehensive characterization of the molecular and cellular organization of a fully tractable olfactory system in fish. He will discuss the implications of this model for the organization of the peripheral olfactory pathway. **D. Lancet** will delineate mechanisms for olfactory signal modulation: desensitization, possibly by receptor phosphorylation, and termination, by binding proteins, cytochrome P-450s and UDP glucuronosyl transferase. He will also report on genome mapping of human olfactory receptors, with implications for diversity and polymorphisms in human odor recognition.

529

SYMPOSIUM. REGULATION OF NEURONAL PEPTIDE GENE EXPRESSION: LESSONS FROM THE NEUROHYPOPHYSEAL SYSTEM.
C. D. Sladek, Chicago Med. Sch. (Chairperson); E. Mohr, Univ. Hamburg; F. Bloom, Scripps Clin. Res. Found.; F. W. Van Leeuwen, Netherlands Instit. Brain Res.; D.M. Dorsa, Univ. Washington.

The goal of this symposium is to present and discuss several recent and exciting developments in our understanding of the mechanisms involved in neurosecretion. For decades, the neurohypophyseal system has served as a model system for elucidating cellular mechanisms of neurosecretion which have proved, in general, to be applicable to other neuronal systems. **Evita Mohr** will present evidence for transport of endogenous vasopressin (VP) and oxytocin (OT) mRNA from the hypothalamus to the posterior pituitary and discuss the potential functional significance of these mRNAs in the neural lobe. **Floyd Bloom** will discuss the finding that intrahypothalamic microinjection of VP mRNA leads to selective uptake, retrograde transport and expression of VP exclusively in the magnocellular neurons of the Brattleboro rat leading to a temporary reversal of diabetes insipidus for up to 5 days. **Fred Van Leeuwen** will present evidence for VP gene repair in Brattleboro rats, and discuss its impact on the expression of co-localized peptides. **Celia Sladek** will discuss in vitro approaches to studying the regulation of gene expression in the neurohypophyseal system including the role of second messenger systems, and **Daniel Dorsa** will present new information on the regulation of VP gene expression by hormone activated transcription factors. These new findings in the neurohypophyseal system promise to alter our view of the regulation of peptide secretion by neurons in general.

532.1

VALIDATION OF DUAL-DETECTOR PROBE SYSTEM FOR MONITORING HUMAN DOPAMINE D-2 RECEPTOR OCCUPANCY BY HALOPERIDOL IN VIVO K.J. Jeffries*, C.A. Tamminga, D.E. Dubois, R.R. Conley, D.F. Wong, H.L. Loats, E.K. Shaya, L.T. Young, C.J. Gounaris, B.B. Chin, B.C.K. Yung, R.F. Dannals, T.R. Guilarte, and H.N. Wagner University of Maryland, MPRC, Balto., MD 21228, Johns Hopkins Medical Institutes, Balto., MD 21205-2179

A dual detector probe (Bice, A.N., J Nucl Med 27:184-191, 1986) permits positron emission studies of the brain at much reduced radiation dose and cost in comparison to conventional PET. Coincidence counts obtained from the device can be used either directly or in an MRI-registered computer model if measurement of activity within specific regions of the brain is desired. Studies of the correlation between probe measurements and PET region-of-interest (ROI) data in humans have been carried out. In these studies, subjects were scanned with the probe immediately following a PET scan. Multiple studies were performed on each subject in either a haloperidol dose response or withdrawal paradigm. Haloperidol occupancy of dopamine D-2 receptors in the striatum was measured by its blockade of 3-N-[C-11]methylspiperone binding. The ratio of counts from a position directed at the striatum over a position directed at the cerebellum was used for the probe measure of receptor occupancy. The ratio of the patient's PET ROI sample for striatum over cerebellum was extrapolated to the time of the probe scan. Comparison of the probe measurements with the PET measurements in 17 studies demonstrated a linear correlation (r=.93). These data suggest that a simple dual-detector probe system can provide estimates of dopamine receptor occupancy that are useful for drug kinetic studies and reflect ratios obtained by positron emission tomography.

BLOOD VOLUME MEASURE OF BRAIN ACTIVITY DURING VISUAL STIMULATION USING MRI. F.A. Barrios[a], J.R. Zigun[a], J.A. Frank[b,c], K. Vladar*[,a], D.W. Jones[a], G. Sobering[d], C.T. Moonen[d], D.Z. Press[a], D.R. Weinberger[a]. Clinical Brain Disorders Branch, NIMH, Neuroscience Center at St. Elizabeths[a], Washington, DC. 20032. Diagnostic Radiology Research Program, OIR[b]. Diagnostic Radiology Department, CC[c]. Biomedical Engineering Instrumentation Program, NCRR[d] NIH, Bethesda MD 20892.

Advances in ultra fast image acquisition and in the application of contrast susceptibility effects have made it possible to perform dynamic physiological scanning with magnetic resonance imaging (MRI). We studied fourteen subjects during visual activation and during a dark control state. Scans were obtained every 2.05 seconds for two minutes using an unmodified GE SIGNA 1.5T scanner and a Turbo GRASS pulse sequence. Signal potentiation from a surface coil (N=7) and a standard quadrature head coil (N=7) was used. A bolus of Gd DTPA was injected during each condition. Cines produced from the series of rapid scans clearly depict an arterial, parenchymal, and venous phases. A pixel by pixel analysis of serial concentration maps derived from the rapid scans revealed expected cerebral blood volume (CBV) differences between gray and white matter as well as significantly increased CBV in calcarine cortex during visual activation versus control state (average increase of 15.59%, t=2.674, p<0.05 for the surface coil and 20.29%, t=3.495, p<0.05 for head coil).These results confirm earlier findings and demonstrate that dynamic CBV can be assessed with MRI during physiological activation.

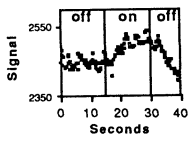
REAL-TIME MAGNETIC RESONANCE IMAGING (MRI) OF BRAIN ACTIVITY IN HUMANS KK Kwong, JW Belliveau, CE Stern, JR Baker, DA Chesler, IE Goldberg, BP Poncelet, DN Kennedy, RM Weisskoff, MS Cohen, R Turner, H-M Cheng, TJ Brady, BR Rosen* MGH-NMR Center, 13th St. Building 149, Charlestown MA 02129 and Harvard Medical School. *RT at NIH NHLBI*

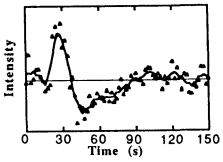
High-speed, noninvasive MRI methods sensitive to changes in cerebral blood flow (CBF) and oxygenation have been used to generate real-time functional MRI maps of human visual and motor cortex activation. Two different techniques, which do not require the injection of contrast agents, were used to study perfusion changes associated with neuronal activity. The first approach is sensitive to changes in blood flow. As regional CBF increases during brain activation, the number of magnetic spins flowing out of an activated volume leads to a shortening of tissue T1, and thus, higher signal in T1 weighted images. In the second approach, signal intensity is inversely proportional to the concentration of deoxyhemoglobin. As CBF exceeds local oxygen consumption, this leads to an increase in venous blood oxygenation and thus higher signal in T2* weighted images. Over 15 subjects underwent dynamic MR imaging using an echo planar imaging (EPI) technique. Changes in blood oxygenation were detected using a gradient echo imaging sequence sensitive to variations in T2* (TR=250-3000 ms, TE=50 ms). Changes related to CBF were evaluated using a spin echo inversion recovery, T1-sensitive pulse sequence (TI=1100 ms, TR=3500 ms, TE=42 ms). Typically, a series of 80-160 images were acquired in under 5 minutes. The figure shows signal intensity changes as a function of time for a region-of-interest within primary visual cortex, during darkness and during 8 Hz visual stimulation. Our non-contrast agent dependent, non-invasive MRI methods can be repeated safely in human subjects, thereby expanding the spatial-temporal window of *in vivo* brain investigation.



532.4

CEREBRAL BLOOD OXYGENATION AND BLOOD FLOW IN HUMAN SUBJECTS: MRI EVIDENCE FOR DECOUPLING DURING FOCAL BRAIN ACTIVITY. CE Stern*, KK Kwong, JR Baker, JW Belliveau, TJ Brady, BR Rosen Harvard Medical School and MGH-NMR Center, Charlestown, MA 02129.

High speed echo planar imaging techniques were used to track MR signal changes which reflect cerebral blood flow (CBF) and cerebral blood oxygenation levels. Gradient echo (GE) imaging sequences were used to track changes in blood oxygenation, while changes reflecting CBF were evaluated using an inversion recovery (IR) technique (for methods see abstract by Kwong *et al.*). Neuronal activity was altered in primary visual cortex using 8 Hz pattern-flash visual stimulation goggles. Activity within primary motor and somatosensory cortex was induced by active finger movements and passive tactile stimulation. In eight normal volunteers, the duration of the visual stimulus was altered repeatedly between 15, 30, 60, and 90 seconds to examine the effect of prolonged neuronal activation on the recovery time course of the MR measurements. During the stimulation period, MR signal intensity rose significantly above baseline on both the CBF and oxygenation sensitive sequences. Following the cessation of stimulation, the GE signal fell below the pre-stimulus baseline (see Figure); whereas, the flow sensitive IR signal did not drop below baseline. The recovery time of the GE signal undershoot ranges between 30 s and 50 s, and does not appear to be sensitive to variations in stimulus duration. The increased GE signal intensity during activation is strong evidence for increased postcapillary blood oxygenation, as the GE signal intensity is sensitive to changes in paramagnetic deoxyhemoglobin. In agreement with previous PET results, the results suggest that during normal neuronal activity, blood flow and oxygenation levels become uncoupled, with CBF far exceeding increases in O_2 utilization. The relatively long recovery time course of the undershoot may reflect increased O_2 extraction as a result of activity induced changes in pH.



532.5

QUANTITATIVE REGISTRATION OF FILM AUTORADIOGRAPHY AND ITS APPLICATION TO 3D ANALYSIS OF CEREBRAL BLOOD FLOW. W. Zhao*, J.Y. Chang, D.W. Smith and M.D. Ginsberg. CVDRC D4-5, Neurology, Univ. of Miami Sch. of Med., P.O. Box 016960, Miami, FL 33101.

Rat models of MCA occlusion are highly useful approximations of ischemia hemispheral infarction in humans. Three-dimensional (3D) representation and calculation of ischemia infarction has long been attracting people's interests. Quantitative registration of serial autoradiographic images can provide detailed 3D information of the entire neural system. We analyzed and compared several existing registration algorithms and applied them to 3D data set of rat brains with MCA occlusion. The principal axes scheme characterized by its efficiency is based on the calculated moments which indicate the centers of mass and the orientations of serial sections. With the cross-correlation method, one image is held fixed, while the second is repositioned by translation to overlay the first in every possible position. The point of maximum cross-correlation provides the necessary information for correction of translational misregister. Since the algorithm repeatedly uses the pixel gray values, it does not require well-defined serial section shapes and is less sensitive to noise. A novel image registration scheme using disparity analysis developed at this center is based on a linear affine model to analyze point-to-point disparities in two images. It is a direct method that estimates scaling, translation and rotation parameters simultaneously with mapping accuracy up to 100 microns. Quantitative comparisons and registered serial rat brain sections using these algorithms are presented. We also demonstrate the 3D shape of ischemia infarction at MCA occlusion studies.

SPECT STUDIES OF COGNITIVE ACTIVATION: INITIAL STUDIES OF A NOVEL DUAL-ISOTOPE TECHNIQUE. D.S. O'Leary*, M.T. Madsen, R. Hurtig, P.T. Kirchner, K. Rezai, M. Rogers, and N.C. Andreasen. Depts. of Psychiatry, Radiology, and Speech Pathology and Audiology, University of Iowa Hospitals and Clinics, Iowa City, IA, 52242.

We report an initial series of human studies using a novel SPECT technique to assess changes in regional cerebral blood flow (RCBF) due to cognitive activation. I^{123}-IMP and Tc^{99m}-HMPAO are administered to the same individual during different tasks. Images of the two tracers can subsequently be separated using a high-energy resolution scanner because the photopeaks of the two radionuclides differ (140 KeV for Tc99m versus 159 KeV for I123). A number of initial control studies were performed with the two tracers administered simultaneously, or at different times, but during performance of the same cognitive task. These studies indicated that the two tracers distribute similarly in the brain under similar physiological conditions. The variability in distribution *in vivo* was similar to that found in phantom studies. In two subjects we then administered HMPAO during an eyes-closed baseline task and IMP during visual checkerboard stimlation. Ratio images comparing baseline to activation condition showed a localized increase in RCBF in the occipital lobe. In two additional subjects we administered HMPAO during an easy baseline task and IMP during a difficult language task involving dichotic listening with directed attention instructions. The ratio images showed hemispheric asymmetry, with increased blood flow to the left temporal lobes while subjects listened for the semantic target. The dual-isotope technique permits analysis of RCBF during two different tasks with absolute anatomical registration of the resulting images. This strategy appears promising for study of localization of cognitive processing in normal subjects and in groups suffering from psychopathological conditions such as schizophrenia.

DECREASED GLUCOSE METABOLISM IN NORMAL AGING. W.J. Jagust, J.L. Eberling, B.C. Richardson*, T.E. Nordahl, N. Kusubov, B.R. Reed. Center for Functional Imaging, Lawrence Berkeley Laboratory, University of California, Berkeley, CA 94720, and University of California, Davis, 95616.

Decreases in both regional cerebral blood flow (rCBF) and regional cerebral metabolic rates for glucose (rCMRglc) reportedly occur in normal aging, although this remains a controversial area. Here we present the results of a PET study of rCMRglc in 6 young (mean age = 27, SD = 4.6) and 8 old (mean age = 66, SD = 5.0) normal control subjects using a high-resolution (2.6 mm in-plane) PET tomograph and ^{18}F-fluorodeoxyglucose (FDG). We scanned three contiguous tomographic levels through the temporal lobes. Previously determined rate constants and an operational equation were used to determine rCMRglc. The rCMRglc values for temporal lobe structures were averaged over the three tomographic levels.

The results of a repeated measures analysis of variance revealed that, while the main effect was not significant ($p>0.05$), there was a significant ($p = 0.0001$) group x region interaction indicating that the pattern of metabolism differed for the two groups. A series of Bonferroni corrected t-tests revealed that the older controls had significantly lower rCMRglc only in the right and left anterior temporal cortex. Decreases in rCBF have also been reported for the temporal cortex in aged controls, and more severe decreases in both rCBF and rCMRglc occur in age-related diseases such as Alzheimer's disease. Thus, the current findings may reflect either a regionally specific rCMRglc decrease that occurs with normal aging, or early indications of cognitive dysfunction that is associated with age-related disorders.

532.8

REGIONAL CEREBRAL BLOOD FLOW (rCBF) AND GLUCOSE METABOLISM (rCMRglc) AT REST AND DURING ACTIVATION IN HEALTHY HUMAN AGING ASSESSED BY POSITRON EMISSION TOMOGRAPHY (PET). P. Pietrini *, B. Horwitz, C.L. Grady, J. Maisog, A.Gonzales-Aviles, E. De Micheli, S.I. Rapoport, M.B. Schapiro. Lab. of Neurosciences, Natl. Inst. on Aging, Bethesda MD 20892.

To understand the effects of age on rCBF and rCMRglc, we studied two groups of healthy men (6 young: mean age 24 ± 2 yr, range 22-26; 5 older: 65 ± 5 yr, range 60-74) using PET with [15-O]-water and [18F]FDG. In the same scanning session, subjects were studied under two experimental conditions (EC), at rest (ears/eyes covered; minimal room noise) and during sensory activation (SA) (watching a documentary film), using a Scanditronix PC-2048-15B (FWHM 6mm) PET scanner, and a double FDG injection procedure (Brooks et al., J Nucl Med 28: 53, 1987; Chang et al., J Nucl Med 28: 852, 1987), which allows two sequential FDG injections. rCBF and rCMRglc values were measured in absolute units of ml/100g/min and mg/100g/min, respectively. To reduce inter-subject variability, data were "normalized" to mean sensorimotor rCBF and rCMRglc values, respectively. Effects of age, EC, and age*EC were analyzed by ANOVA. Significant increases of absolute and normalized rCBF and rCMRglc values were found during SA bilaterally in the occipital regions in both age groups. Significant age and age*task effects were shown by frontal regions: at rest, rCBF and rCMRglc were higher in the young than in the old; SA induced increases in the young and decreases in the old, so that difference between the two groups became greater during SA. Coupling between rCBF and rCMRglc was present in both age groups and was stronger during SA. Although the meaning of the differential effects induced by SA on rCBF and rCMRglc in the frontal areas in young and old subjects is not clear and needs to be further investigated in a larger sample, these results suggest that rCBF and rCMRglc undergo more age-related changes in frontal than in other brain regions, and support brain activation as an ideal condition to enhance differences in brain metabolism between young and old subjects.

532.9

IN VIVO METABOLIC ABNORMALITIES OF THE FRONTAL LOBE IN AUTISM

N.J. Minshew, G. Goldstein, K. Panchalingam, S.M. Dombrowski, and J.W. Pettegrew*. Western Psychiatric Institute and Clinic, Univ. of Pgh. Med. Ctr., Pittsburgh, PA 15213.

Recent neurophysiologic and neuropsychologic studies in autism have implicated the cerebral cortex including the frontal lobes in the pathophysiology of this disorder. In this pilot study, the high-energy phosphate and membrane phospholipid metabolism of the brain were examined in the dorsal prefrontal cortex of 11 high functioning autistic adolescent and young adult males and 11 age, sex, IQ, race, and SES matched normal controls using *in vivo* ^{31}P NMR spectroscopy. When compared to the normal control group, the autistic group had decreased levels of phosphocreatine ($p<0.04$) and α-ATP ($p<0.02$). The levels of the high energy phosphate and membrane phospholipid metabolites were then compared within each subject group with IQ, and selected scores from tests of reasoning ability, secondary memory, and pragmatic-semantic language comprehension. Across clinical indices, a common pattern of clinical-metabolic correlations emerged in the autistic group. As test performance declined, the levels of the labile high energy compounds and of the membrane building blocks decreased, and the levels of the membrane breakdown products increased. Significant correlations were not observed in the control subjects. These data provide preliminary evidence of alterations in brain high energy phosphate and membrane phospholipid metabolism in the frontal lobes in autism which correlate with the clinical deficits. The findings suggest a hypermetabolic energy state and hypometabolism of brain membranes. The increase in phosphocreatine utilization is consistent with PET findings and may reflect less efficient pathways for processing information. The alterations in membrane phospholipid metabolism may be related to the truncation in dendritic tree development which has been observed in histoanatomic studies of autism.

DIFFERENT VULNERABILITY OF HIPPOCAMPAL GABA, PARVALBUMIN AND CALBINDIN IMMUNOREACTIVE NEURONS TO NEONATAL ANOXIA IN RATS. M.E.Dell'Anna, M.Molinari, M.Magarelli, M.C.Geloso, M.L.Rodrigo-Angulo*. Experimental Neurology Lab., Inst. of Neurology, Catholic University, Rome (Italy).

In adulthood, anoxic lesions of the hippocampus primarily affect GABAergic neurons while calcium binding proteins (CBPs) containing neurons are relatively spared. It has been recently demonstrated that neonatal anoxia induces a permanent cell reduction in the CA1 sector of the hippocampus (Dell'Anna et al.,Behav. Brain Res, 1991,45,125-134). The neurochemical characterization of this neuronal loss is still largely unknown. The present study was aimed at investigating the effects of neonatal anoxia on the development of the immunoreactivity (IR) for GABA or for the CBPs parvalbumin (PV) and 28 kd-calbindin (CB) in the hippocampus. Anoxia was induced by exposing rats at 30 hours after birth to nitrogen 100% for 25 minutes. Adjacent sagittal 40 um sections, obtained from animals sacrified at P7, P21, P30, P45 and P60, were processed for GABA, PV or CB according to the ABC-peroxidase immunohistochemistry. Animals exposed to neonatal anoxia, when compared with age-matched controls, showed a highly significant reduction of the number of GABA-IR neurons in CA1, CA2, CA3 sectors and in GD of the dorsal hippocampus at all the stages of life analyzed. Significant effects of neonatal anoxia on PV-IR neurons were evident only at P7 and P21 in CA1 and CA3, while no differences between the two experimental groups were observed at the P30 and P60 analyses. CB-IR neurons were significantly reduced in anoxic rats, with respect to the controls, at P7, P21 and P60 in CA1, CA2 and CA3 sectors, while no statistically significant differences between the two groups were evident at P30 and P45. In spite of the effects of neonatal anoxia on the number of neurons IR for GABA, PV or CB, the postnatal pattern of development of these antigens was similar in the two experimental groups. During postnatal development of both anoxic and control rats GABA-IR did not show significant modifications; PV-IR presented a progressive increment from P7 to P60, while CB-IR had a more variegated pattern with a decrement from P7 to P21 and a subsequentnt increment from P30 to P60. The present data demonstrate that, contrarily to that described after adult anoxia, neonatal anoxia induces permanent reduction of the number of GABA and CB-IR hippocampal neurons while it affects only temporarily the PV-IR neuron density.

IMMUNOHISTOCHEMICAL OBSERVATIONS ON GABAERGIC NEURONS FOLLOWING CARDIAC ARREST CEREBRAL ISHEMIA. K. Kawai, C. Ruetzler, L. Nitecka, J. Lohr, and I. Klatzo*. Stroke Branch, NINDS, NIH, Bethesda, MD 20892

Description of characteristic, early changes affecting predominantly GABAergic neurons (J. CBF&Metab. 12: 238-249, 1992), prompted the present study concerned with evaluation of changes in parvalbumin (PV) and glutamate decarboxylase (GAD), both proteins related to the GABA neurotransmitter. Observations with application of specific antibodies to these compounds revealed a marked reduction of both PV and GAD immunoreactivity in the neurons of the n. reticularis thalami (NRT), at 1 hr-interval following ischemia,Staining with GAD at that time also showed an intense immunoreactivity of enlarged and seemingly degenerating terminals and boutons in the ventral thalamic nuclei, medial geniculate, inferior colliculus and other structures. During the first week after ischemic insult, the GABAergic terminals and boutons in these areas appeared inconspicuous or absent. After 2 weeks, there was an indication of the regeneration and sprouting of new terminals, especially conspicuous in the ventral thalamic nuclei. Our study confirms early reactivity of GABAergic system following global ischemia, which may secondarily affect non-GABAergic neurons in various locations connected by GABAergic circuitry. Also, our study demonstrates a postischemic attempt at regeneration as shown by sprouting of presumably GABAergic terminals.

533.3

GLUTAMATE RELEASE INDUCED BY OXYGEN/GLUCOSE DEPRIVATION IN CORTICAL CELL CULTURES. D. Lobner* and D.W. Choi. Dept. of Neurology, Washington Univ. School of Med., St. Louis, MO 63110.

Murine cortical cell cultures, containing both neurons and glia, exposed to combined oxygen-glucose deprivation for 45-75 min developed acute neuronal swelling, and widespread neuronal degeneration by the next day. At termination of oxygen-glucose deprivation, an increase in bathing medium glutamate could be detected by HPLC using phenylisothiocyanate derivatization and UV detection: typically the glutamate concentration in the extracellular medium increased from about 200 nM to 2-3 μM. Assuming the glutamate originated from neurons (about 180,000 neurons per 16 mm well containing 375 μL medium), this would correspond to the release of 2.3 X 10^9 molecules of glutamate per neuron. Distributed in available neuronal cell body volume (mean neuronal cell body radius 7.8 microns), a concentration of 2 mM would result. Most likely, much of this glutamate originates from presynaptic terminals where original glutamate concentrations may be much higher. Both the increase in extracellular glutamate and neuronal death were attenuated by addition of 10 μM N6-cyclohexyladenosine, an A1-adenosine receptor agonist, or 100 μM Di-(o-tolyl)guanidine, to the cultures during the oxygen-glucose deprivation, consistent with the idea that the increase in extracellular glutamate is related to observed neuronal injury. While the measured increase may be too small to cause excitotoxic injury itself, higher glutamate concentrations may build up local to synaptic release sites.

533.4

EFFLUX OF (3H)-D-ASPARTATE FROM RAT HIPPOCAMPAL SLICES DURING IN VITRO ISCHEMIA IS NOT BLOCKED BY THE NA-COUPLED CARRIER INHIBITOR, DIHYDROKAINATE. V. Roettger* and P. Lipton. Dept. of Physiol., Univ. of Wisconsin, Madison, WI 53706.

Excess release of glutamate (GLU) very probably contributes to ischemic brain damage. The mechanism of ischemia-induced release is unknown but one widely suggested possibility is reversal of the Na-coupled high-affinity glutamate transporter. We examined this hypothesis using the transporter substrate (3H)-D-aspartate (ASP) and the transporter inhibitor dihydrokainate (DHK). 500 μM DHK completely blocked Na-coupled uptake of ASP.

Slices were loaded with ASP, then exposed to in vitro ischemia (IVI, 0-glucose/N_2 equilibrated buffer/37°C) for 3 successive 5 minute periods. ATP fell to <5% within 5 minutes. ASP efflux increased x1, x2.5, and x3.6 in the three periods. These increases were unaffected by 20 min. pre-incubation in 0-Ca buffer. 500 μM DHK did not affect ASP efflux during control period or during IVI.

50 μM veratridine increased ASP efflux by x1, x1.7, and x2.3 during 3 successive 5 minute periods. DHK completely blocked this increase, showing DHK very probably blocks ASP release when it occurs via reversal of the coupled transporter. Thus, Ca-independent GLU release during ischemia does not appear to occur via reversal of the Na-coupled transporter. Release of 3H-leucine from slices is not increased by IVI, indicating release does not result from membrane "leakiness". Other mechanisms are being investigated.

533.5

SODIUM REGULATES ANOXIA-INDUCED INTRACELLULAR CALCIUM CHANGES IN CA1 HIPPOCAMPAL NEURONS. J.E. Friedman* and G.G. Haddad, Dept. Pediatrics, Section of Respiratory Medicine, Yale Univ. Sch. of Med., New Haven, CT 06510

Anoxia is believed to induce neuronal damage by causing a sustained increase in Ca_i^{2+}, possibly via glutamate excitotoxicity. Using freshly dissociated adult rat hippocampal CA1 neurons, fluo-3 and confocal microscopy, we have previously shown that anoxia causes a rapid (within 2 min) increase in Ca_i^{2+} accompanied by swelling, but that this increase is not glutamate mediated. In addition, neuronal injury does not have to be accompanied by an increase in Ca_i^{2+}. To further understand the mechanisms underlying swelling and injury, we focused on the role of Na_o^+. Upon replacing Na_o^+ with N-Methyl-D-Glucamine (NMDG), Ca_i^{2+} increased, but anoxia caused a sharp decrease to below baseline level. Neurons remained morphologically intact, without swelling, for up to 90 minutes after anoxia. Adding Na^+ at any time after reoxygenation resulted in immediate swelling and injury. Addition of Bepridil (10μM), a Na^+/Ca^{2+} exchange blocker, caused this same sequence of events to occur as with NMDG, although the neurons did eventually swell following anoxia. EIPA (10μM), a Na^+/H^+ exchange blocker, had no effect. The Na^+-channel blocker TTX (9μM) did not affect baseline fluorescence, but caused a rapid decline in Ca_i^{2+} after an anoxia-induced transient rise. We conclude that 1) the increase in Ca_i^{2+} that occurs with anoxia is Na^+-dependent; 2) anoxia-induced neuronal swelling is caused by Na^+ entry and removal of Na_o^+ can protect against anoxia-induced injury; 3) to a great extent Na^+ does not enter through voltage-sensitive Na^+ channels and 4) possible reoxygenation injury requires the presence of Na_o^+.

533.6

REGIONAL DISTRIBUTION AND PHARMACOLOGICAL MODULATION OF BDNF mRNA EXPRESSION IN THE RAT BRAIN FOLLOWING THE PHOTOCHEMICAL STROKE. M.C. Comelli, M.S. Seren*, R. Canella, D. Guidolin and H. Manev. FIDIA Research Laboratories, 35031 Abano Terme, Italy

In order to understand the molecular mechanisms involved in degeneration and survival of neurons following an ischemic insult, we studied the expression of the brain-derived neurotrophic factor (BDNF) mRNA in the photochemical model of unilateral cortical stroke in rat (Ann. Neurol. 17: 497, 1985). We followed: 1) the time course (2,4,18 hrs after stroke) of expression of BDNF and NGF mRNAs by quantitative in situ hybridization; 2) the involvement of different glutamate receptors in BDNF mRNA regulation by pretreating the rats with MK 801, a non-competitive N-methyl-D-aspartate (NMDA)-sensitive glutamate receptor antagonist, or with 1S,3R-ACPD, a metabotropic glutamate receptor agonist (i.c.v.); 3) the effect of the neuroprotective drug GM1 (ganglioside which antagonizes glutamate excitotoxicity) on the expression of BDNF. The BDNF but not the NGF mRNA content increased and peaked in the ipsilateral cortex at 4 hours after the stroke (no changes were observed contralaterally at any time studied). MK 801 diminished the BDNF mRNA upregulation, thus indicating that most of the BDNF mRNA expression is related to the NMDA sensitive glutamate receptor activation. Both the 1S,3R-ACPD and GM1 pretreatment potentiated the BDNF mRNA upregulation consequent to the stroke.

533.7

RAPID RECOVERY OF INTRACELLULAR pH DURING RESUSCITATION FROM CARDIAC ARREST IN RATS. J.C. LaManna*, J.K. Griffith, B.R. Cordisco, C.-W. Lin, H.N. Ferimer, H.M. Kabert, K.L. Kutina and W.D. Lust. Dept. Neurology, Case Western Reserve Univ. Sch. of Med., Cleveland, OH 44106.

Brain intracellular pH (pHi) falls dramatically during the total cerebral ischemia that occurs during cardiac arrest. The level of acidosis depends upon the pre-arrest plasma glucose level and the amount of lactate accumulated during the arrest. Because hyperglycemia at the time of ischemia has been associated with poor recovery, tissue acidosis has been proposed as being responsible for tissue damage due to ischemia. The purpose of this study was to determine the time course of pHi and tissue lactate recovery and to find out if they are correlated in the postischemic recovery period.

Reversible cardiac arrest was produced in male Wistar rats (200-300g) by KCl administration, followed after 5-7 min by resuscitation by chest compression and mechanical ventilation. The pHi was determined in frozen rat brains by histophotometry of neutral red before cardiac arrest, at the end of the 7-10 min ischemic duration, and at 5, 15 and 60 minutes after succesful resuscitation. Control brain cortical pHi was 7.13 ± 0.06 (SE, n=3). During ischemia, pHi fell below 6.5 and then returned to control values within 5 min of resuscitation (7.15 ± 0.03, n= 3) and remained constant thereafter. This also occurred in rats made hyperglycemic before arrest. In both groups brain lactate levels after 5 min of resuscitation remained at ischemic levels. Reversal of acidosis was delayed by treatment with inhibitors of Na+/H+ exchange transport.

In conclusion, reversal of brain intracellular acidosis after resuscitation from cardiac arrest is rapid, and thus postischemic acidosis can play no continued role in tissue damage.

533.8

EXCITATORY AMINO ACIDS STIMULATE NEURONAL LACTATE PRODUCTION. S.H. Graham* and R.A. Swanson. Neurology Dept., U. California and VAMC, San Francisco, CA 94121.

It is well known that lactic acidosis occurs during stroke and may injure glia. Excitatory amino acids do not kill glia, yet N-methly-D-apartate (NMDA) antagonists prevent the death of glia in stroke. The effect of EAAs upon lactic acid production was studied in primary rat cortical cultures. Experiments were performed in pure neuronal cultures at day 11-13 after they developed NMDA sensitivity and at day 24-31 in astrocyte cultures. Medium lactic acid was measured by an enzyme-linked flurometric assay. Glutamate increased lactate production in pure neuronal cultures in a dose dependent manner from 57±11 in controls to 449±40 nmole/mg protein/hr at 1mM. NMDA had similar effects, but 100mM K+ increased lactate formation to only 160±11 nmole/mg protein/hr. Glutamate induced lactate formation was partially inhibited by MK801 and calcium free medium. Glutamate had no effect in astrocyte culture, but 100mM K+ doubled lactate production. These results suggest that EAAs could increase lactic acid formation in brain by two mechanisms: 1) by direct effects on neurons, and 2) by depolarizing neurons resulting in K+ release and increased glial lactate production. Since lactic acidosis may selectively injure glia, inhibition of EAA induced lactic acid production could explain why NMDA antagonists spare glia as well as neurons in stroke.

533.9

GLUCOCORTICOID PREVENTION OF HYPOXIC-ISCHEMIC DAMAGE: ROLE OF HYPERGYLCEMIA AND OXIDATIVE ENZYMES. U.I. Tuor*C.S. Simone, R. Arellano, K. Tanswell and M. Post. Neonatology, Hosp. for Sick Children and University of Toronto, M5G 1X8, Toronto, Canada.

Pre-treatment of neonatal rats with dexamethasone prevents brain damage associated with hypoxia-ischemia (unilateral carotid occlusion + 3hr hypoxia) (Ped Res 29:558-63, 1991). We presently investigate whether hyperglycemia or an induction of endogenous free radical scavengers explains dexamethasone's neuroprotective effect.

Pathological damage was examined in rats maintained hyperglycemic during hypoxia-ischemia by the administration of 10% dextrose (.1ml,ip) at 0, 1, 2 and 3 hr of hypoxia (n=14) and compared to that in control (n=15) or dexamethasone (.1 mg/kg ip, n=15) treated animals. Despite similar elevations in blood glucose at the end of hypoxia, dextrose treated animals had greater damage than dexamethasone treated animals and both of these groups had less damage than controls (volumes of damage of approx. 32.3±9.5, 3.1±2.2, 59±7.2 % ipsilaterally, respectively; $p<0.0001$).

Antioxidant enzymes were measured within brains of animals treated with dexamethasone or vehicle (n=44). Cerebral concentrations of catalase, glutathione peroxidase and CuZn or Mn superoxide dismutase were similar in both treatment groups, with or without exposure to hypoxia-ischemia.

Thus, the relative hyperglycemia associated with dexamethasone treatment may partially contribute to the protective effect of dexamethasone. However, an additional glucocorticoid mediated effect other than hyperglycemia or a change in antioxidant enzyme activity must also be involved in dexamethasone's prevention of hypoxic-ischemic damage. (Supported by the Heart and Stroke Fndn of Ont (T2065) and MRC (PG-42).

DEXAMETHASONE POTENTIATES HEAT SHOCK PROTEIN 72 INDUCTION IN PRIMARY ASTROCYTE CULTURES.
**S.C. Zhang, R.A. Swanson, F.R. Sharp and S.M. Sagar*
Dept. of Neurology, Univ. of California and VAMC, San Francisco, CA 94121.**

Hsp 72, one of the 70 kDa family of heat shock proteins, was induced in primary rat astrocyte cultures subjected to heating to 44°C for 40 minutes. Pretreatment with dexamethasone, 10^{-9} to 10^{-5}M increased hsp72 expression in the heated astrocytes with its peak effect at 10^{-7}M. Other steroids (cholesterol, estradiol, progesterone and aldosterone) had little effect. RU486, a glucocorticoid receptor antagonist, blocked the effect of dexamethasone. Heat shock decreased protein synthesis, as measured by incorporation of [^{35}S]-methionine into perchloric acid precipitable material; and this effect was antagonized by dexamethasone but not by the other steroids. These results suggest that dexamethasone potentiates the heat shock response in astrocytes by acting through the glucocorticoid receptor. The functional significance of this effect is being investigated.

PHOTOCHEMICALLY INDUCED CORTICAL LESIONS CHANGE THE IONOTROPIC GLUTAMATE RECEPTOR EXPRESSION PATTERN. D.M. Armstrong*, A.N. Kharlamov, D. Grayson, L. Marlier, R.J. Wenthold, E. Costa, A. Guidotti. FGIN, Georgetown Univ. Med. School, Washington, D.C. 20007 & (RJW) NIH, Bethesda, MD 20892.

The neuronal damage surrounding the primary foci of brain ischemia is in part mediated by the persistent stimulation of ionotropic glutamate receptors. It is therefore conceivable that the expression of these receptors may be modified in the process. In the photochemical rodent model (Watson B.D. et al., Ann. Neurol. 17:497-504, 1985) we studied whether there was a change in ionotropic glutamate receptor expression in the focal and perifocal areas. The ionotropic glutamate receptor subunits were visualized immunocytochemically using antibodies directed against GluR1, GluR2/3 or GluR4 or by in situ hybridization using cRNA probes that detect mRNA's for GluR1 and GluR2 and their alternatively spliced forms. In control brains the various antibodies and the two RNA probes yielded very unique cytological and topographical profiles. Following focal ischemia and in an area immediately surrounding the foci of the lesion (i.e., perifocal area) GluR1 and GluR2/3 immunolabeled cells were dramatically reduced in number and in staining intensity as early as 6 hours post-lesion. A similar rapid decrease was also observed for GluR1 and GluR2 mRNA. Importantly, in this perifocal area the relatively early decrease in the expression of glutamate receptor subunit proteins and message expression probably precedes any neuronal loss. In fact, these neurons still maintain the ability to respond to a glutamate induced event as demonstrated by the increased expression of c-fos mRNA and FOS. In contrast, GluR4 immunoreactivity was not reduced but rather in several instances displayed elevated levels which correspond both temporally and topographically with the rise in vimentin-positive and glial fibrillary acid protein-labeled elements both within the perifocal area and throughout the ipsilateral cortex. Importantly, the perifocal area is a region in which profound cellular reorganization occurs and is a key region to target various neuroprotective drugs.

ALTERATIONS IN THE DISTRIBUTION OF CYTOSKELETAL PROTEINS FOLLOWING TRANSIENT CEREBRAL ISCHEMIA. L.C. Pettigrew*, C. Schwab, S. Craddock, and J.W. Geddes. Stroke Program, Sanders-Brown Center on Aging and Dept. Anatomy & Neurobiology, Univ. Kentucky, Lexington, KY 40536.

The rat 4-vessel occlusion model of transient cerebral ischemia results in the loss of hilar neurons within a few hours and a delayed loss of CA1 pyramidal neurons. The purpose of this study was to determine whether alterations in the localization of cytoskeletal proteins precede neuronal death. We examined the distribution and levels of several cytoskeletal proteins (tau, MAP1, MAP2, MAP5, ß-tubulin and neurofilaments) at various reperfusion times (30 min, 2h, 6h, 24h and 72h) following 20 min of ischemia. Thirty min following reperfusion, a loss of tau immunoreactivity was evident in the inner 1/3 of the dentate gyrus molecular layer (DGML) and tau staining was increased in DG granule cells and in non-neuronal cells. By 6h the staining pattern in the granule and non-neuronal cells was similar to controls. At 24h, there was an accumulation of tau in the soma and proximal dendrites of CA1 and subicular neurons. By 72h, tau staining was normal except for the inner DGML and the necrotic CA1 neurons. In contrast to tau, the axonal distribution of phosphorylated neurofilaments was not altered following ischemia and reperfusion. With dendritic markers such as MAP2, a loss of staining was evident in CA3c 30 min following reperfusion. At 2h and 6h, the staining was similar to controls but at 24h there was a loss of MAP2 in the dendrites of CA1 and subicular neurons. At 72h, MAP2 had recovered except in necrotic CA1 neurons. The results demonstrate that alterations in the distribution of microtubule-associated proteins precede neuronal death in vulnerable neurons but that similar alterations occur, and are reversible, in other neuronal populations.

CARDIOVASCULAR REGULATION II

534.1

THE 10-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE IS GENERATED BY A SYSTEM OF COUPLED NONLINEAR OSCILLATORS. S. Zhong*, Z.-S. Huang, G.L. Gebber, and S.M. Barman. Dept. Pharmacol. & Toxicol., Michigan State Univ., East Lansing, MI 48824.

We previously reported that the interval between the coherent discharges of different postganglionic sympathetic nerves can be frequency dependent in the 8- to 12-Hz band. In the current study we consider the possibility that the frequency-dependent interval is a property of a system of weakly coupled nonlinear oscillators. This model was tested by forcing the central system responsible for the 10-Hz rhythm in sympathetic nerve discharge (SND) with single or repetitive electrical stimuli applied to sympathoexcitatory sites in the medullary lateral tegmental field (LTF) or sympathoinhibitory sites in the medullary raphe. Recordings were made simultaneously from the postganglionic inferior cardiac, vertebral, and renal nerves of baroreceptor-denervated, decerebrate cats. Single shocks applied to the LTF or raphe reset the 10-Hz rhythm in SND whereas periodic stimulation at frequencies between 8 and 12 Hz entrained the rhythm (phase locking ratio of one). Lower frequencies (<6 Hz) of medullary stimulation entrained the 10-Hz rhythm in SND to a harmonic of the stimulus frequency. Most importantly, the preferred phase locking ratio of 10-Hz bursts of SND to each stimulus for one postganglionic nerve could be different than that for a second nerve when the stimulus frequency was <6 Hz. On the basis of these observations, we propose that the circuits responsible for the 10-Hz rhythms in SND may be modelled as a system of coupled nonlinear oscillators, each of which either influences one postganglionic nerve or nonuniformly affects different postganglionic nerves. (Supported by NIH grants HL-13187 and HL-33266.)

534.2

ARE THE DISCHARGES OF INDIVIDUAL ROSTRAL VENTROLATERAL MEDULLARY (RVLM) AND CAUDAL MEDULLARY RAPHE NEURONS CORRELATED TO BOTH THE 10-HZ AND 2-to 6-HZ RHYTHMS IN SYMPATHETIC NERVE DISCHARGE? S.M. Barman* and G.L. Gebber. Dept. Pharmacol. & Toxicol., Michigan State Univ., East Lansing, MI 48824.

We have used spike-triggered averaging of sympathetic nerve discharge (SND) to identify RVLM and caudal medullary raphe neurons with activity correlated to the 10-Hz rhythm in SND of decerebrate cats and to the 2- to 6-Hz rhythm in SND of anesthetized cats, but no one has yet determined if the discharges of individual medullary neurons are correlated to both rhythms. In many baroreceptor-denervated, decerebrate cats SND contains a mixture of 10-Hz and 2- to 6-Hz rhythms. In 13 such experiments we constructed spike-triggered averages of inferior cardiac SND that was selectively filtered with a low-pass setting of 6 Hz or a bandpass of 8 to 14 Hz. This allowed us to test for a relationship between medullary unit activity and each rhythm independently. We identified six raphe and two RVLM neurons with activity correlated to both rhythms in SND. Spike-triggered averaging revealed that the discharges of 17 other neurons (seven RVLM and 10 raphe) were correlated to the 10-Hz but not to the 2- to 6-Hz rhythm in SND. We also recorded from four RVLM neurons with activity correlated to the 2- to 6-Hz but not to the 10-Hz rhythm in SND. Since the discharges of ~38% of the raphe and 15% of the RVLM neurons were correlated to both the 10-Hz and 2- to 6-Hz rhythms in SND, to some extent the networks responsible for these rhythms used a common pool of medullary neurons. There was more convergence from the sources of the two rhythms onto raphe neurons than onto RVLM neurons. The significance of this finding remains to be determined. It is also not known whether RVLM and raphe neurons with activity correlated to only one of the rhythms in SND would have developed a discharge pattern correlated to the other rhythm under different experimental conditions. (Supported by NIH grants HL-33266 and HL-13187.)

534.3

THE 2- TO 6-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE (SND) IS AN EMERGENT PROPERTY OF A BRAINSTEM NETWORK COMPOSED OF NONRHYTHMICALLY ACTIVE NEURONS. G.L. Gebber*, Z.-S. Huang, S. Zhong, and S.M. Barman. Dept. Pharmacol. & Toxicol., Michigan State Univ., East Lansing, MI 48824.

Individual medullary neurons with activity correlated to the 2- to 6-Hz rhythm in SND of baroreceptor-denervated cats have firing rates that generally are lower than the frequency of the rhythm recorded from postganglionic nerves. These neurons miss firing in a variable number of cycles of SND. Thus the rhythm in SND is not strictly represented in the spike trains of single medullary neurons. This suggests that each cycle of SND reflects synchronization of the discharges of a small and continuously changing subset of the neurons comprising the brainstem network responsible for this rhythm. We tested this hypothesis by determining whether the 2- to 6- Hz rhythm appears in population recordings (i.e., field potentials) made from the rostral ventrolateral medulla (n=6), medullary raphe (n=5), and lateral tegmental field (n=1). Autospectral analysis revealed peaks in the 2- to 6-Hz band of activity recorded from these brainstem sites and the inferior cardiac and renal sympathetic nerves. The shapes of the autospectra of brainstem activity and SND were indistinguishable. Coherence analysis demonstrated that the rhythms in brainstem activity and SND were significantly correlated. Peak coherence values were as high as 0.56. Cervical spinal cord transection reduced inferior cardiac and renal SND to 12±4 and 11±4% of control, respectively, and eliminated the coherence of brainstem activity to SND. In contrast, spinal cord transection only modestly reduced the power in brainstem population activity to 85±2% of control. Most importantly, the shape of the autospectrum of brainstem activity was unchanged. We conclude that the 2- to 6-Hz rhythm in SND arises from a network of brainstem neurons whose discharges are probabilistically related to the phases of the population rhythm. (Supported by NIH grants HL-13187 and HL-33266.)

534.4

ROLE OF THE SPINAL CORD (SC) IN GENERATING THE 2-6 Hz PEAK IN THE POWER SPECTRUM OF RAT SYMPATHETIC DISCHARGE (SND). A.M. Allen*, J.M. Adams and P.G. Guyenet. Depts. of Pharmacology and Biomedical Engineering, Univ. of Virginia, Charlottesville, VA 22908.

The existence of a 2-6 Hz "rhythm" in SND, and the fact that the discharge of various types of medullary neurons is statistically correlated with this rhythm, have fueled arguments against the pacemaker theory of SND generation. The latter states that the basal SND largely arises from the intrinsic pacemaker discharges of excitatory premotor neurons located in the rostral ventrolateral medulla (RVL PMNs). The main objection to the theory is that the discharge rate of these cells (5-35 Hz) is much faster than the peak frequency of the SND "rhythm" in rats (3-4 Hz). This objection rests on the assumption that the discharge rate and/or pattern of RVL PMNs is critical to the generation of the 2-6 Hz "rhythm". The following data (in debuffered, urethan-anesthetized rats) suggests this assumption may be invalid. SND synchronization was determined by measuring the fractional power contained in the 2-8 Hz band of 0-50 Hz power spectra derived from bipolar recordings of lumbar SND (0.3-1000 Hz recordings). Unilateral microinjection of muscimol ($GABA_A$ agonist), or bilateral injection of a mixture of kynurenic acid (KYN, EAA receptor antagonist) and bicuculline ($GABA_A$ receptor antagonist), into RVL, produced little effect on the 2-6 Hz rhythm. Intrathecal injections of KYN, at mid-thoracic levels slightly reduced the 2-6 Hz peak but SC transection at C_2 had no effect, after SND had been restored close to control level by intrathecal injections of kainic acid (EAA receptor agonist). We conclude that i) the firing rate and pattern of the RVL input to the SC is not critical for production of a 2-6 Hz peak in SND power spectra, ii) in the rat this synchronization may be essentially of SC origin and iii) the existence of a 2-6 Hz rhythm of SND does not constitute an objection to the pacemaker theory of SND generation. DIRECT PROJECTIONS FROM A VASODEPRESSOR AREA IN THE GIGANTOCELLULAR RETICULAR NUCLEUS ONTO NEURONS IN THE THORACIC SPINAL CORD. S.A. Aicher*, D.J. Reis and T.A. Milner. Dept.of Neurol. & Neurosci., Cornell Univ. Med. College, NY, NY 10021.

We have recently identified a vasodepressor area within the ventral and caudal region of the medullary reticular nucleus gigantocellularis, the gigantocellular depressor area (**GIDA**), that is topographically distinct from other vasoactive sites in the medullary reticular formation (Aicher & Reis, Neurosci. Abstracts, 1991). We sought to determine if efferents from the GiDA project to the intermediolateral cell column (IML) and lamina VII of the thoracic spinal cord and to characterize their synaptic relations with neurons in these areas. The anterograde tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L) was iontophoresed into the GiDA of rats. In some cases, the GiDA was identified as a vasodepressor site by microinjection of glutamate into the site prior to the PHA-L iontophoresis. Ten days later, rats were anesthetized and perfused with acrolein and paraformaldehyde. Sections of the thoracic spinal cord (T2) were processed for immunocytochemical localization of PHA-L. The injection sites were located and verified as being confined to the GiDA. PHA-L labelled punctate fibers were seen in the medial aspect of the IML and throughout lamina VII. Electron microscopic analysis of the IML and lamina VII in these cases showed that PHA-L immunoreactivity was seen in myelinated and unmyelinated axons, as well as terminals (0.3 - 0.8 μm diameter). PHA-L labelled terminals contained small, clear vesicles and formed symmetric synaptic contacts primarily on large and small dendrites of neurons in the IML and lamina VII. These data demonstrate that neurons of the GiDA project directly to autonomic laminae of the thoracic spinal cord. Moreover, the present results indicate that this may be a direct and novel medullospinal sympathoinhibitory pathway. (Support: NIH #HL08251 & #HL18974).

BAROSENSORY NEURONS IN THE CAUDAL VENTROLATERAL MEDULLA MONOSYNAPTICALLY PROJECT ONTO BULBOSPINAL NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA. I. Jeske*, D.J. Reis and T.A. Milner. Div. of Neurobiology, Dept. of Neurology & Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021.

Neurons of caudal ventrolateral medulla (CVL) may function as interneurons in the baroreceptor reflex arc by inhibiting sympathoexcitatory bulbospinal neurons in rostral ventrolateral medulla (RVL). While some CVL neurons are excited orthodromically by baroreceptors and antidromically from RVL (Jeske et al., *Am. J. Physiol.*, 1992, in press), evidence is lacking that these neurons monosynaptically innervate bulbospinal neurons of RVL. We sought to establish a direct CVL-RVL bulbospinal synapse. The CVL was explored in 10 anesthetized rats with microelectrodes containing biocytin (BCT). Six neurons excited by elevating arterial pressure and with cardiac-related activity met criteria of barosensory interneurons. BCT was iontophoresed into the CVL site, while gold-conjugated wheat-germ agglutinated apo-horseradish peroxidase (WAHG) was injected into the spinal (T3) intermediolateral cell column. After 18-24 h, sections of RVL were processed for both markers. By light microscopy, numerous BCT-labeled varicose processes overlapped RVL neurons containing WAHG. Ultrastructurally, the BCT-labeled terminals were large (0.6-1.2 μm in diameter) and contained small clear vesicles. These formed symmetric (inhibitory) synapses on somata and large dendrites within the RVL, many containing WAHG (associated with lysosomes). The results indicate: (a) barosensory sympathoinhibitory neurons in the CVL terminate on bulbospinal neurons in the RVL; (b) the synaptic profile is consistent with an inhibitory interaction, possibly GABAergic. The findings demonstrate a direct CVL-RVL projection supporting the hypothesis that the CVL is an intermediate relay in the baroreceptor reflex arc. (Supported by HL 18974 & HL 08326)

534.7

ACTIVATION OF Ca^{2+} CURRENTS IN RETICULOSPINAL PACEMAKER NEURONS OF RAT ROSTRAL VENTROLATERAL MEDULLA BY CYANIDE AND HYPOXIA: ARE THEY CENTRAL OXYGEN SENSORS? M.-K. Sun* and D.J. Reis. Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021.

Reticulospinal sympathoexcitatory (pacemaker) neurons of rostral ventrolateral medulla (RVL) are rapidly excited (<2 sec) *in vivo* by systemic hypoxia or by cyanide (CN) applied by microinjection and/or ionophoresis (Sun et al., *Am. J. Physiol.* 262:R182, 1992). It is not known whether hypoxia/CN directly excite RVL neurons and if so by what cellular mechanism. Electrophysiological studies were conducted in slices of rat medulla maintained in an interface-type chamber at 31°C. Pacemaker neurons were spontaneously active. Hypoxia (75% N_2, 5% CO_2, 40s) or CN (30-300 μM, 40s application) rapidly and substantially increased their activity. The activity of adjacent neurons was unaffected or reduced. The excitatory response to CN was dose-dependent, reversible and reproducible at 10 min intervals. It was characterized by membrane depolarization (21.4±4.2 mV with 300 μM CN) and a decrease in membrane resistance (38.2±4.1 M ohm at 300 μM CN). The response persisted in the presence of tetrodotoxin (TTX, 10 μM), which eliminated evoked and spontaneous action potentials indicating that hypoxic excitation was not a consequence of synaptic excitation. Under single electrode voltage clamp, CN evoked an inward current (peak: 0.58±0.08 nA) which was voltage-dependent and transient at membrane potentials between -70 and -40 mV (when stepped from -100 mV). The current was abolished by 2 mM $CoCl_2$ or 100 μM $NiCl_2$, but not 50 μM $CdCl_2$. The results are consistent with a view that RVL pacemaker neurons are excited by hypoxia by increasing low voltage-activated calcium channel conductance. RVL neurons may, like glomus cells of carotid body, act as oxygen sensors. They may be responsible for initiating the sympathetic excitation associated with cerebral ischemia.

534.8

ELECTROPHYSIOLOGICAL IDENTIFICATION OF DEPRESSOR NEURONS IN THE CAUDAL VENTROLATERAL MEDULLA WITH PROJECTIONS TO ROSTRAL VENTROLATERAL MEDULLA IN THE RABBIT. W.W. Blessing* and Z.I. Gieroba. Centre for Neuroscience, Flinders University, Bedford Park, SA 5042, Australia.

The caudal ventrolateral medulla oblongata (CVLM) contains depressor neurons whose activity tonically inhibits sympathetic vasomotor tone, probably by inhibiting sympathoexcitatory neurons in the rostral ventrolateral medulla (RVLM). In urethane-anesthetized rabbits (1.5 g/kg, i.v.) we recorded extracellularly from CVLM neurons identified by antidromic activation from RVLM and examined their responses to changes in blood pressure and electrical stimulation of the aortic depressor nerve. Peristimulus time histograms were constructed using an ITC16 interface and a Macintosh IIfx computer programmed with IGOR. We identified 134 spontaneously active neurons in the CVLM with projection to or through the RVLM. Twenty nine of 107 neurons tested (27%) were activated by increase in blood pressure, 60% were inhibited and 13% were unaffected. Injection of noradrenaline increased discharge rate of 29 neurons from 1.7 ± 0.3 spikes/s to 6.5 ± 1 spikes/s. Electrical stimulation of the ipsilateral aortic depressor nerve (3 pulses, 200 Hz, 0.5 ms) activated these neurons (latency 55 ± 4 ms, conduction velocity 0.6 m/s). Neurons excited by an increase in blood pressure were located in the previously defined caudal vasodepressor region and also as far rostrally as 0.5 mm rostral to the obex. These neurons may form part of the central inhibitory link in the baroreceptor-vasomotor pathway. Other neurons may be inhibitory vasomotor cells with functions independent of baroreceptor inputs or they may be A1 catecholamine neurons with axons passing through the RVLM.

534.9

CONNECTIONS BETWEEN PONTINE RETICULAR FORMATION AND ROSTRAL VENTROLATERAL MEDULLA IN CARDIOVASCULAR CONTROL. A.V. Krassioukov* and L.C. Weaver. The John P. Robarts Research Institute and Dept. of Physiology, Univ. of Western Ontario, London, Ontario, Canada N6A 5K8

A previous study in our laboratory established that the pontine reticular formation (PRF) is involved in the neural control of circulation (Hayes and Weaver. Neurosci. Abst.17: 706,1991). The connections between PRF and the well-known rostral ventrolateral medulla (RVLM) are undefined. To determine these connections we investigated responses of renal sympathetic nerve activity (RSNA), arterial pressure (AP) and heart rate (HR) to microinjection of the inhibitory amino acid glycine (1.0M, 60nl) into the PRF before and after unilateral or bilateral injection of the synaptic blocking agent cobalt (4.0mM, 200nl) into the RVLM in propofol-anesthetized rats (n=19). Glycine injection into the PRF caused decreases in AP (-20±2 mmHg), HR (-7±1 bpm) and RSNA (-38±4%). Following microinjection of Co^{++} into the ipsilateral RVLM, responses to PRF blockade were significantly decreased: AP (-9±3 mmHg), HR (-4±0 bpm), RSNA (-6±2%). In contrast, injections of Co^{++} into the RVLM contralateral to the site of PRF blockade did not affect responses to this PRF blockade. Responses to PRF blockade after bilateral injection of Co^{++} into RVLM were similar to responses after unilateral injection of Co^{++}. Somato-sympathetic reflexes elicited in the renal nerve by electrical stimulation of the sciatic nerve were significantly inhibited after unilateral injection of Co^{++} into the RVLM and, after bilateral injection, they were abolished. The Co^{++} injections had no effect on basal firing of the sympathetic nerve or on arterial pressure or heart rate. These results suggest that the PRF influences on RSNA are relayed ipsilaterally from pons to RVLM to influence spinal sympathetic neurons. Supported by the Ontario Heart and Stroke Foundation.

534.10

ACTIVITY OF NEURONS IN THE PONTINE RETICULAR FORMATION PROVIDES TONIC EXCITATORY DRIVE TO NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA IN RATS. K. Hayes* and L.C. Weaver. The John P. Robarts Research Institute and Department of Physiology, University of Western Ontario, London, Ontario, Canada.

Recent studies have shown that neurons located in the pontine reticular formation (PRF) make an important contribution to ongoing activity of sympathetic nerves. To determine if the PRF is a source of tonic activity for sympathoexcitatory neurons in the rostral ventrolateral medulla (RVLM), discharge of PRF neurons was inhibited by unilateral microinjections of glycine (1.0M;50nl) while recording spontaneous discharge of neurons in the RVLM in 14 Saffan-anesthetized rats. Each RVLM unit was characterized by means of three tests. Units that displayed spontaneous activity inhibited by baroreceptor activation and synchronized to the cardiac cycle were regarded as "cardiovascular" neurons. RVLM neuronal spike-triggered averages of renal sympathetic nerve discharge were also constructed to determine temporal correlation of unit activity to sympathetic activity. Spontaneous activity was recorded from 15 cardiovascular neurons in the RVLM. Glycine injection into the ipsilateral PRF silenced the spontaneous activity of 10 cardiovascular units. Activity of these units returned to control discharge rate after 53±6s. Glycine injection had no effect on the discharge of 5 cardiovascular units. Spontaneous activity of 6 control units was not changed by baroreceptor activation and was not synchronized to the cardiac cycle. PRF blockade had no effect on the spontaneous activity of these control units. Glycine injection into the PRF caused decreases in arterial pressure (-28±5mmHg), heart rate (-23±3bpm) and renal nerve activity (-43±9%) that also returned to control in 50±6s. These results indicate that PRF neurons provide significant tonic excitatory drive to some cardiovascular neurons located in the RVLM. (Support: Ontario Heart & Stroke Foundation).

534.11

EFFECTS OF KAINIC ACID MICROINJECTIONS IN THE LATERAL TEGMENTAL FIELD ON THE SYMPATHOLYTIC ACTION OF 8-OH-DPAT M.E. Clement* and R.B. McCall, Cardiovascular Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

Sympathetically related neurons have recently been identified in the lateral tegmental field (LTF). A sub-population of these, the sympathoexcitatory (LTF-SE) neurons, have been shown to project to and provide an excitatory input to the rostral ventrolateral medulla. We have demonstrated that these LTF-SE neurons are inhibited by i.v. 8-OH-DPAT and iontophoretic 8-OH-DPAT and 5-HT. On the other hand, i.v. 8-OH-DPAT increased the firing rate of sympathoinhibitory neurons in the LTF (LTF-SI). LTF-SI units were insensitive to iontophoretic 8-OH-DPAT but were excited by iontophoretic 5-HT. The present experiments were designed to investigate the effects of kainic acid microinjections into the LTF on the sympatholytic effects of 8-OH-DPAT. Kainic acid has been reported to destroy cell bodies while leaving fibers of passage intact. Bilateral microinjections of kainic acid resulted in slight (6% ± 5.5 %) increases in MAP, negligible alterations in HR, and a 20% ± 16% increase in CNA. The maximum dose of 8-OH-DPAT caused a 19% decrease in MAP, an 8% decrease in HR, and a 26% increase in CNA (n = 14). Cardiac nerve activity could subsequently be inhibited by administration of clonidine. These values differed significantly from control animals in which 8-OH-DPAT reduced CNA and MAP 95% and 40% respectively. Histological examination of microinjection sites revealed the extent of diffusion of kainic acid to range from 300 to 500 microns from the point of injection, with diffusion being slightly greater along the dorso-ventral axis. These results indicate that the sympathetically related neurons in the LTF play an important role in the sympatholytic action of 8-OH-DPAT, and suggest disparate central sites for the action of 8-OH-DPAT and clonidine.

CARDIOVASCULAR PROJECTIONS FROM THE AMYGDALA (AMG) TO THE BED NUCLEUS OF THE STRIA TERMINALIS (BST). S. Roder* and J. Ciriello, Dept. of Physiology, Univ. of Western Ontario, Canada, N6A 5C1.

Two series of experiments were done to investigate the possibility that the depressor responses elicited by electrical stimulation of AMG were mediated via projections to BST. In the first series, to determine whether AMG neurons innervate the cardiovascular region of BST, projections to BST from different subnuclei within AMG were investigated in the rat using the retrograde tracer Fluorogold (FG; 2%) and the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L; 2.5%). FG (50-100nl) injections overlapping the cardiovascular region of BST resulted in retrogradely labelled neurons throughout the AMG. Iontophoretic PHA-L injections in the central nucleus of the AMG (ACe) and basolateral nucleus of the AMG (ABL) resulted in dense fiber and presumptive terminal labelling within the cardiovascular region of BST. In the second series, the effect of blocking synaptic transmission in BST with $CoCl_2$ or chemical lesions of BST with ibotenic acid (5ug/ul) on the depressor response elicited by stimulating AMG was investigated in the chloralose anesthetized, artificially ventilated and paralyzed rat. Five mM microinjections (200nl) of $CoCl_2$ into BST significantly reduced (41.2±7.3%) the depressor response during stimulation of ACe. On the other hand, the depressor response to stimulation of ABL was significantly potentiated (57.0±16%) after $CoCl_2$ injections into BST. Microinjections of ibotenic acid (200nl) into BST resulted in similar affects on the depressor responses to AMG stimulation. Taken together, these results suggest that AMG neurons innervate neurons in cardiovascular regions of BST and that these BST neurons are a component of the neuronal circuit that mediate cardiovascular responses elicited during stimulation of AMG. (Supported by MRC and HSFO).

CALCIUM CHANNEL MODULATION

535.1

TWO VOLTAGE INDEPENDENT CALCIUM CHANNELS ARE ACTIVATED BY PERTUSSIS TOXIN IN PC12 CELLS. S.A. Scott* and J.A. Strong, Dept. of Biol. Sci., Purdue University., W. Lafayette, IN 47907.

Voltage independent calcium channels have been described in a variety of cell types. This broad class of Ca^{++} channels includes channels that are regulated by either extracellular or intracellular ligands. We have observed two novel voltage-independent Ca^{++} channels with different slope conductances (3pS and 16pS using 20mM Ca^{++} as the charge carrier) in undifferentiated PC12 cells. We found that these channels open rarely during cell-attached recordings. The 3pS channel was activated by patch excision into a defined K-aspartate EGTA solution (n=13). Channel activity could be observed even at very negative potentials (eg. -110 mV). However, if the cells were pretreated with pertussis toxin (8-10 hours), both the small conductance Ca^{++} channel and the larger conductance Ca^{++} channel were active even in the cell-attached configuration (n=10). Like the 3pS channel, the 16pS channel also was seen over a wide range of potentials. Activity of both channels was observed at the cells' resting membrane potential. The effect of pertussis toxin suggests that these channels are normally under the control of a GTP-binding protein. The 3pS channel maybe similar to the pertussis toxin activated Ca^{++} channel reported by Ceña *et al* [1] in bovine chromaffin cells. Preliminary results suggest that bradykinin (10uM) also activates the smaller conductance channel (n=3) via an intracellular pathway. This suggests that this channel maybe responsible for the sustained Ca^{++} infux seen in cells treated with bradykinin. A physiological activator of the 16pS channel has yet to be found .

SUBSTANCE P INHIBITS Ca^{2+} CURRENTS IN RAT SYMPATHETIC NEURONS VIA A PERTUSSIS TOXIN-INSENSITIVE G-PROTEIN. M. S. Shapiro and B. Hille*. Dept. Physiology and Biophysics, Univ. Washington, Seattle, WA 98195.

We studied inhibition of N-type Ca^{2+} channels in adult rat superior cervical ganglion (SCG) neurons by substance P (SP) using the patch clamp. In whole-cell configuration with external 5 mM Ca^{2+}, 70 of 82 acutely dissociated SCG cells showed inhibition by 500 nM SP. Peak currents elicited by 12 ms voltage steps to 0 mV were reduced by 37 ±2% (mean±SE). Treatment of overnight SCG cultures with 500 ng/ml pertussis toxin (PTX) had no effect on SP inhibition compared to treatment with 500 ng/ml heat-inactivated PTX (59±7%, n=8 *vs.* 60±8%, n=7). Dialysis with 2 mM GDP-β-S for >7 min. reduced SP inhibition (to 16±3%, n=12 *vs.* 33±5%, n=12), implicating G-proteins. Inhibition measured by tail currents to -60 mV following voltage steps to 0 mV (38±6%) and 120 mV (38±5%) was not voltage dependent, and current activation was not slowed or biphasic, indicating a mechanism other than a "reluctant-willing" type. Exposure of cells to 1 μM neurokinin A (n=10) or 1 μM neurokinin B (13 of 14 cells) was without effect, suggesting NK_1 but not NK_2 or NK_3 subtypes of tachykinin receptors. Intracellular Ca^{2+} levels seem unimportant since SP inhibition with 0.1 mM BAPTA in the pipette (48±8%, n=9) was only slightly greater than with 20 mM BAPTA (33±5%, n=9). Cell-attached patches with SP applied to the bath were used to test for a diffusible messenger. With 120 mM $BaCl_2$ in the pipette and 150 KCH_3SO_4, 0 Ca in the bath, only 1 of 12 cells showed inhibition of currents in the patch upon addition of 500 nM SP. We conclude that the SP signaling pathway is BAPTA insensitive, membrane delimited and may operate by direct action of a PTX-insensitive G-protein on Ca^{2+} channels in SCG neurons.

MU-OPIOID-RECEPTOR-MEDIATED REDUCTION OF N-TYPE NEURONAL CALCIUM CURRENT OCCURS VIA A Go-TYPE GTP-BINDING PROTEIN. H.C. Moises* and R.L. Macdonald#, Dept. of Physiology and #Neurology, Univ. of Michigan, Ann Arbor, MI 48109.

Mu-opioid receptor activation can decrease calcium currents in sensory neurons of the dorsal root ganglion (DRG) in rat (Schroeder et al.1991) and in the SH-SY5Y human neuroblastoma cell line (Seward et al., 1991), and in the latter case a pertussis-toxin (PTX) sensitive G-protein was shown to be involved. In this study, we sought to determine whether a PTX sensitive G-protein also mediates the inhibitory coupling between mu-opioid receptors and calcium channels in rat sensory neurons, and if so to identify the specific subtype (Gi or Go) involved. We recorded whole cell calcium currents from acutely dissociated DRG neurons from 19-25 d rats, using Ca^{++} (5mM) as charge carrier. The effects of puffer application of the mu-selective agoinst PLO17 (300-3000 nM in the pipet) were examined on low-threshold transient (T-type) and high-threshold inactivating (N-type) and sustained (L-type) current components, isolated on the basis of their voltage dependency of inactivation and sensitivity to ω-conotoxin (ω-CTX, 1μM). PLO17 selectively reduced high threshold ω-CTX sensitive inactivating currents, whereas T-type and L-type currents were largely unaffected. The effects of PLO17 (1 μM) were blocked by naloxone (10-300 nM) and by ß-FNA (10 μM), but not by nor-BNI (10-50 μM), a kappa specific antagonist. The inhibition by PLO17 was irreversible in cells dialysed with GTPγS and was blocked by pretreatment with PTX. Moreover, intracellular application of antibodies specific for Go_α markedly attenuated the response to PLO17, whereas cells injected with antibodies for $Gi1_\alpha$/$Gi2_\alpha$ responded normally. These data indicate that Go is involved in coupling mu-opioid receptors to calcium channels in DRG neurons. (DA03365 and DA04122)

DYNORPHIN A-MEDIATED REDUCTION OF CALCIUM CURRENTS IN RAT DORSAL ROOT GANGLION NEURONS IS ANTAGONIZED BY ANTI-$G_{O\alpha}$ ANTISERUM. J.W. Wiley*, R.A. Gross#, H. Moises, & R.L. Macdonald, #University of Minnesota, Minneapolis, MN. & University of Michigan, Ann Arbor, MI. 48109

Kappa opioid receptors are important regulators of neural function. Previous studies suggested that dynorphin A(Dyn)-mediated activation of the kappa opioid receptors was associated with a reduction in calcium current via a pertussis toxin-sensitive (G_i/G_O-type) G-protein. The goal of this study was to examine the selectivity of the kappa receptor- G-protein coupling mechanism. Calcium currents were recorded in media that blocked Na^+ and K^+ currents in acutely dissociated postnatal rat dorsal root ganglion (DRG) neurons using the whole cell version of the patch clamp technique. Selected sera and antisera were included in the internal medium allowing diffusion into the cell after patch rupture. Intracellular delivery of sera was confirmed using a fluorescein-tagged IgG.

DRG neurons demonstrated at least three voltage-gated calcium currents, transient low-threshold (T-type), transient high-threshold (N-type) and slowly inactivating high-threshold (L-type) components. Dyn (3 μM) reduced the peak and slowed activation of the N-type current. Dyn's inhibitory action was antagonized by a selective anti-$G_{O\alpha}$ antiserum in a concentration-dependent manner but was unaffected by either nonimmune serum or a selective anti-Gi_α antiserum. We conclude that kappa receptor-mediated reduction of a transient high-threshold calcium current in rat DRG neurons involves selective coupling via the G_O subtype of G-proteins.

ETHANOL SUPRESSES NEURONAL CALCIUM CURRENTS BY G-PROTEIN ACTIVATION. A. HERMANN*, E. LAHNSTEINER and H. KERSCHBAUM. University of Salzburg, Dept. of Physiology, 34, A-5020 Salzburg, Austria.

Recent research indicates that voltage- and ligand gated ion channels are involved in the action of ethanol. In mollusc neurons calcium currents are suppressed by ethanol (CAMACHO-NASI and TREISTMAN, 1987), its mechanism of action is not understood, however. To study the action of ethanol in more detail we have used neurons in the central nervous system of the snail, Helix pomatia. Voltage clamp experiments show that ethanol (0.5-1%) suppresses calcium currents in a time- and voltage dependent manner. Intracellular buffering of calcium using BAPTA abolished the ethanol effects. Employing confocal laser microscopy imaging techniques revealed that ethanol at low doses does not alter the intracellular calcium concentration. GTP-γ-S injection also suppressed the calcium current whereas GDP-ß-S was ineffective. Staurosporin completely abolished the ethanol effects on calcium currents. Phorbol ester (OAG) also decreased the calcium current, addition of ethanol after a maximum effect was obtained was ineffective. A block of ethanol effects by staurosporin and phorbol ester (PdBu) have recently also been found in hippocampal slice preparations (LAHNSTEINER et al., 1992). Addition of ethanol, after application of dopamin which also reduces calcium currents, had no further suppressing effect. Employment of cAMP activators (8-Br-cAMP, bt-cAMP) decreased the peak calcium current as well as its time course of inactivation; application of ethanol further decreased calcium currents. The results taken together suggest that the suppression of calcium currents by ethanol is caused by activating a G-protein - protein kinase C transduction pathway.

Facilitation of Ca Current in Bovine Adrenal Chromaffin Cells May be Due to Voltage-Dependent Phosphorylation

Cristina R. Artalejo+, Philip C. Hoffman+*, Sandra Rossie‡, Robert L. Perlman+, Aaron P. Fox+, +The University of Chicago, ‡Purdue University

Calcium currents in chromaffin cells exhibit facilitation; currents during test depolarizations are greatly potentiated by large pre-depolarizations or by repetitive depolarizations in the physiological range. Facilitation of the Ca current was also recruited by the activation of protein kinase A (PKA), in response to D_1 dopamine receptor agonists or to cAMP analogues. Thus, phosphorylation of the facilitation channel itself or a regulatory protein can play a role in facilitation. We have now investigated the role of phosphorylation in the recruitment of Ca currents by pre-pulses or repetitive depolarizations. Recruitment of facilitation by pre-pulses was a rapid ($\tau \sim 30$ ms) first order process. Activation of G-proteins was not required for recruitment of facilitation by pre-pulses. Broad spectrum protein kinase inhibitors such as H-7 or K252a inhibited the recruitment of facilitation by pre-pulses or repetitive depolarizations. PKA was not involved in the recruitment of facilitation by voltage. After recruitment by a pre-pulse to +120 mV, facilitation was normally transient, lasting ~60 s; in the presence of the phosphatase inhibitor okadaic acid, however, facilitation became irreversible. Substitution of ATPγS for ATP in the pipette solution also greatly prolonged facilitation. Further, recruitment of facilitation was slowed with ATPγS present in the pipette. Intracellular injections of the catalytic subunit of phosphatase 2A inhibited the recruitment of facilitation by pre-pulses. Taken together, these results indicate that recruitment of facilitation Ca currents in bovine chromaffin cells by pre-pulses or repetitive depolarizations involves the voltage-dependent phosphorylation of the facilitation Ca channel or a closely associated regulatory protein; voltage-dependent phosphorylation may represent a novel mechanism for modulating ion channel activity.

ENHANCEMENT OF NEURONAL N- AND L-TYPE Ca^{2+} CHANNEL ACTIVITY BY PROTEIN KINASE C. J. Yang & R. W. Tsien*. Dept. of Mol. & Cell. Physiol., Stanford Univ., Stanford, CA 94305

We studied effects of phorbol esters on Ca^{2+} channel activity in frog sympathetic neurons. High-voltage activated Ba^{2+} currents in whole-cell recordings were consistently augmented (27 ± 3%, mean ± s.e.m., n=12) by 1 μM phorbol dibutyrate (PDBu), a stimulator of PKC. The inactive congener 4-α-phorbol produced no such increase (-3 ± 3%, n=10). The PDBu-induced enhancement was blocked by the inclusion of the PKC-blocking peptide PKC(19-31) in the pipette (internal) solution (5 ± 4%, n=4), or staurosporin in both the external and internal solutions (-12 ± 2%, n=6). These observations indicate that Ca^{2+} channel activity can be increased via stimulation of PKC.

Enhancement by PDBu was not caused by removal of tonic G-protein inhibition since it was observed in cells dialyzed with 2 mM GDP-ß-S (35%, n=2). N-type current (defined as resistant to 10 μM nimodipine but susceptible to inhibition by ω-CgTx or norepinephrine) was increased by 31 ± 5% (n=7); L-type current (resistant to 3 μM ω-CgTx but susceptible to block by nimodipine) was also enhanced (31 ± 14%, n=5). Moreover, PDBu augmented L-type tail currents made prominent by Bay K 8644 in the presence of ω-CgTx.

Dramatic increases in unitary N- and L-type channel activity were seen in cell-attached patches following application of PDBu to the bulk of the cell. In most recordings, the control activity was of the low open probability (p_o) mode. PDBu did not affect the unitary current size or mean open time but increased p_o several-fold by sharply decreasing closed time intervals between adjacent openings. Enhancement of Ca^{2+} channel activity by PKC may be important for various neuronal functions such as synaptic plasticity and development.

535.8

PHORBOL ESTERS ENHANCE N-TYPE CA CHANNEL CURRENT AND REDUCE ITS SUPPRESSION BY THE METABOTROPIC GLUTAMATE RECEPTOR

K.J. Swartz* and B.P. Bean, Dept.Neurobiol., Harvard Med.Sch.,Boston,MA

We studied the actions of phorbol esters on Ca channels in rat CA3 pyramidal and superior sympathetic neurons using whole-cell patch clamp recordings. Phorbol-12-myristate-13-acetate (PMA; 500 nM) had two actions on CA3 neurons. First, high-voltage activated Ca channel current was enhanced (29 ± 3 % at -10 mV; 12 cells). Enhancement typically began within 10 seconds of PMA application and reached steady-state within ~ 1-3 min.. In most cells the enhancement was larger for small depolarizations; in one CA3 neuron enhancement was 49 % at -20 mV, 31 % at 0 mV, 20 % at +20 mV and 12 % at +40 mV. Second, the ability of metabotropic glutamate receptor agonists to modulate Ca channel current is greatly reduced after application of PMA; 1S,3R-ACPD suppressed Ca channel current by 22 ± 4 % prior to, and 2 ± 0.4 % following, PMA application. Both of these actions were blocked by including PKC 19-36 in the pipette (10 cells). Neither of these effects were seen after similar application of 4-α-PMA (6 cells). In 10 control cells 10 μM ω-CgTx-(GVIA) blocked 17.4 ± 1.3 pA/pF of current while in 9 cells where PMA was applied 10 μM ω-CgTx-(GVIA) blocked 27.7 ± 1.9 pA/pF of current. In CA3 neurons 10 μM ω-CgTx-(MVIIC) reversibly blocked 10 μM ω-CgTx-(GVIA) sensitive current; block by 10 μM ω-CgTx-(GVIA) occluded further block by 10 μM ω-CgTx-(MVIIC). In 4 cells 10 μM ω-CgTx-(MVIIC) blocked 17.2 ± 2.4 pA/pF of current prior to, and 32.1 ± 2.4 pA/pF of current following, PMA application. In contrast 10 μM nimodipine blocked 12.6 ± 2.5 pA/pF of current prior to PMA and 10.2 ± 2.1 pA/pF of current following PMA. PMA also enhanced Ca channel current in rat sympathetic neurons (25 ± 2.7 %; n=9). Experiments with blockers in sympathetic neurons confirm the notion that PMA stimulates N-type Ca channels.

Metabotropic glutamate receptor stimulation increases calcium currents in rat cerebellar granule cells. J.L. Bossu, L. Fagni, J.M. Nooney, J. Bockaert and A. Feltz*, Neurobiologie Cellulaire, 5 rue Blaise Pascal, F-67087 Strasbourg, Pharmacologie, rue de la Cardonille, F-34094 Montpellier.

Stimulation of metabotropic glutamate (Qp) receptors on cerebellar granule cells in culture increases IP3 and, subsequently, internal [Ca^{2+}] with a rise of Ca-dependent K^+ channel activity (Fagni *et al.* (1991) Eur. J. Neurosci.,3, 778-789). The latter effect is sensitive to external [Ca^{2+}] which suggests that Qp receptor stimulation may promote Ca influx. The effect of t-ACPD, a selective Qp agonist, on Ca whole-cell and channel activity were studied on granule cells maintained in elevated K^+ culture media for 5-14 days.

10^{-4} M t-ACPD increases both macroscopic and unitary Ba currents in a percentage of cells. Both activities are sensitive to dihydropyridines. Application of t-ACPD to the cell body during cell-attached recordings indicate that a second messenger pathway is involved. t-ACPD increases single channel activity following pre-treatment of the cells with the membrane permeable Ca chelator BAPTA-AM (50 μM for 30 min). Moreover 100 μM thapsigargin does not mimic the action of t-ACPD on Ca channels. Both observations suggest that intracellular Ca^{2+} is not the second messenger.

ENKEPHALIN INDUCES TWO DISTINCT MODULATORY EFFECTS ON CALCIUM CURRENTS IN ADULT RAT SENSORY NEURONS

A.Formenti* E.Arrigoni D.Venturoli and M.Mancia. Inst. of Human Physiology II, University of Milan, I-20133 Milan, ITALY.

Aim of this study was to investigate the electrophysiological caracteristics of Ca channel modulation.Neurons were acutely isolated and recorded with whole-cell patch-clamp technique. D-ala-D-leu-enkephalin (DADL) (400 to 1000 nM), a potent analgesic, reduces high voltage activated (HVA) Ca current amplitude (-60% ±2.7 SEM n=40) in 90% of the cells tested. In 27 out of 40 cells sensitive to DADL, the reduction in Ca current amplitude was associated with a prolongation of current activation. The activation time course was single exponential in control, with time constant τ=2.3 msec and double exponential with DADL, with τ_1 =2.4 and τ_2 =11 msec (22°C). A conditioning depolarizing prepulse [Formenti A. & Sansone V. (1991) Neurosci.Lett. 131:267-272] speeded up the activation time course completely eliminating the slow, voltage sensitive component, but it was only partially effective in restoring the current amplitude to control values. After the conditioning pulse, the voltage-sensitive component returned and its amplitude increase with a monoexponential time-course (τ=230msec). The voltage range at which the conditioning pulse was effective was that in which HVA channels were activated. The current amplitude could be restored close to control values only washing out DADL. In the remaining 13 cells, DADL decreased Ca channel current amplitude without prolongation of Ca channel activation. In these cases the conditioning pulse was not effective in relieving the inhibition of DADL, therefore this type of inhibition was voltage independent. The voltage-dependent inhibition occurred slowly after DADL superfusion (30-60sec), whereas the voltage-independent one developed rapidly (at least one order of magnitude less in time). These two types of modulation could play different roles in controlling nociceptive sensory information.

SELECTIVE ADENOSINE RECEPTOR ACTIVATION BLOCKS N-TYPE BUT POTENTIATES P-TYPE HIPPOCAMPAL Ca CURRENT

D.J. Mogul*[1], M.E. Adams[2], & A.P. Fox[1], [1]Dept Pharmacol/Physiol, Univ of Chicago, Chicago, IL 60637; [2]Dept Entomol, Univ Calif, Riverside, CA 92521

Adenosine, released in response to increased neuronal electrical activity or metabolic demand, has been shown to both decrease synaptic transmission (Ginsborg & Hirst, *J. Physiol.* 1972; Dunwiddie & Hoffer, *Br. J. Pharmac.* 1980; Silinsky, *J. Physiol.* 1984) and to produce an excitatory response (Sakurai & Okada, *J. Physiol.* 1991) in hippocampal synapses. Previous reports have shown that adenosine or its analogues reduce Ca current in dorsal root ganglion and hippocampal neurons (Dolphin et al., *J. Physiol.* 1986; Madison et al., *Biophys. J.* 1987; Gross et al., *J. Physiol.* 1989). The effect of selectively activating adenosine receptors was examined on Ca channels from acutely isolated pyramidal neurons from the CA3 region of guinea-pig hippocampus using the whole-cell voltage-clamp technique. Activation of A_1 receptors inhibited primarily ω-Conotoxin-sensitive N-type Ca current although a fraction of Ca current inhibition by A_1 activation was not ω-Conotoxin sensitive. In contrast, activation of A_{2b} receptors resulted in significant potentiation of ω-Agatoxin-IVA-sensitive P-type but not N-type Ca current. This potentiation occurred via a cAMP-dependent pathway and was blocked by inclusion in the patch pipette of WIPTIDE (10 μM), a specific protein kinase A inhibitor. Conditions which augment Ca current have been implicated as an important component of synaptic transmission, excitotoxicity, and long-term potentiation. Because of the ubiquity of adenosine, the differential effects of receptor subtype activation on Ca channels may have significant implications for neuronal excitability.

535.12

THE ω-3 FATTY ACID DOCOSAHEXANOEIC ACID INHIBITS L-TYPE CALCIUM CURRENT.

A.R. Rittenhouse,* H. Hallaq, A. Leaf, & P. Hess. Dept. of Cellular & Molecular Physiology, Harvard Medical School & Dept. of Medicine, Massachusetts General Hospital, Boston, MA 02215.

Docosahexaenoic acid (DHA), a C22:6 ω-3 fatty acid found in high concentrations in fish oil, is thought to protect both the brain and cardiovascular tissues from cytotoxicity during periods of acute ischemia, though the exact mechanism by which this is accomplished is unclear. Recently Hallaq et al. (PNAS, 1992, 89: 1760) reported that concentrations of DHA which had no effects of its own blocked the agonist and antagonist effects of dihydropyridines (DHPs) on cardiac muscle contraction. It also noncompetitively inhibited the binding of the DHP antagonist ^{3}H-nitrendipine to membranes of cardiac myocytes. Here, we have examined whether DHA acts as a modulator of L-type Ca current in a manner similar to that of DHPs in undifferentiated PC12 cells, a pheochromocytoma cell line that contains mainly L-type Ca channels. Bath application of DHA at a concentration that had no effect of its own (1 μM), did not block the effects of the DHP agonist (+)-202-791 or antagonist (-)-202-791 on the whole cell L-type Ba current. 5 μM and 10 μM DHA decreased whole cell Ba currents 36 ±7% (N=10) and 78 ± 4% (N=3) respectively. Arachidonic acid (5 μM; C20:4 ω-6) also decreased the peak current 64 ± 6% (N=7) while oleic acid (10 μM; C18:1 ω-9) had no significant effect (N=3).

The effects of DHA at the single channel level were consistent with its effects at the whole cell level. 10 μM DHA puffed onto cells decreased the mean average current (67% ± 7%, N=6) and the open probability of multichannel patches recorded in the cell-attached patch configuration in the presence of 500 nM (+)-202-791. Mode 1 and 2 activity of single L-type currents decreased in the presence of DHA, but were still apparent. These results indicate that DHA and DHPs have overlapping but distinct effects on L-type Ca channels.

AXON GUIDANCE MECHANISMS AND PATHWAYS V

536.1

FASCICLIN IV: STRUCTURE, EXPRESSION, AND FUNCTION DURING GROWTH CONE GUIDANCE IN GRASSHOPPER.

A.L. Kolodkin*, D.J Matthes, T.P. O'Connor, D. Bentley, and C.S. Goodman, HHMI, Dept. of Molecular and Cell Biology, U. of California, Berkeley, CA 94720

Three different surface glycoproteins were previously identified (fasciclin I, II, and III) that are expressed on subsets of axon pathways during embryonic development. To identify additional pathway recognition molecules, we used the 6F8 MAb to study the structure, expression, and function of fasciclin IV in the grasshopper embryo. Fasciclin IV is initially expressed in the embryonic CNS on the U longitudinal pathway, on the three medial axon tracts and commissural bifurcations from the MP4, 5, and 6 progeny, on a set of anterior axon tracts in the segmental nerve root, and on axons in the intersegmental nerve root. Fasciclin IV is also expressed in circumferential stripes on the surface of epithelial cells in the developing limb bud. The boundaries of these stripes correspond to the limb segment boundaries and, in particular, to the precise location where the growth cones of the limb bud pioneer neurons (Ti neurons) make a characteristic ventral turn during their extension to the CNS. Embryos cultured in the presence of 6F8 MAb and FAb during Ti axon migration exhibit aberrant formation of this pioneer pathway specifically at the trocanter/coxa segment boundary, where normally both fasciclin IV is expressed and the Ti axons turn ventrally. Based on protein microsequence data, oligonucleotides were used for both PCR and library screens to isolate cDNA clones encoding fasciclin IV. Conceptual translation of these cDNAs suggests that fasciclin IV is an integral membrane protein with a signal sequence, a long extracellular domain, a transmembrane domain, and a short cytoplasmic domain. The extracellular domain has three clusters of cysteine residues (16 in total). No homologies have been found between fasciclin IV and any other protein in the available data base. We are looking for the fasciclin IV homologue in Drosophila.

536.2

AXONAL PROJECTION PATTERNS ARE ALTERED IN A NEW *DROSOPHILA* MUTANT, *midline uncoordinated (muc).*

R. K. Murphey* and Randall W. Phillis. Neuroscience and Behavior Program and the Department of Zoology University of Massachusetts, Amherst, MA 01003.

Our objective was to uncover new mutations that alter the neural circuitry of the thoracic nervous system of flies. New mutants were isolated in an F2 screen of lines mutagenized by the controlled mobilization of a P element (P[lacW]; Bier et al. 1989). Mutant flies were identified in a screen for abnormal grooming behavior; mutants did not remove dust from their bodies as efficiently as wildtype. In one of these mutants (*muc*) the legs are brought into the proper position at the midline, rubbing movements occur, but the legs do not touch at the midline and dust particles are not removed.

This defect in coordination of movements along the midline led us to examine sensory neurons whose axons normally cross the midline in the CNS and arborize bilaterally. The axonal projections of the sensory neurons innervating large tactile hairs called ASC and PSC in mutant flies lacked the axonal branch contralateral to the cell body. This branch is present in 100% of the wildtype flies but was reduced or missing in more than 50% of the mutant flies. When the P element was excised from the second chromosome, both the behavioral and the axonal phenotypes reverted to wildtype, confirming that the defect was caused by the insert. Analysis of the lacZ reporter gene expression patterns in the peripheral nervous system demonstrated that the cells of the tactile receptors were stained. A variety of cells in the central nervous system are also stained and analysis of these lacZ expression patterns is continuing. The results suggest that the mutation is causing a defect in the assembly of the midline. Supported by NIH grant NS15571 to R.K.M.

536.3

MUTATIONS WHICH PERTURB THE FORMATION OF LONGITUDINAL AXON PATHWAYS IN DROSOPHILA. G. Tear, M. Seeger*, D. Ferres-Marco, and C.S. Goodman, HHMI, Dept. of MCB, U. C., Berkeley, CA 94720

In order to elucidate the molecular mechanisms that guide the growth cones that pioneer the longitudinal and commissural axon pathways in the developing CNS of the Drosophila embryo, we performed a large-scale F2 genetic screen for mutations that disrupt the formation of these pathways. Approx. 13,000 independent lines, with ~3 lethal hits per chromosome, were screened for mutations that produce specific defects in the major CNS pathways as recognized by MAb BP102. Last year we reported on mutations in *commissureless* which perturb the commissural pathways (Seeger et al., 1991). Here we report of mutations which perturb the longitudinal pathways.

We saved ~250 mutant lines, and separated them into several discrete phenotypic classes; some appear to have normal pattern formation and cell fate decisions, but show specific guidance defects. Mutations in one gene, *longitudinals lacking* (*lola*), lack most longitudinal tracts while having nearly normal commissures, peripheral nerves, muscles, and body organization. The neurons that pioneer the MP1 pathway project their growth cones at the normal time and initial orientation; however, they often stall and fail to form the pathway. The longitudinal glia are born, initially migrate, and divide as normal; the earliest defect is seen about the time that the pioneering growth cones contact these glia and fail to extend along them. A mutation in a second gene, *roundabout* (*robo*), leads to a dramatic misrouting of the MP1 pathway. Defects are seen in a number of pioneering growth cones, including the MP1 growth cone, which extends posteriorly, but at the anterior commissure of the next posterior segment, makes a 90° turn towards the midline where it often contacts its contralateral homologue. The MP1 and other axons then form large circles of axons around the midline of two adjacent segments. We believe that these genes and others under investigation may encode proteins which function in the guidance of pioneer growth cones. The cloning of several of these genes is currently underway.

536.4

GENETIC ANALYSIS OF MOTONEURON PATHFINDING AND NEUROMUSCULAR CONNECTIVITY. D. Van Vactor and C.S. Goodman*, HHMI, Dept. of Molecular and Cell Biology, U. C., Berkeley, CA 94720

The ability of motoneuron growth cones to find and recognize their correct muscles has been a model system for studies on the mechanisms of target recognition; in both vertebrates and invertebrates, motoneuron growth cones extend toward and innervate the appropriate target muscles in a highly stereotyped fashion. Neuromuscular specificity in Drosophila is particularly well suited for studies on the molecular mechanisms of pathway and target recognition. The body wall musculature of Drosophila embryos and larvae consists of 31 individually identified muscle fibers in each abdominal hemisegment. Most if not all of these muscle fibers are innervated by one or only a few motoneurons. Extensive analysis from several labs of normal and manipulated embryos in both grasshopper and Drosophila argue for a high degree of specificity in the ability of motoneuron growth cones to recognize particular muscle fibers. Monoclonal antibody 1D4 directed against the cytoplasmic domain of fasciclin II specifically labels a large subset of motoneuron growth cones and axons (but not sensory neurons) in the periphery. We have used this and other probes to characterize the specific pathfinding of the aCC, three U's, and RP2 growth cones as they extend from the ventral nerve cord towards the most dorsal muscle fibers. In order to gain insights into the molecular mechanisms underlying pathway and target specificity, we have embarked upon a large-scale F2 mutant screen using MAb 1D4 to evaluate the pattern of neuromuscular connectivity directly in whole-mount embryos. Our goal is to nearly saturate the Drosophila genome for mutations that produce specific defects in pathfinding by identified motoneurons. Even though the screen is still in its infancy, we have already isolated a number of new mutants that perturb the projection of motoneuron growth cones.

536.5

AXONAL RECEPTOR-LINKED PROTEIN TYROSINE PHOSPHATASES IN THE EMBRYONIC DROSOPHILA CENTRAL NERVOUS SYSTEM. Shin-Shay Tian, Bruce Hamilton, Sarah Fashena, Chand Desai, and Kai Zinn*. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

Receptor-linked protein tyrosine phosphatases (PTPases) often contain adhesion molecule-like extracellular domains, and may thus couple cell recognition to signal transduction *via* control of tyrosine phosphorylation. We previously showed that three adhesion molecule-like PTPases are selectively expressed on CNS axons during the period of axon outgrowth. We have now found that another *Drosophila* PTPase, $DPTP_{69D}$, is also expressed primarily on CNS axons. $DPTP_{69D}$, which was previously sequenced, contains two immunoglobulin-like domains and two fibronectin type III (FN) domains. To define the roles these PTPases play in neural development, we are making mutations in the genes encoding them. We have developed a 'local transposition' method for isolating insertions of P-element transposons at specific locations, and have been able to use this method to make a mutation in the $DPTP_{99A}$ gene. We have shown that $DPTP_{99A}$ and $DPTP_{10D}$ do not act as homophilic adhesion molecules in transfected tissue culture cells, suggesting that if they are involved in cell recognition they must recognize other cell surface ligands. In preliminary experiments, we have obtained evidence that a ligand for the distal 4 FN domains of $DPTP_{10D}$ is also localized to CNS axons, and we are attempting to clone cDNAs encoding this ligand. Support: NS28182, MOD 5-816, Pew Foundation, McKnight Foundation, Sloan Foundation, American Cancer Society.

GUIDANCE OF MOTONEURON OUTGROWTH BY A SERIES OF PERIPHERAL CUES DURING DEVELOPMENT OF DROSOPHILA. **L.S. Wang*and H. Keshishian, Dept. of Biology, Yale University, New Haven, CT 06511.**

During neural development of Drosophila, axons of motoneurons follow stereotypic pathways and innervate specific body wall muscle fibers. Muscle fibers 5 and 8 are innervated by a group of up to 4 motoneurons whose axons (here termed group 1 axons) form part of the efferent component of segmental nerve A (SNa). Other motor axons (group 2 axons) in the SNa make connections with transverse muscle fibers. It was shown previously that group 1 axons are capable of reaching the normal innervation region in the absence of their target muscle fibers 5 and 8 (Cash et al., J. Neurosci. 1992, in press). Our study of the temporal and spatial development of SNa shows that efferent axons first extend in the anterior half of the segment along the preexisting afferent axons of the ventral campaniform sensilla 4 and 5 (vc4 and vc5). The two groups of motor axons contact the cell bodies of vc5 and branch at the lateral edge of muscle fiber 12 where group 1 axons turn posteriorly and ventrally to make contact with muscle fibers 5 and 8. Laser ablation of muscle fiber 12 results in the early posterior turning of both group of axons. Ectopic endings on muscle fiber 4 by group 2 axons are also observed. In the absence of both muscle fibers 12 and 5, delayed branching and turning of the group 1 axons are seen. We propose that the outgrowth of the motor axons of the SNa is guided by a series of peripheral cues provided by afferent axons, sensory cell bodies, and both intermediate and target muscle fibers.

DOUBLE MUTATION OF FASCICLIN I AND FASCICLIN III CAUSES ERRONEOUS GROWTH CONE BEHAVIOR OF *DROSOPHILA* EMBRYONIC MOTONEURONS. A. Chiba*, T. N. Chang, & H. Keshishian, Dept. of Biology, Yale Univ., New Haven, CT 06511.

The membrane proteins fasciclin I (fas I) and fasciclin III (fas III) are expressed by overlapping populations of *Drosophila* embryonic neurons in spatio-temporally specific manners. The two molecules do not interact directly *in vitro* (Elkins et al., Cell 53,577). To assess their possible involvement during axon pathfinding and synaptic targeting, we have examined null mutants of fas I and/or fas III using immunocytochemistry and intracellular dye-injections. Although the CNS of these viable mutants appears normal at a gross level, upon closer examination some identified motoneurons demonstrated consistent errors when both fas I and fas III were missing. Within the embryonic CNS the axons of motoneurons RP1, RP3, and RP4, revealed by antibody 22C10, repeatedly failed to maintain tight fasciculation within the normal pathways. The motoneuron axons in the periphery, labeled by neuron-specific (anti-HRP) antibody, showed aberrant filopodial spread during synaptogenesis. These observations were further confirmed by dye-injections into the RP motoneurons. The motor endings in the mature (third instar) larvae sometimes exhibited anomalous branch extensions. In contrast to the double mutant, the mutants lacking either protein alone had no detectable differences from wild type. The results suggest that a subset of *Drosophila* embryonic growth cones may respond to at least two functionally redundant signals during their pathfinding and synaptic targeting.

HIERARCHICAL GUIDANCE CUES AND THE FORMATION OF MOLECULARLY DISTINCT AXONAL TRACTS DURING LEECH DEVELOPMENT. K.K. Briggs*, K.M. Johansen and J. Johansen, Department of Zoology and Genetics, Iowa State University, Ames, Iowa 50011.

In the CNS of leech, the central projections of peripheral sensory neurons during early development segregate into three distinct axonal tracts, which are labeled by the monoclonal antibody lan 3-2 (Johansen et al., Neuron 8:559, 1992). We have also shown that a subset of these neurons, recognized by the mab lan 4-2, projects its axons selectively into only one of these fascicles. Here we report on a molecular and developmental characterization of another fascicle specific antigen recognized by the monoclonal antibody lan 3-6. We have found that as is the case with the lan 4-2 epitope the lan 3-6 epitope is only expressed by a subset of the peripheral neurons. The axons of these neurons also show selective fasciculation in the CNS, but only to a single one of the three lan 3-2 positive tracts, which, very interestingly, is a different one from the lan 4-2 positive tract. Thus, these observations provide further evidence for the existence of a hierarchy of guidance cues mediating specific tract formation in this system.

We have screened an expression vector library with the lan 3-6 antibody and pulled out several potential lan 3-6 positive clones. Partial sequencing of one of these clones have revealed a protein with homology to proteins with EF-hand Ca-binding domains. However, apart from this general domain homology the sequence obtained appears to be unique. Immunoprecipitations followed by SDS-PAGE and silver-staining suggests that the antigen has a molecular weight of approximately 200 kd. Experiments with Northern and *in situ* hybridizations with the isolated clone are in progress in order to verify that the identified clones are indeed corresponding to the lan 3-6 antigen. IN VITRO-STUDIES ON THE TOPOGRAPHIC PROJECTION OF NASAL RETINAL FIBERS ONTO THE CHICK POSTERIOR TECTUM. Ysander v. Boxberg, Silvia Deiss, and Uli Schwarz*.
Max Planck-Institut für Entwicklungsbiologie, Tübingen, F.R.G.

The stripe assay has been introduced as a model system to study the projection of retinal fibers from embryonic chicken onto their topographically correct target regions on the tectum (Walter et al., 1987, Dev. 101, 909-913). By combining it with a novel membrane protein fractionation method we have been able to demonstrate that not only the temporal but also the nasal fibers can recognize guiding cues present on cell membranes derived from their proper target area. In addition, we could show that the survival of nasal fibers *in vitro* can be substantially prolonged by supplementing the culture system with membrane preparations from posterior tectum. We therefore suggest that tropic as well as trophic interactions may be involved in the homing process of nasal axons within the posterior tectum.

536.10

RETINAL GANGLION CELL AXONS FAIL TO FORM AN OPTIC CHIASM FOLLOWING EMBRYONIC ABLATION OF VENTRAL DIENCEPHALON NEURONS. D.Sretavan*, M.Siegel & L.Reichardt. Howard Hughes Med. Inst., Univ. Calif. San Fran. & Genentech, South San Francisco, CA.

Developing retinal ganglion cell axons arriving at the ventral diencephalon establish an "X" shaped intersection of axonal projections from the two eyes known as the optic chiasm in which axons from specific retinal regions sort into the correct optic tract. We previously found that the region of the future chiasm, prior to arrival of retinal axons, contains a population of neurons arranged in an inverted "V" formation straddling the midline; and suggested that they may play a role in axonal guidance and formation of the optic chiasm.

We have now identified a monoclonal antibody (Mab) recognizing a ~90kd cell surface molecule selectively expressed on these early chiasm neurons which is capable of labeling these neurons in live embryos. Injection of this Mab together with complement into the CNS ventricles of mouse embryos at E11-E11.5, prior to arrival of retinal axons, ablates early chiasm neurons within 24 hours. Examination of injected embryos subsequently at E16 shows the ventral diencephalon at light and EM levels to be histologically normal, but the "X" shaped optic chiasm which is normally present by this age is not observed. Axons in injected embryos have grown from both retinas into the optic nerves, but have failed to enter the diencephalon to reach the midline and form optic tracts. The formation of the optic chiasm was not prevented in animals treated with either complement or Mab alone or with a control Mab combined with complement. These results indicate that early ventral diencephalon neurons play a crucial role in the guidance of retinal axons and chiasm formation in the embryonic diencephalon.

CUTANEOUS AND MUSCLE AFFERENTS: INTERACTIONS WITH POTENTIAL TARGET TISSUES IN VITRO. S.A.Scott*. Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794.

During embryonic development, cutaneous and muscle afferents appear to use different cues as they grow toward their respective targets. To test whether cutaneous and muscle afferents also differ in their response to the targets themselves, explants of the trigeminal mesencephalic nucleus (TMN), which contains only muscle afferents, or the dorsomedial pole of the trigeminal ganglion (DM-TG), which is largely cutaneous, from E10 chick embryos were co-cultured with explants of epidermis or dermis from E7 embryos; interactions of individual growth cones with these potential targets were followed with time lapse videomicroscopy. *In vivo* few cutaneous axons penetrate the epidermis and most terminate in the dermis. Interactions of growth cones with myotubes, the target of muscle afferents *in vivo*, are also being investigated.

Neither DM-TG nor TMN growth cones advanced onto epidermal explants, but over half of the TMN neurites remained in contact with the epidermis for >1 hr. In contrast, many (10/19) DM-TG growth cones collapsed and retracted within 15 min of touching epidermis, and very few (1/19) maintained contact for >1 hr. The behavior of both types of neurons was different upon encountering dermis. The majority (9/14) of DM-TG growth cones grew readily across dermis at rates comparable to their growth on the polyornithine-laminin substrate. In contrast, growth cones of TMN neurons did not advance well on dermis, and most (5/6) subsequently retreated to the substrate. Thus, there appear to be differences in the behavior of growth cones of E10 trigeminal cutaneous and muscle afferents. These differences could play a role in the selection of targets or could instead be a consequence of target innervation. Additional studies involving younger neurons that have not yet innervated targets will investigate these possibilities. (Supported by NIH grant NS16067)

536.12

THE LAMINATION OF HIPPOCAMPAL AFFERENTS IS NOT CAUSED BY THEIR SEQUENTIAL ARRIVAL DURING ONTOGENETIC DEVELOPMENT. B. Heimrich and M. Frotscher*, Inst. Anat., Univ. Freiburg, D-7800 Freiburg, FRG.

Afferents to the hippocampal formation are known to terminate in a laminated fashion. Bayer and Altman (1987) have provided evidence that the lamination of hippocampal afferents correlates with the neurogenetic gradients between cells providing input to the hippocampus. Thus, afferents from progressively later originating cells terminate progressively closer to the cell bodies of pyramidal neurons and granule cells. Early arriving entorhinal fibers meet the yet short dendrites of the hippocampal target neurons. With further dendritic growth the entorhinal fibers eventually terminate on the most peripheral dendritic segments, whereas later arriving hippocampal (associational and commissural) fibers impinge on proximal dendritic portions. We have tested this temporal hypothesis of hippocampal lamination in an in vitro system. Two slices of hippocampus were co-cultured. Seven days later a slice of the entorhinal cortex was added to the two hippocampal slices. Fiber connections between the cultures were then labeled by using biocytin as an anterograde tracer. In contrast to the normal situation in vivo, the entorhinal fibers arrived later than the hippocampal fibers in this experimental paradigm. However, like in vivo, the entorhinal fibers terminated on the most peripheral dendritic segments of the co-cultured hippocampal target cells. We conclude that the sequential arrival of hippocampal afferents does not determine their termination in distinct layers.

VISUAL CORTEX: BEHAVIOR AND BEHAVIORAL CORRELATES

537.1

CATS WITH STRIATE CORTEX LESIONS CAN DETECT FINE GRATINGS BUT CANNOT IDENTIFY THEIR ORIENTATION T. Pasternak*and †C. R. Olson, Dept. Neurobiology and Anatomy, Univ. of Rochester, Rochester, NY 14642; †Univ. Maryland; Baltimore, MD.

In the cat, areas 17 and 18 receive largely separate and distinct inputs from the lateral geniculate nucleus, the X-cells and the Y-cells respectively. Similarly to X-cells, neurons in area 17 respond linearly to spatial frequencies that are about three times higher than neurons in area 18. In this study, we examined the contribution of area 17 to visual function in two cats with fixation controlled by means of scleral search coils. Ibotenic acid lesions were made within the physiologically identified representation of the lower left visual field of area 17. Since neurons in this area respond to higher spatial frequencies than those in area 18, we expected to find deficits in the ability to detect higher spatial frequencies.

Initially, contrast sensitivity and visual acuity for the intact and the lesioned hemifields were measured in a detection task in which the cats indicated the presence or the absence of a vertical grating. With this task, sensitivity loss increased with spatial frequencies and then decreased again at higher spatial frequencies, with no loss in spatial resolution. The preserved sensitivity to high frequencies appeared inconsistent with loss of area 17 neurons. To examine the possibility that the preserved detection of fine gratings involved non-veridical perception, we repeated the measurements with a task in which the cats discriminated between vertical and horizontal gratings. With this task, sensitivity loss was minimal at low spatial frequencies and increased drastically at higher spatial frequencies. Visual acuity was reduced by about an octave. These results suggest that, in the cat, area 17 is critical to the veridical perception of stimuli containing high spatial frequencies. The apparent preservation of sensitivity to fine gratings suggested by the detection performance may be due to signals from Y-cells which respond non-linearly to frequencies that are as high as those carried by linear X-cells to area 17.

EFFECTS OF V1 AND V2 LESIONS ON THE VISUAL PERFORMANCE OF MACAQUES. William H. Merigan*, Tara A. Nealey, and John H. R. Maunsell. Depts. Ophthalmology and Physiology and Center for Visual Science, University of Rochester, Rochester, N.Y. 14642

This study measured the detection and discrimination performance of macaques, tested with controlled fixation, after localized cortical lesions produced by multiple injections of ibotenic acid. Primary visual cortex, area V1, is the target of most cortical afferents from the geniculate, and there is substantial evidence that under most conditions, lesions of this area result in blindness. A V1 lesion of about 6 by 6 mm caused a 1.5 deg diameter scotoma at 4 deg eccentricity for all functions tested, which persisted throughout the 10 month post lesion test period.

Cortical area V2 receives a substantial portion of the output from V1, although there are also pathways through V3, MT and other areas. Visual acuity and chromatic and luminance contrast sensitivity were measured by testing discrimination between gratings of horizontal and vertical orientation and no deficits were found. Measurements were also made of more complex visual discriminations. In the first task, the monkey discriminated vertical from horizontal orientation of two lines of irregularly spaced dots. The number of background dots that brought this discrimination to threshold was measured as an index of the ability to extract collinear groups of dots from a display of irregularly placed dots. V2 lesions substantially reduced the tolerable number of background dots. A second task required that the animal discriminate the orientation of a group of three distinctive neighboring stimuli embedded in a six by six array of otherwise identical stimuli. The three stimuli could be discriminated from the others on the basis of orientation, color, or luminance. We found that this task could not be done in the region corresponding to a V2 lesion when the three stimuli differed from the others in orientation, but could be done when they differed in color or luminance. These results are consistent with the hypothesis that utilization of second-order spatial relationships requires the activity of cortical area V2.

SELECTIVITY FOR FIGURE-GROUND DIRECTION AT OCCLUDING CONTOURS IN MONKEY AREA V2. E. Peterhans* and R. von der Heydt, Department of Neurology, University Hospital Zurich, CH-8091 Zurich, Switzerland.

Visual processing in situations of spatial occlusion involves the detection of occluding contours and the distinction between foreground and background. We studied the neural mechanisms of such processing in the alert monkey during behaviorally induced fixation. In area V2 we recorded the responses of single neurons to light and dark edges and to stimuli that mimicked situations of spatial occlusion, for example a light rectangle overlaying a grating of dark lines, or the same figure in reversed contrast. In neurons responding to the borders of such rectangles we studied the effects of figure-ground direction and contrast polarity.

About half of the neurons studied (19/40) were selective for figure-ground direction. In 9 of these cells this selectivity was independent of contrast polarity, 10 cells showed interaction. These cells preferred stimuli with a certain figure-ground direction and a contrast polarity consistent with their edge preference. Even with the non-preferred contrast polarity most of them preferred the same figure-ground direction. These findings can be interpreted in terms of a previously proposed model assuming that the figure-ground direction is inferred by asymmetric end-stopped cells (see TINS 14:112-119, 1991).

We conclude that mechanisms for the segregation of figure and ground are present at the level of area V2.

NEURAL RESPONSES TO TEXTURE BORDERS IN MACAQUE AREA V1. H. C. Nothdurft, J. L. Gallant*, D. C. Van Essen, Div. Biol., CalTech, Pasadena, CA 91125, and Max Planck Inst. Biophys. Chem., Goettingen, FRG.

We have studied the responses of neurons in area V1 of anesthetized macaque monkeys to oriented texture elements that were part of a large texture field containing a texture border across which the element orientations differed by 90 deg.. The texture border was presented at different positions and different orientations relative to the cell's classical receptive field. The single texture element within the classical receptive field was either matched or was orthogonal to the preferred orientation. Out of 161 cells tested, about one third showed a significantly greater response when the texture border was adjacent to the receptive field than when the texture border was more distant. In most instances, the border enhancement was evident for only a subset of the border orientations tested. However, ~10% of the total population showed a significant border enhancement for all orientations. We also tested for an orientation contrast ('popout') effect: the responses to an oriented texture element were determined for an isolated element, an element embedded within a uniform texture field, and a single element within a field of elements of the orthogonal orientation. There was a clear, but imperfect correlation between the two tests; many cells showing a border enhancement effect also showed a differential effect in the single-element popout test.

Altogether, these data support the hypothesis (derived from psychophysical studies) that texture segmentation is based on local feature contrast rather than on feature analysis extending over large texture regions (Nothdurft, Vis. Res., 1991).

DO CELLS IN AREA V2 RESPOND TO THE ORIENTATION OF KINETIC BOUNDARIES ? V.L. Marcar*, S.E. Raiguel, D. Xiao, H. Maes & G.A. Orban, Lab. Neuro- en Psychofysiologie, Medical School, KULeuven, B-3000-Leuven, Belgium.

Human observers and monkeys can perceive the orientation of a boundary defined by differences in the direction of motion of two random dot fields. We reported (Marcar et al, Soc. Neurosci. Abstr. 1991, 17: 525) that MT cells of macaca fascicularis were not selective for the orientation of such kinetic boundaries. We have now extended this investigation into area V2.

We tested V2 cells with contrast luminance gratings and edges as well as kinetic boundaries generated using two random dot fields moving coherently in opposite directions. Their receptive fields were mapped, to enabled us to align the center of the display with the centre of the receptive field and select the optimal stimulus size. In one type of kinetic boundary the motion was parallel, while the other type the motion was orthogonal to the orientation of the boundary. Only cells tuned to the same orientation for two types of boundaries qualify as selective.

Five out of 44 V2 cells were tuned to the same orientation for both types of kinetic boundary and were considered selective. Their orientation preference for the kinetic boundary was also found to be within 23° of their orientation preference for a luminance contrast boundary. Four of these kinetic boundary cells have been placed in layer V. These results together with that of others (e.g. Peterhans & von der Heydt, J. Neurosci. 1989, 9: 1749-1763) suggests that area V2 plays an essential role in the perception of boundaries.

FACILITATION ALONG THE LONG AXIS OF VISUAL CORTICAL RECEPTIVE FIELDS: A POSSIBLE EXPLANATION FOR THE BARBER-POLE PHENOMENON ON THE CELLULAR LEVEL ? F. Wörgötter* and U.T. Eysel Inst. Physiol. Univ. Bochum, FRG.

Usually, the strongest response of a visual cortical cell is obtained when the receptive field (r.f.) is *crossed* with an oriented moving stimulus (orientational component). Recently, we have shown that small dots moving *along* the long axis of the r.f. elicit equally strong reactions in 80 % of the cells (axial component, Wörgötter & Eysel, Exp. Brain Res. 76, 307-314, 1989). With small bar stimuli tuning curves with 4 peaks occur because the orthogonally directed orientational and axial components overlap. Strong axial responses are also obtained during repetitive stimulation with long bars using a grating with low spatial frequency. This observation was made in 43 simple and complex cells in area 17 of the anesthetized cat at moderate to fast temporal frequencies. In 8 cells the axial component was substantially stronger than the orientational component. Covering the OFF subfield with a dark mask strongly enhances the axial component while diminishing the orientational component in cells with a clear ON-OFF subfield separation. In these cases the cell's preferred direction turns by 90°. The "barber-pole" phenomenon is described by the effect that an edge will interfere with motion perception. While viewing a moving grating partly obscured by an elongated edge a human observer will in most cases perceive motion along the edge regardless of the actual angle at which the grating is moving. The above described masking effect which shifts the preferred direction of the cells by 90° could be involved in this percept. The r.f.s distant from the edge will all be stimulated identically by the moving grating which will lead to adaptation effects. Thus, they should add little to the precept. On the other hand, r.f.'s overlapping the edge are partly obscured and produce strong responses along the r.f. long axis which is parallel to the axis of perceived motion.

537.7

A SIGNIFICANT PROPORTION OF THE TOTAL INFORMATION IS ENCODED IN A SHORT PERIOD AT THE BEGINNING OF A SPIKE TRAIN OF NEURONS RECORDED IN THE PRIMATE TEMPORAL VISUAL CORTEX. E.T.Rolls*, M.J.Tovee and A.Treves. Univ. Oxford, Dept. Exptl. Psychol., Oxford OX1 3UD, England.

Principal component and information analyses (Optican and Richmond, 1987, J. Neurophysiol. 57: 162-178) were performed on spike trains recorded from single neurons in the temporal cortical areas of macaques performing a visual fixation task during the presentation of static face and non-face stimuli (Rolls, 1992, Phil. Trans. Roy. Soc. 335, 11-21). We subtracted a correction from the calculated information to allow for the small number of trials, and showed that the first principal component, which was highly correlated with firing rate, reflected most of the information available from the spike train. We then showed that the information about the stimulus derived from the firing rate in a short period of 50 ms near the start of the elicited spike train was 0.57 of that which could be obtained using temporal encoding during a 400 ms analysis period. In a period of 20 ms, 0.43 of the information was available. When visual recognition of objects is performed by the visual system, there is time for only about 20-40 ms of processing within each cortical area before the next area must start its processing (see Rolls, 1990, Current Opinion in Neurobiology 1: 274-278). The present results show that a significant proportion of the total available information is present within such short periods of the spike trains of neurons in the visual system, and are consistent with the hypothesis that information from each cortical area is extracted from a short estimate of neuronal firing, rather than a long estimate which allows temporal encoding to be analysed.

537.8

SPATIAL-FREQUENCY-SPECIFIC INTERACTIONS AND THEIR ROLE IN BRIGHTNESS PERCEPTION AND BRIGHTNESS CONSTANCY. M.A. Paradiso*. Center for Neural Science, Brown University, Providence, RI 02912

One can distinguish two major hypotheses which have been proposed to account for brightness (and color) perception. One hypothesis is that surface attributes of objects are explicitly represented in the activities of mechanisms sensitive to luminance contrast over a range of spatial scales. Alternatively some feature, such as luminance contrast at edges, might play a special role in determining brightness. Our experiments demonstrate spatial-frequency-specific interactions which alter the relationship between brightness and luminance contrast depending on stimulus size and complexity. In one experiment contrast discriminations were made with squarewave gratings missing energy at the fundamental spatial frequency. While thresholds with squarewave gratings above about 1 cy/deg are comparable to thresholds for the fundamental sinewave in isolation, at lower frequencies thresholds are significantly elevated. The presence of higher components in the squarewaves decreases sensitivity for the lower frequencies. A similar conclusion is reached from masking experiments. Detection thresholds for sinewave gratings were measured in the presence of high contrast squarewave gratings. The squarewave masks have an asymmetrical effect on thresholds for the sinewaves. Whereas there is a modest effect on the detectability of high frequency gratings, there is a much larger effect on low frequency gratings and this effect covers a broader frequency range. These findings indicate that the representation of areas of uniform brightness becomes increasingly more "edge-based" as these areas get larger (i.e. sensitivity is preferentially lost to the low frequencies). The underlying frequency-specific interactions may be important for understanding brightness constancy and gradient illusions as they support the idea that visible luminance gradients become imperceptible in the presence of other stimuli.

537.9

SPECTRAL SENSITIVITY FOLLOWING CORTICAL HEMISPHERECTOMY IN MAN. P. Stoerig*[1], J. Faubert[2], M.Ptito[3], F.Lepore[3], and A.Ptito[4], Inst. Medical Psychology, Munich University, FRG[1], School of Optometry[2], Dept. of Psychology[3], Université de Montréal and Montreal Neurological Institute[4], Montreal, Canada.

Increment-threshold spectral sensitivity was measured in the normal and blind visual hemifields of three patients who had undergone hemispherectomy 1.5-10 yrs previously. Measurements were taken under photopic and scotopic conditions with the patients monocularily fixating a fixation spot 17^{o} eccentric from the center of the 9x9^{o} 1s stimuli produced on an Apple Macintosh colour monitor. The monitor screen around the stimulus was covered with a mask, and eye movements were monitored with an IScan Eye Movements Monitoring System. Stimuli with the dominant wavelength from 465 to 610nm were presented in random alternation with blanks, and their luminance was increased until the patients' detection reached the 80% correct criterion. The resultant spectral sensitivity curves show that the patients have a normal Purkinje-shift in both hemifields, although sensitivity in the blind field is reduced by 2 to 3 log units. Under photopic conditions, the curves exhibit the discontinuities attributed to colour-opponent interactions, showing that colour-opponent channels subserve the blind field even in the absence of one hemisphere. Unless the patients have abnormal retinal connections to the other hemisphere, this indicates that as yet unknown subcortical colour-opponent pathways survive the removal of a hemisphere with its massive degenerative consequences.

VISUAL SUPPESSION WITH THE MAGNETIC COIL (MC): OPTIMAL DIRECTION OF MONOPHASIC CURRENT. P.J. Maccabee* ,V.E. Amassian, R.Q. Cracco, J.B. Cracco, L.P. Eberle, M. Somasundaram and K. Henry. Depts. of Neurology and Physiology, SUNY Health Science Ctr., Brooklyn, NY 11203

We previously demonstrated perceptual suppression of briefly presented horizontal letter trigrams when a Cadwell round MC was energized over calcarine cortex with a polyphasic pulse. Given the topography of the macular projection, this implies a powerful effect at the midline where the induced electric field is maximal. However, classic axonology predicts that excitation occurs near the negative-going first spatial derivative of the electric field, i.e. at least 4cm lateral to the midline. Using a monophasic pulse, recent studies of mammalian peripheral nerve in-vitro showed highest excitability at a bend or abrupt termination of a straight nerve when the induced electric field was maximal there and directed along the nerve toward the bend or nerve ending.

To see if a similar mechanism explains the activation of inhibitory visual processing, the experiments were repeated with monophasic MC pulses. In subjects sensitive to current direction, when the induced current flowed from left to right, the right-most letter was significantly suppressed more, implying preferential inhibition of left calarine cortex, and vice-versa. These findings fit with excitation by induced current directed medially towards the terminations of either geniculocalcarine fibers or of visual cortical neurons.

537.11

DEPTH AND STIMULATION SITE OF MAGNETICALLY INDUCED PHOSPHENES IN THE BRAIN. D. P. Rudiak and E. Marg*. School of Optometry, University of California, Berkeley, CA 94720.

Cortical phosphenes were induced in normals with magnetic stimulator coils over the posterior pole. Peripheral phosphenes (5-50°) along the horizontal meridian are much more common than central ones (<5°) or along the vertical. This pattern is puzzling since: (1) the central representation in visual cortex is much closer to the coil, and (2) there is no obvious reason why one meridian should be favored. Also, when we measured the stimulation depth using 2 coil sizes[1], it was ~4 ± .5 cm from the coil near the midline, or ~2.5 cm below the cortical surface at the pole, regardless of whether the phosphene was central or peripheral. Thus, there seems to be a lowered threshold site for stimulation deep in the occiptal lobe, like that found in the wrist[2]. Such sites, e.g., should lie at sharp bends in the nerve fibers or large tissue conductance changes. We postulate that our site lies near the tip of the posterior horn of the lateral ventricle, because it has: (1) a large conductance change between it and adjacent white matter, (2) about the same depth as our site, (3) the optic radiation fibers surrounding it laterally, the horizontal meridian fibers being adjacent and the vertical fibers more distant, (4) peripherally projecting radiation fibers roughly parallel to induced currents (whereas central fibers are oblique), and (5) the calcarine sulcus (representing the peripheral horiz. meridian in V1) medial and adjacent. This may explain why phosphenes are more common in the horizontal meridian. Fiber tracts adjacent to ventricles elsewhere in the brain may also be sites of preferred stimulation. (Supported in part by the Minerva Foundation, Berkeley, CA.)

REGULATION OF AUTONOMIC FUNCTION

538.1

EMETIC REFLEX ARC REVEALED BY EXPRESSION OF C-FOS PROTEIN IN CATS. A.D. Miller*and D.A. Ruggiero. Rockefeller Univ. (ADM) and Dept. of Neurology, Cornell Univ. Medical Center (DAR), New York, NY 10021.

In order to investigate the organization of the central neuronal circuitry that produces vomiting, the distribution of c-fos protein (Fos)-like immunoreactivity (FLI) in brainstem and spinal cord was determined in 3 cats receiving multiple emetic drugs (cisplatin, lobeline, protoveratrine, naloxone, apomorphine) and in 3 controls given matched saline injections. Two pairs of animals were decerebrated, paralyzed, and artificially ventilated to avoid sensory feedback. Fictive vomiting was identified in these animals by characteristic respiratory muscle nerve discharge. Tissues were immunoprocessed using an antibody against amino acids 1-131 of FOS (kindly obtained from Dr. T. Curran) and the A.B.C. method. Enhanced nuclear FLI was observed in experimental animals along portions of the entire sensorimotor emetic reflex arc, including the nodose ganglia, area postrema, nucleus tractus solitarii (especially medial subnuclei), intermediate reticular zone, dorsal vagal motor nucleus, nucleus retroambigualis, C2 inspiratory propriospinal cell region, and phrenic motor nucleus. Labeled neurons were also found in the raphe magnus and pallidus, lateral parabrachial nucleus, and spinal dorsal horn. No unique group of labeled neurons that might function as a "vomiting center" has been identified. Emesis is mediated by a localized reflex arc of constituent neurons expressing the immediate-early gene c-fos. Supported by NIH grants NS20585 (ADM) and NS28200 (DAR).

THE EFFECT OF SUPRANODOSE VAGOTOMY UPON THE VAGALLY EVOKED NON-NICOTINIC INHIBITION OF GASTRIC SMOOTH MUSCLE TONE IN THE RAT. A.J.Carnell, P.J.Roberts* and R.G.Williams, Department of Physiology and Pharmacology, University of Southampton, UK. SO9 3TU.

We have previously described a non-nicotinic vagal inhibitory pathway which modulates gastric smooth muscle tone in the rat (Carnell *et al*, Br.J.Pharmacol. **104**: 290P, 1991). This inhibitory influence might be elicited by vagal efferents or by the antidromic activation of afferents (Delbro *et al*, Acta Physiol.Scand. **114**: 433-440, 1982). Here we establish that this inhibitory pathway involves vagal fibres which have their cell bodies central to the nodose ganglion. Under Hypnorm and diazepam anaesthesia, nine rats (200-500g) received a unilateral supranodose vagotomy. After 7 days, the animals were re-anaesthetised and True blue (TB) was injected into the wall of the stomach at multiple sites. After a further 7 days the animals were anaesthetised with urethane and prepared for the study of the effect of vagal stimulation upon intragastric pressure (IGP). Supramaximal (20V, 20Hz, 20s, 1ms square wave), stimulation of the control vagus elicited an initial contraction to 44.2 ± 9.6% of basal IGP (mean s.e.mean), followed by a long lasting relaxation to 41.7 ± 4.1% of basal IGP. Hexamethonium (30mg/Kg) abolished the excitatory component but a resistant inhibitory component remained, stimulation causing a 33.1 ± 5.0% decrease from basal IGP. Stimulation of the lesioned nerve failed to evoke any change in IGP or mean arterial blood pressure in any animal studied. The success of the supranodose vagotomy was verified by the presence of comparable numbers of TB labelled perikarya within the nodose ganglia of the lesioned and control nerves. Abundant TB labelled perikarya were observed in the dorsal motor nucleus of the control side but none on the lesioned side. These observations indicate that the vagally evoked non-nicotinic inhibition of IGP in the rat is mediated by vagal parasympathetic preganglionic fibres and supports observations that such fibres employ transmitters other than acetylcholine.

TWO HYPERPOLARIZATION-ACTIVATED CURRENTS ARE PRESENT IN RAT NEURONS OF THE DORSAL MOTOR NUCLEUS OF THE VAGUS (DMV). R.A. Travagli, Y.M. Hernandez* and R.A. Gillis. Depts. of Pharmacology and Anesthesiology, Georgetown Univ. Med. Ctr., Washington, D.C. 20007.

The whole cell patch clamp recording technique applied to the in vitro brain slice preparation was used to record voltage and current responses from visually identified neurons of the DMV. The majority of DMV neurons (59 out of 85) showed a slowly developing hyperpolarization-activated current (I_H). The time constant of activation was described by a monoexponential equation and proved to be strongly voltage-dependent, decreasing with hyperpolarization. The I_H was K^+- and Na^+-sensitive. Raising the K^+ concentration from 4.1 to 20mM, increased 2-3 fold the peak amplitude of the I_H, while lowering the Na^+ concentration from 146 to 26mM decreased the current to approximately 60% of the peak amplitude. The I_H was completely blocked by externally applied Cs^+ (5mM) but it was insensitive to externally applied Ba^{++} (200μM) and TEA (20mM). A subset of DMV neurons (16 out of 85) exhibited an instantaneous inward rectification but no I_H. The instantaneous inward rectification was K^+- sensitive, increasing with higher extracellular K^+ concentrations, but was Na^+-insensitive, being unaffected by the lowering of the external Na^+ concentration. The instantaneous inward rectification was completely blocked by 5mM Cs^+ and significantly reduced by both externally applied Ba^{++} (0.2mM) and TEA (20mM). Current clamped DMV neurons exibiting I_H were hyperpolarized in a voltage-related manner upon perfusion with Cs^+; at -50mV, Cs^+ (5mM) induced a 7.7 $\pm$ 2.7 mV hyperpolarization while at -65mV, Cs^+-induced hyperpolarization was 30.3 $\pm$ 6.7 mV. We conclude that DMV neurons can be distinguished on the basis of the presence of two hyperpolarization-activated currents. The I_H current is tonically active at resting potentials, and, by increasing the ionic conductance during hyperpolarization, the I_H may be in part responsible for the pacemaker activity of these neurons.

538.4

EFFECTS OF SUBSTANCE P AND TRH MICROINJECTED INTO THE NUCLEUS RAPHE OBSCURUS (NRO) ON GASTRIC TONE AND MOTILITY IN THE RAT. Z.K. Krowicki* and P.J. Hornby. Dept. of Pharmacology and Experimental Therapeutics, Louisiana State University Medical Center, New Orleans, LA 70112.

The caudal NRO is an important site for CNS control of gastric function. Since both substance P (SP) and TRH are co-localized within the same neurons in the NRO we speculate that there should exist a functional interaction between these neurotransmitters in the NRO. To test this, we used seven-barelled glass micropipettes to investigate the effects of SP and TRH on intragastric pressure (IP), pyloric (PM) and greater curvature motility (GCM) in α-chloralose anesthetized rats. SP lowered IP at doses of 135 and 435 pmol [peak change (cm H_2O) $\pm$ SEM(n); -1.9$\pm$0.1(12) and -2.0$\pm$0.1(4), $p<0.001$], but not at a dose of 45 pmol. TRH (6, 15 and 45 pmol) increased IP [4.81$\pm$0.85(4), 7.49$\pm$0.69(6) and 8.98$\pm$1.32(6), $p<0.001$] as well as PM and GCM. Effects of both peptides were inhibited by atropine methyl bromide (1.0 mg/kg i.v.) and abolished with bilateral vagotomy or chlorisondamine (5 mg/kg i.v.). SP (135 pmol), injected into the NRO 30-60 sec before TRH (15 pmol) inhibited the effect of TRH on IP ($p<0.001$), PM ($p<0.01$) and GCM ($p<0.01$). SP (135 pmol) injected into the NRO 30-60 sec after TRH (15 pmol) was no longer able to reduce IP. We conclude that SP and TRH influence the gastric function in the caudal NRO via a vagally-mediated pathway and that SP modulate the effect of TRH on both gastric tone and motility. Supported by PHS grant DK42714.

CONVERGENCE OF VISCERAL AFFERENT AND SOMATOSENSORY INPUTS ON SINGLE HYPOTHALAMIC NEURONS IN CAT. C.S. Yuan and W.D. Barber*. Department of Anatomy, College of Medicine, University of Arizona, Tucson, AZ 85724

Studies in anesthetized cats evaluated convergent visceral afferent and somatosensory inputs on single neurons in the hypothalamus. Gastric vagal branches, serving the proximal stomach, and the T-9 intercostal nerve were electrically stimulated with pulses 0.3 msec in duration, 300 uA at 0.5 Hz. Unitary responses were recorded in the hypothalamus. Seventy five, of a total of 87 gastric vagal evoked (GVE), hypothalamic units were phasic evoked responses and 12 were tonically active units. The GVE effect was predominantly inhibitory on tonically active units with a mean duration of 493 msec. Eighty-one (93%) of the GVE hypothalamic phasic responses also received input from the T-9 intercostal nerve. When the gastric vagal and T-9 intercostal nerves were stimulated simultaneously the hypothalamic evoked convergent response was characterized by an initial excitation followed by inhibition. The condition-test paradigm evaluated the time course of GVE/intercostal convergent inputs on hypothalamic neurons. There was decreased excitability of the GVE hypothalamic response when the intercostal nerve stimulation occurred within $\pm$ 250 msec of gastric vagal activation. These data identified somatosensory/visceral afferent convergence on single hypothalamic neurons and suggested that the central processing of visceral input can be substantially affected by somatosensory stimuli. HEPATIC MECHANORECEPTORS WITH PHRENIC AFFERENTS IN THE DOG. D.R. Kostreva* and S.P. Pontus. Depts. Anesthesiology and Physiology, Med. Col. of Wis. and VA Med. Ctr., Milw., WI 53295.

The objective of this study was to determine if there are mechanoreceptors located in the liver or hepatic vasculature that have phrenic nerve afferents. Mongrel dogs (20-24 kg) were anesthetized with pentobarbital sodium (35 mg/kg i.v.), intubated and placed on positive pressure ventilation. Arterial blood pressure and ECG were monitored. The chest wall was removed on the right side to allow unimpeded access to the phrenic nerve. An upper abdominal incision provided direct access to the inferior vena cava, the hepatic veins and the liver. The phrenic nerve was transected at the level of the first rib. The cut distal end of the nerve was then placed into a nerve dissecting tank filled with warm 37° C mineral oil. The nerve was desheathed and further dissected into fine filaments and laid across a pair of recording electrodes. The electrodes were connected to a preamplifier and a filter amplifier. The nerve activity was recorded on magnetic tape as well as an oscilloscope. Mechanoreceptors with phrenic afferents were then located in the pericardium, inferior mediastinum and the diaphragm as previously reported (FASEB J. 6:1699, 1992). The gall bladder, quadrate and right medial lobes of the liver, the hepatic veins, and the inferior vena cava were then probed for mechanoreceptors. Mechanoreceptors were found primarily in the hepatic veins both on the cranial and caudal sides of the liver. Although these receptors were very sensitive to light touch and probing, they did not respond to increases in venous pressure produced by occlusion of the inferior vena cava above the level of the diaphragm. A few receptors were located on the inferior aspect of the right medial lobe, while some receptors responded to compression of the capsular surface. This study is the first to describe phrenic afferent recordings from mechanoreceptors in the liver and hepatic veins.

EFFECTS OF CENTRALLY ADMINISTERED CRH AND TRH ON CARDIOVASCULAR CONTROL OF THE ANESTHETIZED RAT C. Schulz, A. Bock, D.H. Hellhammer*, E. Christodulopulu, H. Lehnert Dept. of Endocrinol., Univ. Hospital of Mainz, FRG; *Inst. of Physiol. Psychol., Univ. of Trier, FRG

The icv-injection of TRH and CRH in conscious rats causes increases blood pressure (BP), heart rate (HR) and plasma epinephrine (EPI) and norepinephrine (NE) as well as a rise in locomotor activity. Thus, the question arises whether or not the cardiovascular response to these hormones represents cardiovascular adaption to locomotor activation. To rule out this activation we studied the effect of icv injections of CRH and TRH in urethane anesthetized rats (1.5 g/kg, i.p.). Application of TRH (0.9, 1.8, 2.7, 15 nmol/10 μl, n=7) resulted in a dose-related increase in BP of 8 to 28 mmHg and HR of 50 to 73 beats/min. NE increased from 4.14 $\pm$ 0.50 to 7.04 $\pm$ 1.49 pmol/ml plasma and EPI tended to increase. Injection of 0.57 nmol CRH had no effect on BP but tended to elevate HR as well as EPI and NE. We show that the cardiovascular effects of TRH are expressed in the absence of motor activity whereas the effect of CRH was strongly attenuated. We conclude that the rise in motor activity is not a requisite for pressor and tachycardic effects of TRH and probably of CRH. Supported by DFG (Le 493/2-1).

CARDIOVASCULAR EFFECTS PRODUCED BY INTRACISTERNAL (IC) INJECTIONS OF S-NITROSOCYSTEINE (SNC) IN CONSCIOUS RATS. S.J. Lewis, H. Ohta, J.N. Bates and A.K. Johnson*. Depts. Pharmacol., Neurol., Anesthesia, Psychol. & Cardiovasc. Ctr., Univ. of Iowa, Iowa City, IA 52242.

The intracerebroventricular injection of the L-isomer (L-SNC) but not the D-isomer (D-SNC) of SNC produce marked changes in regional hemodynamics. This study examined the effects of IC injection of SNC in conscious rats. IC L-SNC (10 - 250 nmoles) produced dose-dependent hypotension, bradycardia and facilitation of baroreflex function (BRF). The higher doses also produced a subsequent hypertension, tachycardia and BRF inhibition. IC D-SNC produced hypertension, tachycardia and BRF-inhibition only. The L-SNC-induced hypotension, bradycardia and BRF-facilitation were abolished by the inhibitor of soluble guanylate cyclase, methylene blue (MB, 100 pmole). The L-SNC- and D-SNC-induced hypertension, tachycardia and BRF-inhibition were abolished by hemoglobin (100 nmole). Biochemical studies showed that L-SNC and D-SNC release equal amounts of nitric oxide (NO). These results suggest that the initial effects of L-SNC may be due to the activation of stereoselective nitrosothiol receptors and that the NO released from L-SNC and D-SNC may produce the hypertension, tachycardia and BRF-inhibition. PHENYLEPHRINE INCREASES OPTICAL REFLECTANCE IN THE CAT VENTRAL MEDULLARY SURFACE. R.M. Harper*, D. Gozal, X-W. Dong, and D.M. Rector Brain Res. Inst. and Dept. of Anatomy & Cell Biology, UCLA Sch. of Med.; Div. Neonatology and Ped. Pulmonology, Children's Hospital, USC Sch. of Med., Los Angeles, CA.

We examined regional neuronal activation on the surface of the cat ventral medulla (VM) during phenylephrine-induced blood pressure elevation using large-array optical recording procedures. The VM was exposed through a ventral surgical approach in ten adult cats under pentobarbital anaesthesia. Arterial pressure, end-tidal CO_2, costal diaphragmatic EMG and ECG were monitored. A coherent image conduit was attached to a charge coupled device camera and positioned over the VM. Reflected 700 nm light was digitized continuously at 2-3 sec intervals during a baseline period, and after 10ug/kg i.v. phenylephrine administration. Forty images within each epoch were averaged, and were subtracted from baseline. Regional differences within the image were determined by ANOVA procedures (α=.05). Phenylephrine induced a significant transient elevation of blood pressure associated with diminished respiratory EMG activity. A pronounced increase in optical reflectance (decreased neural activity) was found over widespread regions of the VM surface during the early pressor response with a subsequent return to baseline values. We conclude that pharmacologically induced rapid blood pressure elevations result in a generalized decline in neural activity in areas of the VM traditionally associated with cardiorespiratory control.

FLEXIBLE MOTOR PATTERNS IN CHICKS: BI- AND TRIPHASIC ELEMENTS. R. M. Johnston * and A. Bekoff, Department of EPO Biology and Center for Neuroscience, Box 334, University of Colorado, Boulder, CO 80309-0334

There is much evidence which supports the conclusions that the outputs of pattern generating networks are inherently flexible; flexibility and diversity of motor patterns results in part from both intrinsic and extrinsic sources of modulation. With this in mind we have examined the muscle activity patterns in walking, swimming and airstepping in chicks.

Our results show that these three behaviors share the same basic motor output consisting of a biphasic pattern (extensor-flexor alternation) at the hip and ankle coupled with a triphasic pattern (extensor-flexor-extensor alternation) at the knee. Flexibility and the diversity of rhythmic motor patterns results from the modulation of biphasic and triphasic elements. The elements of the biphasic components can be independently modulated. The elements of the triphasic pattern can also be independently modulated, but such modulation affects the interaction among the elements of the triphasic pattern.

Kinematic data show that the hindlimb movements in these behaviors occur within a triphasic framework which consists of one retraction period and two protraction periods per cycle. EMG data synchronized with kinematic data will be presented to establish the relationships between these muscle and behavioral patterns.

TIMING *VS.* PATTERN IN CYCLIC MOTOR PATTERNS IN CHICKS. A. Bekoff* and D. L. Nicholl. Department of EPO Biology and Center for Neuroscience, University of Colorado, Boulder, CO 80309-0334.

In previous work we have postulated that there is a timer for episodes of hatching movements in chicks that is separable from the motor pattern generating mechanism (Bekoff and Kauer, 1982; 1984). In the current work, we examine the characteristics of these two features of cyclic motor activity across the perinatal transition.

Spontaneous motor activity is videotaped in late stage chick embryos and continuous videorecordings are made from the time of hatching until walking is well established (6-8 hours posthatching). Quantitative measurements of cycle durations, number of movements per minute, and durations of activity and inactivity periods are made to examine temporal features of motor behavior. Interlimb coordination is analyzed to examine one aspect of the motor patterns.

In hatching, synchronous leg movements occur during each hatching episode (Bekoff and Kauer, 1982). Episode duration is approximately 1-3 sec and inter-episode interval is 10-30 sec. Preliminary observations suggest that immediately posthatching, the interlimb coordination pattern switches abruptly to one of alternation of the two legs. Episode durations increase slightly, but inter-episode intervals remain similar to those seen during hatching. Both episode durations and inter-episode intervals gradually increase over the next few hours, while alternation continues to be the primary pattern of interlimb coordination. Thus changes in timing and pattern can occur independently.

A MODEL OF A LAMPREY NEURON: PARAMETER ESTIMATION ON IMPEDANCE DATA. C.R. Murphey, L.E. Moore* and J.T. Buchanan. Physiology & Biophysics Dept., Univ. of Texas Medical Branch. Galveston, TX 77555.

Fictive swimming can be induced in the isolated lamprey spinal cord by exposing the entire cord to N-methyl-D-aspartate (NMDA) even in the absence of movement-related sensory stimulation. In this study the voltage and frequency dependence of the cell membrane impedance of an individual neuron are measured from the soma by point clamp methods both with and without application of NMDA. The impedance measurements are fitted to a Hodgkin-Huxley model similar to that of Grillner (J. Neurophysiol. 66:473-84, 1991) which characterizes the NMDA sensitive, slow Ca^{2+} activated K^+ and leakage currents using non-linear least squares optimization. The model is based on voltage clamp and frequency domain analysis of the ionic channels activated during fictive locomotion and is capable of reproducing the the membrane potential oscillations observed during fictive swimming. In addition, parameter sensitivity analysis is used to determine the influence of parameters changes on model-generated impedance and membrane potential waveforms. We are extending the model to simulate activity of a network of neurons during fictive locomotion using the Williams and Zipser algorithm (Neural Computation 1:270-280, 1989) to estimate synaptic weights. Supported in part by DHHS-R01-MH45796.

POSTINSPIRATORY NEURONAL ACTIVITIES IN THE INTACT UNANESTHETIZED CAT. J. Orem* and R.H. Trotter. Physiology Dept., Sch. of Med., Texas Tech Univ. HSC, Lubbock, TX 79430.

Cells that discharge in early expiration and inhibit other respiratory cells purportedly cause a separate phase, postinspiration, of the respiratory cycle (Richter *et al. NIPS* 1:109,1986). Our objective was to study postinspiratory cells in the intact, unanesthetized cat during sleep, wakefulness, and behavioral inhibition of inspiration. Activities of 226 respiratory neurons were recorded extracellularly with tungsten microelectrodes. Of these, 35 were active in early expiration. They were located in the dorsal or ventral respiratory group from behind the obex to the retrofacial nucleus. None of these 35 cells had strong and consistent activity confined to early expiration. Instead, various cell-types were active in early expiration. They included inspiratory-expiratory phase-spanning cells, retrofacial augmenting expiratory cells with bursts in early expiration, retrofacial decrementing expiratory cells, tonic expiratory cells, and cells with variable activity in the early part of expiration. Activities during behavioral inhibition of inspiration and sleep were variable also and depended in part on the strength and consistency of the respiratory signal of the cell, i.e., its η^2 value (Orem and Dick, *J. Neurophysiol.* 50:1089,1983). These results suggest that the state of early expiration is determined by many different cell-types rather than a single class of postinspiratory cells.

Supported by grant HL 21257.

A HYBRID PACEMAKER - NETWORK MODEL FOR THE RESPIRATORY OSCILLATOR IN MAMMALS. J.C. Smith*, G.D. Funk, S.M. Johnson, and J.L. Feldman. Systems Neurobiology Lab, Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527.

Our studies of cellular and synaptic properties of medullary respiratory neurons in *in vitro* neonatal rat brainstem-spinal cord and medullary slice preparations suggest that the respiratory oscillator contains bursting pacemaker neurons (q.v. Smith et al., Science 254: 726-729, 1991) embedded in a complex network. To explore the dynamical properties of this network, we constructed a computational model of synaptically coupled, conditional bursting pacemaker cells which receive synaptic inputs from three other interneuron populations, based on cell mapping experiments (see Funk et al., this volume): two populations of beating (tonic) excitatory or inhibitory cells, and; inhibitory neurons, synaptically driven by the pacemaker cells, that provide phasic recurrent inhibitory inputs. All neurons were modeled as Hodgkin-Huxley type neurons with at least four membrane conductances. Pacemaker cells had eight membrane conductances (e.g. see Johnson et al., this volume), chosen to mimic measured neuronal voltage-dependent oscillatory behavior. Simulations exhibited: i) Synchronization within the pacemaker cell population; ii) Control of voltage-dependent oscillatory behavior of pacemaker cells by tonic inputs; iii) cycle-cycle dynamic resetting of pacemaker cell oscillations by recurrent inhibitory inputs; iv) state-dependent transformation of network oscillatory behavior. With strong excitatory and recurrent inhibitory input, pacemaker cells transformed from bursting to beating behavior, and the oscillatory membrane potential trajectories of pacemaker and follower cells transformed from decrementing to augmenting trajectories. These modes of behavior correspond to different functional states of the respiratory network observed *in vitro* and *in vivo*. Supported by NIH Grants HL40959 & HL02204 to JCS.

539.6

EARLY EXPRESSION OF THE RESPIRATORY PATTERN IN THE FETAL LAMB. I.R.C. Cooke*, D.J. Gould and P.J. Berger. Dept. of Biological Sciences, Deakin University, Geelong, Vic. 3217, Australia and Monash University Centre for Early Human Development, Clayton, Vic. 3168, Australia.

We have previously shown that episodes of stereotyped rhythmic bursting activity which occur in the diaphragm of the fetal lamb at 65 days gestation (G65; term = 147 days) are produced by a neural system which exhibits the major organizational features of the mature respiratory pattern generating system (Cooke and Berger, 1990, Brain Res. 522: 333-336). We have now examined the ontogeny of patterns of activity in the diaphragm of the fetal lamb over the period from G44 to G70. Using maternal general anaesthesia, fetal lambs at G43 were instrumented for the chronic recording of EMG activity in the right and left sides of the costal diaphragm (Di) and from the longissimus dorsi (Lo) muscles. Spontaneous EMG activity was recorded daily for 4-hour periods until G60, then at 2-day intervals until G70. Sustained discharges lasting up to 1min occurred coincidentally in both the Di and Lo as early as G44: this activity persisted after spinal cord transection at C1. Rhythmic bursting activity occurred only in the Di: these bursts occurred synchronously in the left and right sides of the Di and were abolished after cord transection at C1. Di bursting at G44-G50 was much less stereotyped than at G65, with considerable burst-to-burst variability in the shape, duration and intensity of individual bursts. Furthermore, rhythmic Di bursting and sustained discharge activity at G44-G50 did not exhibit the temporal segregation characteristic of G65 fetuses. Instead, episodes of Di bursting usually occurred at the end of, or during, sustained discharges. Our results suggest that the respiratory pattern generating system is active as early as G44 and that a control system develops between G44 and G65 which regulates the expression of the respiratory pattern of the Di.

539.7

SCP-CONTAINING RADULA MECHANOAFFERENT NEURONS IN THE BUCCAL GANGLION OF *APLYSIA*: RESPONSE PROPERTIES AND BIOCHEMICAL CHARACTERIZATION. M.W. Miller*, S.C. Rosen, E.C. Cropper, S. L. Schissel, I. Kupfermann, and K.R. Weiss. Ctr. for Neurobiol. & Behav., Columbia Univ., and NYS Psychiat. Inst., NY, NY 10032; Dept. Physiol. & Biophys., Mt. Sinai Sch. of Med., 1 Gustave Levy Pl., NY, NY 10029.

A cluster of neurons located on the rostral surface of each buccal hemiganglion of *Aplysia* has been studied using electrophysiological, immunocytological, and biochemical techniques. This cluster exhibits SCPb-like immunoreactivity and corresponds to the 'rostral group' previously identified in juvenile specimens (Lloyd et al., 1985). In mature animals (300 - 400 g), this cluster consists of 30 to 50 electrically-coupled cells ranging in size from 15 to 150 um. These neurons exhibit considerable diversity of size and form, with smaller spherical cells located laterally and larger ovoid cells positioned closer to the buccal commissure. Axons from these neurons exit the buccal ganglion via the radula nerve, typically branching at the initial radula nerve bifurcation. These axons project to specific regions of the membranous sheath underlying the radula surface, where they ramify extensively and appear to end in terminal specializations. Brief application of von Frey hairs (0.1 - 1.0 g) to the radula surface produces rapidly adapting trains of impulses in these cells. They are not responsive to chemical stimulation (NaCl, seaweed) of the radula. Their receptive fields exhibit considerable overlap, with the highest density occurring at the grasping surface of the radula. Radiolabelling and fractionation by HPLC of the peptides synthesized by physiologically and functionally identified radula mechanoafferent neurons demonstrated that these cells produce authentic SCPa and SCPb. The presence of sensorin-A-like immunoreactivity (see Brunet et al., 1991) was not detected histologically in these cells, indicating that they represent a novel class of mechanosensory cells in *Aplysia*. Their receptive fields, relatively low threshholds to tactile stimuli, and synaptic connections (Rosen et al., this vol.) suggest that these neurons may play an important role in the generation or modulation of feeding-related behaviors.

539.8

SCP-CONTAINING RADULA MECHANOAFFERENT NEURONS IN THE BUCCAL GANGLION OF *APLYSIA*: SYNAPTIC CONNECTIVITY OF IDENTIFIED CELLS. S. C. Rosen*, M. W. Miller, K. R. Weiss, and I. Kupfermann. Ctr. Neurobiol. & Behav., NYS Psychiat. Inst., NY, NY 10032; Dept. Physiol. and Biophys., Mt. Sinai Sch. of Med., NY, NY 10029.

A rostral cluster of SCPb-containing cells is comprised of diverse radula mechanoafferent neurons (Miller et al., this vol.). Two of these cells (designated B21 and B22, each immunopositive in 30 of 30 cases) were identified by morphological and electrophysiological criteria. Similar properties of B21 and B22 include spike amplitude, spike duration, sensory threshold (low), and receptive field location (grasping surface of radula). They differ however, in morphology and synaptic connectivity. B21 is a bipolar neuron (80-120 μm) that projects axons to the ipsi- and contralateral buccal hemiganglia. The contralateral axon sends peripheral branches, via the radula nerve, to the membrane underlying the chitin of the radula, near the sites of insertion of the I4 and accessory radula closer (ARC) buccal muscles. Its central axons have short tufted processes. B22 is a smaller cell (50-80 μm) with a similar distribution of axons. Its central axons have long filamentous processes. B21 receives a monosynaptic IPSP from neuron B4, whereas B22 does not. B21 and B22 make various monosynaptic chemical and electrical synaptic connections to motor neurons and interneurons. All the known connections to motor neurons are to those (B8a, B8b, B15, B16) that innervate muscles (I4, ARC) controlling radula closure. B21 produces a slow chemical EPSP in neuron B15 that can modulate B15 excitablity. Sensory evoked excitability changes in B15 might explain increases in B15 activity seen in intact animals when food is drawn into the buccal cavity (Cropper et al., 1990). Both B21 and B22 make electrical connections to buccal-to-cerebral interneuron B19. B19 regulates the actions of command-like interneuron CBI-2. Stimulation of B21 modulates the feeding motor program driven by CBI-2. The sensory properties and connections of B21 and B22 suggest that they provide peripheral sensory information that modulates the strength and timing of radula closure during food ingestion.

539.9

NETWORK MODEL OF A CENTRAL PATTERN GENERATOR IN THE BUCCAL GANGLIA OF *APLYSIA*. I. Ziv*, D.A. Baxter and J.H. Byrne Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225

A pattern of neural activity (pattern 2) in the buccal ganglia is associated with a depolarization of identified neurons B31/32 and B35 and is followed by activation of B4 and by repolarization of B31/32 and B35 (Susswein & Byrne, 1988). Several neurons have been identified that are believed to be elements of the central pattern generator (CPG) that produces pattern 2: including B31/32, B35, B51 and B52 (Susswein & Byrne, 1988, Plummer & Kirk, 1990). The aim of the present study is to determine whether a network model of these neurons can exhibit pattern 2.

The network was simulated with SNNAP (Ziv et al., 1991), in which membrane conductances are simulated by H-H type equations and chemical synaptic conductances by second-order differential equations. Our strategy in simulating the network was first to simulate the characteristic firing properties of the individual neurons, then to simulate the features of the synaptic connections and finally to incorporate the components into the network. At each step, parameters were adjusted to match experimental data and then fixed.

Although we simulated the intrinsic properties of the neurons and their interconnections, the network failed to exhibit pattern 2. We then added an additional neuron that provided feedback inhibition to B31/32 and B35 and excitation to B4. With this modification, the network exhibited pattern 2, and exhibited rhythmic bursts of activity in B31/32 and B4 in response to sustained depolarization of B31/32. Preliminary recordings from buccal ganglia indicate the presence of such an additional neuron. As this cell is characterized further and incorporated into the network model it will be possible to determine the quantitative contribution that individual neurons and synaptic connections make to the different phases of pattern 2.

539.10

AN IDENTIFIED MODULATORY NEURON EXHIBITS DIFFERENT ACTIVITY PATTERNS IN SPATIALLY SEPARATE ARBORS. M.J. Coleman* and M.P. Nusbaum. Neurobiology Research Center and Dept. of Physiology & Biophysics; Univ. of Alabama at Birmingham; Birmingham, AL 35294.

The modulatory axon SNAX 1 excites the pyloric and gastric mill networks and also receives local rhythmic synaptic feedback from these networks in the stomatogastric ganglion (STG) of the crab, *Cancer borealis* (Nusbaum et al., J. Neurosci. 12:In Press). SNAX 1 recordings are made intra-axonally, at the entrance to the STG. We have now recorded intracellularly within the commissural ganglion (CoG) from the SNAX 1 cell body, which we have named Modulatory Commissural Neuron 1 (MCN 1).

Intra-somatic stimulation of MCN 1 mimics the effects of intra-axonal stimulation of SNAX 1 on the STG networks. Furthermore, like SNAX 1, MCN 1 receives both pyloric- and gastric mill-timed synaptic feedback. However, the feedback to these two regions of the same neuron is different. For example, the gastric mill neuron LG synaptically inhibits SNAX 1 in the STG, but does not influence MCN 1 in the CoG. Thus, when the gastric mill rhythm is driven by SNAX 1 stimulation, SNAX 1 activity is suppressed during each LG neuron impulse burst. In contrast, during MCN 1 stimulated gastric mill rhythms, there is no suppression of MCN 1 activity during LG impulse bursts. Similarly, while the pyloric-timed feedback onto SNAX 1 occurs in the STG, the pyloric-timed feedback onto MCN 1 occurs in the CoG. We are now attempting to make paired recordings from MCN 1 and SNAX 1, to directly determine whether this identified neuron simultaneously produces distinct activity patterns in its spatially separate arbors.

THE USE OF GENETIC ALGORITHMS TO EXPLORE NEURAL MECHANISMS THAT OPTIMIZE RHYTHMIC BEHAVIORS: QUASI-REALISTIC MODELS OF FEEDING BEHAVIOR IN *APLYSIA*. I. Kupfermann, D. Deodhar*, S.C. Rosen, and K.R. Weiss. Center for Neurobiology and Behavior, Columbia University, New York, NY 10032 and Fishberg Center, Mt. Sinai Schl. Med., New York, NY 10029.

We have begun to explore how behavior may be optimized by means of simple neural models, in which the effects of parameters in the model are systematically studied. As a beginning we have attempted to define the simplest model of the process by which a strip of food is rhythmically drawn into the buccal cavity and swallowed. The operation of a 2 neuron, 2 muscle model was determined using an integrate-and-fire algorithm (Perkel and Mulloney; Getting). As a first approximation, the fitness of our model was defined as the difference between the energy expended by the muscles and the energy gained as the radula pulls in seaweed. The parameters of 4 synapses in the model were evolved using a genetic algorithm (Goldberg), and this produced a number of "fit" solutions that generated rhythmic behavior that resulted in a net gain of energy. The defined models lack any modulatory mechanisms, and therefore, as predicted, their fitness was dramatically reduced when the system was challenged by even small variations of the evolved parameters. Current work is extending this approach, utilizing genetic algorithms to increase the number of variables that can be explored, and to study how the models improve by including sensory feedback and modulatory mechanisms that can dynamically alter relevant parameters according to the environmental conditions, as we have postulated to occur in the *Aplysia* feeding system.

MODELING A HALF-CENTER OSCILLATOR THAT TIMES HEARTBEAT IN THE MEDICINAL LEECH.
Ronald L. Calabrese, Erik De Schutter and Ted W. Simon*
Dept. of Biology, Emory University, Atlanta, GA 30233

Heartbeat in the leech, *Hirudo medicinalis*, is timed by half-center oscillators comprising pairs of reciprocally inhibitory heart interneurons. Oscillation is sustained through the interaction of synaptic and voltage-gated membrane currents. Physiological experiments (J Neurosci 9:2846, 1989; J Neurosci 11:746, 1991) indicate: a) a hyperpolarization-activated inward current (I_h) is crucial in pacing oscillation. b) inhibitory interactions involve a strong graded component in addition to spike-mediated transmission. c) low-threshold Ca^{2+} currents [I_{CaS} (slowly inactivating) and I_{CaF} (rapidly inactivating)] underlie graded transmission.

We have developed a model of graded transmission in this system in which postsynaptic conductance is dependent on presynaptic Ca^{2+} entry, accumulation and removal. This model has permitted us to study the interaction between synaptic transmission, low threshold Ca^{2+} currents and I_h in sustaining oscillation. The model was created with Nodus software (Comput Bio Med 19:71, 1989) and all voltage gated currents were represented as Hodgkin-Huxley equations derived from biophysical data. Our results indicate that the transition from the inhibitory to the burst phase of the oscillation is determined by voltage gated-conductances in the inhibited interneuron, not by postsynaptic conductance and that the period of the oscillation depends critically on g_h-max. A primary interaction between synaptic and voltage-gated conductances occurs when I_h limits deinactivation of I_{CaS} that sustains graded synaptic transmission. We are also studying the role of action potentials in generating oscillation. (NIH NS24072).

BLOOD-BRAIN BARRIER II

540.1

ASSESSMENT OF BLOOD-BRAIN BARRIER IN THE MAGGOT (Delia platura; Insecta, Diptera).
J. L. Juang, S. D. Carlson and C. Chi*, Department of Entomology; Neuroscience Training Program, University of Wisconsin, Madison, WI 53706. *Nicolet Instrument Corp., 5225 Verona Rd. Madison, WI 53711

Insects are one of only several classes of invertebrates that possess a blood-brain barrier (BBB). Very little knowledge of the BBB exists for immature insects, yet larvae undergo sweeping changes in CNS development and are the most metabolically energetic form. Because of this plasticity and other positive experimental attributes, dipteran larvae may be a useful ('throwaway') first animal model for BBB studies involving higher animals. A fully formed BBB exits for the earliest postembryonic larva. The BBB remains intact for the duration of larval life only to be compromised in early pupal life. From TEM data the BBB consists of a widespread array of septate junctions that bind perineurial cells overlying ventral ganglion and abdominal nerves. Ionic La^{3+} accumulates in the (pleated sheet) septate junctions and does not gain access to neuronal surfaces. No tight junctions have been found in the larval CNS. X-ray microanalysis indicates absence of La^{3+} in TEM sections where La^{3+} is not detected. The BBB can be manipulated using various osmotic gradients. Supported by NSF BNS89080881.

540.2

BLOOD-BRAIN BARRIER GLUCOSE TRANSPORTER IN DEVELOPING RABBITS: REGULATION OF GENE EXPRESSION.
K.J. Dwyer, A. Yuwiler*, and W.M. Pardridge. Departments of Medicine and Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA, 90024.

Physiological studies have described developmental changes in blood-brain barrier (BBB) glucose transporter activity. Recent studies have shown that the GLUT1 isoform is the predominant BBB glucose transporter. The present studies examine molecular mechanisms underlying the developmental modulation of BBB GLUT1 gene expression. Initially, a capillary depletion technique was performed to demonstrate selective localization of brain GLUT1 mRNA levels at the microvasculature of rabbit brain. BBB GLUT1 mRNA levels were measured by Northern analysis of poly A+ mRNA, and were generally stable in the postnatal period despite marked downregulation of brain mRNA levels for cytoskeletal proteins such as actin or tubulin. In parallel to the postnatal stabilization of GLUT1 mRNA levels, immunoreactive GLUT1 protein, as detected by quantitative Western blotting employing a purified human erythrocyte GLUT1 protein as standard, demonstrated initial downregulation of immunoreactive GLUT1 at 14 days followed by upregulation by 28 and 70 days in isolated brain capillaries. The concentration of immunoreactive GLUT1 in 70-day rabbit brain capillaries was 87 ± 1 pmol/mg capillary protein. Immunocytochemistry of developing rabbit brain sections demonstrated differential regulation of choroid plexus and microvascular GLUT1 with overexpression of choroidal GLUT1 at 28 days relative to the microvascular GLUT1. The opposite regulation of GLUT1 mRNA and GLUT1 immunoreactive protein provides support for the hypothesis that a principal mechanism of GLUT1 gene expression in the developing BBB is post-transcriptional.

540.3

DEVELOPMENTAL MODULATION OF BLOOD-BRAIN-BARRIER GLUCOSE TRANSPORT. E. M. Cornford, S. Hyman, E. M. Landaw and A. V. Escueta*. Dept. of Neurology, UCLA School of Medicine, and West Los Angeles VA Medical Center, Los Angeles, CA 90073.

Blood-brain barrier (BBB) glucose transport has been characterized in newborn, 14-day-old suckling, 28-day-old weanling and adult rabbits. A polyclonal antiserum immunocytochemically identified the GLUT-1 isoform in rabbit brain capillaries. Cerebral blood flow rates increased from 0.19 and 0.26 ml/min.gm (neonates and sucklings) to 0.51 (28-day) and 0.70 (adults) ml/min.gm ($p < 0.05$). BBB Extraction (E) of water decreased with age. The Permeability-Surface Area product (PS) of water was 0.80 ml/min.g in neonates, decreased to 0.39 ml/min.g in sucklings and increased in weanlings (0.47 ml/min.g) and adults (0.75 ml/min.g). The Km (half-saturation constant) for glucose transport (13-19 mM) was not significantly different at any of the ages examined. Maximal velocities (Vmax) of glucose transfer (an indicator of the activity and relative number of transporter proteins) increased significantly ($p < 0.05$) with age. In neonates Vmax = 0.61, in sucklings = 0.68, in weanlings = 0.88, adults = 1.01 umoles/min.g; indicating developmental up-regulation of the BBB glucose transporter.
Supported by NIH Grant NS 25554.

540.4

EXPRESSION OF Na,K-ATPase AT THE BLOOD-BRAIN INTERFACE IN RATS. B.V. Zlokovic*, J.B. Mackic, L. Wang, C. Magyar, J.G. McComb and A.A. McDonough. Depts. Neurol. Surg., Physiol. & Biophys.*, and Divn. Neurosurg. CHLA, USC Sch. Med., LA, California

Regulation of ionic composition of brain extracellular fluid (ECF) and cerebrospinal fluid (CSF) is essential for normal neuronal functions, and for control of brain volume and intracranial pressure. The blood-brain barrier (BBB) and choroid plexus (CP) play major roles in Na^+ and K^+ homeostasis in brain ECF and CSF. Na,K-ATPase is a key enzyme responsible for active transport of these ions between blood, ECF and CSF. The pumps are composed of αß heterodimers. Three α and two ß isoforms have been characterized in brain. In this study we utilized isoform specific antibodies to test for Na,K-ATPase subunits α_1, α_2, β_1 and β_2 in cerebral microvessels, capillary-depleted (CD) brain tissue and CP of rats. Microvessels isolated from cerebral cortical mantles by dextran density centrifugation, and CPs from lateral ventricles were prepared for SDS-polyacrylamide electrophoresis Western blot analysis as described [Am.J.Physiol. (1985) 248: C247-C251], and quantitated by scanning densitometry. α_1, α_2, β_1 and β_2 subunits were all detected in CD-brain tissue, as previously reported in brain. The CP expressed α_1 and β_1, while β_2 signal was weak and α_2 was absent. In contrast, microvessels expressed α_1, α_2, β_1 and β_2. When comparing subunits levels in different samples relative to a constant amount of protein, α_1 was expressed the highest in CP. Expression of α_1 and α_2 in BBB was higher in comparison to CD-brain tissue. The data support the concept [Soc. Neurosci. Abstr. (1991) 17: 240] that BBB and blood-CSF barrier regulate brain ionic composition of brain ECF and CSF by different mechanisms. (Supported by TRDRP grant 2RT0071. Antibodies to rat Na,K-ATPase subunits are provided by Dr. K. Sweadner).

540.5

CONFORMATIONALLY CONSTRAINED PEPTIDES AND THE BLOOD-BRAIN BARRIER. S.J. Weber and T.P. Davis. Department of Pharmacology, University of Arizona College of Medicine, Tucson, AZ 85724.

The present study examined structural modifications that should enhance peptide blood-brain barrier (BBB) penetration. Halogenation at the Phe[4] position of DPDPE has been previously shown to increase lipophilicity. Therefore, the intent of this study was to examine halogenation's effect upon BBB penetration using an *in vitro* BBB model and the whole animal (*in vivo*). The *in vitro* BBB model consisted of a monolayer of confluent primary bovine brain microvessel endothelial cells (BMEC) grown on 3μm polycarbonate filters. Permeability coefficients (P) were calculated based on the diffusion of DPDPE or [ρ-ClPhe[4]]DPDPE (0-120 min) across the BMEC. *In vivo* BBB penetration was determined by tail-vein injection of [^{3}H]DPDPE or [^{3}H][ρ-ClPhe[4]]DPDPE, saline perfusion via the left ventricle of the heart at a specified time (5-40 min postadministration) followed by removal, solubilization, and counting of the brain. The BMEC permeability coefficient of DPDPE (P=0.0021 cm/min) was significantly less ($p<0.01$) than that of [ρ-ClPhe[4]]DPDPE (P=0.0031 cm/min). Data from the *in vivo* study showed the amount of [^{3}H][ρ-ClPhe[4]]DPDPE crossing the BBB (0.166-0.188%) was significantly greater ($p<0.01$) than that of [^{3}H]DPDPE (0.059-0.067%). The data from the *in vitro* and *in vivo* studies provide strong evidence that the halogenation of DPDPE at the Phe[4] position increases BBB penetration and that the BMEC model may be useful in predicting *in vivo* BBB penetration. Supported by U.S.P.H.S. grant DA-06284, MH-42600 and HD-26013.

540.6

A VASOACTIVE INTESTINAL PEPTIDE ANALOGUE COUPLED TO A BRAIN DRUG DELIVERY VECTOR INCREASES CEREBRAL BLOOD FLOW. T. Yoshikawa, U. Bickel, S. Diamond*, and W.M. Pardridge. Departments of Medicine and Neurology and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

An in vivo CNS pharmacological effect is demonstrated for the first time by systemic administration of small doses of a neuropeptide (12 μg/kg) employing a blood-brain barrier (BBB) transport vector for drug delivery. An analogue of vasoactive intestinal peptide (VIP) was synthesized, and monobiotinylated using a cleavable biotin linker. The VIP analogue (I) and the biotinylated (II) and des-biotinylated (III) derivatives showed retained affinities to the VIP receptors in a binding assay with rat lung membranes. K_i values for the high affinity binding site were 3.160 nM (I), 0.999 nM (II) and 1.635 nM (III), compared to 0.260 nM for native VIP. Recent studies have shown that a monoclonal antibody to the transferrin receptor, OX26 may serve as a potential brain drug-transport vector (Friden et al., P.N.A.S., 88, 4771, 1991). A covalent conjugate of avidin and OX26 was prepared for brain delivery of the biotinylated VIP analogue through the BBB. Brain uptake of ^{125}I-labeled biotinylated peptide was investigated in rats with an internal carotid artery perfusion/capillary depletion technique. The transport vector, avidin/OX26, mediated the transcytosis of the VIP analogue through the BBB. Effect of biotinylated VIP analogue coupled to avidin-OX26 conjugate on cerebral blood flow rate in rats was measured from the tissue uptake of ^{3}H-diazepam. Rats were immobilized and ventilated with 70% N_2O and 30% O_2 to keep blood pCO_2 level constant. Cerebral blood flow in rats was not changed by intracarotid infusion of the biotinylated peptide. However, a 65% increase in cerebral blood flow was elicited when the peptide was coupled to the BBB transport vector.

540.7

AN EXCEPTION TO THE CONCEPT THAT A GRAFT DETERMINES ITS TYPE OF VASCULARITY. S. Ishihara, L. Chang and M. Brightman*. N.I.H., Bethesda, Md. 20892.

The hypothesis, that the type of vessel supplying an organ is determined by the organ rather than the vessel's source, (Stewart and Wiley, 1981) has been verified, by others, for brain. An exception is reported here in muscle grafted to mature rat hosts. In autografts of mature skeletal muscle, inserted into the IV ventricle of adult rats, some of the vessels were of the fenestrated type, like that of adjacent choroid plexus and area postrema, rather than of the muscle type. Two days, one and four weeks after pieces of neck muscle had been inserted into the IV ventricle, the grafts became vascularized by fenestrated blood vessels (FBV) that lay among muscle cells. The intact cerebral cortex of rats contain FBV up to a fetal age of 17 days. In order to see whether brain tissue responded as did muscle, pieces of 18 day old fetal brain were grafted to the rats' ventricle. These grafts came to contain only barrier vessels. Thus, the components of mature skeletal muscle did not normalize the morpholgy of its vessels whereas the components of a brain tissue graft, presumably its astrocytes, permitted the expression of its endothelial barrier properties.

540.8

A STUDY OF MICROVESSELS DURING HUMAN BRAIN DEVELOPMENT. L. Wang*, W.X. Tang, D.C. Liu, D.Y. Hong and Y.R. Liang. Dept. of Pathology, and Lab of Electron Microscopy, Hunan Medical University, P.R.China, and *Dept. of Neurosurgery, USC School of Medicine, LA, CA 90033.

Kinetic studies have demonstrated that fetal blood-brain barrier (BBB) is more permeable to large and /or small polar molecules than adult BBB. However, the structural basis of increased permeability of fetal BBB is still not fully understood .In this paper, an ultrastructural examination was performed on cerebral capillaries of human fetuses aged from 5 to 9 months, and several structural parameters were determined (Brain Res. 1987; 429: 271-281). The results were as follows: (1) endothelial tight junctions of fetal BBB became longer and tortuous; clefts were found within the junctions and there was no an significant change between 5 and 9 months; (2) plasmalemmal vesicles were larger in 5th month fetuses than in 9th month fetuses, and the density of vesicles was low (<2/μm^2 cytoplasm); (3) capillary diameter was decreased ($P< 0.01$) while the thickness of capillary wall was increased with the fetal age; (4) no significant difference was observed in the nucleo-cytoplasmic ratio and in surface area of pericyte per vessel profile; the basal laminae became thicker and denser obviously, while perivascular space narrowed gradually. The results indicate that capillaries of human fetuses between 5 and 9 months are immature. It is suggested that incomplete development of the tight junctions may play more important role in fetal BBB permeability than plasmalemmal vesicular transport.

540.9

CELLULAR LINE OF DEFENSE UPON BREACHMENT OF THE BLOOD-BRAIN BARRIER (BBB). B. Baker and R. Broadwell*. Div. Neurosurgery, Univ. Maryland Sch. Med., Balto., MD 21201

Rats administered native HRP, the lectin WGA-HRP or the ligand transferrin-HRP into the blood exhibit CNS populations of perivascular and pial surface phagocytes labelled with each of the blood-borne macromolecules. These probes enter the CNS by transcytosis through the BBB and/or by extracellular pathways circumventing the BBB. The labelled cells likely represent pericytes, macrophages, or micoglia. Immunostaining for macrophages (ED2 antibody) revealed such cells on the pial surface, within Virchow-Robin spaces and perivascular clefts throughout the brain parenchyma, and in all circumventricular organs (CVOs) of the adult CNS; similar cells on the pial surface and in CVOs also stained immunohistochemically for major histocompatibility complex class II expression (OX6 antibody). In the 2 day neonatal CNS, macrophages were on the pial surface, in CVOs and white matter; in the 20 day fetal CNS, macrophages occupied the pial surface and CVOs. Staining for microglia (OX42 antibody and the lectin Griffonia simplicifolia) revealed microglia throughout the CNS, including the pial surface, CVOs, and perivascular clefts. The data suggest that phagocytic and potential antigen-presenting cells exist everywhere in the CNS where the BBB is breached either by transcytosis through the barrier or by extracellular circumvention. The phagocytic/antigen-presenting cells represent a cellular component of the BBB and are the first line of defense in the brain once the BBB is breached. Supported by NIH grant #NS18030.

540.10

TISSUE FACTOR EXPRESSION IN ASTROCYTES *IN VITRO* AND *IN VIVO*. M.P. Eddleston*, J.C. de la Torre, M.B.A. Oldstone. Div. of Virology, Dept. of Neuropharmacology and N.Mackman. Dept. of Immunology, The Scripps Research Institute, La Jolla, CA 92037.

Tissue factor (TF) or tissue thromboplastin is a transmembrane glycoprotein that functions as the initiator of the coagulation protease cascades. The widespread distribution of TF in the body is consistent with it forming a 'haemostatic envelope' around the vascular system. The brain contains very high levels of both TF mRNA and functional protein and is the major source of commercial tissue thromboplastin used in clotting assays. However, until this report the localisation of TF in a specific brain cell was unclear. Initial *in situ* hybridisation studies suggested that astrocytes may express TF mRNA. Therefore, TF expression in astrocytes *in vitro* and *in vivo* was examined. TF mRNA was expressed constitutively in both primary mouse astrocytes and a mouse astrocyte cell line, termed JCT. mRNA was also present in one rat (C6) and two human (U373,CCF) glioma cell lines. JCT cells expressed high levels of procoagulant activity in a single-stage clotting assay. Lipopolysaccharide (LPS) and serum are known to induce TF in other cell types; we noted that serum induced a 4-6 fold increase in both TF mRNA levels and procoagulant activity in JCT cells, whereas stimulation with LPS did not alter the mRNA level. Use of a mouse TF ^{35}S riboprobe and antibody to glial fibrillary acidic protein (GFAP) on consecutive sections of mouse brain indicated that astrocytes express high levels of TF mRNA in both normal and gliotic brain. After damage to the blood brain barrier by needle injury, the highest levels of TF mRNA were in GFAP nil cells, presumably representing either activated microglia or infiltrating macrophages. Our results indicate that astrocytes express functional TF *in vitro* and are a major source of TF *in vivo*. We propose that astrocytes form the 'haemostatic envelope' in the CNS. Moreover the very high level of TF expression in astrocytes and its induction by serum raises the possibility of further roles for TF in the brain during trauma and development.

540.11

DIFFERENTIAL EXPRESSION OF 5-LIPOXYGENASE TRANSCRIPTS IN HUMAN BRAIN TUMORS. R.J. Boado, W.M. Pardridge, and K.L. Black*. Departments of Medicine and Surgery and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

In addition to the important role of leukotrienes as mediators in allergy, inflammation and neurotransmitter release; these compounds have also been linked to pathophysiological events in the brain including cerebral ischemia, cellular and vasogenic brain edema and increased permeability of the blood-brain barrier in brain tumors. Although brain tumors have been shown to secrete leukotrienes, no studies to date have provided evidence for the tumor expression of genes encoding enyzmes involved in leukotriene production. Therefore, the present study determined the abundance of the 5-lipoxygenase (5-LO) transcript (limiting step of leukotriene synthesis) in a series of human brain tumors. Macrophage/monocyte infiltration was evaluated by measuring the abundance of the phagocyte-specific transcript cytochrome b heavy chain (gp91-phox). A single 2.8 kb 5-LO transcript was observed in bovine brain. In human brain tumors and in the dimethyl sulfoxide-induced promyelocytic human leukemic HL-60 cells, the 5-LO gene is expressed as a multitranscript family (2.7, 3.1, 4.8, 6.4, 8.6 kb). The relative abundance of these transcripts in HL-60 cells was 40.4, 30.5, 25.3, 2.5, and 1.4%, respectively. The abundance of 5-LO transcripts, the expression of the larger transcripts, and the 5-LO/gp91-phox ratio were found to be correlated with the tumor malignancy.

Conclusion: the present study supports the hypothesis that the 5-LO gene product may play an important role in human tumor-induced brain edemas and provides evidence for a differential tumor-specific expression of high size 5-LO transcripts in human brain tumors.

CELL MIGRATION AND MOTILITY II

541.1

THYMOSIN $\beta 4$ IN BRAIN CELLS OF HIV INFECTED (HIV^+) INDIVIDUALS. L.C.Stanley*, R.E.Mrak, L.J. Perrot, M.+Morrison-Bogorad, and W.S.T.Griffin. Departments of Anatomy, Pathology, and Pediatrics, UAMS, Little Rock, AR 72205 and +Departments of Biochemistry and Neurology, UTSWMC, Dallas, TX 75235.

Thymosin $\beta 4$ ($\beta 4$) is a member of the β thymosin actin-binding protein family. Cellular levels of these proteins are sufficient to account for actin sequestration which regulates actin polymerization. $\beta 4$ is present in immune cells, *e.g.*, macrophages, and in non-astrocyte glial cells in rat and human brain. Presuming that activation and mobility of the numerous microglia-macrophages in brain from HIV^+ individuals involves changes in actin polymerization, we compared $\beta 4$-immunoreactive cells in formalin-fixed, paraffin-embedded temporal lobe sections from HIV^+ individuals (n=8) with analogous cells from controls (n=6) to determine if expression of $\beta 4$ is altered in HIV^+ individuals. $\beta 4$ was present in glial cells uniformly distributed in grey and white matter. These GFAP-negative cells appeared to be either activated microglia or enlarged oligodendrocytes. In the microglial nodules commonly observed in brain of HIV^+ individuals, $\beta 4$ was found in the microglia-macrophages that contained elevated amounts of interleukin-1α. Since the number of $\beta 4$ immunoreactive cells in each of these cell types in HIV^+ individuals was greater than that in controls, we conclude that elevated expression of $\beta 4$ in brain is associated with HIV infection and may reflect an alteration in actin metabolism in specific glial cell types. Supported in part by NS27414.

541.2

MIGRATORY MECHANISMS OF FRESH HUMAN GLIOBLASTOMA MULTIFORME. J.J. Bernstein*, E.R. Laws, E. Hattwick, and W.J. Goldberg, G. Tadvalkar, Lab. CNS Inj. Regen., DVA Med. Ctr. Wash., DC 20422, & Dept. Neurosurg. George Wash. Univ. Wash., DC, & Univ. VA Sch. Med., Charlottesville, VA.

Fresh human glioblastoma multiforme (GM, high grade malignant astrocytoma) xenografted into rat brain migrate upon basement membrane lined surfaces. This migratory capacity is now studied *in vitro* using hydrated gel wafers (16.0 mm diameter, 11.0 mm thick) of extracellular matrix components (artificial basement membrane [ABM, Matrigel]; or collagen I [Col I, Vitrogen]). Fresh GM astrocytomas were mechanically disrupted and a heavy cell suspension seeded on hydrated gel wafers. Cultured wafers were prepared for scanning electron microscopy over 7 days. Cells that migrated into both ABM and Col I gels were immunohistochemically positive for GFAP and $p185^{c\text{-}neu}$, the *c-neu* proto-oncogene encoded transmembrane tyrosine kinase receptor protein. $p185^{c\text{-}neu}$ is overexpressed after astrocyte transformation. The fresh tumors were immunohistochemically stained for the presence of plasminogen activators as an index of migratory capacity. Both tissue (tPA) and urokinase (uPA) plasminogen activators were observed as well as guanidinobenzoatase, a serine protease associated with migrating cells. These data demonstrate that migration of the GM malignant astrocytoma cells into ECM hydrated gels is correlated with the expression of plasminogen activators and proteases which can either activate or function as collagenases. Supported by DVA and NIH, NCI 48956 (JJB).

541.3

GABA AND NGF INDUCE EMBRYONIC RAT SPINAL CORD CELLS TO MIGRATE. T. N. Behar*, A. E. Schaffner, C. Colton[1], and J. L. Barker. Lab. of Neurophysiology, NINDS, NIH, Bethesda, Md. 20892 and [1]Dept. of Physiology and Biophysics, Georgetown University School of Medicine, Washington, D.C. 20007.

Chemotactic and chemokinetic migration of acutely dissociated spinal cord cells derived from 12 to 15 day-old rat embryos (E12-E15) was analyzed in vitro using a chemotaxis chamber. Beginning at E13, embryonic cells migrated within 4 hours toward nanomolar concentrations of γ-amino butyric acid (GABA) and picomolar concentrations of nerve growth factor (NGF) and muscimol, a $GABA_A$ agonist. Bicuculline, a $GABA_A$ receptor antagonist, completely blocked the muscimol-induced migration, suggesting that the chemokinetic effect of GABA is specific and involves a bicuculline-sensitive receptor. Cellular migration was also inhibited by pre-incubation of GABA or NGF with specific antibodies. Extending the length of the migration period to 18 hours did not result in a significant increase in the total number of migrated cells, suggesting that all of the cells capable of responding to the chemoattractants responded within the first 4 hours. A modified "checker-board" analysis indicated that GABA exerted a chemokinetic effect on cells, while NGF was predominantly chemotactic, inducing cells to migrate along a chemical gradient.

E13 and E14 spinal cords contained the greatest number of responding cells, which were located primarily in the ventral half of the cord. Immunolabelling indicated that most migrating cells were postmitotic neurons. The majority (>75%) of migrating cells expressed neurofilament protein (NF) and none of the migrating cells incorporated BrdU during the course of an 18 hour assay. These results suggest that both GABA and NGF are capable of directing the migration of newly generated neurons during early spinal cord development.

541.4

ELECTRON MICROSCOPIC OBSERVATION OF MIGRATING GRANULE CELLS BY PERPENDICULAR CONTACT GUIDANCE IN THE CEREBELLAR MICROEXPLANT CULTURE. K.Ono[1]*, N.Nakatsuji[2] and I.Nagata[3], [1]Dept. of Anat., Okayama Univ. Med. Sch., Okayama 700. [2]Natl. Inst. of Genetics, Mishima 411, [3]Tokyo Metropo. Inst. Neurosci., Fuchu 183, Japan.

We have previously found that cerebellar granule cells migrated not only parallel but also perpendicular in cerebellar microexplant cultures (Development 106, 442-447, '89). In the present study, we examined the fine structure of granule cells with special reference to the cytoskeletal architecture at their transitional stage. On the 1st day of culture, asymmetrical bipolar cells migrated out radially from the explant. Microspikes (filopodia) protruded from their perikarya and radial neurites, which frequently contacted the neighboring cells and parallel neurites. Microspikes from perikarya contained microtubules (MT), suggesting that they initiate the perpendicular processes. After 2-3 days in culture, the cells changed orientation perpendicularly to the radial migration. Centrioles (CT) were frequently observed at the base of the perpendicular process, and MT extended from CT. These findings suggest that; 1) microspikes seem to play important roles to determine the initial orientation of perpendicular processes, 2) CT act as MT organizing centers and may be related to formation of perpendicular processes.

THE ROLE OF THROMBOSPONDIN IN GRANULE CELL MIGRATION IN THE DEVELOPING CEREBELLUM. L.J. Boyne*, K.S. O'Shea, V.M. Dixit. University of Michigan School of Medicine, Ann Arbor, MI 48109.

The role of TSP in cell migration, process outgrowth and fasciculation was assessed using cerebellar explants. Glass coverslips were coated with polyLlysine followed by either 20 ug/ml laminin (LN) or 10 ug/ml TSP. Cerebella were dissected from postnatal day 8 mice and the external granule and Purkinje layers removed and plated onto the coverslips and defined medium added. When the distance processes extended and cells migrated from the explants were measured, growth on LN exceeded that on TSP. Immunocytochemical localization of anti-neurofilament (NF) antibodies (Ab) and anti-glial fibrillary acidic protein Ab showed that initial outgrowth on LN was NF positive. The initial outgrowth on TSP, however, was glial with neuronal outgrowth occurring secondarily. Addition of anti-TSP strikingly inhibited granule cell migration on explants growing on LN. When DiI labelled, NGF-primed PC12 cells were added after 3 days in culture, 53.9% of the PC12 cells extended neurites onto the granule cell processes growing on LN. In the presence of anti-TSP Ab only 30.3% of the PC12 cell processes fasciculated. TSP promotes early glial cell differentiation and consistent with its deposition in association with migrating cells and their processes in the developing cerebellum *in situ*, TSP plays a crucial role in granule cell migration and fasciculation *in vitro*. Identification of Polypeptides that Potentially Comprise the Plasmalemmal Microdomain Between Migrating Neuronal and Radial Glial Cells. R. Cameron and P. Rakic*, Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

Detachment of postmitotic neurons from other cellular elements in proliferative zones and their subsequent movement along a scaffold of radial glial cell processes is a basic tenet of cortical development. Although several neuronal cell adhesion components have been described, glial cell counterparts have remained elusive. We have initiated studies to identify glial cell polypeptide components that may participate in the selective affinity for migrating neurons. Of several heterologous polyclonal antisera developed against plasmalemmal fractions obtained from primary cultures of neonatal rat Type-I glial cells, one (D4) immunolabels the surface of astroglial cells in a patchy pattern. Immunofluorescent analyses demonstrate that the plasmalemmal microdomains are present on both Type-I astroglial and radial glial cells but are absent from oligodendrocytes and Type-II astrocytes. The microdomains do not co-localize with vinculin, actin, or integrin subunits. In many cases, immunostaining appears to localize to sites of cell-cell contact, both glial-glial and glial-neuronal. For example, for migrating neuronal cells in dissociated cell cultures, D4 immunoreactivity is detected at sites where the somal region and the leading process are in contact with an elongated glial cell fiber. The integrity of the microdomains is maintained in the absence of extracellular Ca and Mg ions and following the disruption of the actin cytoskeleton, but appears to require the presence of an intact microtubule cytoskeleton. Biochemical analyses suggest that the plasmalemmal microdomains are composed of several antigenic components and the isolation of these microdomains is being pursued. Thus far, we have focused on the characterization of a polypeptide of 70-72 kD. Preliminary glial-neuronal cell co-culture analyses suggest that this glial cell polypeptide undergoes extensive N-glycosylation in the absence of neuronal cell contact. These data suggest that the polypeptide(s) identified may contribute to the neuronal-glial cell migration junction but definitive proof will require analyses ultilizing immunological-based perturbation of cell-cell adhesion and cell migration events. N-METHYL-D-ASPARTATE (NMDA) RECEPTORS MODULATE NEURONAL MIGRATION: A LASER MICROSCOPIC STUDY IN A CEREBELLAR SLICE PREPARATION. H. Komuro* and P. Rakic, Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510

The majority of postmitotic neurons in the brain migrate to their final positions. Recently, we found that Ca ion influx, regulated specifically by N-type calcium channels, is essential for this movement, but the mechanism of regulation was not understood. Here, we report that inhibition of the NMDA receptor-ion channel in a cerebellar slice preparation also slows down the granule cell migration by reducing the Ca ion influx. Cerebellar slices (400-800 μm thick) from postnatal 10 day-old mice (CD-1) were stained for 30 min with the carbocyanine dye-DiI (10 μg/ml) and then maintained in a tissure culture medium for up to 6 hours at 37 C. Use of a confocal laser microscope allows the estimate of the migratory rate by measuring the change in distance between the place of neuron origin in the external granular layer and the front of the labeled cell soma in the molecular layer. Under these conditions the mean rate of granule cell migration in slice preparation of 10-15 μm/hr, is comparable to that measured in vivo. Blockade of the nonNMDA receptors or GABA receptors by their specific antagonists did not change appreciably the rate of granule cell migration. In contrast, blockade of the NMDA receptor by addition of 100 μM D-AP5 or 10 μM MK801 to the culture medium resulted in a significant slowdown in cell movement. On the other hand, the enhancement of NMDA receptor activity by the removal of the Mg ion or addition of 10 μM glycine to the culture medium increased the rate of cell migration. Likewise, the rate of cell migration could be also enhanced by the slight increase in extracellular glutamate produced by addition of p-CMSP which inhibits glutamate uptake by adjacent glial cells. These results indicate that NMDA receptors and extracellular glutamate play an important role in neuronal migration by regulating Ca ion influx in cytoplasm of postmitotic cells. Supported by NS22807.

SUBSTRATES FOR DIVERSE MIGRATORY PATHWAYS IN THE DEVELOPING CORTEX. Nancy A. O'Rourke*, Christine E. Kaznowski, & Susan K. McConnell, Dept. of Bio. Sci. , Stanford Univ., Stanford, CA 94305

In previous time-lapse imaging studies, we examined the migration of DiI-labeled cells through the intermediate zone of cortical brain slices. A number of migratory patterns were revealed, including radial migration directly toward the pial surface, migration orthogonal to the radial direction, and migration in almost all angles in between. Non-radial migration patterns may underlie some of the spread of clonally-related cortical neurons recently revealed in retroviral lineage studies. In addition, the diversity of migration routes suggests that the substrates for cortical migration may be more complex than previously suspected. To examine the most likely cellular substrate, the radial glia, slices were stained in whole mount with antibodies to vimentin. Staining revealed dense palisades of glia extending directly radially or in shallow sinuous curves from the ventricular to the pial surface. These patterns closely resemble those seen in the intact developing cortex and suggest that cortical slices retain normal distributions of radial glia. Additionally, their orientation suggests they could support migration in the radial or near-radial directions. The 3-D morphologies of individual glia, labeled in fixed slices with DiI, were examined with confocal microscopy. While most glia extended radial processes, occasional glia were found with processes that made right angle turns within the intermediate zone, and thus could conceivably serve as substrates for orthogonal migration. While radial glia may provide a viable substrate for the various patterns of migration, other possible substrates could include axons and ECM. To identify definitively the substrates of the individual migrating cells observed in the time-lapse studies, their fluorescent label was photoconverted into a DAB reaction product for future identification. Slices were then either stained with vimentin antibodies or processed for EM. The results confirmed that at least some radially migrating cells use radial glia as their substrate. Similar methods can be used to identify the substrates of orthogonally migrating cells. Supported by NIH EY06314, NSF PYI , and PEW Scholars.

Development and Trajectory of Chick Olfactory Nerve and Its Relationship to GnRH Neuronal Migration. K.A. Sullivan* and A.J. Silverman, Dept. Anat. & Cell Biol, Columbia Univ., NY,NY 10032.

Gonadotropin releasing-hormone (GnRH) neurons originate in the olfactory placode in the chick and migrate across the nasal septum within the olfactory and/or terminal nerve. The importance of these nerves in directing the extracranial course of GnRH neurons and their entry into the CNS was suggested by an analysis of a Kallmann's syndrome fetus (Schwanzel-Fukuda et al., Mol. Brain Res.6:311, '89). The factors involved in targeting GnRH neurons to their final destinations in the forebrain are unknown. The current investigation was undertaken to follow the ontogeny of the olfactory nerve in the chick forebrain and to ask if GnRH neurons use axon branches to migrate within the CNS. Embryonic chicks at E6, E9 and E12 were fixed, the lipophilic dye, DiI (Bioprobes D-3886) applied to the placode [E6] or to the olfactory nerve [E9 and E12] and tissue maintained at 37^{0} C for 5 to 10 days. DiI was observedin 30um cryostat sections in the olfactory nerve and in branches of the trigeminal. Sections containing DiI were immunostained for chicken neurofilament or cGnRH I to verify the axonal character of the DiI^{+} structures and to examine the relationship of olfactory derived axons to GnRH neurons, respectively. DiI was retained by omitting any detergent treatment. Preliminary results indicate that migrating GnRH neurons are closely associated with the olfactory nerve along its entire course on E6 and E9. OBSERVATIONS REGARDING NEURAL CREST CELL MIGRATION IN NEURULATING CHICK EMBRYOS. K.R. Shankar, C.M. Chuong, T. Jaskoll* and M. Melnick. Graduate Program in Craniofacial Biology, University of Southern California, Los Angeles, CA 90089-0641.

Craniofacial abnormalities frequently observed in association with neural tube (NT) defects may be related to altered neural crest (NC) migration. Cephalic NC contributes extensively to mesenchyme from which most of the craniofacial structures develop. The migratory fate of NC appears to depend on the control of initial adhesion of crest cells between themselves and to the extracellular matrix. We have designed experiments to pertubate these interactions in chick embryos with excess retinoic acid (RA) administered in ovo. Immunocytochemistry and 3-D reconstruction of developing NT's so exposed reveal decreased NC associated with a persistent up-regulation of N-CAM as compared to unexposed controls. Direct observations of progressive NT/NC differentiation in unexposed live specimens using high definition, time-lapse microcinematography demonstrates that normal chick cranial NC, unlike trunk NC appear not to migrate in large numbers or as a sheet. Further, our in vitro coculture experiments of head and trunk NT explants support the filmed observations in live specimens; cranial NC migrate in significantly smaller numbers than trunk NC and over shorter distances per unit time. The spatiotemporal immunohistochemical distribution of N-CAM in the NC of these cocultured explants, as well as explants exposed to exogenous RA confirms our observations in ovo. A LONG-DISTANCE CUE FROM EMERGING DERMIS STIMULATES NEURAL CREST MIGRATION. K.W. Tosney *. Biology Department, University of Michigan, Ann Arbor, MI 48109.

Neural crest cells delay entering the dorsolateral path (DLP) between the ectoderm and somite until ventral migration is virtually complete. This delay may be imposed by a temporal regulation of both inhibitory and stimulatory cues. An early inhibition has been documented using surgeries: when the dermatome is absent, markers for inhibition are absent and crest cells enter the DLP precociously (Lasky et al., N.S. Abs., 1991). However, dermatome deletions fail to abolish the delay fully, suggesting a second cue is also needed for crest cell entry.

To test whether crest cells also require a stimulatory cue from dermis which first emerges from distal dermatome as crest cells enter the DLP, I grafted older dermatome from quail embryos to the distal DLP of chick embryos and fixed the embryos after 20-24 hr. I identified quail cells (MAB 275.7B, B. Carlson) and crest cells (DiI label or MAB HNK-1, C. Erickson) in serial frozen sections. When older tissue is grafted and forms dermis, chick crest cells enter the DLP precociously. Larger grafts recruit more crest cells into the DLP and also recruit crest cells from the ventral path into the DLP. Stimulation is specific to dermis since crest cells enter on schedule when younger dermatome or posterior sclerotome are grafted. Dermis stimulates migration at a distance since grafts lie 100-200 μm from the entry to the DLP. Grafts do not alter the distribution of a marker for inhibitory function (peanut agglutinin-binding) in the proximal DLP. The emerging dermis thus provides a putative chemotactic cue that can stimulate neural crest cells to enter the DLP. Supported by NS-21308.

PERIPHERAL CONNECTIONS OF AUTONOMIC MOTOR NEURONS ARE NOT REQUIRED TO SUSTAIN NORMAL MIGRATION PATTERNS *IN VITRO*. R.P. Barber,* P.E. Phelps and J.E. Vaughn. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

The phenotypic differentiation of spinal autonomic motor neurons (AMNs) may be modulated by epigenetic factors encountered during the histogenic migrations of these cells. The dorsal translocation of AMNs from the primitive motor column of embryonic rat spinal cord occurs between embryonic days 14 and 16 (E14 and 16), after AMN axons have reached their peripheral targets. Since this movement also occurs in organotypic slice culture, the present experiments were conducted to determine if the connection of AMNs with their peripheral targets is necessary to sustain the dorsal translocation of these cells. The ventral roots and paravertebral ganglia of E14 spinal trunk slices were injected with DiI and cultured for 4 h. Subsequently, the injection sites were microsurgically removed, and the remaining part of the slice was cultured for a total of 72 h. Confocal microscopy revealed AMN migration patterns that were virtually the same as those observed in control slice preparations. Thus, continuous connection to peripheral targets does not appear to be necessary to sustain the migratory patterns of AMNs in developing rat spinal cord, as is also the case for the less complex histogenic movements of AMNs in chicks (Prasad, A. and Hollyday, M., *J. Comp. Neurol.* 307:237, 1991). *Supported by grants NS25784 and NS18858 from NINDS.*

PROCESS OUTGROWTH, GROWTH CONES AND SPROUTING VI

542.1

EFFECTS OF STAUROSPORINE AND CALPAIN INHIBITORS ON NEURITE OUTGROWTH IN CULTURED PC12 NEURONS. J.B. Denny* Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249.

PC12 cells were cultured in either DMEM or RPMI-1640 medium containing 10% horse serum and 5% fetal calf serum. Neurite extension was induced by the addition of NGF (100nM) to these media. Some cultures were pretreated for 1 hr at 37°C with either 2 uM staurosporine, 13 uM calpain inhibitor I (N-acetyl-leu-leu-norleucinal), or the vehicle DMSO. Calpain inhibitor II (N-acetyl-leu-leu-methioninal) was also used. NGF was then added and the morphology of the cells, and particularly the growth cones, was observed using phase contrast microscopy 1 hr, 24 hrs, and 3 days later. The staurosporine-treated cells produced growth cones, as did the DMSO and calpain inhibitor-treated cells, but the growth cones were distorted morphologically. The same average number of growth cones appeared per cell in the case of all pretreatments. By contrast, the growth cones of the DMSO and calpain inhibitor-treated cells were indistinguishable from those seen in cells receiving no pretreatments. After 24 hrs the staurosporine-treated cells disintegrated, while the other cells continued to extend neurites. When the above treatments were applied to cells that had been allowed to extend neurites for 7 days, staurosporine was found again to induce cell disintegration after 24 hrs, while the other treatments produced no effect.

542.2

EFFECTS OF CALMODULIN INHIBITORS ON NGF-DEPENDENT NEURITE OUTGROWTH AND ON MAINTENANCE OF NGF-DEPRIVED NEURITES BY ELEVATED K^+. *KENNETH K. TENG* AND LLOYD A. GREENE.* Department of Pathology and Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University, New York, N.Y. 10032.

We previously showed that elevated K^+ exhibits a stabilizing, but not growth-promoting, effect on neurites in NGF-deprived cultures of PC12 and PC12-C41 cells and that this effect is mediated via both N- and L-type Ca^{+2} channels. The present work investigated the role of Ca^{+2} on neurite stabilization by elevated K^+ and on the underlying molecular mechanism of NGF-promoted neurite elongation and stabilization. The calmodulin inhibitors TFP or calmidazolium (R 24571), but not TPA-induced down-regulation of PKC, abrogated neurite-maintenance by elevated K^+. The role of calmodulin on NGF-induced neurite outgrowth was tested by treating PC12-C41 cells in the presence of NGF with or without R 24571 (1μM). While R 24571 did not affect generation or maintenance of the neurite networks, the neurites of cells pre-treated with NGF plus R 24571 could not be maintained by elevated K^+, even after wash out of the drug. This suggests that stabilization of neurites by elevated K^+ requires the activation by NGF of a calmodulin-dependent system. Finally, although neither dBtcAMP nor elevated K^+ alone elicits neurite outgrowth, both treatments together yield the formation of neurite-like processes and partially mimic the biochemical effects of NGF on the cytoskeleton. Taken together, these results suggest that neurite outgrowth can be experimentally dissected into at least several discrete components, one of which is calmodulin dependent.

542.3

EFFECTS OF EXOGENOUS (NGF) AND ENDOGENOUS TROPHIC FACTOR (S) ON THE REINNERVATON OF TARGET REGIONS WITHIN FETAL AND ADULT SPINAL CORD BY ISOLATED DORSAL ROOT GANGLIA (DRG) IN ORGANOTYPIC CO-CULTURES. R. Evans and H. Yip*. Dept. of Anatomy, University of Utah, Sch. of Med., Salt Lake City, UT 84132.

The effects of exogenous and endogenous neurotrophic factors on the reinnervation of fetal or adult spinal cord were studied by co-culturing DRG explants. Clusters of 4 DRGs from either 15-day old fetal rat or young adult rats (100 g) were co-cultured in close proximity (0.5 mm) to spinal cords from the same age or different age. The DRG and spinal cord co-cultures are of 4 types (all stripped of DRGs and meninges): (1) fetal DRGs with spinal cord explants from the same age; (2) fetal DRGs with spinal cord explants from adult animals; (3) adult DRGs with spinal cord explants form the same age; (4) adult DRGs with spinal cord explants from fetal animals. The cultures were grown on collagen-coated glass coverslips in the modified polystrene Nunclon 4-well multidishes and maintained in Eagle's minimum essential medium with Earle's balance salt solution. To visualized and trace neurite outgrowth within the spinal cord, DRGs were incubated with carbanocyanine dye (DiI) before they were co-cultured with the spinal cord. The cultures were observed under fluorescence microscopy. Eighty percent of fetal DRG co-cultured with fetal cord had neuritic outgrowth with or without NGF within the first week. NGF seems to increase the number and rate of neuritic outgrowth from the DRG explants. Addition of anti-NGF antiserum to the cultures blocked about 50% of the outgrowth. Intensely fluorescent neurites can be found both in the dorsal and ventral gray matter of the spinal cord. Retrograde HRP tracing confirmed the source of neurites was from the nearby DRG. Most of the neurites tend to avoid the white matter. Little or no neurites outgrowth could be elicited from the adult DRG explants with or without NGF. Neurites outgrowth from the fetal DRGs co-cultures with the adult spinal cord did not grew into the spinal cord.

NGF AND cAMP INDUCE NEURITE GROWTH IN PANCREATIC B-CELLS R. Vidal-Tamayo, T. Martínez, C. Sánchez, M.C. Ramírez-Medeles and M. Hiriart* Inst. Fisiología Celular, Dept. Bioenergética, UNAM, México D.F. 04510, MEXICO.

The embryological origin of pancreatic B-cells is unclear. B-cells share several features with neurons, which include their ability to extend neurites in vitro. We studied whether neurite development by adult and fetal (18 i.u.) rat B-cells is promoted by neural growth factor (NGF and dibutyryl 3'-5'cyclic adenosine monophosphate (DBc-AMP). Dissociated pancreatic islet cells were cultured for 14 days in the presence of 50 ng/ml NGF or 5 mM DBcAMP or both, and stained for insulin. Fetal cells responded better to treatment than adult ones. DBcAMP induced cell flattening and the production of short cytoplasmic extensions.

The overall morphological changes of a population was estimated by the neurogenization index (NI, % neurite-bearing cells times average neurite longitude). NGF and DBcAMP clearly induced phenotypical changes in the cells, showing positive synergism in promoting neurite extension in pancreatic B-cells.

MICROGLIA AND ASTROCYTE PROLIFERATION AND TROPHIC FACTOR GENE EXPRESSION DURING TERMINAL DEGENERATION AND CHOLINERGIC SPROUTING. A.M. Fagan* and F.H. Gage. Dept. Neurosci., Univ. of Calif., San Diego, La Jolla, CA 92093.

Transection of the perforant path (PP) leads to terminal degeneration in the dentate gyrus molecular layer (ML), rapid glial responses and subsequent neuronal sprouting in the denervated zone. Reactive gliosis, characterized by glial hypertrophy and/or hyperplasia, may be a determinant of the degree and/or quality of neural repair. Using combined immunocytochemistry and 3H-thymidine autoradiography, we demonstrate hypertrophy and proliferation of microglia and astrocytes in the denervated ML. Inhibition of glial proliferation with anti-mitotic drug administration does not affect cholinergic sprouting in this model system. Hypertrophic changes, suggesting functional activation, proceed independently of proliferation. Activated microglia and astrocytes produce cytokines and growth factors in vitro, which if induced in vivo, may be involved in neural reorganization. Using riboprobe in situ hybridization, we demonstrate 1) IL-1B mRNA localized to cells surrounding the wound but not in reactive glial cells in the denervated ML, 2) changes in GFAP mRNA in the ML, indicating upregulation of astrocytic structural proteins, and 3) no evidence for NGF or bFGF mRNAs in hypertrophic glial cells. These data demonstrate that glial proliferation is not required for cholinergic sprouting in this model system. Furthermore, upregulation of gene expression for IL-1B, NGF and bFGF by reactive glial cells does not appear to play a role in initiating these sprouting events.

542.6

STIMULATORY EFFECTS OF RETINOIC ACID ON NEURITE OUTGROWTH FROM CHICK SENSORY GANGLIA EXPLANTS. L. Hsu.*Department of Biology, Seton Hall Univ. S. Orange, NJ 07079.

Explants of sensory ganglia from chick embryos ranging from 9-13 days of age developed neurites upon exposure to trans-retinoic acid. Fine outgrowths were detected extending from the periphery of the explants within 20 hrs after as short an exposure period as 5 hrs. Retinoic acid was an effective neurite-promoting agent in growth medium which included insulin but was unable to induce ganglia differentiation in unsupplemented F12 medium or F12 medium with progesterone. Dose concentrations above 5 x 10^{-5}M were cytotoxic to the cultures and caused explants to detach from the collagen substratum. The stimulatory effects of retinoic acid on neurite outgrowth were synergistic with those of 12-0-tetradecanoylphorbol 13-acetate (TPA). When the two agents were combined, the treated explants produced morphologically distinct neurites which formed short, thick fascicles. Explants of central nervous tissue including embryonic brain and spinal cord were unresponsive to treatments of either retinoic acid alone or combinations of retinoic acid and TPA.

542.7

OPTIMIZED SURVIVAL OF HIPPOCAMPAL NEURONS IN B27, A NEW DEFINED SERUM-FREE MEDIUM, G.J. Brewer*, J.R. Torricelli and P. Price+,Southern Illinois Univ. Sch. Med.,Springfield, IL 62794, +GIBCO/BRL Life Technologies,Grand Island, NY 14072.

In B27 (GIBCO 680-7504AB), the concentration of each of the 25 components of a previously developed serum-free medium (Brewer & Cotman, Brain Res. 494:65-74) was optimized. Optimization was assessed by growth of embryonic rat hippocampal neurons at 160 cells/mm^2 for 4 days at 37^{0}C, in a 5% CO_2, 9% O_2 incubator without a glial feeder layer. Viability was determined by staining with fluorescein diacetate and propidium iodide. Above 400 plated cells/mm^2, survival was 70-80% in B27, independent of plating density. Less than 10% of the cells stained as glia with anti-GFAP antibody. At lower cell densities, survival was significantly lower but could be rescued to the 60% level at 40 cells/mm^2 by simply applying a cover slip on top of the cells. This suggests that medium deficiencies or trophic factors affect survival at low cell densities. By optimizing glutamine supplementation, neuron growth could be selected over glial growth. B27 was found to at least double the survival produced by DME/F12 + 10% fetal bovine serum or DME/F12 + Bottenstein's N2 supplements. B27 also supports acceptable survival for as long as one month. This defined medium should be useful for studies of individual and small networks of neurons, their development, plasticity and responses to pharmacologic, toxic and trophic factors.

PROCESS OUTGROWTH, GROWTH CONES AND SPROUTING VII

543.1

PROTEIN SYNTHESIS AND mRNA IN GROWTH CONES FROM DIFFERENTIATED SH-SY5Y NEUROBLASTOMA CELLS. G. Meyerson[1]*, V. Parrow[1], H.H. Pfenninger[2] and S. Påhlman[1]. [1]Department of Pathology, University Hospital, S-751 85 Uppsala, Sweden, [2]Department of Cellular and Structural Biology, Denver, Colorado, USA.

The human SH-SY5Y neuroblastoma cells differentiate into neuron like cells when treated with the phorbolester 12-0-tetradecanoylphorbol-13-acetate (TPA). Phenotypical changes of the differentiated cells include growth inhibition, formation of neurites with growth cones and varicosities containing dense core granules. In this study we have characterized a growth cone and a cell body fraction from differentiated SH-SY5Y cells. The characterization is based on both ultrastructural (EM-analysis) and biochemical (protein markers as GAP-43, synaptophysin and MAP-2) criteria. Ribosomes were commonly found in intact growth cones of differentiated SH-SY5Y cells. By ^{35}S-methionine labeling of fractionated material, local protein synthesis were shown to occur in growth cones. Northern blot analysis shows that both dendritic- (MAP-2) and axon-(GAP-43) specific mRNA are present in the growth cone fraction, as well as mRNA coding for neuropeptide tyrosine. However, mRNA coding for the nuclear proteins c-**jun** and N-**myc** are detectable at very low levels in the growth cone.

543.2

A PHOSPHORYLATION EPITOPE ON MAP 1B THAT IS EXPRESSED IN GROWING AXONS IN THE DEVELOPING RAT CNS. P. R. Gordon-Weeks*, S. G. Mansfield, C. Alberto and F. Moya. Dev. Biol. Res. Cen., King's College London, London WC2R 2LS, U.K. and Dpto. Gen, Mol. Micr., Univ. Alicante, Alicante, Spain.

We are interested in the role of the cytoskeleton in neurite outgrowth. We have isolated a monoclonal antibody (mAb 150) that recognises a phosphorylation epitope on the microtubule-associated protein (MAP) 1B. Immunoblot analysis of developing rat central nervous system (CNS) shows that mAb 150 is directed against a protein of approximately 325 kDa (MAP 1B) that stoichiometrically co-polymerizes with microtubules through successive cycles of temperature-dependent assembly and disassembly. Removal of phosphate from blotted proteins using alkaline phosphatase abolishes the binding of mAb 150 to MAP 1B indicating that the epitope is phosphorylated. In the developing rat nervous system, immunohistochemistry with mAb 150 shows that the phosphorylation epitope on MAP 1B is transiently expressed in growing axons and growth cones but not in dendrites. For instance, in the neonatal rat cerebellum, parallel fibres are stained only during elongation and not after synaptogenesis. Similarly, in the embryonic spinal cord, commissural and other axons express the mAb 150 epitope only while extending. The mAb 150 epitope is also transiently expressed in radial glial fibres and in certain cell nuclei. Immunostaining of sections with mAb 150 was completely abolished by alkaline phosphatase treatment. Immunoelectron-microscopy in the floor-plate region of the embryonic spinal cord confirmed that mAb 150 stains growing axons and their growth cones. These observations and previous ones made by us in cell culture (Mansfield, *et al. J. Neurocytol.* **21**, 1007, 1991), suggest that a developmentally regulated phosphorylation epitope on MAP 1B recognised by mAb 150 may be important in axonogenesis.

543.3

ENTRY OF MICROTUBULES INTO DEVELOPING NEURITES DOES NOT REQUIRE POLYMERIZATION OF TUBULIN. C.L. Smith* and S.A. Walters. Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Our previous work suggested that neurite formation by chick sympathetic neurons grown *in vitro* involves bulk flow of cytoplasm from the neuronal cell body into a filopodium. The simultaneous entry of microtubules and cytoplasm into neurites suggested that assembled microtubules move into the neurite, and that this movement does not require tubulin polymerization. Here, we show that microtubules move into neurites formed in the presence of nocodazole, an inhibitor of tubulin polymerization. Cultures of dissociated sympathetic neurons were exposed to medium containing 1μM taxol for 30 min to stabilize microtubules and then transferred to medium with 2μg/ml nocodazole. This dosage of nocodazole blocked polymerization of tubulin, as assessed by immunolabelling with a monoclonal antibody specific for recently assembled microtubules. Filopodia in living cultures examined by time-lapse video-microscopy were observed to fill with cytoplasm from neuronal cell bodies, thereby transforming into processes resembling neurites. Immunolabelling showed that these neurites contained microtubules, whereas other filopodia that had not filled with cytoplasm did not. The presence of microtubules in neurites formed during inhibition of tubulin polymerization indicates that microtubules assembled in neuronal cell bodies are translocated into filopodia.

543.4

HETEROGENEOUS DISTRIBUTION OF ALPHA1 AND BETAII TUBULIN mRNAs IN ADULT RAT BRAIN REVEALED BY IN SITU HYBRIDIZATION. C.M. Paden*, J.A. Watt, X. Zhou, J. Pickett[1], and M.M. Oblinger[1]. Dept. of Biology, Montana State Univ,. Bozeman, MT 59717 and Dept. of Cell Biology and Anatomy[1], The Chicago Medical School, North Chicago, IL 60064.

Northern blot analysis of rat brain extracts has revealed that expression of various tubulin isotypes is developmentally regulated. Alpha1 and 6II tubulin mRNAs are present in higher levels in the immature brain, where their expression is believed to be correlated with axonal growth. In addition, their expression is upregulated in adult neurons undergoing axonal regeneration or sprouting. Because the capacity for axonal growth may vary in different areas of the adult brain, we sought to determine whether some mature brain regions retain heightened expression of the α1 and 6II tubulin isotypes. Male rats 65-70 days of age were sacrificed by decapitation under ether anesthesia and the brain rapidly removed and frozen. Sets of serial coronal cryosections were collected at 0.5mm intervals and immersion-fixed for in situ hybridization using ^{35}S-labeled cDNA probes specific for 6II tubulin (RBT1) and α1 tubulin (Mα1) mRNAs. Film as well as emulsion autoradiographs were prepared. Initial inspection revealed a marked regional heterogeneity in the density of film autoradiographs, with similar patterns apparent for both Mα1 and RBT1 probes. Areas of greatest density included: piriform cortex, parts of the septal nuclei, nucleus of the diagonal band, hippocampal formation; paraventricular, supraoptic and ventromedial hypothalamic nuclei; anterodorsal and paraventricular thalamic nuclei; habenula, substantia nigra pars compacta, red nucleus, optic nerve layer of the superior colliculus, parabrachial nucleus, dorsal raphe and locus coeruleus, parts of the olivary complex, and numerous cranial nerve nuclei. Further analysis is required to determine to what extent the apparent regional differences in tubulin expression reflect differences in mRNA expression by individual neurons versus differences in neuronal density.

INCREASED EXPRESSION OF ALPHA1 AND BETAII TUBULIN mRNAs DURING COLLATERAL SPROUTING OF CNS NEURONS. J.A. Watt*, C.M. Paden, X. Zhou, J. Pickett[1], and M.M. Oblinger[1]. Dept. of Biology, Montana State Univ,. Bozeman, MT 59717 and Dept. of Cell Biology and Anatomy[1], The Chicago Medical School, North Chicago, IL 60064.

Increased expression of the α1 and 6II tubulin isotypes is known to accompany the axonal growth that occurs during regeneration of peripheral nerves and during collateral sprouting of sympathetic efferents. To our knowledge, however, their possible role in collateral sprouting of central neurons has not been previously investigated. We have utilized a new model of collateral sprouting by peptidergic neurons of the rat supraoptic nucleus (SON) to address this question. Collateral sprouting of neurons in the contralateral SON was induced via a unilateral knife cut of the hypothalamo-neurohypophysial tract (Watt and Paden, *Exp.Neurol.* 111, 9-24,'91); the knife was stopped dorsal to the hypothalamus in sham-operated controls. Rats were sacrificed 10-30 days later by decapitation under ether anesthesia; the brain was rapidly removed, frozen, and cryosectioned. Sections were immersion-fixed for in situ hybridization using ^{35}S-labeled cDNA probes specific for 6II tubulin (RBT1) and α1 tubulin (Mα1) mRNAs. Film as well as emulsion autoradiographs were prepared. Initial results from densitometric analysis of films indicate that, compared to sham-operated controls, expression of both mRNAs is significantly increased in the intact contralateral SON by 20 days post-lesion, coinciding with the period of axonal sprouting. Conversely, expression in the lesioned SON is significantly reduced by 10 days post-lesion, consistent with the effects of axotomy on expression of α1 and 6II tubulins seen in other CNS systems. While these results must be confirmed by grain counting over individual neurons, they suggest that mature CNS neurons retain the capacity to upregulate tubulin expression as required for axonal growth under appropriate conditions, even though they may fail to do so following axotomy.

ANTIBODIES AGAINST MICROTUBULE-ASSOCIATED PROTEINS FROM *DROSOPHILA MELANOGASTER* CROSS REACT WITH DEVELOPING AND ADULT RAT BRAINS. A.A. Alcantara*, A.R. Reilein, K.A. Chaney, T.M. Pazdera, T.L. Karr and W.T. Greenough. Depts. of Psych., Biochem., and Cell & Struct. Biol., Neuroscience Program, Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

We have examined the patterns of immunoreactivity with monoclonal antibodies raised against in vitro purified *Drosophila* microtubule proteins (MTP) (described in the adjacent abstract—Srinivasan et al.). The potential role of microtubule-associated-proteins (MAPs) in neuronal differentiation makes it relevant to study their expression in developing and adult animals. P2C11 expression was examined in rats between postnatal days P1 and P25 and adult ages P97 and 2 yrs. In cerebral cortex, P2C11 was expressed in the marginal zone and in fibers in the cortical plate and underlying layers at P1. Cortical pyramidal cell dendritic labelling remained in adults. Hippocampal mossy fibers, which synapse with CA3 pyramidal cells, were P2C11 positive at P5. Labelling in CA3 was still evident in 2 yr. old adults. The cerebellum revealed intense P2C11 labelling in the lower molecular layer at P5 and became increasingly wide at subsequent ages during dendritic growth, parellel fiber extension and synapse formation.

A subset of adult rat cerebellar lobules exhibited differential staining with these antibodies. Purkinje cells were P2C11 immunoreactive, whereas inhibitory interneurons in the molecular layer were P2C6 positive. P1C5 staining was present in Purkinje cells, basket cells, and other inhibitory interneurons. A similar pattern of *c-fos* expression has previously been reported in rats during forelimb reach training (Alcantara et al., 1991). We are pursuing a possible correlation between the spatio-temporal expression of Fos and these MAPs.

BIOCHEMICAL ANALYSIS OF MICROTUBULE-ASSOCIATED PROTEINS IN *DROSOSPHILA MELANOGASTER* EMBRYOS. S.Srinivasan, A.R.Reilein,M.A.Canady ,W.T. Greenough* and T. L. Karr Dept. of Biochem., and Neuroscience Program, Beckman Institute, Univ. of Illinois, Urbana, IL 61801

Microtubules are involved in a variety of cellular processes such as meiosis, mitosis, cell shape determination, and cytoplasmic transport. Several proteins associate with microtubules and are termed microtubule associated proteins (MAPs). We have taken a biochemical approach, using a well defined genetic organism, *Drosophila melanogaster*, to study the function of MAPs during the development of the embryonic nervous system. We have characterized microtubule proteins (MTP) from different embryonic stages in *Drosophila* and quantitated the average percent yield of MTP during development and noticed a dramatic increase in average MTP yield from 8 to 12 hours. This increase corresponds to the onset of neurogenesis whereby the microtubules are assembled and stabilized in order to form an elaborate set of neurons needed for the formation of the ventral nerve cord. One dimensional and two dimensional SDS-PAGE gels revealed differences in MAP profiles at different developmental stages. As a first step in trying to identify these different MAP species, we have used purified MTP from 16 hour *Drosophila* embryos as antigens and obtained three monoclonal antibodies (MAb), P2C11, P2C6, and P1C5. P2C11 (~55-60 kD) is associated with mitotic spindles of the pre-cellular blastoderm in 2-3 hour *Drosophila* embryos. The same antibody shows a less systematic diffuse pattern in 16 hour embryos. MAb P1C5 (~66 kD) revealed ubiquitous staining which excluded the nerve cord in 16 hour embryos. MAb P2C6 (~46 kD) stained the ventral nerve cord of 16 hour embryos with high specificity. In addition, these MAbs (P2C11, P2C6, and P1C5) cross react with developing and adult rat brains as described in the adjacent abstract (Alcantara et al.).

"WAVES": GROWTH CONE-LIKE STRUCTURES THAT TRAVEL DOWN THE PROCESSES OF CULTURED HIPPOCAMPAL NEURONS. G. Ruthel* and G. Banker. Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908.

By using time-lapse video microscopy to examine the development of isolated hippocampal neurons in dissociated culture, we have observed heretofore undescribed motile structures that we refer to as "waves". Waves are growth cone-like lamellipodial extensions that form at the base of both axons and the processes that will become dendrites and travel toward the tips of the processes at rates of 150-250 μm/hr. Typically, waves form on the axon every 15-25 minutes. Arrival of a wave at the tip of a process commonly results in a growth spurt which lasts five to ten minutes. Axons in hippocampal cultures grow intermittently and sometimes lack growth cones when they are not elongating. When a wave reaches the tip of such an axon, it often appears to become the new growth cone and the axon begins to grow again. To determine whether the molecular composition of waves is similar to that of growth cones, waves were identified by time-lapse video microscopy, then fixed and stained. Like growth cones, waves stain intensely with rhodamine-phalloidin, indicating that they contain a high concentration of filamentous actin. Waves also stain with an antibody against the actin-associated protein ezrin, which has previously been shown to preferentially stain growth cones (Goslin *et al.* 1989. J. Cell Biol. 109:1621). The similarity between waves and growth cones raises the possibility that waves may represent a mechanism by which materials found in growth cones are delivered to the tips of developing processes.

GROWTH CONE FILOPODIA AS SENSORS OF THEIR ENVIRONMENT: ISOLATED FILOPODIA RESPOND TO SPECIFIC STIMULI. P. Dou*, R.W. Davenport, V. Rehder, R.E. Lee, S.B. Kater, Program in Neuronal Growth and Development, Colorado State University, Fort Collins, CO 80523.

Filopodia have been regarded as the sensory extensions of neuronal growth cones, and they are implicated in directing growth cones towards their targets. Therefore, to study how filopodia themselves react to environmental cues, it is necessary to study them in isolation. We developed a technique to isolate filopodia from growth cones on identified neuron B19 of the snail *Helisoma*. The cells were grown in conditioned culture media (L-15) for 18-24 hours. Subsequently, filopodia were mechanically transected from the growth cone with a fine tip glass micropipette. Many isolated filopodia retained their original shape for times exceeding one hour. In order to test the ability of filopodia to act as sensory structures, we asked whether isolated filopodia could respond to environmental stimuli known to affect growth cone morphology. Previous work has demonstrated that focally applied electric fields and elevated extracellular K^+ concentrations dramatically alter growth cone morphology. Isolated filopodia show striking morphological changes in response to these stimuli: they either retracted or beaded, while a few showed no response. Also in accord with whole growth cone responses, isolated filopodia respond to the neurotransmitter serotonin. Additionally, freeze fracture results demonstrate a high density of intramembrane particles on growth cone filopodia. Taken together, these results suggest that filopodia possess a complement of surface molecules including ion channels and specific neurotransmitter receptors that allow them to act as sensors of their environment.

GROWTH CONE FILOPODIA AS SENSORS OF THEIR ENVIRONMENT: INTRACELLULAR CALCIUM AS A SECOND MESSENGER R.W. Davenport*, P. Dou, V. Rehder, S.B. Kater Prog in Neuronal Growth and Development, Colorado State University, Ft Collins, CO 80523.

Neuronal growth cones extend filopodia into their environment. If filopodia act as environmental sensors for growth cones, then filopodia must be capable of responding to stimuli in a manner which allows direct signalling to the growth cone proper. In the previous abstract we addressed the capability of isolated filopodia to respond morphologically to stimuli known to affect growth cone behavior. Here we show that stimuli which affect both growth cone calcium levels and filopodial disposition also affect calcium levels within isolated filopodia. Identified, cultured *Helisoma* neurons were iontophoretically loaded with Fura-2 prior to filopodial transection. Fluorescent images were obtained with a 100X objective and a chilled CCD camera and digitally stored. Signal to noise ratios for isolated filopodia ranged from 3 - 10 for each excitation wavelength (350, 380 nm), thus allowing standard dual wavelength estimates of $[Ca^{++}]_i$ to be made. Focally applied electric fields (10 mV/μm) caused a rapid (≤ 10 sec) rise in $[Ca^{++}]_i$ to approximately twice rest levels. Elevated KCl (10 mM) caused a transient increase in $[Ca^{++}]_i$ (> 100 nM). These results suggest the presence of both voltage dependent calcium channels and some calcium efflux mechanisms on isolated filopodia. Furthermore, the presence of neurotransmitter receptors is suggested by the ability of 5HT (50 μM) to raise $[Ca^{++}]_i$ (up to 15 fold) and ACh (50 μM) to reverse this effect. These results suggest that neuronal growth cone filopodia can independently respond to environmental stimuli due to functional signal transduction machinery. Thus, filopodia which can contact environmental signals up to 2 hours prior to the advancing growth cone proper can convey relevant guidance information via intracellular calcium to the growth cone.

Depolarization-Induced Calcium Responses in Cytoplasm, Nucleus, and Nucleolus of Cultured Adult Rat DRG Neurons. M.N. Rand*, D.L. Eng, S.G. Waxman & J.D. Kocsis, Dept. of Neurology and Sect. Neurobiology, Yale Medical School, New Haven, CT 06510; and VAMC, West Haven, CT 06516.

Adult rat DRG neurons were dissociated and maintained in culture for up to one week. Relative intracellular calcium levels $[Ca^{2+}]_i$ were imaged and measured using the calcium indicator dye fluo-3AM and confocal scanning laser microscopy (CSLM), at various times after plating (AP), either before, during, or after process regeneration and outgrowth. Cells were loaded in 5 μM fluo-3AM for 35 minutes, transferred to a perfusion bath of oxygenated normal Krebs' solution (with 2 mM Ca^{2+}), and resting levels of $[Ca^{2+}]_i$ were imaged with the CSLM in frame-scan mode. Depolarization of cells via high K^+(60 mM) in the bath resulted in elevated levels of $[Ca^{2+}]_i$, with a proportionally greater fluorescent signal seen in the nucleus and nucleolus 24 hours AP (during neurite outgrowth), compared to 5 hours AP, or more than 100 hours AP (after extensive process outgrowth). The nuclear signal was greater than that of the cytoplasm immediately after plating, but attenuated over time in culture. The nucleolar signal was less than the nuclear signal immediately after plating, increased and surpassed the nuclear signal from 12-48 hours AP, and then diminished again at times greater than 100 hours AP. Local bipolar electrode stimulation at 50 Hz, 1 second duration resulted in transient, reversible elevations in $[Ca^{2+}]_i$ in the three cellular compartments. These electrically-evoked changes could be repeated several times sequentially in most cells; occasionally cells responded with chronically-elevated $[Ca^{2+}]_i$ levels to the initial depolarizing current. High-resolution imaging of the nucleus and nucleolus 24 hours after plating revealed elaborate heterogeneity of the intranuclear fluorescent signal, suggesting the involvement of Ca^{2+} in nuclear mechanisms related to process regeneration and outgrowth.

PATTERNS OF SPONTANEOUS TRANSIENT ELEVATIONS OF INTRACELLULAR CALCIUM IN EMBRYONIC SPINAL NEURONS PRIOR TO NEURITE EXTENSION. X. Gu*, E. Olson and N. C. Spitzer. Dept. of Biology & Center for Molecular Genetics, UCSD, La Jolla CA 92093.

Ca^{++}-dependent action potentials are normal features of early development of *Xenopus* spinal neurons. Prevention of Ca^{++} influx alters several aspects of subsequent neuronal differentiation of postmitotic cells dissociated from neural plate stage embryos. Elevations of $[Ca^{++}]_i$ assessed with fura-2 or fluo-3 occur spontaneously during this period. We have used confocal microscopy to image $[Ca^{++}]_i$ at 5 sec intervals in cultured cells over one hr periods using fluo-3 AM. Active cells were scored as those showing spontaneous increases above baseline in fluorescence and thus $[Ca^{++}]_i$. Cell counts indicated that imaging does not promote cell death.

Neurons exhibit distinct signatures of elevation of $[Ca^{++}]_i$ during this early period of development when they are undergoing primary morphological differentiation. Of 65 differentiated neurons, 18 of 26 (69%) and 26 of 39 (67%) were active at 6-7 and 7-8 hr *in vitro*, respectively. Of 15 latent neurons, without neurites at the time of imaging but differentiated at 1 day, 6 of 8 (75%) and 5 of 7 (71%) were active during the same periods. 40% of both differentiated and latent neurons exhibit spikes with a rapid rise to >150% of baseline in <15 sec, followed by double exponential decay with τ's of 10 sec and 2.8 min. Overall spike frequency ranged from 1-7/hr; latent and differentiated neurons showed 2.0 and 2.4 spikes/hr. Only 26% of morphologically undifferentiated cells exhibited elevations of $[Ca^{++}]_i$; this activity was of variable form, including putative neuronal signatures. However elevations were generally of longer duration and showed single exponential decay. Characteristic patterns of Ca^{++} spike activity may direct neuronal differentiation. Supported by NIH NS15918.

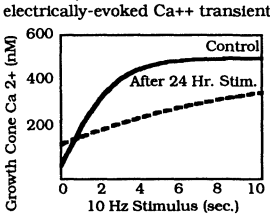
KINETICS OF ELECTRICALLY EVOKED CALCIUM TRANSIENTS IN MOUSE DRG GROWTH CONES. R.D. Fields* and J.T. Russell, Lab. Dev. Neurobiol. NICHD,NIH. Bethesda, MD 20892.

Growth cone motility is exquisitely sensitive to changes in intracellular calcium and electrical stimulation. We measured the kinetics of electrically-evoked Ca++ transients in mouse DRG growth cones and homeostasis of Ca++ during and after 15 min. trains of action potentials (see Fields et al., *J. Neurosci.*10: 2950 for methods). Changes in FURA-2 fluorescence ratio followed exponential kinetics. 10 Hz stimulation induced a rapid increase in Ca++ within the growth cone, with a time constant (τ) of 1.36s. In contrast, in neurons stimulated chronically (> 24 hrs.), electrically-evoked Ca++ transients were slowed (τ = 6.00s).



Intracellular Ca++ recovered during stimulation (τ=90.4s) and after terminating a 15 min. period of stimulation (τ=8.50s). These kinetics were not altered by chronic stimulation. These results suggest that Ca++ homeostasis is regulated by the state of electrical activity of neurons. This may involve decreased Ca++ influx into neurons, or increased activity of a rapidly acting Ca++ removal or buffering mechanism. Activity-dependent regulation of Ca++ homeostasis would make growth cones from electrically active circuits less vulnerable to electrically-induced collapse. In addition, activity-dependent changes in Ca++ homeostasis could have effects on other neuronal processes that are dependent on calcium.

CHRONIC EXPOSURE TO PICROTOXIN INCREASES AXOSOMATIC SYNAPSES AND FUNCTIONAL INHIBITION OF PURKINJE CELLS IN MOUSE CEREBELLAR CULTURES. R. Drake-Baumann [1, 2], A. L. Leiman [4], R. M. Herndon [2, 5], K.L. Tiekotter [5] and F. J. Seil* [1, 2, 3] Neurology Research, VA Medical Center [1] and Depts. of Neurology [2] and Cell Biology & Anatomy [3], Oregon Health Sciences University, Portland, OR, Dept. of Psychology [4], University of California, Berkeley, CA and Good Samaritan Hospital [5], Portland, OR.

Organotypic cerebellar cultures of newborn mice were continuously exposed either to picrotoxin (PTX) or to penicillin (PEN) in nutrient medium from explantation until 13-16 days in vitro (DIV) to examine whether chronic enhancement of neuronal activity would induce specific morphological or physiological changes. The spontaneous electrical activity of explants exposed to PTX by DIV 13-16 revealed numerous units with slow discharge rates. The overall mean discharge rate for PTX treated explants was lower than for controls, while the overall mean discharge rate for PEN treated explants was slightly higher than controls and often revealed a tendency to bursting activity. Cortical stimulation produced a transient inhibition of spike discharge in all groups but the inhibitory effect was significantly enhanced in PTX treated explants. Electron micrographs at DIV 14-15 of explants exposed to PTX revealed an increased number of synapses on Purkinje cell (PC) somata (5/PC), most of which appeared to be with basket cell terminals, while the number of axosomatic synapses present on Purkinje cells of PEN treated explants did not differ from controls (2.2 /PC). The mechanism by which chronic exposure to PTX enhances synapse formation by basket cells may be independent of its inhibitory action on GABAergic transmission.

ROLE OF NERVE GROWTH FACTOR (NGF) IN THE EARLY DEVELOPMENT OF QUAIL DORSAL ROOT GANGLIA (DRG). L. Yao, J. Speight, and P. Bernd.* Department of Anatomy and Cell Biology, State University of New York, Health Science Center, Brooklyn, NY 11203.

We have previously shown that ^{125}I-NGF binding to DRG, *in situ*, is first seen at embryonic day 3.5 (E3.5; stage 23) in cryostat sections of quail. Physiologically important high affinity NGF receptors appear to be present, because specific binding was seen at a low ^{125}I-NGF concentration (2 ng/ml; 80 pM) and cross-linking with HSAB reveals that the high molecular weight ^{125}I-NGF-receptor complex is present. These results are surprising since other labs have shown that avian DRG are unresponsive to NGF, prior to E5, at least with respect to neurite outgrowth. Our recent studies have examined the effects of NGF on neuron-enriched cultures prepared from E3.5 DRG. Cells were grown at a density of 2500/20 mm well in complete medium (MEM with 15% fetal bovine serum and 5% chick embryo extract) on a polyornithine/laminin substrate. Preliminary results have shown that there were approximately 30% more neurons in the presence of exogenous NGF (100 ng/ml) after 24 hrs *in vitro*, as compared to cultures grown in complete medium in the presence anti-NGF (100 ng/ml, Boehringer Mannheim). The effect of NGF was also be blocked by anti-NGF. We have also shown that anti-NGF has no toxic effect on the cultures; cell number remains the same when anti-NGF has been pre-absorbed with NGF. Cultures grown in complete medium with or without exogenous NGF have a similar number of neurons, suggesting the presence of NGF or NGF-like substances in complete medium. Our current studies are aimed at determining whether the increase in cell number is due to a survival or mitogenic effect. Supported by a grant from the Deafness Research Foundation.

OPIOID RECEPTOR BLOCKADE DIFFERENTIALLY MODIFIES NGF AND NGFRs LEVELS DURING RAT BRAIN DEVELOPMENT. E. Pérez-Navarro, J. Alberch*, E. Arenas and J. Marsal. Laboratori de Neurobiologia Cel.lular i Molecular. Dept. de Biologia Cel.lular i Anatomia Patològica, Hosp. Bellvitge, Univ. Barcelona, Casanovas 143, 08036 Barcelona, Spain.

The present work deals with the relationship between naltrexone (NTX), an opioid antagonist, and nerve growth factor (NGF) and its receptors (NGFRs) in the regulation of the central nervous system development.

It has been described that opioid antagonists exert an influence on the growth of neural tissues that is dependent on the duration of opioid receptor blockade (Zagon and McLaughlin, 1986). Thus, we have studied the long term effect of NTX on the content of nerve growth factor (NGF) in the main cholinergic regions of the brain: cortex, hippocampus, septum and neostriatum, and on NGFRs levels in cortical membranes. Chronic NTX treatment, during 14 days (starting P5), induces changes in NGF content or in NGFRs depending on the dose used. 50 mg/kg NTX treatment induced a decrease in the number of ^{125}I-NGF high-affinity binding sites, without detectable changes in NGF levels. However, low doses of NTX (1 mg/kg) produced a decrease in NGF levels in hippocampus, septum and neostriatum with no differences in ^{125}I-NGF binding sites.

Our results suggest that changes in neuronal activity induced by opioid receptor blockade could influence neuronal development through modifications of NGF and NGFRs content.

This work was supported by DGICYT and CIRIT.

OVEREXPRESSION OF NERVE GROWTH FACTOR IN EPIDERMIS OF TRANSGENIC MICE CAUSES SKIN HYPERINNERVATION AND HYPERTROPHY OF TRIGEMINAL GANGLION. K. Albers*, D. E. Wright, B. M. Davis. Departments of Pathology and Anatomy and Neurobiology, University of Kentucky School of Medicine, Lexington, KY 40536.

Nerve growth factor (NGF) is a target derived neurotrophic factor that plays a critical role in the survival and differentiation of neurons in the developing vertebrate nervous system. NGF deprivation in the embryo results in sensory degeneration whereas in neonatal mice, lack of NGF leads to degeneration of neurons in the sympathetic nervous system. In culture, NGF significantly enhances the survival of sensory and sympathetic neurons and neural crest derived cells. We have examined the role of NGF in neuronal survival by targeting the expression of an NGF cDNA (a gift from R. Edwards, UCLA) to the epidermis of transgenic mice. Mouse NGF cDNA expression was driven using the human keratin K14 promoter and enhancer sequences. K14 is an intermediate filament protein expressed in the basal cell layer of the epidermis and other stratified squamous epithelium. The increased levels of NGF resulting from expression of the K14-NGF transgene led to an increase in the density of innervation in the epidermal target tissue, hypertrophy of the trigeminal ganglia, and an increase in the number and size of primary afferents. These results demonstrate that *in vivo* the level of NGF in the target tissue controls cell survival and growth of primary afferents. Supported by NIH NS25617 to BMD & AR40873 to KMA.

PD 90780: A SELECTIVE NON-PEPTIDE LIGAND FOR THE p75 NGF RECEPTOR. R.E. Davis*, M. Dickerson, J. Fergus, T. Hepburn, J. Hopkins, H. Levine, J. Marks, K. Spiegel, J. Jaen, W. Moos. Parke-Davis Pharmaceutical Research, Warner-Lambert Co., Ann Arbor, MI 48106

A series of novel nonpeptide ligands have been discovered that selectively displace NGF from its p75 binding protein (BP). PD 90780 is characteristic of this series. It displaces ^{125}I-NGF from the extracellular domain of p75 in a cell free system with an IC_{50} between 100-200 nM. PD 90780 also inhibits DSS crosslinking of ^{125}I-NGF to p75 but not to gp140^{trk}, suggesting that PD 90780 does not inhibit the binding of NGF to gp140^{trk}. Two ^{125}I-NGF binding components were seen in whole PC12 cells in the presence of PD 90780. A large proportion of ^{125}I-NGF binding was blocked by PD 90780 with an IC_{50} of approximately 200 nM. A smaller component of ^{125}I-NGF binding was not displaced by PD 90780. The relative proportion of PD 90780 sensitive and resistant binding is similar to the proportion of p75 and gp140^{trk} BP immunoprecipitated from native PC12 cells. Therefore, the PD 90780 sensitive binding of ^{125}I-NGF in whole PC12 cells may represent binding of NGF to p75 while the PD 90780 resistant binding may reflect NGF binding to gp140^{trk}.

Despite the ability to completely displace ^{125}I-NGF from the p75 BP, PD 90780 does not block the ability of NGF to stimulate ChAT and MAP kinase activity in PC12 cells. PD 90780 also does not block the ability of NGF to promote survival of rat fetal SCG neurons in culture or inhibit the retrograde transport of NGF from the eye to the SCG in adult rats.

544.5

DISTRIBUTION OF ^{125}I NGF BINDING SITES IN ADULT AND DEVELOPING RAT NERVOUS TISSUE THAT ARE NOT DISPLACED BY PD90780. B. D. Shivers*, P.D. Doyle, C. Raby and R.E. Davis. Neuroscience Pharmacology, Warner-Lambert/Parke-Davis, Ann Arbor, MI 48105.

Nerve Growth Factor (NGF) binds to p75 and p140^{trk} receptor proteins, signalling through the latter. PD90780 is a small organic molecule that displaces NGF binding from the extracellular domain of recombinantly-expressed p75 in a cell-free system. *In vitro* autoradiography was performed using 100pM ^{125}I mNGF in the presence or absence of 100μM PD90780 and the distribution of binding sites determined from film and emulsion autoradiograms. In adult rat brain sections, NGF binding that was not displaced by PD90780 was observed on cell bodies in olfactory tubercule, nucleus accumbens, caudate-putamen, medial septum, diagonal bands, midline thalamic nucleic, cochlear nuclei, interpeduncular nucleus and spinal trigeminal nuclei. Unlabelled, lightly-labelled or heavily-labelled cell bodies were intermingled in all subdivisions of the trigeminal ganglion. Other ganglia were not examined. Neuropil labelling was observed in regions harboring labelled cell bodies as well as presumptive terminal fields of these cell bodies, *i.e.*, cerebral cortex, basolateral amygdala, hippocampal formation, the spinal trigeminal tract and substantia gelatinosa. Spinal intersegmental rootlets and a tract ventral to the central canal were also labelled. On postcoital day (p.c.d.) 12-16, labelled structures included trigeminal nuclei, superior cervical and dorsal root ganglia, spinal cord and regions surrounding whisker follicles. By p.c.d. 20, basal ganglia and forebrain labelling were apparent. In early cerebellar development, transient labelling of the molecular layer was observed. These observations are consistent with the hypotheses that NGF specifies target field innervation and maintains the differentiation state of neuronal subpopulations, *e.g.*, cholinergic neurons. Work is in progress to determine if NGF binding sites that are not displaced by PD90780 represent p140^{trk}. We appreciate the contributions of our Parke-Davis colleagues, J. Marks, K. Spiegel and T. Hepburn, who identified and characterized PD90780.

544.6

NERVE GROWTH FACTOR INCREASES CHOLINE ACETYLTRANSFERASE ACTIVITY IN THE NORMAL AND DAMAGED ADULT RAT BRAIN. W. J. Lipinski*, M. J. Callahan, S. L. Fisher, T. Hepburn and R.E. Davis. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

Nerve Growth Factor (NGF) is an endogenously expressed protein that is responsible for survival and maintenance of select neuronal populations. NGF has been shown to protect basal forebrain cholinergic neurons from atrophy due to age and damage. The effects of NGF on central cholinergic neurons, however, has not been rigorously studied. We report that continuous intracerebroventricular infusions of NGF into otherwise undamaged male rats increases choline acetyltransferase (ChAT) activity in regions of the brain rich in cholinergic neuronal cell bodies: striatum, basal forebrain, and medial septum. Intentional damage to the striatum enhanced the ability of NGF to increase ChAT activity in forebrain cholinergic neurons. This effect of NGF developed gradually over the course of the infusion, reaching a peak following 7 to 10 days of administration. Additionally, intentional damage to the brain shifts the dose-effect curve leftward further suggesting that the damaged brain exhibits heightened responsiveness to NGF. A marked loss or atrophy of forebrain cholinergic neurons is one characteristic of Alzheimer's disease (AD). These data support the cautious therapeutic use of NGF in AD as a means to prevent or reverse cholinergic neuronal atrophy. Because NGF does not travel far from the site of injection, however, procedures must be developed to ensure adequate delivery of NGF to target neuronal populations in the human brain.

544.7

REGULATED EXPRESSION OF NERVE GROWTH FACTOR (NGF) IN BRAIN IMPLANTS: USE OF METALLOTHIONEIN PROMOTER-DRIVEN CONSTRUCTS IN TRANSFECTED GLIAL CELLS. V. Nipper,[1] C.A. Machida[1,2] and G.Nilaver[3]*. [1]Div. Neurosci., Oregon Regional Primate Res. Ctr., Beaverton, OR 97006, [2]Dept. Biochem. & Mol. Biol., and [3]Dept. Neurol., OR Hlth. Sci. Univ., Portland, OR 97201.

Genetically modified cultured cells have been employed to express NGF in brain. We sought to determine if NGF expression in such cells could be modified by regulatory effectors. An 820 bp Pst I fragment containing the entire coding region of mouse NGF gene plus 5′ flanking DNA was directionally inserted into the human metallothionein IIA promoter-driven expression vector pMEP 4 (Invitrogen). This vector contains the zinc-inducible IIA promoter and SV40 polyadenylation signal, and utilizes the hygromycin B gene as the selectable marker. Recombinants were transfected into the rat glioma C6 cell line (calcium phosphate transfection). Transfectants were selected with hygromycin B (1000U/ml; 10-14 days) and colonies isolated using glass cloning cylinders. The transfection efficiency is 7.5 x 10^{-7}. Clonal isolates will be analyzed to determine gene dosage (genomic Southern blot), basal and induced levels of NGF mRNA (Northern blot), and intracellular and secreted NGF (ELISA). Transfectants screened to identify cell clones with minimal leakiness of the IIA promoter will be used as donor cells for transplantation into rat brain. Pilot studies of C6 cell implants in rat brain do not show evidence of metastatic seeding or graft rejection.

PRODUCTION AND ANALYSIS OF TRANSGENIC MOUSE LINES OVEREXPRESSING NGF IN CNS. A. Roghani, T. Farris, J. D. Oh, G.D.Ellison*, L.L. Butcher, D. Hanahan[1] and R.H. Edwards. Depts. of Neurology and Psychology, UCLA School of Medicine, LA, CA 90024 and [1]Dept. of Biochemistry, UCSF, San Francisco, CA 94143.

The basal forebrain cholinergic system is involved in memory processes and the pathogenesis of Alzheimer's disease. NGF is normally produced in small quantities by the target cells to which this system projects. To determine whether or not the expression of NGF in targets affects the synaptic contacts of afferent cholinergic neurons, we placed the mouse NGF cDNA under the control of the regulatory region of the somatostatin gene and used this construct to generate three lines of transgenic mice. S1 nuclease protection assays performed on the total RNA from the adult brain, liver, and kidney of these mouse lines, as well as those of normal C57BL/6 mouse, demonstrated that only one of the three lines (#4) expressed the NGF transgene in the brain, but not in the liver or kidney. We are currently in the process of immunohistochemically analyzing the morphologic response to the expression of this transgene. Among the antibodies we have tested so far, our NGF antibody clearly stains clusters of neurons in various regions of basal forebrain in both normal and transgenic tissues. Preliminary quantitation of cross-sectional area of neurons in the olfactory tubercle of the basal forebrain showed that the cholinergic somata of the #4 transgenic line were increased in size compared to the nontransgenic mouse brain.

CONSEQUENCES OF INCREASED NGF GENE EXPRESSION IN THE HEARTS OF TRANSGENIC MICE. A. Hassankhani#, M. Steinhelper, L. Field, M. Geschwind#* and H.J. Federoff#. #Albert Einstein College of Medicine, Bronx, N.Y. 10461 and Krannert Institute of Cardiology, Univ. of Indiana School of Medicine

To examine the role of nerve growth factor (NGF) in determining the extent of innervation of sympathetic neurons in a target organ, a transgenic mouse model has been created. The cardiac specific α-myosin heavy chain (α-MHC) promoter has been used to drive the expression of an NGF minigene (α-MHC-NGF). α-MHC is activated prior to the ontogenic development of cardiac innervation, becoming the predominant myosin heavy chain expressed in the adult rodent heart. Five independent α-MHC-NGF founders were initially obtained, all of which expressed the transgene exclusively in the heart as demonstrated by RNAase protection and reverse transcription PCR. These lineages all exhibited an interesting albeit variable phenotype consisting of gross cardiomegaly and the presence of immature neural cells which appear to be infiltrating the epicardial region and particularly the atrio-ventricular groove. We have observed death (possibly due to arrythmia) in all transgenic lineages. Increased NGF would be expected to cause sympathetic hyperinnervation and an attendant increase in cardiac catecholamine content. Examination of all transgenic lineages reveal a significant, 20-fold rise in the level of cardiac tissue catecholamines. The extent of cardiomegaly has been best correlated with the level of total catecholamines. During propagation of the α-MHC-NGF lineages, we observed a decline in the penetrance of phenotype and expression of the transgene. Available data indicate that methylation of the transgene, within CpG rich regions is responsible for the diminished expression of the transgene. Studies are currently underway to further characterize physiological and neurobiological issues related to this model.

544.10

A RHOMBOTIN PROMOTER 1-NGF CONSTRUCT FOR THE PRODUCTION OF TRANSGENIC MICE

K. STALEY*, S.J. PICKERING, J.B. UNEY, M.H. JOHNSON, T.H. RABBITTS[1] AND M.V. SOFRONIEW. Department of Anatomy, University of Cambridge and [1]MRC Laboratory of Molecular Biology, Cambridge, U.K.

Nerve growth factor (NGF) influences transmitter-associated enzyme expression in developing basal forebrain cholinergic neurons, but it is not known if NGF regulates developmental cell death in this system. This question could be addressed by altering the levels of NGF produced in the hippocampus or neocortex, the target regions of these neurons. Towards this end, we have generated a rhombotin (rbtn) promoter 1-NGF fusion construct for production of transgenic mice. We have previously found that mice transgenic for a rbtn promoter 1-lac Z construct show promoter 1 activity in the CA1 and CA2 regions of the hippocampus, layers 3 and 5 of the cerebral neocortex, and the cerebellum, which are also major sites of NGF production. NGF cDNA was obtained from mRNA isolated from mouse submaxillary glands and selectively amplified by PCR. The PCR product was cloned and sequenced, and the biological activity of the recombinant protein confirmed. The NGF sequence was subcloned into a plasmid containing the rbtn promoter 1 and an SV40 polyadenylation sequence. Mice generated by injection of a gel-purified 10 kb Not 1 fragment into fertilised MF1 eggs are currently being examined for insertion and activity of the transgene. Analysis of developing basal forebrain cholinergic neurons in these transgenic mice should allow a direct investigation of the putative neurotrophic role of NGF in the septo-hippocampal system and may provide clues as to the function of NGF in other brain regions such as the cerebellum.

544.11

HISTIDINE AND CARBOXY-TERMINAL MUTANTS OF MOUSE ß-NERVE GROWTH FACTOR (NGF) Sang B. Woo, Yuling Luo, and Kenneth E. Neet*. Dept. of Biological Chemistry, UHS/ Chicago Medical School, N.Chicago.

Histidine residues 75 or 84 of mouse NGF were replaced with an alanine residue by site-directed mutagenesis. Mutant genes were transiently expressed in COS-7 cells and proteins were partially purified with an NGF-specific, N60-monoclonal immunoaffinity column. The bioactivity of each His mutant was compared with authentic NGF from mouse submaxillary glands by neurite outgrowth in PC12 cells. H75A showed about 5-fold less activity, while H84A showed far less activity than ß-NGF. These results indicate that His 75 and 84 may be involved in the interaction of NGF with its receptor(s) and support previous chemical modification studies of His residues with diethylpyrocarbonate. However, the lower activity of these mutants could result from incomplete protein folding when transiently expressed in COS-7 cells.

Recombinant mouse NGF (rNGF) was isolated from insect cells infected with a recombinant baculovirus containing a prepro-NGF insert. Three purified forms of rNGF were separated on Mono-S chromatography and had distinct binding and biological activity in DRG and PC12 cell assays. Each form of rNGF differed from mature submaxillary gland mNGF in that the C-terminal Arg-Gly dipeptide had not been processed. Removal of the C-terminal dipeptide by γ-NGF peptidase treatment converted the three forms into a single form, identical to mature mNGF in structure and bioactivity. Thus, a single polypeptide of rNGF can exhibit three distinct biological activities due to the C-terminal dipeptide. We suggest that C-terminal processing of NGF may be physiologically important. NEUROTROPHIN EXPRESSION IN THE DEVELOPING CHICK RETINA. X.-Y. Xie*, A.S. Garner, J.M. Voci and T. H. Large. Dept. of Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

The biological actions of the neurotrophins in the developing nervous system are not limited to survival, but now appear to include the regulation of stem cell proliferation and commitment to a phenotype by post-mitotic cells. We have begun to examine these potential roles using the embryonic chick retina as a model system.

Northern analysis of RNA from embryonic chick retina indicates that neurotrophins and their receptors are expressed during the period of cell proliferation (E3-7) and the subsequent formation of retinal layers. Transcripts for *trk*B (a receptor for BDNF, NT3 and NT4) are present at E5, the earliest age tested. An increase in *trk*B mRNA levels is observed at E13 and corresponds to the period of ganglion cell (RGC) dependence on target-derived factor(s) and maximal expression of BDNF in the tectum. In the retina, NT3 mRNA is present at E7 and is maximal by E14, but BDNF mRNA remains relatively low throughout development. NGF mRNA has previously been shown to be present as early as E6. Thus NGF and NT3 may be "intrinsic" regulators of retinal development while BDNF is a candidate "extrinsic" factor supporting RGC survival.

In order to further examine neurotrophin actions, we have begun to express recombinant neurotrophins in baculovirus. The coding sequence for the precursors of chicken NGF, BDNF and rat NT3 (differs from chick by one K-R substitution) were subcloned into the Bluebac transfer vector for color selection of recombinants. The use of linearized baculovirus DNA improved the efficiency of recombination to 30-40%. Finally, the adaptation of Hi-5 cells to suspension culture in serum-free medium yielded higher expression of recombinant factors compared to Hi-5 monolayer or Sf9 suspension cultures. Bioassays using PC12 cells and chick DRGs indicate Hi-5 cells properly process the precursor proteins to the active, mature factors. In addition, the 13 kD mature chicken NGF protein has been identified on Western blots using an antibody against mouse NGF. These recombinant neurotrophins and the ongoing production of factor-specific, function blocking antibodies will allow us to manipulate neurotrophin levels and to test neurotrophin functions in the developing retina.

544.13

DEVELOPMENTALLY REGULATED EXPRESSION OF THE NEUROTROPHIN HIGH AFFINITY RECEPTORS. T. Ringstedt[1,2], H. Lagercrantz[2] and H. Persson[1]*.1/ Department of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institutet, 2/ Department of Pediatrics, Karolinska Hospital, Stockholm, Sweden.

Tyrosine protein kinases trk, trkB and trkC are essential components of the high affinity receptors necessary to mediate the biological effects of the neurotrophins NGF, BDNF, NT-3 and NT-4. Here we report on their expression during neonatal and perinatal development in the rat brain. Cells expressing mRNAs encoding different members of the trk family were identified by in situ hybridization using oligonucleotides complementary to their respective mRNA. In septum, striatum and brainstem, higher levels of trk mRNA was detected at 2 and 4 weeks than at 1 weeks of age. In certain thalamic nuclei, trkB and trkC mRNA were highly expressed at P1 to P7, but the expression declined gradually in 2 and 4 weeks old animals. TrkB was not detected in tenia tecta and piriform cortex until 2 weeks of age. In P1 and P4 animals a high labeling was seen for trkC mRNA in the deeper parts of neocortex, while in 2 and 4 weeks old animals the highest labeling was seen over the outer neocortical layers. Several brainstem nuclei showed a higher labeling for trkC mRNA at P1 to P7 than in animals of older age. These data suggest that high-affinity neurotrophin-receptors mediate a transient response to neurotrophins in many regions during brain ontogeny.

544.14

EXPRESSION OF THE TRK PROTO-ONCOGENE IN THE DEVELOPING RAT. S. Elkabes*, C. F. Dreyfus, W. J. Friedman and I. B. Black. Department of Neuroscience and Cell Biology, Robert W. Johnson Medical School, UMDNJ, 675 Hoes Lane, Piscataway, NJ 08854.

The trk proto-oncogene has recently been identified as an important component of the nerve growth factor (NGF) receptor and has been implicated in high affinity binding of NGF. To begin investigating the regulation of the trk proto-oncogene (trk) during development, we have studied prenatal and postnatal expression in the rat, by in situ hybridization. Our results indicate temporal and spatial regulation of trk expression. At early embryonic stages (E13.5 and E14.5), trk mRNA was exclusively localized to spinal and cranial ganglia. In the central nervous system trk expression occurred at later developmental stages. During the first postnatal weeks (P1 and P15), highest levels of trk mRNA were observed in the hippocampus. However, in the adult CNS, expression of trk in regions such as the basal forebrain and piriform cortex was comparable to that in hippocampus. Our studies suggest that actions of NGF on various cell types during development may be modulated by temporal and spatial regulation of trk proto-oncogene expression.

NEUROTROPHIN RECEPTOR EXPRESSION IN THE DEVELOPING RAT EMBRYO. N.G. Carri*, S. Söderström and T. Ebendal. Department of Developmental Biology, Uppsala University, Biomedical Center, S-751 23 Uppsala, Sweden and IMBICE (*), CC 403, 1900 La Plata, Argentina.

Expression of neurotrophin receptors was studied using antisense oligonucleotides specific for the low-affinity NGF receptor (LNGFR) and for the neurotrophin high-affinity receptors *trk*, *trk*B and *trk*C. *In situ* hybridization was performed on sections of rat embryos at days E16, E20 and E22. The hybridization patterns were quantitatively analyzed in contact-exposed X-ray films using video-based image processing. The percentage of neuron area covered by silver grains in emulsion-dipped microscopic slides was also studied using this system. The results show distinct patterns of distribution for mRNA for each of the receptors. In the E16 embryo, LNGFR mRNA was highly expressed in the trigeminal and dorsal root ganglia, in the ventral part of the spinal cord. Weaker labelling was found also in the retina. The *trk* oligoprobe intensively labelled the trigeminal and dorsal root ganglia but only marginally the retina and spinal cord. *trk*B was highly expressed in the telencephalon, retina, trigeminal ganglion and was abundant throughout the spinal cord. *trk*C expression was intense in the hippocampus at E16. The same pattern was found at E20, although *trk*B labelling in the retina. Also at E22 similar patterns were found but with an increased labelling of retinal neurons with the LNGFR probe. Our results show that neurotrophin receptors are expressed in neurons in a developmentally regulated pattern. The temporo-spatial expression of neurotrophin receptors may regulate the trophic response of a given neuronal population such as the retinal ganglion cells to a particular neurotrophic factor during development. REGULATION OF $p75^{NGFR}$ AND $p140^{trk}$ EXPRESSION IN DEVELOPING SENSORY NEURONS IN RELATION TO INNERVATION AND CHANGES IN NEUROTROPHIC FACTOR RESPONSIVENESS Sean Wyatt[1], Luis Parada[2], Susan O. Meakin[3] and Alun Davies *[1] [1]St. George's Hospital Medical School, London SW17 ORE, UK; [2]NCI, Fredrick, MD21701; [3]Stanford University, CA94305.

When embryonic mouse trigeminal neurons are extending axons to their targets they survive independently of neurotrophic factors. As their axons approach their targets they display a transitory survival response to BDNF and NT-3 which is lost as the neurons become dependent on NGF for survival. Before acquiring NGF dependence, these neurons express low levels of $p75^{NGFR}$ and $p140^{trk}$ mRNAs. At this stage, BDNF and NT-3, but not NGF, increase the level of $p75^{NGFR}$ mRNA in cultured neurons. With the acquisition of NGF dependence, the levels of $p75^{NGFR}$ and $p140^{trk}$ mRNAs increase markedly. At this stage, NGF, but not BDNF or NT-3, up-regulate $p75^{NGFR}$ mRNA. We are currently studying the effects of neurotrophic factors on $p140^{trk}$ mRNA expression in this system.

544.17

IMMUNOHISTOCHEMICAL DETECTION OF $p75^{NGFR}$ IN NEONATAL AND ADULT OLFACTORY NEUROEPITHELIUM OF RAT. C.P. Turner* and J.R. Perez-Polo, Human Biological Chemistry and Genetics, Univ. Texas Med. Branch, Galveston, TX 77555-0652.

We have shown expression of the low affinity receptor for NGF, $p75^{NGFR}$, using monoclonal antibody 192. In neonates, we have observed $p75^{NGFR}$-immunoreactivity ($p75^{NGFR}$-ir) in the olfactory neuroepithelium (ONE) that was confined to a well defined band, superficial to the lamina propria (LP). A stain-free, single cell layer between the LP and band of $p75^{NGFR}$-ir was very obvious at all neonatal ages. The absence of $p75^{NGFR}$-ir in this stem cell layer suggests that only immature and/or mature olfactory receptor neurons (ORNs) express $p75^{NGFR}$. In adults, staining of the ONE was now confined to the deepest layer, indicating that stem cells now express $p75^{NGFR}$. However, the profiles displayed in neonates versus adults may be a reflection of the change in cell dynamics that takes place in the ONE as the animal matures. Within the LP, we observed staining of the olfactory fascicles at all ages. We believe glial cells are responsible for this staining. Not all fascicles were stained, perhaps because there is a mixed population of mature and immature ORN axons. The mammalian ONE is capable of continuous regeneration throughout life and expression of $p75^{NGFR}$ in both adults as well as neonates implies that neurotrophic support is required at all times. Supported in part by NINDS Grant #18708.

544.18

THE p75 NEUROTROPHIN RECEPTOR IN HUMAN RETINA. I. M. Hopkins*, N. Kleitman†, and K. Spiegel. Parke-Davis Pharmaceut. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48106 and †The Miami Project to Cure Paralysis, Univ. of Miami, Miami, FL 33136.

The p75 neurotrophin binding protein (low-affinity NGF receptor) is a transmembrane receptor for NGF, BDNF, and NT3, with no known signal transduction activity. In previous studies of rat and primate retina, p75 immunoreactivity appeared to be confined to Muller glia, with rare p75-positive retinal ganglion cells (RGC) in adult rat. One report of p75 in the optic nerve fiber layer of developing primate retina suggested p75 involvement in the growth of RGC axons. As part of a study of neurotrophin receptors in the human retina, we have examined the distribution of p75 in normal embryonic human retina, normal adult human retina, and regenerating adult human retina. Adult human donor eyes were a generous gift of the Mid-America Eye and Tissue Bank, St. Louis, MO. Retinas were either cultured on a monolayer of transformed rat Schwann cells or prepared for cryostat sectioning. Sections of embryonic human retina were prepared as part of an approved study at the University of Miami. Sections and cultures were immunostained with a monoclonal antibody (ME20.4) directed against human p75. p75 appeared to be confined to Muller glia in the adult human retina. In embryonic retina at 6 weeks gestational age, p75 was evenly distributed through the retina, with no enhancement of p75 staining in the RGC fiber layer. ME20.4 staining did not detect p75 on adult human retinal neurites regenerating in vitro, due to unexpected staining of the underlying monolayer of transformed rat Schwann cells. We conclude that human retinal ganglion cells and their axons do not express significant amounts of p75 protein in the normal adult or the early embryo..

544.19

RAS p21 PROTEIN PROMOTES SURVIVAL AND NEURITE OUTGROWTH OF NGF-DEPENDENT HUMAN EMBRYONIC NEURAL CREST DERIVATIVES *IN VITRO*.

V.Silani*[1], A.Markus[2], G.Scarlato[1], R.Heumann[2] and G.D.Borasio[3]. [1]"Dino Ferrari" Center, Inst. Neurology University, I-20122 Milan, Italy; [2]Lehrstuhl für Neurobiochemie, Ruhr-Universität Bochum, D-4630 Bochum and [3]Neurologische Universitätsklinik, Klinikum Großhadern, D-8000 München 70, Germany.

In previous studies we demonstrated dose-dependent survival and neurite outgrowth induced by the ras p21 protein after microinjection into cultured chick embryonic neurons. To determine whether similar effects could be induced in human cells, we introduced the oncogenic form of ras p21 into the cytoplasm of cultured human neural crest derivatives (11th to 12th gestational week): adrenal chromaffin cells, dorsal root ganglion (DRG) and sympathetic neurons. We verified that these cells are dependent on nerve growth factor (NGF) for survival and neurite outgrowth *in vitro*. In DRG neurons, ras p21 (30 mg/ml) promoted survival and neurite outgrowth comparable with NGF (84% vs. 92%, respectively). Sympathetic neurons in the chick embryo were demonstrated to be unresponsive to ras p21. Intriguingly, this molecule promoted survival in human sympathetic neurons, albeit less strongly than NGF (67% vs. 94%). The effect of ras p21 on purified human chromaffin cells was indistinguishable from NGF (41% vs. 40% neurite outgrowth). These results are compatible with the involvement of ras or ras-like proteins in the intracellular transduction of NGF in human neural crest derivatives and suggest species-specific differences in neurotrophic signal transduction.

544.20

DISTRIBUTION OF VGF mRNA IN THE POSTNATAL RAT BRAIN.

S. E. Snyder*, R. D. Streck, J. E. Pintar, and S. R. J. Salton.
Fishberg Research Center. for Neurobiology, Mt. Sinai School of Medicine, New York, NY 10029, and Dept. of Anat. and Cell Bio., Columbia College of Physicians & Surgeons, New York, NY 10032.

VGF is a neural immediate-early gene product which is rapidly and selectively induced by neurotrophic factors (e.g., nerve growth factor, NGF) relative to nonneurotrophic factors in PC12 cells. We have determined the anatomical distribution of VGF mRNA in the P5 rat brain by *in situ* hybridization using [^{35}S]-labeled antisense or sense control VGF cRNA probes. Selective labeling of limbic and paralimbic cortex, including cingulate, retrosplenial, entorhinal, and piriform cortices, was noted in contrast to a distinct lack of signal in frontoparietal, occipital or temporal regions. Strong labeling was also seen in olfactory bulb, the hippocampal formation (particularly CA1 and dentate), amygdala, basal forebrain, striatum, nucleus accumbens, lateral geniculate, gelatinosus and ventroposterolateral/ventroposteromedial thalamic nuclei, septal nuclei, inferior colliculi, cerebellum, and portions of the pons and medulla. A previous study of whole brains found VGF mRNA to first be detectable at embryonic day 18 (E18), peak at P4, and decrease to intermediate levels in the adult [Salton *et al.*, 1991]. Also, preliminary studies have shown high levels of VGF mRNA in developing cerebellum but very low levels in adult. Ongoing *in situ* hybridization studies of animals from embryogenesis through adulthood will determine the ontogeny of VGF expression in specific brain structures.

NEUROTROPHINS AFFECT THE ISTHMO-OPTIC NUCLEUS IN CHICK EMBRYOS: CELL DEATH *ENHANCED* BY NGF IN VIVO.

C.S. von Bartheld*, Y. Kinoshita, and M. Bothwell. Department of Physiology & Biophysics (SJ-40), University of Washington, Seattle, WA 98195.

The isthmo-optic nucleus (ION) is the source of centrifugal innervation of the retina. Neurons in the ION express p75 neurotrophin receptors during the period of normal developmental cell death (E13-17, von Bartheld et al., 1991, J. Comp. Neurol. 310: 103-129). To determine which neurotrophin supports ION neurons, we tested NGF, BDNF, and NT-3 (1-10 ng/ml) on ION neurons in primary culture. ION neurons were identified by intraocular injection and retrograde transport of the fluorescent tracer DiI, and labeled cells were plated from embryos at ages E11, E12 and E13. BDNF increased survival and neurite extension of ION neurons. The survival effect was most pronounced for neurons from E11 embryos, but still significant for ION neurons from E12/13 embryos. Neither NGF nor NT-3 increased survival rates. To determine effects of neurotrophins on ION neurons in vivo, we injected 75-900 ng NGF in the eye daily from E10-15. This treatment enhanced cell death in the ION by 25-72% in the embryos, but not at later ages. Injections of vehicle only did not increase cell death. The negative effect of NGF on developing ION neurons may be due to competition at the level of the neurotrophin receptor. NGF may act as a competitive antagonist, possibly to BDNF, thus preventing trophic action. Competitive interactions among the neurotrophins may play a role in the specificity of target innervation and the regulation of neuronal survival. **Supported by NIH grants NS 08990, 23343 and 29582.**

RECOMBINANT HUMAN NGF, ITS PRECURSOR AND THE FORMATION OF A "7S NGF"-LIKE COMPLEX.

L.E. Burton*, W.P. Chan, A.T. Gorrell and C.H. Schmelzer. Genentech, Inc., South San Francisco, CA 94080.

We investigated whether purified alpha and gamma subunits from murine 7S complex could form a complex with either mature rhNGF or precursor forms of rhNGF. The mature and precursor forms of rhNGF were isolated by classical purification techniques (Schmelzer, et al. (1992) J. Neurochem., in press and unpublished experiments, respectively). Multiple forms of the precursor were observed as two major groups of bands on SDS-PAGE: ~26 kDa and ~18 kDa. A more complete characterization of the precursor forms will be presented. We observed complex formation with several forms of mature rhNGF as well as precursor processing to mature rhNGF after the addition of the alpha and gamma subunits. For precursor, both limited tryptic digestion and the formation of a 7S NGF-like complex caused each form of the precursor to be reduced to a band migrating in the region of 13 kDa on SDS-PAGE, corresponding to a mature NGF. The activity of the processed precursor and its resulting processed product was compared using PC-12 cell-based neurite extension and chick dorsal root ganglion cell survival assays. Processed precursor yielded mature rhNGF showing full activity while precursor itself exhibited minimal activity.

OTHER FACTORS AND TROPHIC AGENTS: GLIA

545.1

ASTROCYTES PROTECT DOPAMINERGIC NEURONS AGAINST TOXICITY PRODUCED BY 1-METHYL-4-PHENYLPYRIDINIUM (MPP$^+$) AND 6-HYDROXYDOPAMINE (6-OHDA) IN CULTURE.

T.H. Park* and C. Mytilineou, Dept. of Neurology, Mt. Sinai Sch. of Medicine, New York, N.Y. 10029.

We studied the trophic effect of astrocytes upon dopamine (DA) neurons to examine whether or not glia can modify the toxicity produced by the dopaminergic neurotoxins, MPP+ and 6-OHDA. Glial cultures, enriched in astrocytes, were prepared from the striatum or mesencephalon of newborn rats in serum containing medium and 24 hrs before use were switched to chemically defined medium. Mesencephalic cells from embryonic day 14 rats were plated on either polyornithine coated 35mm dishes or on dishes with a confluent layer of astrocytes. MPP$^+$ (5μM) was applied for 48 hrs at 4 days in vitro (DIV) and 6-OHDA (100μM) for 45 min at 6DIV. Neurotoxicity was assessed at 7DIV by ^{3}H-DA uptake and morphometric analysis of TH immunostained cells to measure the extent of neuritic damage and neuronal survival. We found that the presence of either striatal or mesencephalic glia modified the extent of neuronal toxicity produced by both MPP$^+$ and 6-OHDA. ^{3}H-DA uptake in pure neuronal cultures was approximately 5% of control after treatment with either MPP$^+$or 6-OHDA, while DA uptake was ~15% of control after MPP$^+$ and ~60% of control after 6-OHDA treatment. Similarly, the number of surviving TH+ cells was between 20-40% of control after MPP$^+$ or 6-OHDA treatment in neuronal cultures, compared with ~90% of control in mixed cultures. Our results show that the presence of glia can protect DA neurons against uptake reduction and cell loss produced by both toxins. However, the glial protective effect against 6-OHDA toxicity is greater than against MPP$^+$. (Supported by NIH grants and by the United Parkinson Foundation).

545.2

TYPE 1 ASTROCYTE CONDITIONED MEDIUM PROTECTS SUBSTANTIA NIGRA DOPAMINE NEURONS AGAINST EXCITOTOXIC CELL DEATH.

B.-A. Sieber*, E.K. O'Malley, H. Mount, I.B. Black and C.F. Dreyfus. Dept. Neuroscience and Cell Biology, UMDNJ-R.W. Johnson Medical School, Piscataway, NJ 08854.

Previous work from our laboratory has indicated that Type 1 astrocytes from the substantia nigra selectively enhance the survival of substantia nigra dopamine neurons in dissociated cell culture. Further, conditioned medium from Type 1 astrocytes (CM) is able to elicit dopaminergic survival (O'Malley et al., 1992). To determine whether the CM effect on survival could be extended to protection against neurotoxic insult, we established an *in vitro* model of neurodegeneration using two well known neurotoxins, glutamate and 6-hydroxydopamine (6-OHDA). Substantia nigra from E16 rats were dissociated and plated in either serum-free medium (SFM) or CM. After 7 days *in vitro*, cells were exposed to 100 µM glutamate for 90 min. The cultures were returned to original plating medium for two additional days. Dopamine neurons were visualized by immunostaining for tyrosine hydroxylase (TH), the rate limiting enzyme in dopamine synthesis. Exposure of SFM cultures to glutamate resulted in cell death. However, CM rescued dopamine neurons from excitotoxic death. To determine whether this protective effect was specific for excitotoxins, or whether it could be generalized to toxicants with different mechanisms of action, we treated cultures with 100 µM 6-OHDA. In contrast to the experiments with glutamate, CM did not protect nigral dopamine neurons against cell death caused by 6-OHDA. These data indicate that a factor elaborated by nigral Type 1 astrocytes protects nigral dopamine neurons from cell death caused by an endogenous excitotoxin. (Support: NIH HD23315, NS20788; NIDA DA05132, DA05403-01)

545.3

SUBSTANTIA NIGRA TYPE I ASTROCYTES ELABORATE A SOLUBLE FACTOR THAT AUGMENTS DOPAMINERGIC NEURON SURVIVAL.
E.K. O'Malley*, B-A. Sieber, I.B. Black, and C.F. Dreyfus. Neuroscience & Cell Biology, RWJ Med. Sch., UMDNJ, Piscataway, NJ 08854

We have previously demonstrated that local glia, specifically Type I astrocytes, selectively increase substantia nigra (SN) dopaminergic (DA) neuron survival. However, the mechanism of action remains unclear. To determine whether effects are elicited through diffusible agents, partially purified Type I astrocyte conditioned medium (CM) was tested on embryonic day 16 rat SN dissociates. After 3 days of exposure to CM, DA neuron number was monitored immunocytochemically with antibody to tyrosine hydroxylase (TH), the DA biosynthetic enzyme. CM increased TH+ cell number 2-fold, suggesting that a soluble factor(s) promoted neuron survival.

Neurons cultured in serum free medium are known to contain few, but detectable numbers of glia. To determine whether CM affected neurons directly, or indirectly through glia, cultures were labelled with antibody against the glial marker, glial fibrillary acidic protein (GFAP). CM increased GFAP+ cells 2-fold, implying that CM may affect DA neuronal survival indirectly. To test this possibility, cultures were exposed to a concentration of the gliotoxin α-amino adipic acid that eliminated detectable GFAP+ cells. Under these conditions, CM still elicited a 2-fold increase in TH+ cells. Our observations suggest that CM directly enhances substantia nigra DA neuron survival, in culture. TGFα SELECTIVELY INCREASES DOPAMINERGIC CELL SURVIVAL IN VENTRAL MESENCEPHALIC CULTURES.
T. Alexi* and F. Hefti. Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089.

Transforming growth factor α (TGFα) mRNA and protein have been localized to rodent brain (Wilcox and Derynck 1988; Fallon et al., 1990). Based on its high expression in the striatum, TGFα has been proposed as a trophic factor for dopaminergic neurons. Therefore, we characterized the actions of TGFα on E15 fetal rat cultures of dopaminergic cells. Addition of TGFα (10ng/ml) for 1 day to low-density mesencephalic cultures selectively promoted dopaminergic cell survival after 4 days as measured by an increase in the number of tyrosine hydroxylase (TH) immunopositive cells. These cells represent only 1% of the total neuron number. In contrast, the total number of neurons (neuron specific enolase immunopositive) was unaffected. The number of vimentin immmunopositive astrocytes was elevated by 175% above control. Dopamine (DA) uptake and TH activity were also enhanced approximately 100% and 45% above control, respectively. In cultures lacking a poly-cationic substrate, TGFα dramatically amplified neuronal adhesion to astrocytes. This adhesion was blocked by the anti-mitotic agent, cytosine arabinoside. Two other growth factors, epidermal growth factor (EGF) and insulin-like growth factor-1 (IGF-1), stimulated DA uptake to a lesser degree than TGFα. EGF shares the same receptor with TGFα, and in combination the two did not show additive effects, while the IGF-1-induced elevation was additive with TGFα. Inhibition of possible actions of endogenous neurotrophins with K252b did not alter TGFα's effects on DA uptake or neuron-astrocyte adhesion. Ciliary neurotrophic factor was ineffective in altering control or TGFα-induced DA uptake. These findings indicate that TGFα selectively promotes survival of dopaminergic neurons and that this effect is probably mediated by glial cells.

DEVELOPMENTAL ASPECTS OF THE PRIMARY CULTURE OF MESENCEPHALIC DOPAMINERGIC NEURONS.
T. Takeshima¶, K. Shigematsu*, K. Shimoda§ and J.W. Commissiong†. Tattori West Hosp.¶ and Div. Neurol., Inst. Neurol. Sci.§, Tattori Univ. Sch. Med., Yanago 683, Japan. Dept. Neurol. 2*, Nagasaki Univ. Sch. Med., 12-4 Sakamoto-machi, Nagasaki 852, Japan. LMCN-NINDS-NIH†, Bldg. 10/5N214, Bethesda, MD. 20892.

We have recently described a primary culture of mesencephalic dopaminergic cells from the E14 rat brain that is 20% TH+ between 4 hr and 10 days in culture (Soc. Neurosci. Abs 17.: 982, 1991; Brain Res. In press). Progressive neuronal death occurs, and by 14 days in culture (DIV14), <10% of all neurons survive. Those TH+ cells that survive, however, develop extensive, elaborate, neurofilament positive (NF+) dendritic arborizations, at DIV14 when the astrocytes (GFAP+) become confluent, providing an astrocyte feeder layer (AFL) for cell growth. When the cells were grown on poly-D-lysine, and seeded at 5.0 x 10^4 cells/cm^2, or less, 99% of the neurons died by DIV5. However, when grown on an AFL, even at 1000 cells/cm^2, neuronal survival was >95% even at DIV14. The results suggest that confluent astrocytes produce a factor that promotes dopaminergic cell survival in culture. Preliminary results suggest that the conditioned medium from the DIV10 to DIV14 cultures also promotes dopaminergic neuronal survival. Extracts from astrocytes of DIV14 to DIV21 are also being tested. Experiments are in progress to identify and isolate the putative neurotrophic factor(s) (NTF) for dopaminergic neurons. Antibodies to several proposed NTFs for dopaminergic neurons did not inhibit dopaminergic cell rescue by the AFL or the conditioned medium. Isolated pockets of cells develop in some cultures, all of which are TH+, suggesting that TH+ cell clones may develop in the cultures spontaneously. In addition, in some cultures, some TH+ cells developed elongated neurites that were devoid of varicosities, suggesting the existence of a specific, varicosity-inducing factor.

CHARACTERIZATION OF GLIA-DERIVED CHOLINERGIC NEUROMODULATORY ACTIVITY INDUCED BY EPIDERMAL GROWTH FACTOR (EGF) IN SEPTAL CULTURES.
I.E.Mazzoni and R.L.Kenigsberg*. Centre de Recherche Pédiatrique, Hôpital Ste. Justine, Montreal, Quebec, Canada, H3T 1C5.

We have demonstrated that EGF in the nanomolar range can decrease the activity of choline acetyltransferase and the number of acetylcholinesterase positive neurons in cultures from the fetal rat medial septal area without affecting cholinergic or general neuronal cell survival. The effects of EGF on these cholinergic cells first became evident after 5 days of continuous treatment with this factor and was indirectly mediated as it depended upon active glial cell proliferation. Both astroglia and macrophage/microglia were induced to proliferate in these mixed culture preparations following EGF application, while the number of oligodendrocytes remained unchanged. By combined immunocytochemistry and autoradiography we found the astroglia to actively incorporate ^{3}H-thymidine transiently between 2 to 4 days of EGF application, while the microglia only began to proliferate after 4 days of factor treatment and continued to increase thereafter. Consequently, changes in the number of these 2 glial cell types either preceded (astrocytes) or occurred concommitantly (microglia) with the changes seen in cholinergic cell expression in EGF-treated cultures thus rendering both cell types potential sources of cholinergic neuromodulatory activity. In order to assess whether astroglia or microglia are implicated in the cholinergic cell response to EGF, the microglial cells were eliminated by treating cultures with l-leucine methyl ester. Elimination of the microglia did not affect astroglial cell proliferation nor the changes observed in the cholinergic neurons following EGF treatment. These data suggest that the astroglia represent the cell source of the cholinergic neuromodulatory activity, the properties of which are currently under investigation.

IN VIVO EXPRESSION OF PDGFRα IN PHENOTYPICALLY DEFINED GLIA.
J.A. Ellison* and J. de Vellis. Laboratory of Biomedical and Environmental Science, Dept. of Anatomy and Cell Biology, and the Mental Retardation Research Center, UCLA, Los Angeles, CA 90024

Growth factors such as basic fibroblast growth factor and platelet derived growth factor (PDGF) can modulate oligodendrocyte (OL) development influencing migration, proliferation and differentiation. Recent studies have demonstrated the presence of PDGFα receptors (PDGFRα) in the rodent brain (Schatteman et al.,Dev. in press, 1992; Reddy et al., J. Neurosci. Res. 31;1992) and on cells of the OL lineage *in vitro* (McKinnon et al. Neuron 5; 1990; Hart et. Dev. 105;1989). No study, however, has demonstrated the presence of PDGFRα on phenotypically defined cells *in vivo*

We show using combined immunocytochemistry and in situ hybridization, PDGFRα mRNA in cells in both the gray and white matter of the neonatal rat cerebral cortex. We carried out a spatial and temporal analysis of PDGFRα mRNA expression in the rat forebrain on postnatal days 1,3,6, and 9. PDGFRα message is detected in cells which are immunoreactive for vimentin, GD3 or O4. In contrast, cells which are galactocerebroside + (GC), glial fibrillary acidic protein + (GFAP), or 68 Kd neurofilament protein + (NF) do not express a detectable message. *In vivo* studies are important not only to verify *in vitro* data, but also to understand the cell-cell interactions which occur only when the cytoarchitecture is maintained. Our results support the *in vitro* data which suggest that: 1) PDGFRα is expressed by immature OL, 2) GD3+ and O4+ immature OL have the potential to respond to PDGF, and 3) GC+ OL, GFAP+ astrocytes, and NF+ neurons are not responsive to PDGF. Supported by NICHD and DOE.

GRAFTED SCHWANN CELLS AND INFUSION OF A SCHWANN CELL-DERIVED GROWTH FACTOR (DNTF) ENHANCE MORPHOLOGICAL RECOVERY IN THE DAMAGED ADULT RAT DOPAMINE SYSTEM.
T.J. Collier*, P. N. Martin, B.A. Maguire, and J.E. Springer. Dept. Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, NY 14642; and Dept. Neurology, Hahnemann University School of Medicine, Philadelphia, PA 19102.

We have previously demonstrated that co-cultured Schwann cells, or a partially purified fraction of conditioned medium from peripheral nerve or a Schwann cell line, denoted as dopamine neurotrophic factor (DNTF), promote survival and neurite outgrowth of cultured embryonic rat tyrosine hydroxylase (TH)-positive ventral mesencephalic neurons. In the present studies, we have begun to characterize the in vivo effects of grafted Schwann cells and DNTF infusion in rats with varying degrees of damage to the nigrostriatal dopamine (DA) system. Implantation of Schwann cells from primary cultures derived from neonatal rat sciatic nerve into the striatum of rats with partial lesions of the DA pathway yielded effects on amphetamine-induced rotational behavior and TH-positive fiber staining in a pattern that varied with the level of striatal denervation: implantation of 60,000 Schwann cells at each of two locations in the striatum of rats with partial lesions yielded good recovery; similar implants in rats with near-complete lesions had no effect. In a second experiment, we infused DNTF via osmotic minipump (0.5ul/hr for 2 weeks) into the lateral ventricle of adult rats with large unilateral lesions of the nigrostriatal DA pathway. At 3 weeks following completion of the infusion, rats receiving DNTF exhibited a marked increase in staining of TH fibers present in the lateral septal area proximal to the intraventricular infusion, corresponding to fibers of midbrain DA neurons spared by the lesion. This enhanced fiber staining was not observed in the hemisphere contralateral to infusion, or in control rats receiving comparable infusion of culture medium which did not contain DNTF. Thus, grafting of cultured rat Schwann cells or intraventricular infusion of DNTF produce morphological effects consistent with possible stimulation of DA fiber proliferation in adult rats. Supported by AG08133, NS24032 (TJC), AG08969 (JES).

An Assay for Detecting Schwann Cell Secretory Activity *In Vitro*. Daniloff, J.K.*, K. Crossin#, A. Smith, T. Yoes, S. Gibson and M. Powell, Department of Veterinary Anatomy, Louisiana State University, Baton Rouge, Louisiana and Department of Neurobiology, Scripps Research Institute, LaJolla, CA.

Schwann cells have broad contributions to development, regeneration, and tumor formation. In many situations, activity involves the coordinated production and secretion of molecules. Our goals were 1) to select *in vitro* conditions that mimicked Schwann cell reactions to development, nerve injury and tumor formation *in vivo* and 2) to establish methods to detect, quantify and localize these molecules *in vitro*. The neural adhesion molecule, N-CAM, is a membrane glycoprotein of M_r 180,000, 140,000 and 120,000; it is responsible for homophilic neural cell binding. The substrate adhesion molecule, cytotacin, is an extracellular glycoprotein of M, 200,000 and 220,000; its distribution in the brain is highly specialized. The specific source of these molecules under the conditions we have described has not been established. Our rationale was to verify Schwann cells as a source of these molecules. *In vitro* conditions involved cultures of Schwann Cells isolated from neonatal nerves, nerves recovering from transections, and a Schwannoma cell line. Sciatic nerves from neonatal (2-4) old Sprague Dawley rats were sacrificed 10 days post surgery for aseptic removal of injured nerves. All tissues were minced and digested in 0.25% trypsin containing 0.03% collagenase. Washed cells were cultured in a petri dish with Minimum Essential Medium 2-4 hrs for attachment of fibroblast. Suspension cells were then transferred to a flask and re-incubated for 12 hrs. Supernates were analyzed via SDS polyacrylamide gels (PAGE), immunoprecipitation and immunoblots. Schwann cells were capable of producing both molecules. Variabilities in quantity, and modulations of N-CAM form, will be described. Although this assay was used to test the secretion of adhesion molecules, its use is not restricted to these proteins. Supported by NIH grant #R29-NS-25102-05 and in part by a grant from Sentron Medical Inc., Cincinnati, Ohio.

TRANSFORMING GROWTH FACTOR ALPHA IS PRESENT IN DEVELOPING BRAIN AND A POTENT ASTROCYTE MITOGEN. Kenneth R. Huff* and Qi-Xiao Yuan. Harbor/UCLA Medical Center, Dept of Pediatrics. Torrance, California.

Transforming growth factor alpha (TGFa) regulates the growth and replication of nontransformed cells. Epidermal Growth Factor (EGF)-like proteins may have critical morphogenic functions in the developing brain as mutant homeotic genes encoding for homologous peptides produce lethal anomalies. In non brain tissues TGFa binds competitively to the EGF receptor (EGFR) and no other receptor has been found for it. The majority of the EGFRs in the brain are on astrocytes. We have measured TGFa in developing rat brain and investigated a potential role of TGFa as a ligand for the EGFR on purified developing astrocytes.

A specific radioimmunoassay was developed and the antisera displayed no immunoblot reactivity with EGF. The antisera was not competed by over 100 times the concentration of rat TGFa by several species of EGF, NGF, or human TGFa. This RIA measured whole brain levels of TGFa to be 160 pg, 119 pg, and 55 pg per gram at ages 7 days, 15 days, and 120 days (adult) respectively. Thyroid hormone treatment of the animals for 6 days starting at birth reduces the level at day 7 from 160 pg to 64 pg. Astrocytes grown in primary culture were studied for TGFa mitogenicity and binding activity with 125-Iodine labelled TGFa. Increased thymidine incorporation occurs at 5-10 nM after 16 hours. Maximum cellular binding is reached by 60 minutes. A scatchard analysis of saturability data indicates a dissociation constant of 330 pM and 6200 receptors per cell assuming the high affinity receptor class. These calculations correspond well with similar affinity and receptor number data obtained respectively using the A431 cell line with an amplified EGFR and using astrocytes with EGF as the ligand.

We conclude that TGFa is present and may be developmentally regulated in the brain. This growth factor binds to the EGF receptor with high affinity in purified astrocytes. These findings may have implications for astrocyte mediated structural development of the brain or glial proliferation disorders such as gliosis or glioma.

ESTRADIOL REGULATES S-100ß mRNA EXPRESSION IN CULTURED RAT ASTROCYTES. D.A. Hinkle, D.C. Hilt, P.J. Yarowsky, S.R. Max*, and P.M. Wise. Department of Physiology, University of Maryland School of Medicine, Baltimore, MD 21201.

Estradiol is implicated in reproductive senescence of the hypothalamus, a brain region which becomes markedly gliotic with increasing age and in response to treatment with estrogens (Biol. Repro. 42:21-8, 1990). S-100b, a glia-derived protein which moderates the growth and development of neurons and glial cells, is reported to be elevated in reactive astrocytes in gliotic brains. The aim of this study was to determine if and to what extent estradiol regulates S-100ß mRNA expression in cultured rat astrocytes. Primary astrocytes were cultured from various brain regions of 1 day old rats, grown to confluence in serum-containing medium, then passaged and treated in steroid-free medium with 0, 50 nM, 100 nM, or 1 µM estradiol for 3 weeks. Astrocyte RNA was subsequently harvested, hybridized to radiolabelled antisense riboprobes to S-100ß and cyclophilin mRNAs, and subjected to RNase protection. We report that, while cyclophilin mRNA levels remain constant regardless of treatment, estradiol increases S-100ß mRNA expression in cortical astrocytes. We are currently analyzing the effect of estradiol on hippocampal, cerebellar, and hypothalamic astrocyte S-100ß mRNA. We speculate that estradiol regulation of S-100ß mRNA expression may be involved in the mechanism of estrogen- and age-related gliosis in reproductive senescence.

545.12

IN VITRO DIFFERENTIATION OF THE BASAL FOREBRAIN CHOLINERGIC NEURONS FROM THE TRISOMY 16 MOUSE. P. Corsi*, S.M. Cozza, M. Troia, T. Lettini, V. Del fino Pesce. Ist. di Fisiologia Umana, Fac. di Medicina, Univ. di Bari, Italy, 70124; Consorzio di Ricerca DIGAMMA, Bari, Italy, 70100.

The trisomy 16 mouse (Ts16), which shares genetic and phenotypic homologies with Down syndrome, exhibits impaired development of the basal forebrain (BF) cholinergic system with significant reductions of the choline acetyltransferase activity. In the present study the BF obtained from Ts16 fetuses and their euploid littermates (EUPL.) at 15 days of gestation, were enzimatically dissociated and cultured either in defined medium with trophic factors or in the presence of conditioned medium from astrocites cultures in order to rescue the developmental impairments of the cholinergic neurons (ChN) from the Ts16 brains. Another group of cultures have been obtained by plating the ChN from Ts16 BF on normal glial cultures and the "in vitro" differentiation of these neurons have been compared to that of the ChN from EUPL. BF plated on Ts16 glial cultures. In these experimental conditions we considered the following parameters: neuronal survival, neuronal morphology, number of ChN, length of processes and activation of a set of genes, c-fos and c-jun, mediating neuronal differentiation. Our preliminary observations suggest that the differentiation of the Ts16 ChN "in vitro" depends on the degree of maturation of the glial cells and on cell to cell contact interactions between neurons and glia.

ASTROGLIA REACTING TO EXPERIMENTAL SPINAL CORD INJURY EXPRESS INSULIN-LIKE GROWTH FACTOR I (IGF-I) AND VIMENTIN. D.-L. Yao, N. West, C. Bondy, M. Brenner, G.H. Collins*, and H.deF. Webster. LENP, DEB, LMB, NIH, Bethesda, MD 20892 & Dept. Path., SUNY Hlth. Sci. Cntr., Syracuse, NY 13210.

To study astrocytic responses associated with spinal cord regeneration in adult rats, the procedure of Collins and West (Brain Res. Bull., 22:71-79, 1989) was used to produce cryogenic posterior column lesions. After 3d, lesions contained cells which expressed IGF-I mRNA; the cells were identified as immature astroglia by their vimentin immunoreactivity, their failure to stain with anti-GFAP and their electron microscopic appearance. At 7d, IGF-I mRNA levels in these cells were significantly higher and by 14d had decreased to 50% of the 7d levels. Hypertrophic astroglia around the lesions did not contain detectable IGF-I mRNA at these early intervals; instead they expressed high levels of GFAP mRNA and peptide. EM observations 20-60d after similar cryogenic lesions have shown that regenerating neurites and myelin sheaths are present (West and Collins, J. Neuropath. Exp. Neurol. 48:94-108, 1989). Studies of IGF-I expression at these intervals are in progress.

545.14

NEUTRALIZING ANTISERUM TO ACTIVITY-DEPENDENT NEUROTROPHIC FACTOR PRODUCES NEURONAL CELL DEATH IN MAMMALIAN CNS CULTURES

I. Gozes*, Y. Gozes, R. Avidor, A. Davidson, D.E. Brenneman.

Dept. Chem. Pathol., Tel Aviv Univ., Tel Aviv, Israel; Israel Inst. for Biol. Res., Ness Ziona, Israel; Lab. of Dev. Neurobiol. NICHD, NIH, Bethesda, MD 20892.

Activity-dependent neurotrophic factor (ADNF) is a glia-derived protein survival factor that is released by vasoactive intestinal peptide. ADNF has been purified to homogeneity and has been shown to increase the survival of neurons derived from spinal cord, cerebral cortex and hippocampus at concentrations <1 pM. Physical properties (16 kD, pI 8.1) and partial sequence data indicated ADNF is novel. Neutralizing antiserum was obtained by serial injections of ADNF into mice. In cerebral cortical or spinal cord cultures, ADNF antiserum (1:10,000) decreased neuronal counts (50-65% of control) after five days treatment. Co-administration of purified ADNF prevented neuronal cell death associated with the antiserum. Control antiserum had no effect. These data support the conclusion that ADNF is important to the survival of a subset of cortical and spinal cord neurons.

545.15

VASOPRESSIN INDUCTION OF THE IMMEDIATE EARLY GENE, *zif/268*, IN CULTURED HIPPOCAMPAL GLIAL CELLS.

R.D. Brinton*[O], K. O'Neill[◆], P. Kim[O], S.S.Schreiber[✚], [O]Dept. Molecular Pharmacology and Toxicology, [◆]Bravo Medical Magnet High School & [✚]Dept. of Neurology, University of Southern California, Los Angeles, CA 90033

The neural peptide, vasopressin (AVP), has been associated with growth responses in both neural (Brinton & Gruener, 1987; Brinton, 1990) and nonneural cell types (Rosengurt, 1979). The immediate early gene (IEG), zif/268, is one of several genes induced in response to growth factors (Bartel et al., 1989). Because of AVP effects on nerve cell growth, we investigated the influence of AVP on induction of zif/268 expression in cultures of hippocampal neurons and glial cells. Hippocampal cells from E18 rat pups were cultured onto polylysine coated chamber slides in serum containing medium. Following 3 days in culture, cells were exposed to 10, 100, 500 or 1000 nM AVP or other peptides for 15 or 30 min. Paraformaldehyde fixed cells were treated with TEA and $C_4H_6O_3$ prior to hybridization with a ^{35}S-labeled zif/268 cRNA probe. Slides were dipped in NTB-2 emulsion, exposed at 4°C for 3-4 wks and analyzed using a BioQuant image analysis system. Results of those studies showed AVP-induction of zif/268 in glial cells that was dose and time dependent. Greatest grain density was observed in cells treated with 10 or 100 nM AVP whereas grain densities in glial cells treated with 500 or 1000 nM AVP were not as dense. Maximal induction of zif/268 was observed in glial cells exposed to AVP for 15 min. AVP-induction of zif/268 was IEG and cell specific, in that cfos was not induced by AVP and AVP-induction of zif/268 was specific to glial cells and not observed in neurons. Experiments to determine receptor specificity indicated that AVP-induction of zif/268 is mediated via a V1 receptor since the specific V1 agonist Phe^2,Orn^{8}Vasotocin at a concentration of 10 nM induced zif/268 expression. *Supported by NIH grants MH46036 and SO3 RRO3011 to R.D.B. and NS01337 to S.S.S.*

545.16

VIP RECEPTOR DISTRIBUTION IS RELATED TO ONTOGENETIC EVENTS IN THE DEVELOPING CORTEX, HIPPOCAMPUS AND CEREBELLUM.

J. M. Hill* and S. K. McCune Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

VIP has trophic effects in the CNS through its action as an astroglial mitogen and by stimulating astrocytic secretion of neurotrophic agents (Brenneman *et al. PNAS*: 83:1159, 1986: *J. Neurosci. Res.* 25:386, 1990). *In vitro* autoradiography with ^{125}I-VIP was performed on E14, E16, E19, DO, D7, D14, D21 and adult CNS tissue to determine the patterns of VIP receptor distribution in the cortex, hippocampus and cerebellum throughout development. VIP binding was high from E14, and was localized to the intermediate layers in cortex and hippocampus. In the intermediate layer of the cortex, the presumptive astrocytes and pioneer neurons of the cortical plate are developing. During this period neurogenesis takes place in the germinative zones and VIP binding was moderate to low in these layers. By E19 the highest VIP binding occurred in the germinal layers which are the sites of gliogenesis at this time. Binding remained very high in these layers until the end of gliogenesis. From D0 to D14, a period characterized by glial and neuronal migration, differentiation, axogenesis, dendrogenesis, synaptogenesis and the beginnings of myelination, a relatively uniform blanket of moderate VIP binding was seen throughout the brain. By D21 the adult pattern of VIP binding to discrete neuroanatomical sites began to emerge. The changing patterns of VIP receptor distribution occurring in relation to ontogenetic events, especially those related to gliogenesis and glial maturation, suggest that VIP plays an important role in the developing nervous system.

OTHER FACTORS AND TROPHIC AGENTS: INJURY

546.1

NEUROTROPHIN-3 mRNA EXPRESSION IS STIMULATED IN DEGENERATING PYRAMIDAL CELL LAYERS OF CA1 AND CA4 HIPPOCAMPAL FIELDS OF THE RAT.

N. Rocamora[1], L. Massieu[2], E. Boddeke[2], G. Mengod*[3] and J.M. Palacios[4]. [1]Unit Cell Biology. Fac. Biology. Univ. Barcelona. Spain. [2]Sandoz Pharma LTD. Basel. Switzerland. [3]Dept. Neurochemistry. CID-CSIC. Barcelona. Spain. [4]Res. Inst. Lab. Almirall. Barcelona. Spain.

Unilateral intrahippocampal injection of the endogenous excitotoxin quinolinic acid (120 nmols) induces seizures together with a delayed ipsilateral neurodegeneration particularly of the pyramidal cell layer of CA1 and CA4 hippocampal fields. In situ hybridization histochemistry was used to analyze the spatio-temporal pattern of hybridization of brain-derived neurotrophic factor (BDNF), nerve growth factor (NGF) and neurotrophin-3 (NT3) mRNAs after this treatment. As in other excitatory paradigms, a rapid and transient increase of BDNF and NGF mRNAs together with a delayed and also transient decrease in the NT3 mRNA level, were observed in the contralateral hippocampus. Analysis of mRNA levels in the ipsilateral hippocampus showed a different situation. BDNF and NGF mRNA expression was only stimulated in the areas not-directly in contact with the excitotoxin. Around twelve hours after the insult, and in parallel with the begining of the neurodegenerative process there is an increased expression of NT3 mRNA in the specifically degenerated CA1 and CA4 pyramidal cell layers.

The main findings from this work are: (i) the increased expression of NT3 mRNA in the adult brain, associated with neurodegeneration, (ii) the differential regulation for the different neurotrophic factor genes in response to seizures, (iii) the stimulatiom of BDNF and NGF mRNA expression not direct but transynaptically mediated by NMDA receptors.

546.2

BDNF AND *trk*B mRNA REGULATION FOLLOWING SELECTIVE DEAFFERENTATION OF ADULT RAT HIPPOCAMPAL NEURONS

M. M. Dugich-Djordjevic*, J. R. Day, P.A. Lapchak and F. Hefti, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089.

We have previously suggested that BDNF may participate in the synaptic remodelling responses observed in the adult hippocampus following the administration of systemic kainic acid (Dugich-Djordjevic et al., Neurosci., 47, 303-315, 1992). In order to further investigate the possible role of BDNF in neuronal plasticity in the adult, we used in situ hybridization histochemistry to examine the alterations in BDNF and *trk*B mRNA expression following selective deafferentation of the rat hippocampus. After selective destruction of CA3 pyramidal neurons by intrahippocampal kainic acid (IHKA) injections, BDNF mRNA was no longer detectable in the ipsilateral CA3 pyramidal population but was increased in the ipsilateral DG and medial CA1 region at 3 d post lesion. At 10 d following lesion, BDNF mRNA was elevated only in the ipsilateral DG and control levels were observed at 21 d. *Trk*B mRNA expression was elevated in apparent non-neuronal populations of the septal aspect of the ipsilateral dentate molecular layer at 10-21 d following IHKA. Unilateral destruction of dentate granule cells by colchicine resulted in a loss of expression in the ipsilateral DG and a pronounced increase in BDNF mRNA in the ipsilateral CA3 pyramidal layer and hilar region on day 3, with slightly elevated expression in the contralateral DG and CA3 at 10 d post lesion. *Trk*B mRNA expression was increased along the entire septotemporal portion of the ipsilateral dentate molecular layer from 10-21 d post lesion, with elevated expression in areas adjacent to the CA1, CA3, and DG regions at 10 d following lesion.

In summary, the expression of BDNF mRNA was increased at neuronal sites of axonal projections of deafferentated areas, while altered expression of *trk*B was localized to apparent non-neuronal populations adjacent to denervated target regions. This finding suggests that BDNF and *trk*B may participate in neuronal plasticity in the adult rat brain following injury. Alternatively, the more delayed increases in *trk*B mRNA expression suggest a coordination with neurodegenerative processes.

546.3

EXPRESSION OF NEUROTROPHIN RECEPTOR mRNAS IN AXOTOMIZED FACIAL AND RUBROSPINAL NEURONS.

W. Tetzlaff*, C.A. Leonard and K.C. Harrington. Department of Physiology, University of Ottawa, Ottawa, ON, Canada.

Neuronal atrophy and/or cell death after axonal injury is a major component of the failure of CNS neurons to regenerate. This problem is compounded by the lack of information as to the trophic dependencies of CNS neurons. We have examined the expression of the *trk* family of high affinity neurotrophin receptors, on facial motoneurons or rubrospinal neurons after axotomy, using *in situ* hybridization with oligonucleotide probes. **Facial** motoneurons contralateral to axotomy express significant levels of mRNA for *trk*B and *trk*C, but not *trk*A nor p75^{NGFR}. Seven days after axotomy *trk*B expression increased two-fold while *trk*C expression decreased. As reported by others, the expression of p75^{NGFR} was dramatically enhanced following axotomy. **Rubrospinal** neurons express significant levels of *trk*B mRNA, and to a lesser extent *trk*C, but as for facial motoneurons no detectable levels of *trk*A nor p75^{NGFR}. Seven days after transection of the rubrospinal tract, at cervical level C3, there were no significant changes in *trk* mRNA expression. Nevertheless, at this time point p75^{NGFR} expression was significantly increased - this message was not detectable in the contralateral red nucleus. These data suggest that after axotomy, facial motoneurons and rubrospinal neurons may become responsive to BDNF and NT3. (Supported by MRC)

IMMUNOREACTIVITY TO MOTONEURONOTROPHIC FACTOR 1 (MNTF1) IN TONGUES OF ADULT RATS FOLLOWING DENERVATION AND REINNERVATION.

F. Ren[1], R.M.W. Chau[1], W.H.A. Yu[2] and M.C. Yu*[3]. [1]Dept. of Anat. Univ. of Hong Kong, Hong Kong, [2]Dept. of Cell Biol. & Anat. Sci., City Univ. of New York Med. Sch., New York, NY 10031 and [3]Dept. of Anat., Cell Biol. & Injury Sci., New Jersey Med. Sch., Newark, NJ 07103.

Monoclonal antibody raised against MNTF1, a 35 kD muscle-derived motoneuronotrophic factor shown to promote survival of motoneurons in vitro and in vivo after axotomy, was used to study its cellular localization in the tongue following denervation and reinnervation. The right hypoglossal nerve of female Sprague-Dawley rats 2-3 months old was transected under anesthesia. Rats were perfused with 4% paraformaldehyde in PBS at 4 d, 1,2,3,5 wk, and 2,5 month postaxotomy (PO). Tongues were embedded in Paraplast and cut transversely for immunocytochemical procedures. Positive immunoreactivity was observed in the sarcoplasm of skeletal muscle fibers and in the axoplasm of many large, myelinated nerve fibers on both intact and denervated sides 4 d PO. At 1 wk PO, the intensity of immunostaining and number of immunopositive muscle fibers were reduced on the denervated side, and immunopositive nerve fibers were virtually absent. By 2 wk PO, most muscle fibers were stained immunonegative on the denervated side. By 5 wk PO, the immunostaining of muscle fibers on the denervated side had returned to levels close to that of the contralateral intact side, at a time when reinnervation of muscles had occurred and the contractile force of muscles had reached plateau. However, immunopositive nerve fibers reappeared later. These results suggest that MNTF1 is present in the lingual muscles of adult rats, probably taken up into axoplasm from motor end-plate regions, and production of MNTF1 is neurally regulated.

SPINAL INJURY ALTERS CIRCULATING NEUROTROPHIC ACTIVITY. F. Roisen*, C.L. Lu, J.R. Johnson, R.D. Linden, G. Niznik, L. Ray, C.B. Shields, L-J. Wang, G. Yorke, and Y.P. Zhang. Departments of Anatomical Sciences & Neurobiology, Orthopedic Surgery, and Surgery (Division of Neurosurgery), University of Louisville School of Medicine, Louisville, KY 40292.

It is likely that trophic agents play a key role in regulating neuroplasticity and regeneration. To determine if circulating neurotrophic activity is altered by spinal cord injury, we used T_2 weight drop to produce known levels of injury and *in vitro* neuronal models to determine the resultant trophic response. Anesthetized adult Wistar rats (250 g) underwent surgery to produce a mild or medium spinal lesion. Blood was collected every 2 days, separated and stored in aliquots at -70°C. Serum taken at day 0 prior to trauma served as a control. Control or trauma-derived sera were incorporated into the medium at 5% and applied to cultures of 6 day embryonic chick spinal cord (AHC) or 9 day sensory ganglia (DRG) which were maintained for 4 days. The degree of resultant neuronal development was evaluated microscopically on coded cultures. Cell viability was determined by measuring mitochondrial dehydrogenases via MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyl tetrazolium bromide, Sigma cell growth determination kit). Sera obtained from normal rats established that minimal intra- and inter-animal variation occurred during the 28 day testing period. Our preliminary studies demonstrate that sera from lesioned animals contain factor(s) which increased the viability of the heterogeneous cell population. The degree of enhancement was dependent on the severity and time after injury. Maximum DRG and AHC viability was obtained with sera collected around day 15, both returned to pre-injury levels by day 28. The viability level was related to extent of injury; sera obtained from animals with mild lesions were more supportive than those obtained from animals given a medium lesion. The effects of spinal-lesioned-sera on neuronal survival are under evaluation with immunohistochemistry and quantitative microscopy. At present the nature and role of the factor(s) are unknown. TROPHIC INTERACTIONS OF AFFERENT NERVES AND EPIDERMIS: NORMALIZATION OF CUTANEOUS ABNORMALITIES FOLLOWING NEURAL LESIONS IN MONODELPHIS DOMESTICUS. S. A. Bogush and B. L. Munger.* Dept. Neurosci. Anat., Penn. State Univ., Hershey, PA 17033 and Dept. Anat., Univ. of Tasmania, Hobart, Tasmania 7001.

The present study evaluates the long-term effects of neural lesions on the differentiation of the skin in post-natal opossum pups. Lesions of dorsal root ganglia &/or spinal cord produce acute effects in the skin including hyperplasia of the epidermis, hyperinnervation of the dermis and epidermis, and suppression of hair formation in the first week following neural lesions. By the second week precocious hairs (more mature than expected) are present often with significantly abnormal shape and direction of the shaft relative to the skin surface. By three weeks the skin appears grossly normal and no abnormalities are visible to the eye. However on studying serial sections the residual lesions of neural tube, DRG, and neural arches confirm the prior neural lesion. The only microscopic abnormality in the skin is the presence of isolated abnormal hairs in terms of shape and direction. These findings indicate the extent of trophic interaction of afferent nerves and the skin, and that afferent nerves control the differentiation of their targets in skin as well as muscle (Zelena, 1957). COMPARATIVE EFFECTS OF BASIC FGF (bFGF) AND NGF ON HIPPOCAMPAL CHOLINERGIC FUNCTION IN FIMBRIECTOMIZED RATS. D. M. Araujo*, P. A. Lapchak and F. Hefti, Andrus Ger. Ctr., USC, Los Angeles, CA, 90089-0191.

Although bFGF, like NGF, appears to be trophic for cholinergic neurons of the basal forebrain, its effects on cholinergic function have not been demonstrated. In rats with unilateral partial fimbrial transections, chronic administration (icv, qod for 21 days) of bFGF (10 ng) or NGF (1 μg) resulted in increases of ChAT activity in the lesioned hippocampi of similar magnitude (39 and 46%, respectively), compared to that of a control group of rats treated with cytochrome c (cc). In the control cc-treated group, ACh content, basal and evoked ACh release, were significantly reduced by the lesion by 56, 40 and 53%, respectively. However, whereas only modest increases in these measures (10-18%) in the bFGF-treated group compared to the control cc-treated group were observed, marked enhancements in the NGF-treated rats were apparent. Thus, in the NGF-treated group, ACh content, basal and evoked ACh release in the lesioned hippocampi were augmented by 67, 46, and 51%, respectively. In addition, no synergism between bFGF and NGF was observed, since in rats receiving combined administration of bFGF/NGF, the increases in hippocampal cholinergic parameters were not markedly different from those measured in rats treated with NGF alone. Moreover, the binding of [^{3}H]vesamicol, a presynaptic cholinergic marker, was similar in the lesioned hippocampi of the NGF- and the bFGF/NGF-treated groups, and modestly enhanced compared to either the cc- or the bFGF-treated group. In conclusion, the limited effectiveness of bFGF in counteracting lesion-induced reductions of cholinergic function, indicates that it may not be the treatment of choice in reversing the cholinergic deficit associated with certain neurodegenerative diseases.

CHRONIC NEUROTROPHIN ADMINISTRATION TO FIMBRIECTOMIZED RATS: EFFECTS ON PRESYNAPTIC HIPPOCAMPAL CHOLINERGIC FUNCTION AND WEIGHT GAIN. P.A. Lapchak*, D.M. Araujo and F. Hefti, USC, Andrus Ger. Ctr., Los Angeles, CA, 90089-0191

Recent pharmacological studies have shown that BDNF increases ChAT activity in cultured septal cells suggesting that BDNF may be effective in stimulating the expression of the cholinergic phenotype in the adult brain. The present study determined the effects of chronic administration (icv, 1.4 μg qod for 21 days) of recombinant human (rh) NGF or rhBDNF on hippocampal cholinergic function measured in vitro in adult rats with partial fimbrial transections. Partial fimbrial transections reduced hippocampal high affinity choline uptake (by 54%), ChAT activity (by 41%), and [^{3}H]ACh synthesis (by 63%). Chronic rhBDNF treatment failed to enhance the level of these cholinergic parameters. In contrast, chronic treatment with rhNGF increased high affinity choline uptake (by 112%) compared to lesioned control values. rhNGF treatment also increased hippocampal ChAT activity by 54%. Moreover, rhNGF treatment increased [^{3}H]ACh synthesis by hippocampal synaptosomes by 65% compared to lesioned control values. Thus, chronic rhNGF treatment, but not rhBDNF treatment effectively enhances markers of presynaptic hippocampal cholinergic function following partial fimbrial transections. Lastly, chronic treatment with either rhNGF or rhBDNF produced significant reductions in body weight (23-26 grams) over the 21 day treatment schedule. Thus, although rhBDNF does not affect central cholinergic function it does seem to interact with CNS neurons to regulate weight gain. The results of the present study suggests that NGF will be more effective than BDNF in counteracting the cholinergic deficit associated with the cognitive decline observed in Alzheimer's disease.

Brain Derived Neurotrophic Factor (BDNF) Increases the Survival of Basal Forebrain Cholinergic Neurons Following a Fimbria-Fornix Transection. J.K. Morse,* R.F. Alderson, Y.You, N.Cai, C.A. Altar, S.J. Wiegand, R.M. Lindsay, Regeneron Pharmaceuticals, 777 Old Saw Mill River Rd., Tarrytown, NY 10591.

We have demonstrated an increase in septal cholinergic neuron survival and phenotypic differentiation in response to BDNF *in vitro* (Alderson, et. al., 1990). We show here the efficacy of BDNF *in vivo* in rescuing this neuronal population from the cell death associated with transection of the fimbria-fornix pathway.

The fimbria-fornix was transected unilaterally by knife cut in adult (175-225 gm) Sprague-Dawley female rats. A cannula was implanted for delivery of BDNF into the caudal pole of the septum. BDNF was delivered continuously at rate of 12 μg/day for two weeks, via an osmotic pump.The ability of BDNF to increase cell survival was evaluated on the basis of cell counts in 30 μm coronal sections stained for choline acetyltransferase (ChAT) or low affinity NGF receptor (LNGFR). Cells were counted in sections taken at 180 μm intervals through the rostral-caudal extent of the medial septal nucleus. In control animals a 64% decrease in the number of ChAT- and a 45% decrease in LNGFR- positive cells was observed on the side of the lesion compared to the intact side. In contrast only 37% of ChAT- and 21% of LNGFR- positive neurons were lost when BDNF was delivered into the septum.

These *in vivo* results substantiate our previous *in vitro* findings and suggest a role for BDNF in rescuing cholinergic neurons following deafferentation injury or disease.

546.11

EFFECT OF INTRAVENTRICULAR BDNF ADMINISTRATION ON HIPPOCAMPAL BDNF AND *trk*B mRNA EXPRESSION IN ADULT RATS WITH PARTIAL SEPTO-HIPPOCAMPAL LESIONS. J.L. Venero*, B. Knüsel, K.D. Beck and F. Hefti. Andrus Gerontology Center, University of Southern California. Los Angeles, CA 90089-0191.

In situ hybridization was used to evaluate changes of mRNA expression of BDNF and its *trk*B receptor after daily intraventricular administration of BDNF and after unilateral partial fimbrial transections. 24 and 48 h after the lesion, expression of BDNF was decreased in the pyramidal cell layer of Ammon's horn, this effect being most prominent in CA2, CA3 and CA4. In contrast, expression of BDNF mRNA in the granule cell layer of the dentate gyrus was enhanced at these time points. BDNF administration not only completely abolished the lesion-induced increase of BDNF mRNA in the dentate gyrus but reduced levels on the lesioned side below control values in this area. No effect of BDNF administration was seen on the lesion-induced decrease in the different fields of Ammon's horn. Neither fimbrial transections nor BDNF administration affected *trk*B mRNA levels after 24 or 48 h. Emulsion in situ hybridization analysis is in progress to assess whether, at the level of individual cells, BDNF and *trk*B share common patterns of mRNA expression. Our data suggest that injury of septal inputs result in sub-region specific changes of hippocampal BDNF mRNA expression, whereas *trk*B expression does not seem to be affected. The experiments with exogenously administered BDNF suggest that BDNF can specifically alter its own expression in the dentate gyrus.

546.12

NEUROTROPHIN-3 INCREASES THE REGENERATIVE SPROUTING OF THE LESIONED RAT CORTICOSPINAL TRACT. M.E. Schwab*(1), R. Kolbeck(2), Y.-A. Barde(2) and L. Schnell(1). (1) Brain Research Institute, University of Zurich, 8029 Zurich, Switzerland and (2) Max-Planck-Institute for Psychiatry, Dept. of Neurobiochemistry, 8033 Planegg-Martinsried, Germany.

Sprouting occurs as a spontaneous reaction to axotomy in many CNS and PNS tracts. In case of the adult rat corticospinal tract (CST) spontaneous sprouting is very limited. Transplants of E14 rat spinal cord tissue greatly increased this sprouting in a zone of 1 - 4 mm proximal to a thoracic CST lesion in young adult rats. The frequently occurring retraction of lesioned axons was also prevented. Very similar results were obtained following a single injection of the neurotrophic factor NT-3 (0.2 - 0.5 µg into the lesioned spinal cord). No effect was seen after injection of BDNF. The maximal distance of regenerative growth was restricted to 0.5 - 1.5 mm in all these cases. - Applications of mABs IN-1 or IN-2 directed against the neurite growth inhibitory constituents NI-35/250 of CNS myelin resulted in 1.) a further increase in local sprouting, and 2.) a subsequent elongation of CST fibers over distances of 2.5 - 20 mm. Regenerating fibers were often found in anatomically aberrant positions, largely related to their way across the lesion site. Branching and terminal arborizations could be seen in the gray matter. Our results confirm that regenerative sprouting and elongation are two distinct processes; CST sprouting can be enhanced specifically by NT-3, wherease elongation strictly depends on the neutralization of the powerful myelin-associated neurite growth inhibitory proteins.

TGF-β1 REGULATION OF HIPPOCAMPAL mRNAs FOLLOWING ENTORHINAL CORTEX LESION. T.E. Morgan, N.J. Laping, N.R. Nichols, C.S. Young-Chan, B.W. Bernstein*, and C.E. Finch. Andrus Gerontology Center, Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191.

This study examines the role of transforming growth factor-β1 (TGF-β1) in regulating glial fibrillary acidic protein (GFAP) and sulfated glycoprotein-2 (SGP-2) mRNAs during lesion-induced synaptic reorganization. GFAP, a marker for reactive astrocytes, and SGP-2, with a putative role in membrane transport, increase in the deafferented hippocampus after unilateral entorhinal cortex lesion (ECL). TGF-β1 is a multifunctional peptide that plays an important role in peripheral wound healing. Results of RNA titration indicate that TGF-β1 mRNA increases 3-fold in the deafferented hippocampus 4 days after ECL. *In situ* hybridization indicates that TGF-β1 mRNA is localized to brain regions that show elevated microglial reactivity (OX-42 immunoreactivity) after ECL. To assess TGF-β1's contribution to lesion-induced synaptic reorganization, a cannula was implanted into the lateral ventricle of adult male rats on the same day as ECL. TGF-β1 (100 ng) or vehicle was infused 24 hours before sacrifice; rats were sacrificed 2 or 4 days after ECL. Two days after ECL, the GFAP and SGP-2 levels were unaffected by TGF-β1 infusion. However, preliminary results show the expected elevation in GFAP and SGP-2 mRNAs at 4 days after ECL was prevented by TGF-β1 infusion. Thus, TGF-β1 may regulate astrocytic reactivity and other events involving membrane transport during synaptic reorganization. Supported by NRSA AG-05589 (TEM), NRSA AG-05528 (NJL) and AG-07909 (CEF).

MDF INCREASES TYROSINE HYDROXYLASE ACTIVITY AND CATECHOL LEVELS IN INJURED BUT NOT INTACT DOPAMINERGIC NEURONS. B.K. Jin*, J.S. Schneider, X.Y. Du and L. Iacovitti. Dept. of Neurology, Hahnemann University, Philadelphia, Pa. 19102.

We have previously demonstrated that a 10,000-fold purified muscle-derived factor termed MDF will increase tyrosine hydroxylase (TH) activity and catechol levels in lesion-spared dopamine neurons following a 6-hydroxydopamine (6-OHDA) lesion of the nigrostriatal system. In the present study, we examined whether prior damage to dopaminergic neurons that resulted from 6-OHDA treatment was essential for MDF's effect. To test this hypothesis, either partially-purified MDF or PBS+BSA (control) was infused unilaterally into the intact rat striatum. In order to minimize mechanical damage and maintain the intact state, we used a 28 gauge cannula connected to a mini-osmotic pump (ALZET 2002: infusion rate of 0.5 µl/hr). After 12-13 days of infusion, rats were sacrificed and postmortem tissue on both the ipsilateral and contralateral sides was rapidly dissected for TH immunocytochemistry/in situ hybridization and biochemical measurement of TH enzyme activity, dopamine (DA) and its metabolite, dihydroxyphenylacetic acid (DOPAC). Evidence of a mechanical lesion was not observed anatomically or biochemically in control (PBS-treated) rats. Thus, there was no disruption of TH immunoreactive fibers except in the area immediately adjacent to the cannula tip, and no differences in TH enzyme activity, DOPA or DOPAC levels when compared to untreated or contralateral striata. Similar to PBS, but in marked contrast with the changes previously observed in 6-OHDA-lesioned rats, MDF infusion failed to increase biochemical indices of DA function in the intact striatum. Thus, TH activity in MDF-treated striata (371±59) remained at PBS-treated (366±45) levels. Similarly, there was no change in postmortem levels of DA (97%) and DOPAC (106%) (expressed as a % of contralateral striata). In situ hybridization analysis of TH mRNA also showed no detectable change in TH mRNA/cell in the parent cell bodies of the substantia nigra. These findings indicate that MDF treatment has no effect on the intact dopaminergic neuron. Taken together with our previous studies on 6-OHDA lesioned rats, these data suggest that prior damage is essential for MDF's effect on adult nigral dopaminergic neurons in vivo.

546.15

MUSCLE-DERIVED MOTONEURONOTROPIC FACTORS PROMOTE SURVIVAL OF AXOTOMIZED MOTONEURONS OF THE FACIAL NERVE. **W.H.A. Yu*[1], R.M.W. Chau[2] and F. Ren[2]. [1]Dept. of Cell Biol. and Anat. Sci., City Univ. of New York Med. Sch., New York, NY 10031 and [2]Dept. of Anat., Univ. of Hong Kong, Hong Kong.**

Two motoneuronotrophic factors (MNTF1 & MNTF2), isolated from the peroneal muscle of 3-week old rats and shown to promote the survival of anterior horn motoneurons in vitro and in vivo after axotomy, were tested for their efficacy on axotomized motoneurons of the cranial region. The facial nerve of 10-day old rats was transected unilaterally distal to its exit from the stylomastoid foramen under hypothermia. MNTF1 and MNTF2, separated by Phast gel electrophoresis and migrated at 35 and 22 kD, respectively, were cut out from the Phastgel, minced into small pieces and placed between the two nerve stumps. For controls, either blank or Phastgel devoid of neuronotrophic activity was used. At 1 and 2 wk postaxotomy, rats were perfused with 4% paraformaldehyde in PBS, and brain stems were embedded in Paraplast. Neuronal cell numbers in the motor nuclei of the facial nerve were counted on serial transverse sections stained with cresyl violet. The total number of motoneurons on the side of axotomy was divided by the respective contralateral number to determine the percentage survival. Results indicated that MNTF1 and MNTF2 individually reduced the severity of chromatolysis and increased the survival of axotomized facial motoneurons. However, mean percentage survival with each factor was less than that observed in motoneurons of the sciatic nerve, and MNTF1 and MNTF2 in combination did not show synergistic action. It is concluded that responsiveness to neuronotrophic activity of MNTF1 and MNTF2, isolated from hindlimb muscles of young rats, extends not only to somatic motoneurons of the spinal cord, but to cranial motoneurons as well.

546.16

SYNERGETIC EFFECT OF MOTONEURONOTROPHIC FACTORS (MNTF) 1 AND 2 ON SURVIVAL OF AXOTOMIZED MOTONEURONS OF SCIATIC NERVE. R.M.W. Chau, W.H.A. Yu, L.S. Jen* and F. Ren. Dept. of Anatomy, Univ. of Hong Kong, Hong Kong; Dept. of Cell Biology & Anatomical Sciences, CUNY Medical School, New York, USA and Dept. of Anatomy, Charing Cross & Westminister Medical School, London, UK.

MNTF1 (35kD) & MNTF2 (22kD) were isolated from the peroneal muscles of 3-week-old rats by the "protein band-fishing by cells" method. In vitro, both factors could support the survival of anterior horn motoneurons. In vivo survival of axotomized motoneurons of sciatic nerve of 10-day-old rats were studied. The factors in minced gel were placed near the site of the lesion for rescue experiments for 2 weeks. The results revealed that the percentages of axotomized motoneuron survival compared to those of the respective contralateral side were 44.6±7.5 for the control without factor, 76.5±10.8 for the rescue experiment with MNTF1, 71.3±8.7 for those with MNTF2, and 86.8±5.8 for those with both MNTF1 and MNTF2. These results indicated that MNTF1 and MNTF2 can individually promote the survival of axotomized motoneurons of the sciatic nerve, in vivo, both with statistical significance $P<0.05$, $n=7$; however, when both MNTF1 and 2 are used concurrently they can provide a very significant synergetic effect on the survival of axotomized motoneurons, in vivo, with $P<0.01$, $n=7$. These results are consistent with previous in vitro evidence.

Low molecular weight brain-derived proteins and neurotrophins can prevent motoneuron cell death induced by spinal deafferentation. Y. Qin-Wei*, R.W. Oppenheim, J.E. Johnson and D. Prevette. Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, N.C. 27157-1010

Our previous studies have shown that extracts prepared from embryonic (E16) chick brains can enhance the survival of developing spinal motoneurons during normal cell death or death induced by spinal deafferentation. The current experiments were designed to partially separate and characterize brain extract (BEX) survival activity, and to determine the effects of members of the NGF-like neurotrophin family on deafferentation-induced motoneuron cell death.

Thoracic spinal cord segments were removed from chick embryos (E2) creating a spinal gap and lumbar segments were assayed for motoneuron survival on E16. Daily treatment (E9-E15) with protein from a 25%-75% ammonium sulfate fraction of BEX prevented motoneuron cell death induced by spinal deafferentation. BEX activity was partially separated and characterized with tandem gel exclusion chromatography (Sephadex G-50 and BIO-GEL P-60), preparative isoelectric focusing electrophoresis and PAGE. Preliminary results suggest that activity is confined to low molecular weight proteins (<20 Kd) with a pI of 8 (high activity) or 5 (low activity). Interestingly, while all members of the neurotrophin family tested (NGF, BDNF and NT-3) promote motoneuron survival following spinal deafferentation, only BDNF appears to support survival during normal cell death.

ACTH/MSH PEPTIDES PROMOTE NEUROMUSCULAR EFFICIENCY FOLLOWING TRAUMA OF THE DEVELOPING NERVOUS SYSTEM. L.A. Zuccarelli* and F.L. Strand, Dept of Biology, Center for Neural Science, New York University, New York, NY 10003.

ACTH 4-10 and α-MSH positively affect the development and regeneration of peripheral nerve[1]. Here we investigate their effects on integration at the developing neuromuscular junction and on the contractile properties of muscle following denervation. 2 d old Sprague-Dawley rats are subjected to sciatic nerve crush and peptide or saline vehicle treatment (10μg/kg/48h/8d). At 18, 21 and 35 d of age, the extensor digitorum longus muscle is attached to a force transducer and the sciatic nerve exposed. A stimulating electrode, placed proximally to the crush site, delivers graded stimuli (0.1 V) to determine motor unit recruitment and maximal twitch contraction amplitude. Super-maximal stimuli elicit isometric twitches, tetani at fusion frequency and at 120 Hz, twitches after fatigue at 400Hz for 10s and 10Hz for 10 min.

Results at 18 d indicate that α-MSH prevents fatigue in that twitch amplitude and rate are not different from sham controls. At 21 d, peptide treatment significantly ($p<.05$, ANOVA) promotes the recovery of numerous contractile properties of both twitch and tetanus: amplitude, rate, post-tetanic twitch amplitude and post-tetanic twitch rate as compared to saline treatment. After 10 min of stimulation at 10 Hz, no differences exist among sham and peptide groups in 1/2 relaxation time. Preliminary data at 35 d indicate peptide efficacy on twitch rate and tetanic fusion frequency, tetanic rate and post-tetanic twitch amplitude, and post-tetanic twitch rate. These results continue to support the efficacious role of ACTH/MSH peptides in PNS regeneration during development. [1]Strand et al., Prog. in Neurobio. 33, 1989.

SEX STEROID AND CASTRATION EFFECTS ON THE REGENERATING EDL MUSCLE AFTER PERONEAL NERVE CRUSH. **J. Kume*, R. Baradarian, and F.L. Strand. New York University Depart. of Biology and Center for Neural Science. NY, NY 10003.** Sex steroids have been shown to affect peripheral nerve regeneration in a muscle that has been typically characterized as essentially non-androgen sensitive, the rat extensor digitorum longus muscle (EDL). (Kume, J. and Strand,F.L. Soc. Neuroscience, Nov. 1991). We investigated the influence of sex steroids on regeneration of the crushed peroneal nerve from the perspective of muscle reinnervation and motor functional recovery. Sprague-Dawley male and female rats were divided into 3 groups: sham-nerve crushed; nerve-crushed; and castrated, nerve crushed. Another group of castrated male rats was nerve-crushed, implanted with testosterone propionate (TP)(20mm, id.058",od.077"), and given ORG 2766, an ACTH 4-9 analog (40ug/kg/48 hrs). To assess motor functional recovery, changes in toespread and print length were measured from footprints. 1-5 digit distances, peroneal functional indices, and % toespread recovery were calculated. At 9 days post-crush, rats were anesthestized with a xylazine/ketamine combination (5mg/kg; 75mg/kg respectively) and EDLs were indirectly stimulated via the peroneal nerve. Nerve crushing, regardless of sex, results in significant ($p<.05$, ANOVA) decreases in twitch and tetanic peak responses, a lower fusion frequency, and an altered peak rate. PTP responses were similarly smaller in response peak and altered peak rate. Twitch/tetanic peak response ratios are significantly greater in castrated, nerve crushed rats but are restored in males to normal values with TP. It can be concluded that removal of sex steroids for either gender seriously hinders recovery from peroneal nerve crush. This deleterious effect is apparent when corresponding to motor functional recovery tests.

OTHER FACTORS AND TROPHIC AGENTS: CYTOKINES

547.1

TEMPORAL EXPRESSION OF BRAIN CYTOKINES INDUCED BY LPS. S. De, R.M. Klein, G. Wood and N.E.J. Berman*. Depts. of Anatomy and Cell Biology and Pathology and Oncology, University of Kansas Medical Center, Kansas City, KS 66160

Extensive tissue remodeling occurs in the brain during development and following injury. Many of the cellular events of tissue remodeling, including phagocytosis of cellular debris, are accomplished by brain macrophages or microglial cells. In culture, these cells produce cytokines in response to stimulation by bacterial lipopolysaccharides (LPS). To determine how these cells respond to LPS stimulation *in vivo*, we injected LPS intraperitoneally or directly into the brain of adult CD-1 mice and studied the mRNA levels for various cytokines (IL-1α, IL-1β and TNF-α) in the brain and liver using Northern blot analysis. Following intraperitoneal injection of 10 μg LPS, tumor necrosis factor alpha (TNF-α) message was increased in the liver at 1 and 2 hr, and decreased by 4 hr. No change was observed in the brain at these times. Following injection of 10 μg LPS into cerebral cortex, TNF-α message levels in the brain increased at 2 hr, decreased by 4 hr, but increased again significantly 4 days later, stayed high for up to 7 days, and declined to the basal level by day 8. TNF-α expression in the liver was stimulated at 2 hr, declined at 4 hr, and stayed low through day 8. Following LPS injection into the brain, changes in interleukin-1-alpha and beta (IL-1α and IL-1β) expression followed the same time course in brain and liver. Both were increased at 4 hr but declined by 1 day and stayed low until 8 days, showing no late second peak in expression levels. These results demonstrate a biphasic temporal response of TNF-α mRNA in brain following LPS stimulation. The differences in expression between liver and brain suggest tissue-specific temporal expression of certain cytokines. Supported by MH38399.

EXPRESSION OF INTERLEUKIN-6 AND INTERLEUKIN-6 RECEPTOR mRNA IN RAT HYPOTHALAMUS. R. A. Gadient, R. G. Bernasconi* and U. H. Otten. Dept. of Physiology, Univ. of Basel, CH-4051 Basel, Switzerland.

The cytokine interleukin-6 (IL-6) mediates a number of biological activi ties, including hepatic acute phase response, maturation of activated B-lymphocytes, and inflammation. In addition, IL-6 exerts specific effects in the central nervous system, such as activation of the hypothalamic-pituitary-adrenal (HPA)-axis, promotion of mesencephalic neuron survival, and modulation of neurotrophin production. Using reverse transcription followed by polymerase chain reaction we investigated the expression of IL-6 and its receptor mRNAs in rat brain during postnatal development. IL-6 and IL-6 receptor signals were compared to the constitutively-expressed ribosomal protein S12, to check RNA integrity and efficiency of reverse transcription. Of the various brain regions examined the hypothalamus showed highest levels of IL-6 and IL-6 receptor mRNA. Hypothalamic IL-6 and IL-6 receptor mRNAs were developmentally regulated. Both mRNAs gradually increased reaching maximal levels at postnatal day 70. At all developmental stages studied the IL-6 mRNA content was about 10-fold lower than that of its receptor mRNA. The results of our work are in close agreement with in situ histochemical studies and suggest that IL-6 is involved in brain function, including in particular the control of HPA-axis.

INTERFERON-γ (IFN-γ) INCREASES CHOLINE ACETYLTRANSFERASE IN CULTURED BASAL FOREBRAIN. G.M. Jonakait* and L. Ni. Dept. of Biol. Sci., Rutgers Univ., Newark, NJ 07102

In order to study the effects of immune cytokines on cholinergic neurons of the basal forebrain, we have grown dissociated cell cultures derived from fetal rats. We measured choline acetyltransferase (ChAT) activity as a marker for cholinergic neurons. Cells plated at 2 X 10^6 cells/ml showed a 12-fold increase in ChAT activity over cells plated at 1/4 that density. In subsequent studies, therefore, density was carefully maintained at 1.5-2 X 10^6 cells/ml. ChAT activity increased steadily over the first week in culture; then it slowly declined.

Recombinant murine IFN-γ (Schering-Plough) produced a dose-dependent increase in ChAT activity in one-week-old cultures taken from embryonic day 16 (E16). At 50 U/ml this activity peaked, showing a 10-fold increase over control. Striatal ChAT activity measured in sister cultures was unaffected by IFN-γ. The effect of IFN-γ was dependent upon fetal age. Cultures taken from E18 rats showed a significant but truncated (1.7-fold) increase in ChAT. E19 cultures did not respond to IFN-γ even at 500 U/ml.

The effect of IFN-γ is partially reversed in the presence of an antibody to NGF (5%; Mike Coughlin, McMaster Univ.), suggesting that NGF or another neurotrophin mediates at least some part of IFN's action.

LEUKEMIA INHIBITORY FACTOR MEDIATES THE INTERLEUKIN-1 (IL-1) INDUCTION OF SUBSTANCE P IN SYMPATHETIC GANGLIA. A.M. Shadiack*, R.P. Hart, and G.M. Jonakait, Dept. Biol. Sci., Rutgers Univ., Newark NJ 07102

Immune cytokines act as growth and differentiation factors in the nervous system. Superior cervical ganglia (SCG), cultured either as explants or as dissociated cells, respond to IL-1 with increased levels of substance P (SP). Since IL-1 does not alter SP expression in pure neuronal cultures, a molecular intermediate derived from non-neuronal cells must exist. Therefore, we collected medium from IL-1-treated ganglia (IL-1CM). IL-1CM elevated SP in naive explanted ganglia even in the presence of an IL-1 receptor antagonist (Synergen). Importantly, IL-1CM raised SP in pure neuronal cultures. Preliminary characterization of the active factor in IL-1CM showed it to be a protein with a molecular weight >10Kd.

Since IL-1CM, leukemia-inhibitory factor (LIF) and ciliary neuronotrophic factor (CNTF) raises both SP and choline acetyltransferase activity in explanted ganglia, we tested LIF and CNTF as possible intermediates. Immunoprecipitation of IL-1CM with an antibody against CNTF (Regeneron) did not affect IL-1CM activity. However, immunoprecipitation with an antibody specific for LIF (Dr. P.H. Patterson, Cal. Tech.) eliminated the SP-inducing activity of IL-1CM on pure neurons. These data suggest that the elevation of SP in response to IL-1 may be secondary to an induction of LIF in sympathetic ganglia.

Sponsored by ONR and NIMH.

INTERLEUKIN-1 RECEPTOR mRNA IS INDUCED IN CULTURED RAT SYMPATHETIC GANGLIA. R.P. Hart*, C.-L. Liu, A.M. Shadiack, C.D. Carlson, R. McCormack and G.M. Jonakait. Dept. Biol. Sci., Rutgers Univ., Newark NJ 07102.

Interleukin-1 (IL-1) increases substance P (SP) gene expression in cultured rat superior cervical ganglion (SCG) explants. This increase is blocked by the depolarizing agents KCl or veratrine. Furthermore, IL-1 induces SP in dissociates but not in "pure" neuronal cultures, suggesting that IL-1 acts at a non-neuronal cell. In order to study the molecular mechanism of IL-1 action, we have cloned IL-1 receptor (IL1R) cDNA from rat brain and SCG. The cDNA sequence is strongly homologous with mouse and human IL1R cDNA of the fibroblast type (type I). mRNA specific for IL1R can be readily detected in intact SCG by S1 hybridization or RT-PCR reactions. However, the level of IL1R mRNA increases 5-fold by 2 days in culture. This increase is independent of the presence of IL-1, IL-1 receptor antagonist protein (Synergen), veratrine or tetrodotoxin. 40 mM KCl reduces the level of IL1R mRNA slightly. Identification of the IL1R mRNA-containing cell type is in progress. The induction of IL1R following explantation, a model of nerve injury, may provide a mechanism linking inflammatory signalling to neuronal phenotypic changes. (Supported by ONR and NIMH).

EFFECTS OF MURINE AND HUMAN CYTOKINES ON PC12 CELLS IN VITRO. W.J. Bell, S. Rudnick, M. Palmatier, L. Christenson* and T.R. Flanagan, CytoTherapeutics, Inc., 2 Richmond Square, Providence, RI 02906.

Neurons are known to be responsive to a broad range of biologically active peptides. Considerable information has been accumulated describing peptide neurotrophic factors. At the same time, a tremendous body of information has been assembled describing immunologically active trophic factors (cytokines). Neurons might reasonably be exposed to a number of these cytokines during acute inflammatory episodes. We have examined the effects of 4 recombinant cytokines (IL-1, IL-2, IFN, TNF) over a 100 fold concentration range on the metabolic activity of a neuronal pheochromocytoma (PC12) cell line during 2 days of culture. Metabolic activity was measured by mitochondrial oxidation of MTT, and, as such, reflects either a proportional loss of mitochondrial oxidative potential or fractional cell death.

In PC12 cells grown in attached cultures in serum-free media, a 10 to 40% depression of net metabolic activity was seen after exposure to the highest doses of all the tested cytokines. However, PC12 cells grown in serum supplemented media displayed a depressed metabolic activity only in response to the highest doses of murine gamma interferon (1000 units per ml). This metabolic depression progressed with increased culture time. Combinations of all four cytokines at half maximal doses did not detectably depress metabolic activity more than interferon alone, and at lower concentrations a 10% metabolic stimulation was suggested in cells cultured with incomplete media. The inhibitory effect of high levels of murine gamma interferon was less pronounced in PC12 cells grown as spinner cultures.

These studies indicate that the metabolic activity of PC12 cell cultures can be depressed by elevated levels of cytokines and that the magnitude of this effect is influenced by the conditions used to culture these cells.

CELL CONTACT REGULATES NEUROPEPTIDE Y EXPRESSION IN CULTURED SYMPATHETIC NEURONS. M. Freidin, C. Kalberg*, and J.A. Kessler. Depts. Neurology and Neuroscience Albert Einstein College of Medicine, Bronx, NY 10461.

Neurotransmitters and neuropeptides coexpressed by the same neuron may be regulated independently. The peptide transmitter, neuropeptide Y (NPY), has been identified in approximately 60% of rat sympathetic superior cervical ganglion (SCG) neurons, virtually all of which are catecholaminergic. However, we find that environmental signals which effect catecholaminergic traits in cultured rat SCG, regulate NPY expression differently. Relatively large increases in neuronal density only slightly alter catecholaminergic properties in sympathetic neurons. However, levels of NPY were highly depependent on cell density. In pure neuronal cultures, increasing cell numbers from 6500 to 12,000 neurons per culture resulted in a 14-fold decrease in NPY. Coculture of SCG neurons with ganglion nonneuronal cells further reduced NPY levels at all neuronal densities examined. Treatment with the neuropoietic cytokine leukemia inhibitory factor, which increases cholinergic traits and SP and decreases catecholaminergic expression, decreased NPY by 50% in cocultures and only slightly in pure neuronal cultures. Finally, neither glucocorticoids nor the immunoregulatory cytokine interleukin-1β, which regulate other transmitter systems, altered NPY expression. These observations indicate that although norepinephrine and NPY are often coexpressed, they are regulated independently in cultured SCG neurons. Further, expression of NPY is highly influence by cell-cell contact.

547.8

MULTIPLE CYTOKINES/GROWTH FACTORS REGULATE TRANSMITTER EXPRESSION IN CULTURED SYMPATHETIC NEURONS. J.A. Kessler, D. Javitz*, J. Kim and M. Freidin Depts. Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461.

Coculture of sympathetic neurons with ganglion nonneuronal cells stimulate neuronal expresssion of cholinergic traits and and of the peptide transmitter, substance P (SP). The molecular mechanism mediating these interactions are not fully understood. Treatment of sympathetic neurons with the cytokine leukemia inhibitory factor (LIF), which is found in conditioned medium from nonneuronal cells, likewise stimulates cholinergic and SP expression (Yamamori, T., et al, 1989). However, treatment of cocultures with an anti-LIF antibody (which completely blocks the effects of exogenous LIF) only reduces choline acetyltransferase activity (ChAT) and SP by 30-50%, suggesting that LIF mediates some but not all of the effects of coculture with nonneuronal cells. Cocultures also produce a molecule similar to or identical with CNTF, suggesting that the factor also mediates some of the effects of culture. Finally, another cytokine, interleukin-1β (IL-1β) is endogenously produced by these cultures. Treatment of cocultures with an antagonist to the interleukin 1 receptor significantly reduced levels of SP. These observations suggest that the effects of nonneuronal cells on sympathetic neurotransmitter and peptide expression are mediated by a complex array of growth factors/cytokines including, but not restricted to, LIF, CNTF, and IL-1β.

547.9

INDIRECT DEVELOPMENTAL MODULATION OF CHOLINERGIC AND DOPAMINERGIC PROPERTIES OF RAT CNS NEURONS IN CULTURE BY D-FACTOR (CDF/LIF). C.H. Schmelzer, L.E. Burton, F. Hefti and B. Knüsel*. Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90089 and Genentech Inc., South San Francisco, CA 94080.

Cholinergic differentiation factor (CDF), identical to leukemia inhibitory factor (LIF), induces cholinergic phenotype in normally adrenergic sympathetic neurons. LIF mRNA is also found in rat CNS. We tested whether LIF might play a role in the transmitter-specific development of rat mesencephalic neurons. Chronic treatment of primary cultures of embryonic (E15) ventral mesencephalon with LIF reduced the uptake activity for radiolabeled dopamine (DA) to approx. 50% of control after 1 week *in vitro*. In identical cultures the activity of the cholinergic marker enzyme choline acetyltransferase (ChAT) was increased two-fold. Immunocytochemical staining of the cultures for neuron-specific enolase, tyrosine hydroxylase, ChAT and glial fibrillary acidic protein revealed little effect of LIF on numbers of neurons, including the dopaminergic and cholinergic ones, but showed a significant effect on prevalence and morphology of astrocytes. Dose requirements for effects on DA uptake and ChAT activity were identical, with ED_{50}s of 1 ng/ml. However, the reciprocal effects on cholinergic and dopaminergic properties were not due to transdifferentiation of DA neurons. Selective elimination of DA cells by pretreatment with 10 μM MPP^+ for 24 hrs abolished DA uptake of both, control and LIF treated, cultures but did not affect the LIF mediated ChAT activity increase. Our data suggest that LIF affects cholinergic and dopaminergic mesencephalic neurons by the same, albeit indirect mechanism, possibly reflecting a specific, receptor mediated effect of LIF on development and differentiation of astrocytes.

547.10

CNTF AND LIF ACT ON NEURONAL CELLS VIA SHARED SIGNALLING PATHWAYS THAT INVOLVE THE IL-6 SIGNAL TRANSDUCING RECEPTOR COMPONENT GP130. N. Y. Ip*, S. H. Nye, T. G. Boulton, Y. Li, S. Davis, S. J. Birren, T. Taga, T. Kishimoto, D. J. Anderson, N. Stahl and G. D. Yancopoulos. Regeneron Pharmaceuticals, Inc., 777 Old Saw Mill River Road, Tarrytown, New York 10591.

Recent analyses suggest that ciliary neurotrophic factor (CNTF) and a number of hemopoietic cytokines including interleukin-6 (IL-6) and leukemia inhibitory factor (LIF) appear to be distantly related, as are some of their receptor components. While LIF shares several common actions with IL-6 outside of the nervous system, it also elicits responses in some neuronal cells similar to those of CNTF. We have identified biologically relevant responses to CNTF in a sympathoadrenal progenitor cell line (MAH), which also responds identically to LIF. Comparison of the tyrosine phosphorylations and gene activations induced by CNTF and LIF in MAH cells, as well as in other neuronal cell lines, reveals that they are indistinguishable and are also very similar to signalling events which characterize LIF and IL-6 responses in hemopoietic cells. We provide a basis for the overlapping actions of these related cytokines by demonstrating that the shared CNTF and LIF signalling pathways involve the IL-6 signal transducing receptor component gp130. Thus the receptor system for CNTF is unlike the trk receptor kinases used by the nerve growth factor family of neurotrophic factors, but instead shares components with the receptor complexes for a subclass of hemopoietic cytokines. Interestingly, we find that the receptors for both the CNTF and the nerve growth factor family are not only expressed in discrete populations of adult neurons, but are also present during early neuronal development. We provide evidence that these two distinct classes of neurotrophic factors, utilizing distinct signalling pathways, can interact to effect the growth and differentiation of neuronal progenitors.

547.11

GROWTH FACTOR REGULATION OF mRNA'S ENCODING RECEPTORS FOR NEUROTRANSMITTERS IN CULTURED SYMPATHETIC NEURONS. W.H. Ludlam*, Z. Zang§, and J.A. Kessler. Depts. of Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx NY 10461, and §Center for Molecular & Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102.

Neuronal receptor and neurotransmitter phenotypes are both regulated by similar factors in cultured sympathetic neurons of the neonatal rat superior cervical ganglion (SCG). Leukemia inhibitory factor (LIF) and ciliary neurotrophic factor (CNTF), factors previously shown to stimulate levels of choline acetyltransferase activity (CAT) and of substance P, have recently been shown by our laboratory to also block the normal developmental increase in muscarinic receptor expression in cultured SCG neurons. In this study we have characterized the muscarinic receptor genes expressed by sympathetic neurons, and defined the effects of LIF and CNTF treatment on muscarinic receptor mRNA (subtypes m1, m3, and m4). In untreated SCG cultures, significant levels of the m1 subtype were detected using solution hybridization/RNase protection analysis. By contrast, m3 and m4 subtypes mRNA's were much less abundant. After 12 days of treatment with LIF or CNTF (both at 5 ng/ml), the level of m1 muscarinic receptor mRNA was approximately 50% lower than control. We are currently investigating the regulation of the m2 and m5 subtypes. Further, we are examining the regulation of other receptor mRNA's which may be elevated by LIF and CNTF treatment. These findings indicate that LIF and CNTF regulate differential receptor expression at the mRNA level, and that these factors may influence both transmitter development and receptor phenotypic expression of the neuron.

NUTRITIONAL AND PRENATAL FACTORS

548.1

EFFECT OF PRE- AND/OR POSTNATAL CHOLINE SUPPLEMENTATION ON WORKING AND REFERENCE MEMORY (SPATIAL AND NONSPATIAL) AND OPEN FIELD BEHAVIOR IN THE RAT.
R.C. Tees* and J.L. Johnston. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1Z4.

Research has shown that choline supplementation during development enhances spatial working and reference memory in adult rats (Meck et al., 1989). Cholinergic blockade studies report spatial memory impairments (Ellen et al., 1986) and diminished responses to novel cues as well as a disruption of normal search and exploratory behaviors (Whishaw & Tomie, 1987).

The present experiment was designed to assess the effect of dietary choline supplementation on spatial and non-spatial memory and exploratory behavior. Subjects received either no supplementation, supplementation pre-natally to postnatal day 30, or supplementation from post-natal days 16 to 30. Test battery consisted of an open field task, visual discrimination task, 17-arm radial arm maze and delayed-nonmatching-to-sample.

Significant group differences were found, as well as a significant group by sex interaction effect in the post-natal group. These findings suggest that dietary choline supplementation enhances several aspects of memory perfor-mance and that postnatal supplementation alone has a differential effect depending on sex.

548.2

SEX DIFFERENCES IN THE EFFECT OF PRENATAL CHOLINE TREATMENT ON SEPTAL CELL SIZE AND HIPPOCAMPAL NGF.
R. Loy,*D. Heyer, J. Miller and M.D. Lindner. Canandaigua VAMC and Department of Neurology, University of Rochester, 435 E. Henrietta Road, Rochester, NY 14620.

Choline treatment restricted to embryonic days 12-17 (E12-17) is sufficient to produce long-lasting enhancement of spatial memory in male and female rats, although the effect in females is not as robust. We tested rats treated *in utero* from ED12-17 with choline chloride (300 mg/kg/day, *p.o.* to the dam) for changes in the size of NGF receptor-positive neurons. Basal forebrain NGF receptor-positive neurons increased in size from 70 sq microns on PD0 to more than 200 sq microns on PD30. Males tended to have larger NGF receptor-positive neurons than females, but choline increased cell size in both males and females. Cells were no longer increasing in size after PD30, and by PD90 only the males still exhibited a significant increase in cell size due to choline treatment. Choline treatment also increased levels of NGF protein in the hippocampi of both males and females at PD20. In males at PD90, NGF levels were higher in the right hippocampus than in the left, and at this age choline treatment increased NGF protein levels equally on both sides. Future studies remain to determine whether the laterality of NGF protein levels is different for females than for males, whether choline effects on hippocampal NGF protein levels persist in females, and what the role of NGF may be in either the increased cell size or enhanced memory function with choline treatment.

548.3

EFFECT OF PRENATAL EXPOSURE TO METHADONE (M) ON ACETYLCHOLINE (ACH) TURNOVER IN ADULT FEMALE RATS. S.E.Robinson,* H. Guo, J.R. Pascua, K.P. McDowell, and H.M. Allen. Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

Prenatal exposure to M affects ACh content and the turnover rate of ACh (TR_{ACh}) in specific brain regions of neonatal and weanling female rats (Dev. Brain Res. 57: 296, 1990; 64: 183, 1991). In order to determine whether abnormalities in cholinergic function persist into adulthood, the following experiment was performed. On gestational day 7, female Sprague-Dawley rats anesthetized with methoxyflurane were implanted with 14-day Alzet osmotic minipumps filled with water (W) or M (9 mg/kg/day). An untreated control (C) group of pregnant rats was also included. Within 24 h of parturition, the litter size was reduced to 10 (5 of each sex) and the pups fostered to untreated dams. On postnatal day 90 (P90) and beginning 11 min after i.p. injection of saline or morphine SO_4 (20 mg/kg), rats were infused via the tail vein with deuterium-labeled phosphorylcholine (15 µmol/kg/min) for 9 min and euthanized by microwave radiation focussed to the skull (10 kW, 1.3 sec). Using a mass fragmentographic technique, relative incorporation of deuterium into choline and ACh, and hence, TR_{ACh} were determined in brain regions. Unlike findings in the weanling rat, prenatal M exposure did not affect TR_{ACh} in the parietal cortex, hypothalamus, or striatum of female rats at P90. However, although morphine reduced TR_{ACh} in the hippocampus of C and W rats, it did not have this effect in M-exposed rats. Thus, although basal cholinergic activity returns to control values in adult females exposed to M prenatally, this treatment affects the cholinergic response to morphine. (Supported by NIDA grant DA-05274).

548.4

ACTIVATION OF PYRIDOXAL KINASE BY ZINC METALLOTHIONEIN IN TROUT BRAIN. R. Hao, R.F. Pfeiffer and M. Ebadi*. Div. of Neurology and Dept. of Pharmacology, Univ. Nebr. Coll. Med., 600 S. 42nd St., Omaha, NE 68198-6260.

With the exception of calcium and magnesium, zinc is the most abundant cation in the brain. Metallothionein (MT) are low-molecular weight metal binding proteins consisting of 25-30% cysteine, containing no aromatic amino acid or disulfide bonds, and binding between 5 and 7 g atoms of group IIB heavy metals per mole of protein. The precise physiological functions of these ubiquitously occurring proteins, which may vary in different organs and tissues, are not fully understood. Since the basal level of MT synthesis varies in the hippocampus, cerebellum, striatum, pineal gland, and retina, we have proposed that MTs may regulate the transport and homeostasis of essential trace metals in these brain regions. By using G75 gel filtration and DEAE Sephadex chromatographies, we have purified MT from trout brain, which exhibited only one band on SDS polyacrylamide gel. Furthermore, the trout brain MT possessed a MW of 6.720 ± 200 as judged by studies on SDS PAGE and G75 gel filtration chromatographies, and contained a zinc content of 9 µg/mg protein. The trout brain zinc metallothionein stimulated the activity of pyridoxal kinase (ATP:pyridoxal 5-phosphotransferase EC 2.7.1.35) at the concentrations of 6-30 µM, whereas the thioenin was devoid of any stimulating activity. The results of these studies are interpreted to suggest that metallothionein stimulates pyridoxal kinase by cross-linking and donating zinc to it (Supported in part from a grant from USPHS ES 03949).

548.5

EFFECTS OF CHRONICALLY ADMINISTERED FLUOXETINE HCl DURING GESTATION ON SPRAGUE-DAWLEY OFFSPRING. M. Stanford, M. Gilbert, L. Mills and J. H. Patton*. Department of Psychology, Baylor University, Waco, TX 76798.

Fluoxetine HCl (Prozac®, Dista) is an antidepressant chemically unrelated to the tricyclic antidepressants. Its antidepressant action appears to be linked to its selective inhibition of 5-HT reuptake in the CNS (Wong, Horng & Bymaster (1974), *Life Sciences*, 15, 471-479). Recent research has demonstrated that Fluoxetine HCl causes a down regulation of ^3H - Imipramine binding sites in the cerebral cortex of rats exposed in utero (Montero, de Ceballos & Del Rio (1990), *Life Sciences*, 46, 1619-1626). In the present study gravid Sprague-Dawley rats were administered 5.62 mg/kg Fluoxetine HCl by gavage beginning day 6 or 7 of pregnancy and ending the day of birth. A control group received distilled water by gavage during gestation. Both groups received distilled water during the lactating period (birth to day 21). At birth Fluoxetine exposed pups showed a statistically higher frequency of skin hematomas when compared to water controls (Fluoxetine: 63 / 189, Water: 2 / 113, $X^2 = 34.61$, $p < .001$). This result is consistent with an earlier report in which Fluoxetine HCl was shown to cause bleeding episodes in 8 patients treated for obsessive-compulsive disorder (Tobias, Kirschen, Ninan & Mosberg (1991), *Am J Psychiatry*, 148, 949).

548.6

EFFECTS OF PRENATAL PROTEIN MALNUTRITION AND AGE ON CENTRAL NEUROTRANSMISSION. J.-C. Chen, G. Turiak and L. Volicer*
Dept. Pharmacology, U.Mass,Med.Sch., Worcester,MA 01655 and Dept. Pharmacol., Boston U.Med.Sch., Boston,MA 02118.

The effects of prenatal protein malnutrition on central neurotransmitters were assessed in postnatal day 1,15,30, 45,90 and 220 days old rats. Malnourished rat (6/25 group) were males born to dams fed a 6% casein diet during gestation and fostered at birth to dams fed a control (25% casein) diet. We observed: (1) in 220 days old rats, there was an enhanced basal release of hippocampal serotonin(5HT) dopamine (DA), norepinephrine (NE) and their acidic metabolites from incubated slices of 6/25 as compared with control (25/25 group). The basal release of these neurochemicals in 90 days old animals showed a similar pattern, however, was less significant. When challenged with 60mM KCl, there was no difference in KCl-induced neurochemical release between the two groups at both ages. (2) Tissue concentrations of 5HT, DA, NE, their precursors and metabolites from hippocampus, striatum, cortex and brain stem were similar in the two groups at each age. However, individual chemicals displayed ontogenic difference during postnatal development and varied in different brain regions. (3) by SDS-PAGE and Western immunoblotting, we found there was a difference in contents of striatal and hippocampal synaptophysin between 6/25 and 25/25 groups in 90 days old rats. We hypothesize that some molecular species that regulate neurotransmission are vulnerable to prenatal protein malnutrition. (HD-22539).

548.7

EFFECTS OF PRENATAL MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION ON THE DENTATE GYRUS OF THE RAT. L. Cintra,* L. Granados, S. Díaz-Cintra, T. Kemper and P.J. Morgane. Inst. Invest. Bioméd., UNAM 04510, and U. de Invest. Salud Infantil INP-SSA 14410, México D.F. Neurology Unit, Boston MA, 02118, and Worces. Found. Exp. Biol., Shrewsbury MA, 01545 USA.

We analyzed effects of prenatal malnutrition and postnatal rehabilitation on areas of granule cells (GC) in the dorsal leaf of the dentate gyrus (DG) and of mossy fibers (MF) stained with Timm's technique. 50 male Sprague-Dawley rats were divided in two groups, control and rehabilitated, consisting of 15, 30, 90 and 220-day-olds. 96 brain sections in the frontal plane at two levels (rostral and medial) of the dentate gyrus were analyzed with an imaging system. Results showed a significant decrease ($p<0.05$) in the area of GC at 220 days of age in the medial part of the DG in malnourished rats. 90-day-old rats showed a significant increase ($p<0.05$) in this parameter. MF area showed significant reductions ($p<0.05$) across two levels, rostral and medial, only in 220-day-old animals. These findings indicate a long-term effect of malnutrition on dentate granule cells and their efferent fibres. **(Supported by DGAPA IN202891, NIH HD-22539-04 and HD-23338-03).**

548.8

PRENATAL MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION EFFECTS ON CA3 HIPPOCAMPAL PYRAMIDAL CELLS IN RATS. M. García-Ruiz,* S. Díaz-Cintra and L. Cintra. Depto. de Fisiol. Inst. Invest. Biomédicas, UNAM, México, D.F. 04510.

Prenatal malnutrition (6% casein diet) and postnatal rehabilitation (25% casein diet), were studied for effects on CA3 pyramidal cells. We used 36 male Sprague-Dawley rats, divided in 2 groups: 1) control (25% prenatal/25% postnatal) and 2) experimental (6% prenatal/25% postnatal). Using the rapid-Golgi method, 216 CA3 cells were selected for morphometric analysis using an imaging system, and measurements of somal size, dendritic linear extent, area of dendritic thorny excrescences and the number of apical dendrites, as well as, the density, length and diameter of the synaptic spine bulbs were made. Results showed significant decreases ($p<0.05$) in somal size, number of spines, diameters of dendrites and spine bulbs, and significant increases ($p<0.05$) in the spine length and dendritic ramification. Rats fed with a 6/25% diet at 30-day-old showed a compensation in the number of spines (83%) and somal size (100%) in CA3 pyramidal cells. Prenatal malnutrition has a differential effect on hippocampal CA3 cells and this effect depends of the age of the rat. **Supported by DGAPA IN202891.**

548.9

EFFECT OF PRENATAL PROTEIN MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION ON CA1 HIPPOCAMPAL PYRAMIDAL CELLS IN RATS OF THREE AGE GROUPS. S. Díaz-Cintra*, A.Aguilar, A.Galván, L. Cintra, T. Kemper and P.J. Morgane. Inst. Invest. Bioméd., UNAM, México,D.F. 04510. Neurol. Unit, Boston City Hosp., Boston MA, 02118 and Worces. Found. Exp. Biol., Shrewsbury MA, 01545.

We have previously analyzed the effects of prenatal malnutrition and postnatal rehabilitation on pyramidal cells in CA1 in adult rats. In this study we used the same paradigm in 30, 90 and 220-day-old rats. 216 pyramidal cells were studied using an imaging system. We measured the somal size, linear dendritic extent in relation to *strata: radiatum and lacunosum moleculare* and the number of spines in three 50 micron segments corresponding to perforant path (PP), Schaffer collateral (SF) and commissural fiber input systems. We found significant reductions ($p<0.05$) in some cellular parameters in 30-day-old rats and most of these parameters in 220-day-old rats in malnourished animals. At 90 days, the spine length and apical dendritic diameters were significantly reduced ($p<0.05$). Prenatal malnutrition produces severe alterations in the apical dendrites where both PP and SF synapse in 30 and 220-days-old rats. **(Supported by DGAPA IN202891, NIH HD-22539-04, HD-23338-03).**

548.10

IMPACT OF PRENATAL PROTEIN MALNUTRITION ON LONG-TERM POTENTIATION IN JUVENILE RATS. P.J. Morgane*, R.J. Austin-LaFrance and J.D. Bronzino. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545 and Dept. of Engineering and Computer Science, Trinity College, Hartford, CT 06106.

We examined the ability of freely-moving 15- and 30-day old prenatally protein malnourished rats (designated 6/25) to support and maintain LTP of the perforant path/hippocampal dentate granule cell synapse. Tetanization in 6/25 animals resulted in a 37% enhancement of the EPSP slope measure at the 5 hr post-potentiation period. This level slowly decayed to 18% after 24 hrs. Enhanced synaptic activation, however, was not translated into enhanced cellular discharge. Population spike amplitudes from 6/25 animals declined continuously, dropping to 50% of baseline 24 hrs after potentiation. Thus, tetanization in the 6/25 group resulted in a net **decrease** in synaptic transmission efficacy. Although preliminary, 3 15-day old, 6/25 animals also failed to exhibit potentiation of the population spike component. Well-nourished controls did show enhancement in this measure beginning 3 hrs after potentiation, reaching levels of 50-70% above baseline 24 hrs after potentiation. Since no significant age-related differences were observed for baseline measures of population EPSP slope or population spike amplitude, the differential response to tetanization seen in 6/25 animals does not appear to result from immature granule cell physiology. We suggest that the dietary insult may impact intrinsic or extrinsic neuronal systems modulating dentate granule cell excitability. The dietary insult was found to alter both the establishment and maintenance of LTP, suggesting possible consequences for learning and memory function as a result of the animal's inability to properly receive, process or store information during the early post-weaning period. **Supported by NIH/CHD Grant # HD-22539**

GLIA AND OTHER NON-NEURONAL CELLS V

549.1

REGULATION OF GLIA-DERIVED NEXIN IN PRIMARY SCHWANN CELLS.
A. Bleuel and D. Monard*.

Glia-derived nexin (GDN) is a 43 kDA neurite-promoting glycoprotein with serine protease inhibitory activity. *In vivo* experiments have shown that expression of GDN is dramatically induced after injury of the rat sciatic nerve (Meier et al., Nature 343, 548-550 [1989]) and following hippocampal lesion caused by transient forebrain ischemia in the gerbil (Hoffmann et al., Neuroscience, in press).

In explant cultures of dorsal root ganglia, the GDN level is down-regulated and, as *in vivo*, can be induced following lesion of the processes emerging from the explants. The GDN increase detected by immunocytochemistry is restricted to the Schwann cells distal to the site of injury, where nerve degeneration has taken place. Neurotrophic factors, also known to be induced after lesion, have been tested for their ability to affect GDN expression in pure Schwann cell cultures. A significant increase of GDN mRNA and protein is seen after NGF treatment. NT-3 and BDNF remained inactive. Some neuropeptides also influence GDN synthesis. These results suggest that neuron-glia interaction, both by cell-cell contact and secretion of macromolecules, plays an important role in the regulation of GDN.

AGE-RELATED DIFFERENCES IN PROLIFERATIVE RESPONSES OF SCHWANN CELLS DURING WALLERIAN DEGENERATION.
A. Komiyama*, O. Hasegawa and K. Suzuki. Dept. of Pathology, Univ. of North Carolina, Chapel Hill, NC 27599 and Dept. of Neurology, Yokohama City Univ. Sch. of Medicine, Yokohama, Japan.

Proliferative responses of Schwann cells during Wallerian degeneration were investigated in the mouse sciatic nerves after nerve-transection at 3, 10 and 60 days, corresponding to the periods of early myelination, active myelination and postmyelination. As assessed by thymidine incorporation for the first 24 h in culture, Schwann cells from adult nerve proliferated rapidly within day 1 post-transection and reached a peak at day 3. In the nerves from neonatal or suckling mice, however, division rate of Schwann cells declined after transection, and was even less in the transected nerves than in the contralateral uninjured nerves. The reduction in thymidine uptake by Schwann cells was more pronounced in nerves sectioned at postnatal day 3 than those sectioned at day 10. By contrast, fibroblasts divided rapidly following transection regardless of age. These data suggest that in the degenerating nerves of young mice, their mitotic capacity of Schwann cells declined because of a loss of axonal mitogens and also the paucity of mitogens from myelin components, whereas proliferation of fibroblasts is stimulated by growth-promoting polypeptides common to any other tissues during wound repair.

IMPROVED YIELDS IN SCHWANN CELL CULTURES FROM ADULT PERIPHERAL NERVE UNDERGOING WALLERIAN DEGENERATION
A.D. Ansselin*, S.D. Corbeil and D.F. Davey, Microsurgery Research Centre, Sydney and Department of Physiology, University of Sydney, NSW 2006, Australia.

We have previously reported to the Society that a conditioning lesion to the sciatic nerve of adult rats facilitates the isolation of Schwann cells from the distal portion of the nerve several days later (Soc. Neurosci. Abstr. 17:932, 1991). It appears that the process of Wallerian degeneration causes both an increase in the number of Schwann cells *in situ* and makes it easier to extract the cells using conventional methods. We have exploited this observation further, and have found that the enzymatic treatment required to isolate cells from lesioned nerves can be much gentler than those required for intact nerve. This change in procedure produces a further marked increase in cell numbers. The left sciatic nerve in young adult Wistar rats was exposed, severed at the sciatic notch and deflected. After various survival times the severed (conditioned) and unoperated (control) sciatic nerves (20 mm each side) were excised using sterile techniques, and processed as previously described except for reduction of the digestion phase from 18h to 4h. The cells from each nerve segment were counted prior to plating approximately 3×10^6 cells per well in 6-multiwell plates (Linbro) coated with a laminin substratum. Schwann cell yield was assessed by counting the spindle shaped cells attached to the substratum 18h later. The identification of these cells as Schwann cells was confirmed with S-100 antibody staining. The optimal delay between lesion and cell harvest using this method is approximately 10 days.

PURIFICATION OF EMBRYONIC CHICKEN SCHWANN CELLS AND ANALYSIS OF P_0 EXPRESSION. A. Bhattacharyya*, R. Brackenbury, and N. Ratner. Dept. of Anatomy & Cell Biology, Univ. of Cincinnati Sch. of Med., Cincinnati OH 45267.

We have previously described an immunocytochemical marker, 1E8, that is specific for Schwann cells and their precursors (Bhattacharyya *et al.*, 1991, Neuron 7:831-844). We have now used the 1E8 monoclonal antibody to immunoselect Schwann cells from embryonic day 14 (E14) chicken sciatic nerve. When cultured, these immunoselected cells displayed many characteristics of mature Schwann cells, including S100-immunoreactivity and O4 antigen-immunoreactivity. As previously described for rodent Schwann cells, purified chicken Schwann cells divided slowly when cultured alone, but were responsive to mitogenic stimulation by neurons and by neuronal membranes.

The 1E8 monoclonal antibody recognizes the peripheral myelin protein, P_0. In rodent, P_0 expression increases at the time of myelination and is downregulated when Schwann cells are removed from axons. However, in chickens, P_0, as detected by 1E8, is expressed prior to myelin formation. We tested whether P_0 expression in the chicken is also regulated by axonal contact by culturing chicken Schwann cells in the presence and absence of axons. As in rodent, most Schwann cells purified using the 1E8 monoclonal antibody lost 1E8-immunoreactivity in 24-48 hours when cultured alone. When axonal contact was restored by adding purified Schwann cells to cultures of embryonic rat dorsal root ganglia neurons, most cells were 1E8-negative even after prolonged culture. Therefore, axonal contact *in vitro* is not sufficient to restore expression of the 1E8 antigen (P_0) in Schwann cells. These results suggest that additional signals may exist in developing nerve to maintain P_0 expression. Supported by NIH grant NS27227 and an Albert J. Ryan fellowship.

GOLDFISH SCHWANN CELLS AND OPTIC NERVE OLIGODENDROCYTE-LIKE CELLS ARE DISTINCT CELL TYPES M.Bastmeyer* and C.A.O.Stuermer; Faculty for Biology, University of Konstanz, Germany

Oligodendrocyte-like cells isolated from the goldfish optic nerve share many properties with mammalian Schwann cells. In particular like mammalian Schwann cells but unlike mammalian oligodendrocytes the fish oligodendrocyte-like cells support the growth of regenerating axons (Bastmeyer et al., J Neurosci 11, 626-640, 1991). Therefore, we isolated fish Schwann cells and compared them to the oligodendrocyte-like cells.

PNS glial cells were obtained by explanting small pieces from the IX. and X. cranial nerves of adult goldfish onto laminin coated coverslips. Two morphologically and immunocytochemically distinct cell types emigrated and multiplied in culture: long, bipolar Schwann cells and fibroblasts. Like goldfish oligodendrocyte-like cells fish Schwann cells expressed the O4-antigen and the fish myelin proteins IP1/2, which are related to mammalian P0. Both, Schwann cells and oligodendrocyte-like cells carried the HNK1-epitope, NCAM and the E587-antigen, which is related to L1 (Vielmetter et al., J Neurosci 11, 3581-3593, 1991). Oligodendrocyte-like cells differed from fish Schwann cells in that they transiently expressed fish-GFAP. Only the Schwann cells but not the oligodendrocyte-like cells were immunoreactive for anti-NGF-receptor.

Thus, despite substantial similarities, goldfish optic nerve oligodendrocyte-like cells and goldfish PNS Schwann cells are distinct cell types.

ROLE OF GLUCOCORTICOIDS IN SCHWANN CELL PROLIFERATION. T.J. Neuberger* and G.H. DeVries, Dept. of Biochemistry, Medical College of Virginia, Richmond Va. 23298.

The axolemma enriched fraction (**AEF**) contains a potent mitogen, which in the presence of serum induces Schwann cell proliferation. In serum free media, the AEF also induces Schwann cell proliferation but only if hydrocortisone is included in the media. Schwann cells grown in defined media containing hydrocortisone demonstrated a 5 to 10 fold greater response to AEF stimulation as compared to Schwann cells grown in defined media without hydrocortisone. The role of glucocorticoids in mediating the response of Schwann cells to the AEF associated mitogen was further investigated using two separate approaches, a) charcoal extraction of steroids from serum and b) inhibition of the glucocorticoid receptor. Addition of the AEF to Schwann cells grown in charcoal extracted serum containing media resulted in a 50% reduction in ^{3}H thymidine uptake as compared to Schwann cells grown in untreated serum containing media. By supplementing the charcoal extracted serum with hydrocortisone, a majority of the AEF associated mitogenic activity for Schwann cells was restored. Furthermore, addition of the glucocorticoid inhibitor, RU-486, to serum containing media and serum free media resulted in a dose dependent inhibition of the AEF induced ^{3}H thymidine uptake. This effect was completely reversed by the removal of RU-486 from serum media 24 hours prior to the addition of AEF. Since the rate of ^{3}H-thymidine by AEF stimulated Schwann cells was not effected by pretreatment with increasing concentrations of RU-486, RU-486 did not appear to adversely affect Schwann cell viability. Finally, increasing concentrations of RU-486 added to serum containing media resulted in morphological changes. Schwann cells grown in serum containing media had short, thick processes and formed large aggregates of cells. In contrast, in serum free media and serum containing media with 10μg/ml RU-486, Schwann cells had long, thin processes and were generally observed as isolated cells. This data suggests that the proliferative response of Schwann cells to the AEF in both serum containing and serum free media is dependent on the availability of glucocorticoids in the media. THE EXPRESSION OF B-50/ GAP 43 IN SCHWANN CELLS IS UPREGULATED IN THE DEGENERATING DISTAL NERVE STUMP FOLLOWING NERVE INJURY. Plantinga,L.C., Verhaagen,J., Edwards,P.M., Jap Tjoen San,E.R.A.*, Bär,P.R., and Gispen,W.H. Rudolf Magnus Inst., Univ. of Utrecht, Utrecht, The Netherlands.

We have detected mRNA for B-50 (GAP 43, pp46, F1, neuromodulin), which was originally believed to be a neuron-specific protein, in non-neuronal cells in the rat sciatic nerve. In control rats, the level of B-50 mRNA in sciatic nerve tissue was much lower than in dorsal root ganglia. Following nerve crush or transection, the expression of B-50 mRNA in the distal nerve stump increased dramatically between 1 and 2 days postinjury. The B-50 mRNA levels in the distal stump of crushed nerves remained elevated for up to 4 weeks and subsequently returned to control levels after 7 weeks. In contrast, after nerve transection, B-50 mRNA levels in the distal nerve portion continued to increase up to 7 weeks postlesion. No changes in the levels of the B-50 transcript were observed in the proximal portion of either crush-lesioned or transected sciatic nerves. In situ hybridisation demonstrated B-50 mRNA associated with Schwann cells in the distal nerve stump. The observation that Schwann cells are capable of producing B-50 mRNA was confirmed by Northern blot analysis of total RNA isolated from primary Schwann cell cultures. Taken together these data suggest that B-50 mRNA is expressed by Schwann cells and that the expression of B-50 mRNA is regulated by contact between Schwann cells and intact axons.

EFFECTS OF NERVE SEGMENT SUPERNATANTS ON CULTURED SCHWANN CELL PROLIFERATION AND LAMININ PRODUCTION. Q. Zhang, G.L. Stoner* and H.deF. Webster. Lab. Exp. Neuropath., NIH, Bethesda, MD 20892.

Mouse sciatic nerves were transected and 3hr-16d later, proximal segments were removed and homogenized. Supernatants of these segments or of normal sciatic nerves were added to Schwann cells maintained in DMEM+15% FCS. After 6d, Schwann cells were solubilized and the protein content was measured using a Biorad protein assay. Samples containing the same amounts of protein were then applied to microtiter plates and the laminin content was determined by ELISA. Samples derived from cultures treated with 24hr supernatants contained significantly higher levels of laminin than controls or other intervals. Increased surface and cytoplasmic α-laminin immunoreactivity was found in Schwann cells treated with 24 hr supernatants. Schwann cell proliferation was compared in supernatant-treated cultures by using a BrdU ELISA. The 24hr and 2d supernatants increased Schwann cell proliferation significantly; 12hr, 4d and 8d supernatants produced smaller increases. The nature and origin of regenerating nerve constituents which increase Schwann cell proliferation and laminin production in our cultures is being investigated.
