* 9,379 volunteer abstracts, 18 symposia abstracts, 17 history of neuroscience abstracts and 46 teaching of neuroscience abstracts.
1992 Program Committee

Stanley J. Watson, Jr., M.D., Ph.D.
Chairperson
University of Michigan School of Medicine

Dennis W. Choi, M.D., Ph.D.
Incoming Chairperson
Washington University School of Medicine

David G. Amaral, Ph.D.
The Salk Institute

Martha C. Bohn, Ph.D.
University of Rochester Medical Center

Andrew G. Bulloch, Ph.D.
University of Calgary Health Science Center

Marc G. Caron, Ph.D.
Duke University Center

Roland D. Ciaranello, M.D.
Stanford University School of Medicine

Antonio R. Damasio, M.D., Ph.D.
University of Iowa College of Medicine

Stephen M. Highstein, M.D., Ph.D.
Washington University School of Medicine

Janice M. Juraska, Ph.D.
University of Illinois

Harvey J. Karten, M.D.
University of California School of Medicine

James E. Krause, Ph.D.
Washington University School of Medicine

Irwin B. Levitan, Ph.D.
Brandeis University

James O. McNamara, M.D.
Duke University Medical Center

Mary L. Oster-Granite, Ph.D.
University of California

Urs S. Rutishauser, Ph.D.
Case Western Reserve University
School of Medicine

S. Murray Sherman, Ph.D.
SUNY, Stony Brook

Roger P. Simon, M.D.
University of California, San Francisco

Gerard P. Smith, M.D.
New York Hospital, Cornell Medical Center

W. Thomas Thach, Jr., M.D.
Washington University School of Medicine

Leslie G. Ungerleider, Ph.D.
National Institutes of Health

Charles J. Vierck, Ph.D.
University of Florida Health Science Center

Monte Westerfield, Ph.D.
University of Oregon

Robert D. Wurster, Ph.D.
Loyola University of Chicago

Richard E. Zigmond, Ph.D.
Case Western Reserve University School of Medicine

Joseph T. Coyle, M.D., ex officio
Harvard Medical School

Ira B. Black, M.D., ex officio
UMDNJ-Robert Wood Johnson Medical School

Story C. Landis, Ph.D., ex officio
Case Western Reserve University
School of Medicine

## SUNDAY, OCTOBER 25

**Decade of the Brain Lecture — 8:00 p.m.**
1. The Human Brain and Behavior: Insights From Modern Imaging Techniques  
   M.E. Raichle ............................................................  No Abstract

## MONDAY, OCTOBER 26

**Symposia — 8:30 a.m.**
2. Emerging Principles of Organization Within the Midbrain Periaqueductal Gray Matter  
   *Chaired by:* M.T. Shipley and R. Bandler ........................ 1
3. The Computational Neuron  
   *Chaired by:* T.J. Sejnowski ............................................. 1

**Special Lecture — 10:00 a.m.**
4. Olfactory Mechanisms in an Insect Model  
   J.G. Hildebrand ............................................................. No Abstract

**Special Lecture — 11:45 a.m.**
5. The Molecular Basis of Electrical Excitability in the Brain:  
   Structure, Gating and Neuromodulation of Sodium Channels  
   W.A. Catterall ............................................................... No Abstract

**Slide Sessions — 8:30 a.m.**
6. Biological rhythms and sleep I ........................................... 1
7. Monoamines and behavior: human disease and animal models ............................................. 3
8. GABA receptors: structure and function ................................ 4
9. Catecholamine receptors: dopamine I ................................... 6
10. Calcium channel toxins I .................................................. 8
11. Visual cortex: functional circuits and oscillations I ............... 10
12. Nerve growth factor I .................................................... 12
13. Invertebrate learning and behavior I ................................... 15
14. Cell lineage and determination I ....................................... 17
15. Degenerative disease: Alzheimer’s—β-amyloid I .................... 19
16. Opioid and sigma receptors .............................................. 21
17. Catecholamines ................................................................ 23
18. Control of posture and movement I ..................................... 25
19. Oculomotor I ................................................................... 27

### Poster Sessions — 8:30 a.m.
20. Genesis of neurons and glia I ............................................. 29
21. Cell shape and differentiation I ......................................... 31
22. Axon guidance mechanisms and pathways I ........................... 34
23. Formation and specificity of synapses I ............................... 39
24. Ion channels: development ................................................. 41
25. Neuronal death: apoptosis ................................................ 43
27. Neuronal death: axotomy .................................................. 47
28. Neuronal death: retina ..................................................... 48
29. Neuronal death: morphology ............................................. 49
30. Neuronal death: sympathetic neurons ................................... 49
31. Neuronal death: cellular response ....................................... 50
32. Molecular and pharmacological correlates of development I .................. 52
33. Sensory development: auditory and olfactory ........................ 54
34. Sensory development: somatosensory ................................... 56
35. Transplantation: Parkinson’s—fetal tissue ............................. 58
36. Transplantation: Parkinson’s—adrenal, PC12 .......................... 61
37. Neuroglia and myelin I ..................................................... 63
38. Cytoskeletal transport and membrane targeting ....................... 66
39. Gene structure and function I ........................................... 69
40. Calcium-activated potassium channels ................................... 72
41. Potassium channels: physiology and molecular biology .......... 74
42. Acetylcholine: neuronal nicotinic receptors I .......................... 78
43. Excitatory amino acids: excitotoxicity I ............................... 81
44. Excitatory amino acids: pharmacology I ............................... 85
45. Excitatory amino acids: receptors I ..................................... 87
46. Serotonin receptors: SHT₁a subtypes ................................... 90
47. Interaction between neurotransmitters I ............................... 94
48. Regional localization of receptors and transmitters:  
   biogenic amines, misc. ...................................................... 97
49. Regional localization of receptors and transmitters:  
   peptides and GABA ......................................................... 100
50. Second messengers I ....................................................... 102
52. Hypothalamic-pituitary-gonadal regulation:  
   neuropeptides ................................................................. 110
53. Hypothalamic-pituitary-gonadal regulation: steroids ............... 112
54. Neuroendocrine regulation: prolactin ................................... 114
55. Hypothalamic-pituitary-gonadal regulation:  
   LHRH and LH I ............................................................... 116

TUESDAY, OCTOBER 27

Symposia — 8:30 a.m.
162. Recent Advances in Neuropeptide Biosynthesis: Molecular and Cellular Biology of Neuropeptide-processing Enzymes
   Chaired by: L.D. Fricker ........................................... 381

Special Lecture — 10:00 a.m.
164. Nerve Growth Factor and Nociception
   L.M. Mendell .......................................................... No Abstract

Special Lecture — 11:45 a.m.
165. The Biology of Sexual Orientation
   S. LeVay ................................................................. No Abstract

Slide Sessions — 8:30 a.m.
166. Auditory system: central physiology II .................................. 382
167. Pain: physiology and behavior ........................................ 384
168. Learning and memory: systems and functions—neuropsychology I ........................................... 386
169. Visual cortex: anatomical studies .................................. 388
170. Other factors and trophic agents: general I ......................... 390
171. Retina and photoreceptors II ...................................... 393
172. Excitatory amino acids: receptors III ............................ 395
173. Receptor modulation, up and down regulation I .................. 397
174. Peptides: receptors I ............................................ 399
175. GABA receptors: function I .................................... 401
176. Long-term potentiation I ....................................... 402
177. Brain metabolism and blood flow II ................................ 404
178. Cerebellum I ...................................................... 406
179. Staining, tracing and imaging techniques I ...................... 408

Poster Sessions — 8:30 a.m.
180. Cell lineage and determination II ................................... 409
181. Cell shape and differentiation II .................................. 411
182. Formation and specificity of synapses III ......................... 413
183. Nerve growth factor II ............................................ 415

82. History of neuroscience

83. Teaching of neuroscience: undergraduate and graduate education

84. Teaching of neuroscience: computer-assisted instruction

85. Teaching of neuroscience: elementary and secondary grades

Symposia — 1:00 p.m.

243. New Waves in Cell Calcium
Chaired by: M.R. Hanley

244. The Role of Sensory Information in the Guidance of Voluntary Movement
Chaired by: I. McCloskey and A. Prochazka

Warner-Lambert Lecture — 1:00 p.m.

245. Neuropeptides in Perspective
T. Hokfelt

Special Lecture — 4:15 p.m.

246. Neurotrophic Factors, Their Receptors and the Signalling Pathways They Activate
G.D. Yancopoulos

No Abstract

294. Basal ganglia and thalamus IV ................................ 695  
295. Oculomotor system: saccades .................................. 698  
296. Oculomotor III ................................................... 702  
297. Learning and memory: physiology III ........................ 705  
298. Motivation and emotion I ....................................... 709  
299. Invertebrate learning and behavior III ....................... 712  
300. Stress: general .................................................. 715  
301. Monoamines and behavior: accumbens, striatum and frontal cortex ........................................... 718  
302. Drugs of abuse: pharmacology of cocaine .................... 721  
303. Psychotherapeutic drugs: lithium, benzodiazepines and antidepressants ........................................ 725  
304. Genetic models II ................................................ 728  
305. Degenerative disease: Alzheimer’s—ß-amyloid III ........... 731  
306. Degenerative disease: Alzheimer’s—cognition ................. 734  
307. Degenerative disease: Alzheimer’s—neuropharmacology and neurotransmitters II ................................ 738  

**82. History of neuroscience ........................................ 180**

**83. Teaching of neuroscience: undergraduate and graduate education ........................................... 183**

**84. Teaching of neuroscience: computer-assisted instruction ........................................... 186**

**85. Teaching of neuroscience: elementary and secondary grades ........................................... 189**

**Social Issues Roundtable — 4:30 p.m.**

308. Neural Circuitry and Free Will: Concepts of Responsibility in the Decade of the Brain  
*Sponsored by:* Social Issues Committee of the Society for Neuroscience, H.J. Ralston, Chairperson ........... No Abstract

**The Grass Foundation Lecture — 8:00 p.m.**

309. Molecular Biology of the Glutamate Receptors  
S.F. Heinemann .................................................. No Abstract

**WEDNESDAY, OCTOBER 28**

**Symposia—8:30 a.m.**

*Chairied by:* J.D. Buxbaum and A. Goate ...................... 740

311. Cell Biology of the Growth Cone  
*Chairied by:* D.J. Goldberg ................................. 740
### CHRONOLOGICAL LIST OF SESSIONS

<tr>
<td>318. Presynaptic mechanisms IV</td>
<td>750</td>
</tr>
<tr>
<td>319. Hypothalamic-pituitary-adenal regulation</td>
<td>752</td>
</tr>
<tr>
<td>320. Cardiovascular regulation I</td>
<td>754</td>
</tr>
<tr>
<td>321. Excitatory amino acids: excitotoxicity IV</td>
<td>756</td>
</tr>
<tr>
<td>322. Drugs of abuse: alcohol, barbiturates and benzodiazepines II</td>
<td>758</td>
</tr>
<tr>
<td>323. Long-term potentiation III</td>
<td>759</td>
</tr>
<tr>
<td>324. Peptides: physiological and behavioral effects</td>
<td>761</td>
</tr>
<tr>
<td>325. Degenerative disease: Alzheimer’s—β-amyloid IV</td>
<td>764</td>
</tr>
<tr>
<td>326. Neural-immune interactions</td>
<td>766</td>
</tr>
<tr>
<td><strong>Poster Sessions — 8:30 a.m.</strong></td>
<td></td>
</tr>
<tr>
<td>327. Genesis of neurons and glia II</td>
<td>768</td>
</tr>
<tr>
<td>328. Development of neurotransmitter systems: catecholamines and neuropeptides</td>
<td>771</td>
</tr>
<tr>
<td>329. Nerve growth factor IV</td>
<td>774</td>
</tr>
<tr>
<td>330. Development of cerebral cortex and limbic system I</td>
<td>777</td>
</tr>
<tr>
<td>331. Transplantation: gene therapy and cell lines</td>
<td>781</td>
</tr>
<tr>
<td>332. Neuroglia and myelin III</td>
<td>784</td>
</tr>
<tr>
<td>333. Gene structure and function V</td>
<td>787</td>
</tr>
<tr>
<td>334. Presynaptic mechanisms V</td>
<td>790</td>
</tr>
<tr>
<td>335. Potassium channels: pharmacology and effects of transmitters</td>
<td>793</td>
</tr>
<tr>
<td>336. Ion channel modulation II</td>
<td>797</td>
</tr>
<tr>
<td>337. Acetylcholine: neuronal nicotinic receptors II</td>
<td>801</td>
</tr>
<tr>
<td>338. Excitatory amino acids: anatomy and physiology II</td>
<td>803</td>
</tr>
<tr>
<td>339. Peptides: anatomical localization—human and primate</td>
<td>805</td>
</tr>
<tr>
<td>340. Ontogeny of serotonin receptors</td>
<td>807</td>
</tr>
<tr>
<td>341. Second messengers V</td>
<td>809</td>
</tr>
<tr>
<td>342. Behavioral pharmacology: benzodiazepines, et al.</td>
<td>813</td>
</tr>
<tr>
<td>343. Receptor modulation, up and down regulation II</td>
<td>815</td>
</tr>
<tr>
<td>344. Hypothalamic-pituitary-gonadal regulation: other</td>
<td>818</td>
</tr>
<tr>
<td>345. Neuroendocrine regulation: other</td>
<td>820</td>
</tr>
<tr>
<td>346. Neuroendocrine regulation: osmotic regulation II</td>
<td>822</td>
</tr>
<tr>
<td>347. Regulation of autonomic function: other</td>
<td>825</td>
</tr>
<tr>
<td>348. Respiratory regulation: chemoreception</td>
<td>826</td>
</tr>
<tr>
<td>349. Somatic and visceral afferents: touch</td>
<td>829</td>
</tr>
<tr>
<td><strong>Session — 1:00 p.m.</strong></td>
<td></td>
</tr>
<tr>
<td>350. Pain pathways: supraspinal</td>
<td>831</td>
</tr>
<tr>
<td>351. Pain modulation: supraspinal</td>
<td>834</td>
</tr>
<tr>
<td>352. Retina and photoreceptors: photoreceptors, horizontal and bipolar cells</td>
<td>837</td>
</tr>
<tr>
<td>353. Auditory system: central physiology III</td>
<td>840</td>
</tr>
<tr>
<td>354. Chemical senses: peripheral mechanisms—taste</td>
<td>844</td>
</tr>
<tr>
<td>355. Motor systems and sensorimotor integration: cortex IV</td>
<td>846</td>
</tr>
<tr>
<td>356. Basal ganglia and thalamus V</td>
<td>849</td>
</tr>
<tr>
<td>357. Cerebellum II</td>
<td>852</td>
</tr>
<tr>
<td>358. Oculomotor IV</td>
<td>855</td>

### Symposia — 1:00 p.m.

381. Mechanisms of HIV-related Injury in the Central Nervous System

*Chaired by:* S.A. Lipton

382. Cognitive and Neurobiological Consequences of Normal Aging: From Rats to Primates

*Chaired by:* C.A. Barnes
Session Number & Title | Page
---|---
**Presidential Special Lecture — 1:00 p.m.**
383. Nitric Oxide: A Novel Neuronal Messenger
   S.H. Snyder ................................................. 915
   No Abstract

**Special Lecture — 4:15 p.m.**
384. Specification of the Zebrafish Body Axis
   C.B. Kimmel ................................................. 916
   No Abstract

**Slide Sessions — 1:00 p.m.**
385. Interactions between neurotransmitters III ............... 917
386. Limbic system IV ....................................... 918
387. Other factors and trophic agents: BDNF, NT3 ........ 919
388. Potassium channel permeation and gating .......... 920
389. Visual development: neuronal and synaptic development .............. 921
390. Cell migration and motility I ....................... 922
391. Receptor modulation, up and down regulation III ....... 923
392. Neuroendocrine regulation I ......................... 924
393. Transplantation I: .................................... 925
394. Human cognition: blood flow/metabolism .............. 926
395. Degenerative disease: Parkinson’s I .................. 927
396. Ingestive behavior: NPY, galanin and insulin ......... 928
397. Motor systems and sensorimotor integration: cortex V .... 929
398. Invertebrate learning and behavior IV ................. 930

**Poster Sessions — 1:00 p.m.**
399. Process outgrowth, growth cones and sprouting IV .... 931
400. Formation and specificity of synapses V ............... 932
401. Nerve growth factor V .................................. 933
402. Other factors and trophic agents: IGF .................. 934
403. Other factors and trophic agents: FGF ................. 935
404. Pattern formation, compartments and boundaries II .... 936
405. Glia and other non-neuronal cells III ................. 937
406. Motor systems I ........................................ 938
407. Regeneration III ....................................... 939
408. Staining, tracing and imaging techniques II .......... 940
409. Calcium channel toxins II ............................ 941
410. Calcium channels: physiology II ...................... 942
411. Acetylcholine: CNS I .................................. 943
412. Excitatory amino acids: receptors V .................. 944
413. GABA receptors: function III .......................... 945
414. Peptides: biosynthesis and metabolism II ............. 946
415. Peptides: physiological effects II ..................... 947
416. Peptides: physiological effects III ..................... 948
417. Opioids: anatomy and physiology I .................... 949
418. Catecholamines: receptors II .......................... 950
419. Purines: adenosine .................................... 951
420. Purines: ATP and guanosine ........................... 952

**Session Number & Title | Page**
421. Uptake, storage, secretion and metabolism III ....... 1001
422. Second messengers VI .................................. 1002
424. Neural-immune interactions: innervation and other ...... 1004
425. Neural-immune interactions: interleukin-1 ............. 1005
426. Cardiovascular regulation: lower brainstem I .......... 1006
427. Subcortical somatosensory pathways:lemniscal and spinothalamic ................. 1007
428. Pain modulation: spinal I ................................ 1008
429. Pain modulation: spinal II ................................ 1009
430. Pain modulation: behavior ................................ 1010
431. Retina and photoreceptors: amacrine, ganglion and glial cells .................. 1011
432. Subcortical visual pathways: cortico-tectal, Accessory Optic System, centrifugal .......... 1012
433. Visual cortex: motion processing I ..................... 1013
434. Auditory system: neurochemistry ...................... 1014
435. Auditory system: anatomy I ............................ 1015
436. Chemical senses: pathways—gustation .................. 1016
437. Basal ganglia and thalamus VI ........................ 1017
438. Cerebellum III ......................................... 1018
439. Vestibular system: behavioral responses ................. 1019
440. Spinal cord and brainstem V .......................... 1020
441. Control of posture and movement II ................... 1021
442. Circuitry and pattern generation II ..................... 1022
443. Learning and memory: systems and functions—misc. I ................. 1023
444. Learning and memory: systems and functions—misc. II .......................... 1024
445. Learning and memory: physiology IV ................... 1025
446. Ingestive behavior: taste aversion and neural mechanisms .................. 1026
447. Monoamines and behavior: behavioral effects of dopamine .................. 1027
448. Drugs of abuse: alcohol, barbiturates and benzodiazepines III ................ 1028
449. Drugs of abuse: stimulants I ........................... 1029
450. Drugs of abuse: cocaine and dopamine neuronal systems .................. 1030
451. Degenerative disease: Parkinson’s II ................... 1031
452. Neuromuscular diseases I ............................. 1032

**82. History of neuroscience** .................................. 180
**83. Teaching of neuroscience: undergraduate and graduate education** ................. 183
**84. Teaching of neuroscience: computer-assisted instruction** .................. 186

**THURSDAY, OCTOBER 29**

**Symposia — 8:30 a.m.**

| 453. Molecular Analyses of Neuronal Physiology and Potential for Gene Therapy Using Herpes Simplex Virus Vectors  | 1085 |
| 454. Thalamic Mechanisms of Nociception                                                     | 1085 |

**Presidential Special Lecture — 11:45 a.m.**

| 455. Neurobiological Foundations of Speech and Language                                   | 1193 |

**Slide Sessions — 8:30 a.m.**

| 456. Neuroendocrine regulation II                                                          | 1085 |
| 457. Trauma                                                                            | 1087 |
| 458. Neuroglia and myelin IV                                                              | 1089 |
| 459. Gene structure and function VI                                                       | 1090 |
| 460. Potassium channel expression and localization                                       | 1092 |
| 461. Process outgrowth, growth cones and sprouting V                                      | 1094 |
| 462. Pattern formation, compartments and boundaries III                                   | 1096 |
| 463. Nerve growth factor VI                                                               | 1098 |
| 464. Visual cortex: motion processing II                                                   | 1100 |
| 465. Neurotoxicity                                                                       | 1102 |
| 466. Transmitters in invertebrates III                                                     | 1104 |

**Poster Sessions — 8:30 a.m.**

| 467. Genesis of neurons and glia III                                                      | 1107 |
| 468. Cell lineage and determination III                                                  | 1109 |
| 469. Formation and specificity of synapses VI                                            | 1112 |
| 470. Nutritional and prenatal factors: alcohol                                           | 1114 |
| 471. Glia and other non-neuronal cells IV                                                 | 1116 |
| 472. Development of cerebral cortex and limbic system II                                 | 1119 |
| 473. Transplantation: cortex                                                            | 1121 |
| 474. Transplantation: retina, olfactory bulb, SCN                                        | 1123 |
| 475. Staining, tracing and imaging techniques III                                       | 1125 |
| 476. Blood-brain barrier I                                                               | 1128 |
| 477. Presynaptic mechanisms VI                                                           | 1130 |
| 478. Sodium channels                                                                     | 1133 |
| 479. Calcium channel molecular biology                                                   | 1138 |
| 480. Acetylcholine: CNS II                                                               | 1140 |
| 481. Acetylcholine: muscarinic receptors II                                              | 1142 |
| 482. Excitatory amino acids: excitotoxicity V                                            | 1145 |
| 483. Excitatory amino acids: anatomy and physiology III                                  | 1148 |
| 484. Excitatory amino acids: pharmacology V                                              | 1151 |

83. Teaching of neuroscience: undergraduate and graduate education ................................................. 183
84. Teaching of neuroscience: computer-assisted instruction ................................................................. 186
85. Teaching of neuroscience: elementary and secondary grades ............................................................ 189

Symposia — 1:00 p.m.
528. Molecular Biology of Olfaction  
    Chaired by: G.M. Shepherd ....................................................................................... 1264
529. Regulation of Neuronal Peptide Gene Expression: Lessons from the Neurohypophyseal System  
    Chaired by: C. Sladek ............................................................................................. 1264

Special Lecture — 1:00 p.m.
530. The Molecular Genetics of Cell-Cell Interactions Regulating Cell Fate in the Drosophila Visual System  
    L. Zipursky ............................................................................................................. No Abstract

Special Lecture — 4:15 p.m.
531. Sensory Information Processing in Electric Fish: Computational Rules and Their Neuronal Implementation  
    W. Heiligenberg ...................................................................................................... No Abstract

Slide Sessions — 1:00 p.m.
532. Brain metabolism and blood flow IV ........................................................................ 1266
533. Ischemia I .............................................................................................................. 1267
534. Cardiovascular regulation II .................................................................................... 1268
535. Calcium channel modulation ................................................................................... 1270
536. Axon guidance mechanisms and pathways V .................................................................. 1272
537. Visual cortex: behavior and behavioral correlates ....................................................... 1274
538. Regulation of autonomic function ............................................................................ 1276
539. Circuitry and pattern generation III .......................................................................... 1278
540. Blood-brain barrier II .............................................................................................. 1280

Poster Sessions — 1:00 p.m.
541. Cell migration and motility II ................................................................................ 1282
542. Process outgrowth, growth cones and sprouting VI ................................................. 1284
543. Process outgrowth, growth cones and sprouting VII .............................................. 1285

FRIDAY, OCTOBER 30

Symposia — 8:30 a.m.

605. GABA, Receptors and Their Role in Neurotransmission, Neuromodulation and Neuropathology
Chaired by: N.G. Bowery ........................................ 1448

606. Neurobehavioral Mechanism of Salt Intake Behavior
Chaired by: E. Stellar and B.S. McEwen .................................................. 1448

Special Lecture — 10:00 a.m.

607. The Translation of Sensory Signals Into Commands for the Control of Saccadic Eye Movements: The Role of the Primate Superior Colliculus
D. Sparks ................................................................................. No Abstract

Slide Sessions — 8:30 a.m.

608. Glia and other non-neuronal cells VI .......................... 1448
609. Peptides: receptors VI ................................................. 1450
610. Ischemia II ............................................................... 1452
611. Visual development: critical period and deprivation ...... 1454
612. Drugs of abuse: cocaine and other stimulants ............ 1456
613. Excitatory amino acids: pharmacology VI .................... 1458
614. Process outgrowth, growth cones and sprouting VIII ...... 1460
615. Regeneration V .......................................................... 1462
616. Degenerative disease: Alzheimer’s—β-amyloid VII ........ 1464
617. Regional localization of receptors and transmitters ...... 1466

Poster Sessions — 8:30 a.m.

618. Process outgrowth, growth cones and sprouting IX ........ 1468
619. Development of neurotransmitter systems: acetylcholine and serotonin ............................................. 1470
620. Other factors and trophic agents: general II .............. 1472
621. Other factors and trophic agents: general III ............. 1475
622. Transplantation: spinal cord ....................................... 1479
623. Aging I .................................................................. 1480
624. Aging II .................................................................. 1483
625. Aging III .................................................................. 1486
626. Neuroglia and myelin V .............................................. 1489
627. Blood-brain barrier III .............................................. 1491
628. Long-term potentiation V .......................................... 1494
629. Ion channel modulation III ........................................ 1500
630. Acetylcholine: choline acetyltransferase and cholinesterase ................................................................. 1504
631. Acetylcholine: neuronal nicotinic receptors III .......... 1506
632. Excitatory amino acids: receptors VIII ....................... 1509
633. Opiate receptor ligands .............................................. 1511
634. Catecholamines: dopamine II ..................................... 1514
635. Regulation of serotonin receptors .............................. 1517
636. Serotonin receptors: pharmacologic characterization .... 1519
637. Serotonin receptors: action on neurotransmission ......... 1522
638. Serotonin: pharmacology I ........................................... 1524
639. Serotonin: pharmacology II ......................................... 1528
640. Interactions between neurotransmitters IV ................... 1531
641. Behavioral pharmacology: dopamine, serotonin, NE ...... 1533
642. Receptor modulation, up and down regulation IV ........ 1536
643. Hypothalamic-pituitary-adrenal regulation: stress ....... 1539
644. Somatosensory cortex and thalamicortical relationships: development and plasticity ........................................ 1542
645. Somatosensory cortex and thalamicortical relationships: psychophysics and networks .................................. 1544
646. Reflex function II ...................................................... 1547
647. Control of posture and movement: arm movement II ...... 1550
648. Control of posture and movement: locomotion ............ 1553
649. Muscle I ................................................................. 1556
650. Muscle II ................................................................. 1558
651. Learning and memory: systems and functions— conditioning I ................................................................. 1559
652. Learning and memory: systems and functions— conditioning II ............................................................... 1562
653. Learning and memory: systems and functions— conditioning III ............................................................. 1564

390.3 ADHESION, ANTI-ADHESION AND MIGRATION OF OLFACTORY NEURONS AND NEURAL PRECURSORS ARE REGULATED BY DISTINCT MOLECULAR DOMAINS OF LAMININ. A.J. Calof 1, E.D. Yurchenco 2, J.J. D'Amelio 1, and A.D. Fishman 1 1The Rockefeller University, New York, NY, USA; 2The Johnson Medical Sch., Piscataway, NJ. 2Mass. Inst. of Tech., Cambridge, MA.

Neuronal precursors and immature neurons of the mouse olfactory epithelium (OEC) migrate into vivo, and can be isolated migrated and are monitored in vitro by the ECM protein laminin (LN) and its homologous merosin (LNα3β3γ). LN and LNα3β3γ are also anti-adhesive, i.e., they cause OEC neuronal cells to adhere weakly to substrata that would otherwise be strongly adhesive (Calof and Lander 1991 J. Cell Biol. 115:779). Investigations into the domains of laminin responsible for its anti-adhesive effects on OEC cells have revealed the following: The anti-adhesive activity of LN is highly heat stable and maps to the E1 fragment of the molecule. Although intact uL15 is a cell-surface receptor known to interact with the E3 domain of LN, function-blocking antibodies directed against this integrin do not inhibit anti-adhesion. The migration-promoting activity of LN is distinct from its anti-adhesive activity, and is not the result of adhesion-altering effects of LN. Migration-promoting activity is heat-labile, maps to the E2 fragment of LN, and can be completely blocked by the monoclonal antibody directed against integrin subunit α3. Migration promoted by MN, however, is only partially blocked by this antibody. Surprisingly, although LN is not detectable adhesive for OEC neuronal cells, some of its domains are. E1 is weakly adhesive, and a recombinant (G-domain) (rG) is strongly adhesive. Adhesion to rG was not dependent on α6-containing integrins, nor could it be blocked by a peptide contained in rG that is thought to represent the binding site of integrin α6β1. Adhesion to rG was blocked, however, by low concentrations of heparin (4 μg/ml) and by antibodies directed against LN E3 fragment (which is composed of a G-domain). These data suggest that neuronal adhesion, anti-adhesion and migration can be independently regulated by distinct domains of LN and distinct receptors.

390.5 NEURAL MIGRATION AND LAMININ - STUDIES ON THE ROLE OF LAMININ, THE NEURITE OUTGROWTH DOMAIN OF THE B2-CHAIN, AND CELLULAR MIGRATION AS REVEALED BY IMPARED VIDEO MICROSCOPY. P. Liese 1, E. Trenkner 1, H-U. Dübner 2, W. Siegling 2, Institutes of Biotechnology (Helsinki) and Basic Res. (New York) 1, and Max-Planck-Institut for Psychiatry (Munich) 2.

Low magnification video microscopy on cerebellar neurons growing on a laminin substrate showed that neurons migrated by first sending out a process that contacted the substratum, which was followed by nuclear movement inside a prefixed process. This was also verified on living slices of cerebellum by a novel technique of infrared video microscopy. This technique showed that external granule cells and Purkinje cell bodies attach to the basement membrane and extend out another process towards the presumptive granule cell layer. Thesvesh showed a back- and forth movement that closely resembled that on a laminin substrate. The role of the neurite outgrowth domain of the B2 chain of laminin on granule cell migration was studied in the cable culture system. Neuronal migration in these cultures was totally inhibited by antibodies against this domain laminin. Immunocytochemistry localized this domain in intimate cell-to-cell contacts between the migrating neurons and other neurons and glia. Studies on weaver granule cells on a laminin substrate revealed that these cells were proteolytically more active than their normal counterparts and deposited large amounts of the neurite outgrowth domain generating peptide antigen on their surfaces. These results indicate that neuronal migration on laminin mimulates that visualized in living slices of newborn rodent cerebellum in situ. The B2 chain laminin may be essential for neuronal migration, and as weaver granule cells are proteolytically active, and over express the neurite outgrowth domain of the B2 chain of laminin, the reported neurotoxicity of this domain may provide a mechanism for granule cell death occurring in this mutation.

Neuronal migration in various parts of the central nervous system depends on the motility of a leading process along a radial glial fiber. In order to investigate whether a monoclonal antibody that had previously been shown to inhibit outgrowth of retinal neurites by arresting their growth cones in vivo (Henke-Fahle and Roosheh, Nature 303, 65; 1983) also interfered with neuronal migration, we performed perturbation experiments in living embryos.

Hybridoma producing antibodies against T6 antigen were injected into the menencephalic ventricle of chick embryos at embryonic day 6 to provide a permanent source of antibody. After further incubation (4-9 days) the distribution of antibodies and the thickness of brain sections were examined. The antibodies had penetrated the tectal wall completely, whereas the hybridoma cells remained confined to the ventricular lumen. The observed reduction was discussed in the following way: 1. The neuroepithelial cell layer appeared thicker and consisted of more cells when compared to controls. 2. The Stratum album centrale (SAC) was dislocated towards the pial wall. 3. The Stratum griseum et fibrosum superficiale (SGFS) was drastically reduced in size. These results suggest that young neurons were impaired in their ability to migrate radially towards the future target layers in the presence of T6 antibodies.

Western blot analysis showed two bands of apparent molecular weight 380 and 170 kD. Solubilization properties of the antigen indicated that T6 is not a transmembrane protein.

Cell lineage in the cerebral cortex can be traced using a library of retroviruses that carry distinct DNA inserts as genetic tags. When the tags are analyzed using the polymerase chain reaction (PCR), they mark clones of cells independent of migration patterns of sibling cells. Cortical clones marked in this way often show widespread dispersion, in some cases covering much of the neocortex (Walsh and Cepko, 1990. Science, 245: 431-433). One such clone, that received viral infection at E14-E16 days (E28-21) or 10 days (P3) later can show how this widespread dispersion occurs. Inoculations were made such that 5-50 clones per hemisphere were labeled. The brains were sectioned, reacted for β-galactosidase histochemistry, and labeled cells were plotted using a three-dimensional computerized reconstruction program (CARP). 1990, Development 110: 713). Labeled cells from tissue sections were processed using PCR to analyze the development of the cell types and distribution of neuronal patterns.

Widespread cortical clones were very common after short survival times, at E21, 32% of all cortical clones showed widespread dispersion. At P5, 47% of clones distributed widely. At P30, widespread dispersion in sagittal sections included 22% of all cortical clones. Widespread cortical clones were widely dispersed, accounting for the overwhelming majority of labelled cortical neurons. At E21, there was extensive clonal dispersion in the neo-caudal or antero-lateral direction, and clones included cells in the cortex and the proliferative zones. This suggests movement of proliferating cells essentially parallel to the ventricle. At P3, dispersion in the medial-lateral plane was greater than at embryonic stages, which may reflect dispersion of pontine neurons into the lateral ventricle (Reillo, L., 1991, Soc. Neurosci. Abst. 17:533). Thus, widespread clonal dispersion reflects several phenomena occurring in sequence. Supported by the Howard Hughes Medical Institute and the NIMH.
390.9 LATERAL DISPERSION OF PREMIGRATORY, NEURAL PROGENITORS WITHIN THE VENTRICULAR ZONE OF CEREBRAL CORTEX: O. Finnila, C.A. Mason and M.E. Hatten. Dept. of Pathology in the Center for Neurobiology, College of Physicians and Surgeons, Columbia University, New York, N.Y., 10032.

In cortical regions of developing brain, neural precursors are generated in compact ventricular zones along the inner surface of the neural tube, after which postmitotic progeny migrate along the glial fiber system to establish the cortical laminae. Although recent evidence suggests significant dispersion of clonally related neurons during development, the relative contribution of movements within the germinal zone and tangential movement across the radial glial fiber system have not been determined. To visualize the dispersion of neural progenitor cells within the ventricular zone of the mouse cerebral cortex, the lateral wall of the telencephalic vesicle was removed on embryonic day 15, and a random population of cells on the ventricular surface was labeled with a dilute solution of the lipophilic dye Dil. Immunostaining with the neural antigen nestin and with BrdU demonstrated that labeled cells were within the VZ. By correlated video-enhanced, fluorescence and phase-contrast microscopy short bursts of motility at distances between 10-100μm were rapidly dispersed labeled cells across the ventricular zone. Labeled, dividing cells gave rise to daughter cells which separated and moved independently across wide areas of the cortical VZ. To determine whether cell dispersion was confined to the cortical VZ, we examined the behavior of labeled cells approaching the boundary with the lateral ganglionic eminence. Labeled cells did not cross from one proliferative zone to the other. Instead they contacted the boundary with filopodial extensions and moved retro-caudally along the interzone. These boundaries separate and maintain a regional pattern of neurogenesis in developing brain. Within the germinal zone of the cerebral cortex, neural progenitors disperse widely prior to radial migration along the glial fiber system.

390.10 RESCUE OF WEaver GRANULE NEURON DIFFERENTIATION BY TRANSLATION OF THEIR PROGENITORS INTO WILD-TYPE DEVELOPING CEREBELLAR CORTEX. W.-Q. Gao* and M.E. Hatten. Dept. of Pathology, Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University, New York, NY 10032.

The migration of postmitotic neurons away from compact, germinal zone in developing brain is a critical step in CNS neuronal differentiation. To examine the autonomy of expression of molecular signals for cerebellar granule cell migration in vivo, neuronal progenitors purified from the neurological mutant mouse weaver, an animal with phenotypic defects in migration, were transplanted into the external germinal layer (EGL) of wild-type developing cerebellar cortex. In wild-type cerebellar cortex, dye-labeled, weaver EGL progenitors progressed through all of the classical stages of granule neuron differentiation, including the extension of parallel fibers, migration through the molecular and Purkinje cell layers, final positioning in the inner granule cell layer, and extension of dendrites. These observations provide evidence that weaver gene acts non-autonomously in vivo, and suggest that local interactions in the cerebellar EGL induces initial steps in neuronal differentiation required for granule cell migration.

In order to compare the mechanism of neuronal migration with axon extension in vitro, granule neurons were purified from early postnatal cerebellar cortex (P4-P6) and cultured with the fluorescent lipophilic dye, Fki-26. Labeled neurons were co-cultured with unlabeled astroglial cells and neuronal migration was examined by a combination of time-lapse video and fluorescence microscopy using a light-automated CCD camera. Examination of labeled neurons revealed frequent extension and retraction of the leading process during migration, as well as lamellopodial and filopodial extension along the entire length of the leading process. The dynamics of leading process motility differed from that of the growing granule neuron axon, where motility was confined primarily to the growth cone, which moved forward steadily without retraction. These observations suggest that neuronal migration in vivo occurs along the lamellipodia and filopodia extension along the entire length of the leading process.

New PET studies have demonstrated the sensitivity of [11C]-methylpyropropioniofuran (a high affinity D2 dopamine ligand) binding to pharmacologic alterations in endogenous dopamine (Dewey et al., 1990, 1991, Logan et al., 1991). The present study was undertaken to further examine drug-induced changes in dopamine using [11C]-raspipride, a lower affinity D2 ligand, and two drugs which increase dopamine by different mechanisms. PET studies were conducted in anesthetized, adult female baboons (Papio anubis) using the CT1931 tomograph. Two [11C]-raspipride scans were performed, two hours apart, prior to and following drug intervention with either d-amphetamine, which releases cytosolic dopamine (1.0 mg/kg, IV, 5 minutes pre-injection) or CH-22909, the selective dopamine reuptake inhibitor (1.5 or 3.0 mg/kg, IV, 20 minutes pre-injection). The data were analyzed with the distribution volume method (Logan et al., 1990). After both interventions, [11C]-raspipride binding was decreased, bilaterally, in the striatum (specific binding), but not in the cerebellum (non-specific binding). These decreases exceed the test-retest variability in the same animals. The rate of metabolism of the radiotracer was unaltered. Therefore, [11C]-raspipride binding is sensitive to alterations in endogenous dopamine. This finding provides further support for the utility of PET in assessing the functional state of the dopamine system, in vivo. Supported by DOE/OHER, NIH: NS15638, NS15380.

Recent PET studies have demonstrated the sensitivity of [11C]-methylpyropropioniofuran (a high affinity D2 dopamine ligand) binding to pharmacologic alterations in endogenous dopamine (Dewey et al., 1990, 1991, Logan et al., 1991). The present study was undertaken to further examine drug-induced changes in dopamine using [11C]-raspipride, a lower affinity D2 ligand, and two drugs which increase dopamine by different mechanisms. PET studies were conducted in anesthetized, adult female baboons (Papio anubis) using the CT1931 tomograph. Two [11C]-raspipride scans were performed, two hours apart, prior to and following drug intervention with either d-amphetamine, which releases cytosolic dopamine (1.0 mg/kg, IV, 5 minutes pre-injection) or CH-22909, the selective dopamine reuptake inhibitor (1.5 or 3.0 mg/kg, IV, 20 minutes pre-injection). The data were analyzed with the distribution volume method (Logan et al., 1990). After both interventions, [11C]-raspipride binding was decreased, bilaterally, in the striatum (specific binding), but not in the cerebellum (non-specific binding). These decreases exceed the test-retest variability in the same animals. The rate of metabolism of the radiotracer was unaltered. Therefore, [11C]-raspipride binding is sensitive to alterations in endogenous dopamine. This finding provides further support for the utility of PET in assessing the functional state of the dopamine system, in vivo. Supported by DOE/OHER, NIH: NS15638, NS15380.

391.2 SIMILARITIES AND DIFFERENCES IN DOPAMINE RECEPTOR SUBTYPE REGULATION: MOLECULAR MECHANISMS. Ian Greenspan and S.-X. Xu, Center for Molecular & Behavioral Neuroscience, Rutgers-Newark, NJ 07102.

Steady state levels of cell surface receptors are determined by many distinct processes, each of which may be subject to different regulatory mechanisms. Both striatal D1 and D2 receptors show a similar developmental pattern where receptor number increases by 6-14 fold over the first 30 days postnatal. However, mRNA levels for both receptors increase by only 2 fold over this period. Whereas denervation, by a 6-OHDN lesion of the nigro-striatal pathway, increased D2A receptor mRNA levels by 53% and receptor level by 38%, D1A receptors and their mRNA were unchanged. In contrast, a 3 week administration of the D2 receptor antagonist SCH23390 (0.5mg/kg/day, s.c.) increased both D1A receptor density and mRNA levels. However, treatment with the D2 receptor antagonist haloperidol (0.5 mg/kg/day, s.c.) had no effect on striatal D2A mRNA levels, in spite of significant increases in receptor Bmax. This was not the result of the intermittent receptor blockade following drug injection, as chronic infusion of haloperidol via osmotic mini-pump also did not increase D2A mRNA, in spite of a 59% increase in receptor Bmax. Interestingly, chronic dopamine depletion with reserpine did not affect mRNA levels for D2A or D2A receptors, with only D2A receptors being significantly upregulated. These findings indicate that the various molecular mechanisms involved in receptor regulation (gene transcription, receptor degradation etc.) are differentially involved in the regulation of each dopamine receptor subtype. Supported by grants from the Stanley Foundation and NIMH.
**391.3** INCREASED S-HT2 AND NK-1 RECEPTOR BINDING ASSOCIATED WITH SEROTONIN/STEROID SUBSTANCE P HYPERSEROTONINERGIC IN RAT INFERIOR OLIVE. M. Pardé, I. Descaurier* and R. Quinton. Centre de recherche en sciences cognitives (Département de psychiatrie), Université de Montréal, and Douglas Hospital Research Center and Department of Psychiatry, McGill University, Montréal and Verdun, Quebec, CANADA. Serotoninergic/S-HT2 and substance P/NK-1 receptors were measured by ligand binding autoradiography with [3H]ketanserin and [125]I-SH-Sp, in the inferior olive of adult rats previously submitted to cerebroventricular or administration of 5,6-dihydroxytryptamine. This experimental treatment was previously shown to be followed by marked S-HT hyperactivity in most subdivisions of IO (e.g. threc the normal number of S-HT axons variates in the lateral dorsal accessory olive, lat DAO). It is also known to induce a parallel augmentation of the density of SP immunoreactive fibers in several parts of IO, which suggests a co-localization of both transmitters in the same hyperinnervating terminals. In normal IO, the density of S-HT2 sites was relatively low and rather homogeneous. NK-1 binding appeared denser and more heterogeneously distributed. After S-HT1/SP hyperinnervation, considerable increases in the density of both classes of binding sites were observed. Specific [3H]ketanserin binding was now strongest in IO subnuclei, including some in which it had not been detected in the normal. [125]I-SH-Sp binding showed even greater elevations or became detectable in a few subnuclei, remaining unchanged in others, and was slightly decreased in the lat DAO. The normal and altered distributions of both ligands did not match the respective patterns of S-HT and SP innervation and hyperinnervation. In view of the current information on the cellular localization of S-HT2 and NK-1 receptors in IO, it seems likely that both compounds, in the hyperinnervated state, were largely the result of an up-regulation, and not the mere reflection of an augmented number of autoreceptors on 5-HT and/or SP terminals. (Supported by MRC grants MT-3544 and MA-8580)

**391.5** AGE-DEPENDENT REGULATION OF CORTICAL AMINO ACID RECEPTORS. B.A. Lanus* and C. Shaw, Dept. of Neuroscience, Ophthalmology and Physiology, University of British Columbia. We have used a rat neocortical slice preparation to examine the regulation of GABA(A) (PH2-SR 95631), AMPA (PH2-CNQX), NMDA (PH2-2CS9 39653) and kainate (PH2-kainate) receptor populations during postnatal development. Regulation of these receptor populations was achieved using either stimulation with the appropriate agonist or using veratridine and glutamate (V/H+). In adult cortex, V/H+ resulted in an up-regulation of GABA(A) receptors in contrast to a down-regulation of AMPA, NMDA, and kainate receptors. During postnatal development, V/H+ showed age-dependent effects; in animals younger than 25d, GABA(A) receptor number was decreased whereas AMPA receptor number was increased; NMDA and kainate receptors decreased after 400 V/H+ treatment led to an increase in GABA(A) receptor number; at ages greater than 60 d AMPA receptors decreased. NMDA and kainate receptor showed decreases to V/H+ treatment led to down-regulation of all four receptor populations. Quisqualate stimulation of AMPA receptors increased down-regulation with increasing postnatal age, an opposite effect to that observed for GABA(A) and kainate receptors. The differing effects with age on receptor regulation for either changes in cell electrical activity or agonist stimulation may suggest a role for such age-dependent receptor regulation in the events leading to neocortical critical period plasticity.

Based on the nucleotide sequence of rat NMDAR1 (Montal and et al., Nature 354, 870-875, 1992) and the corresponding (S) oligodeoxyribonucleotides (D oligos) in an attempt to suppress synthesis of the NMDAR1 receptor protein. Herein described data were obtained with antiseroltemocholesterol and matching S 18-mer D oligos. These D oligos were added under serum-free conditions to primary cultures of rat cortical neurons which were studied with respect to: (1) H-MK-601 binding; (2) basal and NMDA-induced dehydrogenase (LDH) release; and (3) basal and NMDA-induced Ca**2+** influx. A reduction of %MK-601 sites by 40-50% (vs. S or D oligo) could be achieved by 3-5 days incubation of the neurons with 1 μM of the AS D oligo; this down-regulation was less than that with an antisense S D oligo of the NPY Y1-receptor (Yee et al., this meeting). The AS D oligo induced a concentration dependent (0.1-10 μM) reduction of spontaneous LDH release (measured 1-3 days after removal of serum) and evoked release (5 min exposure of 9-day old cultures to 100 μM NMDA). Finally, we found that spontaneous, but not NMDA-induced, Ca**2+** influx (measured over 2 min) was elevated, up to 2-fold, in neurons exposed to AS D oligos, possibly also reflecting increased degrees of neuronal survival in these cultures. However, there may exist a "window" of optimum AS D oligo concentration, since the S D oligo, at 10 μM but not at 1 μM, showed minor effects per se. In conclusion, the present study indicates the usefulness of the antisense approach for down-regulation of (receptor) protein, such as the NMDAR1. I also illustrate that excitation through activation of the NMDA-receptor is associated with neuronal cell death.

**391.8** ANXIOLYTIC AND ANTICONVULSANT DOSES OF ABBEARNIL FAIL TO INDUCE TOLERANCE AND DEPENDENCE IN MICE AND CATS. M. Serra, G. A. Ghiass, A. C. Padda, C. F. Moir and G. Biggio, Department of Experimental Biology, Chair of Pharmacology, University of Catania, Italy. In mice, [S]TPBS binding and exploratory motility were dramatically reduced by the acute administration of abbearnil (AB) (0.2 - 1 mg/kg i.p.). Correspondingly, the administration of this drug (1 mg/kg 3 times a day) induced in two weeks a significant increase in [S]TPBS binding in the mice cerebral cortex with no change in motor behaviour. This biochemical effect was paralleled by the failure of a challenge dose of AB (1 mg/kg) to modify both [S]TPBS binding and motor activity. On the contrary, in mice chronically treated with a lower but pharmacological effective dose (0.2 mg/kg) the exploratory motility was reduced (95%) by a challenge dose of AB (0.2 mg/kg). This evidence may suggest that tolerance develops only with very high doses of AB. This conclusion is consistent with the finding that in brain of this chronic treated mice the binding of the AB homologous (AB) was unchanged or even increased. Moreover, while in mice treated with the high dose of AB (1 mg/kg) the binding of [S]TPBS was altered after drug discontinuation (increased by 26% at 48 h and decreased by 15% at 96 h), we found no change in mice chronically treated with 0.2 mg/kg at the same times. Our data indicate that chronic administration of AB is associated with the development of tolerance and with discontinuation syndrome only at very high doses while it is devoid of these effects at lower, but pharmacologically effective, doses. This conclusion is also consistent with the finding that in cats chronically treated with AB (7 mg/kg 3 times for 15 days) the interperso nal association of 3-methyl (20 mg/kg) to precipitate an abstinence syndrome.

391.0 EFFECTS OF LESIONS OF THE DORSAL RAPHE NUCLEUS ON SEROTONIN TRANSPORTER, 5-HT4, AND 5-HT3 BINDING SITES IN RAT.

Decreases in the serotonin (5-HT) transporter and increases in 5-HT1A binding are found in restricted cortical areas of suicide victims. We sought to determine whether 5-HT binding follows lesions of the dorsal raphe nucleus (DRN) in intact rats. 5-HT binding changes reported in man and to examine the extent of any subcortical changes. Tissue samples (corpus striatum, hippocampus, DRN) were counted in 25 regions. 5-HT binding was measured by in vivo autoradiography using [3H]ketanserin, [3H]iminobenzamide, and [3H]ritanserin. DRN lesions were made by stereotaxic injection of ibotenic acid into the nucleus (n=8). Controls (n=6) received 1 mg of 1% ABD. DRN lesions reduced 5-HT binding in all regions examined from 90% (medial prefrontal cortex) to 29% (cingulate/parietal cortex). 5-HT binding was greatest in prefrontal cortex (101±14%) and least in the caudate nucleus (14±3%). DLN lesions reduced 5-HT binding to 5-HT1A binding with increases in frontal cortex (19% of control, p=0.06), intermediate corpus (175%, p=0.09), and hippocampus (113%, p=0.001). 5-HT ketanserin binding ratio from 314±11 binding (control cortex) to 251±15 binding (corpus callosum) and was unaffected by DRN lesions (p=0.05) in any brain region. We conclude that DRN lesions produce: 1) preferential effects of 5-HT projections to the forebrain and brainstem; 2) reversed changes in [3H]DPAT binding and 3) no effect on [3H]ketanserin binding. These findings parallel those in suicides in several respects: 1) 5-HT transporter binding is reduced; 2) 5-HT1A binding is increased; and 3) 5-HT-ketanserin binding is unchanged. Notable differences include: 1) widespread vs. localized reductions in transporter sites and 2) marked reduction vs no change in 5-HT1A and 5-HT1A. The cortical 5-HT receptor changes in suicide are consistent with a partial lesion of the DRN. Supported by NARSAD award to MDU and MH64745.

Considerable evidence has accumulated for neurotransmission dysfunction in the pathophysiology of major depression. One such line of evidence is the reduction in the density of binding sites for [3H]anipramine or [3H]paroxetine, markers of the 5-HT1A post-synaptic receptor, in select areas of patients with major depression. In an attempt to determine whether changes in platelet [3H]paroxetine binding represents changes in CNS 5-HT function, we investigated whether depletion of 5-HT and 5-HT image analysis. 5-HT 5-HT-5HIAA content in frontal lobe were determined by HPLC. In controls, specific 5-HT transporter binding (measured by competition with [3H]DRN [49:16], free binding, lox, of the corpus callosum (831±1) and not differ from sham-operated controls (p=0.05). DRN lesions reduced 5-HT and 5-HIAA by 78% and 92%, respectively, and reduced (p=0.05) transporter binding in all regions examined from 90% (peripheral cortex) to 29% (cerebrospinal fluid). 5-HT binding was greatest in prefrontal cortex (101±14%) and least in the caudate nucleus (14±3%). DLN lesions reduced 5-HT binding to 5-HT1A binding with increases in frontal cortex (19% of control, p=0.06), intermediate corpus (175%, p=0.09), and hippocampus (113%, p=0.001). 5-HT ketanserin binding ratio from 314±11 binding (control cortex) to 251±15 binding (corpus callosum) and was unaffected by DRN lesions (p=0.05) in any brain region. We conclude that DRN lesions produce: 1) preferential effects of 5-HT projections to the forebrain and brainstem; 2) reversed changes in [3H]DPAT binding and 3) no effect on [3H]ketanserin binding. These findings parallel those in suicides in several respects: 1) 5-HT transporter binding is reduced; 2) 5-HT1A binding is increased; and 3) 5-HT-ketanserin binding is unchanged. Notable differences include: 1) widespread vs. localized reductions in transporter sites and 2) marked reduction vs no change in 5-HT1A and 5-HT1A. The cortical 5-HT receptor changes in suicide are consistent with a partial lesion of the DRN. Supported by NARSAD award to MDU and MH64745.

392.1 AMPULPATEAT PECATION OF GROWTH HORMONE (GH) IN CHRONIC RENAL FAILURE. J.D. Veldhuis, M. Willkowitz, A. Iwama.
W.K. Bolotin, Dept. Internal Medicine, NSF Science Center in Biological Timing, Univ. Washington, Seattle, WA 98195, and Salem Veterans Affairs Hospital, Salem, VA 24153.

Uremia evokes alterations in multiple neuroendocrine axes, including the gonadotropin, corticotropin, and somatotropin (GH) axes. We have studied the neuroendocrine control of episodic GH secretion and simultaneously estimated GH half-life in 7 middle-aged men (mean ages 39 ± 5 years) with endstage renal failure as compared to a group of 7 age-matched controls (mean ages 42 ± 4 years). Multiparameter deconvolution analysis (ENAS 84:7953-90, 1987) of 24-hour serum immunoreactive GH concentrations revealed a calculated half-life of endogenous GH of 21 ± 18 min in the men with ESRF compared to 17 ± 20 min in controls. Uremia was accompanied by an increased frequency of pulsatile GH release namely 16 ± 1.0 secretory bursts/24-hr in uremic patients vs 36 ± 11 in the men with ESRF. The mass of GH secreted per burst was increased in uremia (45±1.2 ng/mL versus 30±1.1). Consequently, the 24 hour endogenous GH production rate was approximately 2-fold higher (73±1.8 ng/kg/24-hr) in uremic patients vs 36±11 ng/kg/24-hr in age-matched controls. In contrast, the duration of GH secretory bursts was not altered in uremia. The mean 24-hr serum GH concentration was 1.5±0.38 (uremia) versus 0.62±0.28 ng/mL (control). In summary, uremia is accompanied by a small increase in the half-life of putatively intact immunoreactive GH as well as an increased frequency and mass of pulsatile GH secretion. We therefore hypothesize that somaostatin withdrawal, and to a lesser extent decreased GH clearance, contribute to elevated plasma GH concentrations observed in uremia in humans.

392.2 PATCH CLAMP ANALYSIS OF GROWTH HORMONE-RELEASING FACTOR (1-44) EFFECTS IN HUMAN GROWTH HORMONE SECRETING CELLS IN VITRO. M. Chen, L. Haynes, L. McConnell, J. Cummings and J. C. Clarke. Prince Henry's Institute of Medical Research, P.O. Box 152, Clayton (Melbourne), Victoria 3168, Australia.

We have previously reported that local application of human growth hormone-releasing factor 1-44 (hGRF) in rat pituitary somatotropes causes a depolarization of cell membrane and growth hormone (GH) secretion that depends upon Ca2+ (Chen et al., Neuroendocrinology 50:679, 1990). This effect can be obtained by conventional micropipette intracellular recording but not by standard whole-cell patch-clamp recording. Alternatively in the present experiment, we used the indirect patch-clamp depolarization technique in the whole-cell configuration, this effect has been observed in identified human growth hormone (GH) secreting tumour cells from acromegalic patients. With local application of hGRF (100 nM), 30 sec, we observed depolarization occurs with the generation of multiple action potentials. Current-induced depolarization in the absence of hGRF causes a single action potential but in the presence of hGRF, multiple action potentials are seen. The characteristics of the action potentials, in terms of Ca and Na flux, are similar to previous seen in rat somatotropes (Chen et al., Life Sci. 48:593, 1990). In particular, hGRF increased the action potential due to Ca influx, the Ca current was enhanced by hGRF in cells treated with TTX (20M) and TTX (1uM) in the bath solution and Ca in the electrode solution to eliminate K and Na currents. These Ca currents were also modified by hGRF application. These results show that hGRF can increase influx of Ca in human tumour derived somatotropes via its effects on Ca channels in a manner similar rat somatotropes. 392.3 INHIBITORY REGULATION OF PULSATILE GHRH RELEASE FROM GT1-1 GHRH CELL LINES BY VASOPRESSIN AND GABA. B.J. Weiger and O. Martinez de la Escalera. Reproductive Endocrinology Center, University of California San Francisco, CA 94143, and Instituto de Investigaciones Biomédicas, National University of México, México City 04510, México.

Arginine vasopressin (AVP) containing nerve terminals synaptic with GHRH neurons and may play a role in stress-induced inhibition of LH secretion. y-aminobutyric acid (GABA) neurons also synapse with GHRH neurons and substantial evidence support their role on GHRH release. GHRH cell lines (GT1-1) release GHRH with a pulse frequency similar to that observed in castrated rats. Supersufusion of GT1-1 cells with AVP (100 mM) inhibited pulsatile release of GHRH. The mechanism by which AVP inhibits GHRH release is not clear since 10-100 nM AVP (110) did not inhibit tyrosine phosphorylation (assayed by phosphorysene Western blots) nor adenylate cyclase activity (assayed by RIA of intracellular cyclic AMP) in GT1-1 cells. GABA (10 mM) did not show a biphasic effect on GHRH release, with a brief and rapid stimulation followed by a long and sustained inhibition. The effect of GABA is correlated with a bicuculline- and saclofen-sensitive inhibition of the basal and stimulated intracellular levels of cAMP. These findings demonstrate that two putative inhibitory neurotransmitter in the regulation of GHRH release are capable of exerting their actions directly on GHRH neurons. (Work supported by NIH Grant HD 08924 and The Rockefeller Foundation).

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

Reports of increased immunoreactivity (IR) for enkephalin (ENK) (Soc. Neurosci. Abs. 15:702.1989) and neuropeptide Y (NPY) (Endo.128:823, 1991) in TIDA neurons of lactating rats with an increase in prolactin (PRL) levels in the milk of the same animals (Podor et al. 1992) led us to investigate whether the expression of peptides in the median eminence (ME) is altered during lactation in rats and mice, and whether PRL receptors (PRLR) might be involved in these changes. IRs for NPY, ENK and neuropeptide (NPY) (1991) in TIDA neurons of lactating rats were increased and the NPYergic fibers are unaligned, suggesting that the PRLR might be involved in these changes. IRs for NPY, ENK and neuropeptide (NPY) levels in the ME were dramatically increased in the ME of post-pubertal (PP) day 8 lactating mice that were pup-deprived for two days, compared to continuously nursing (PNP) mice. Fluorescent double-staining showed colocalization of these IRs in all tyrosine-hydroxylase (TH)-IR endings. Preliminary ultrarstructural studies showed that the IRs are a part of the same cell, suggesting a specific function of these neuropeptides among neurosecretory vesicles in the same nerve terminals. On PNP, NPY and ENK IRs were visible in putative ME-TIDA endings of both intact and PPN-injected lactating rats. Changes in NPY-IR could not be detected. Considerable interlaminar variation in NPY-IR suggested the influence of the underlying paracrine phenotype. When intact lactating rats were separated from their litters for four hours and then reunited, we detected a trend for increased NPY-IR, but not for ENK or NPY-IR, in the ME during the 50-60 min following the onset of suckling, associated with elevated circulating PRL levels. NPY-IR, but not ENK- or NPY-IR, was also expressed in putative TIDA endings in orchidectomized rats maintained on estrus. Changes in PNP-IR contain insulin-like growth factor (IGF) in hypothalamic cells of the same animals. These results suggest that 1) an ovarian influence may not be required for the expression of NPY- and ENK-IRs in the TIDA neurons during lactation, 2) PNP may be responsible for inducing NPY expression in these cells, and 3) additional factors may regulate expression of ENK- and NPY-IRs in TIDA neurons with both sex and species differences in their actions.

392.9 SUPPRESSED TYROSINE HYDROXYLASE (TH) AND INCREASED NPY GENE EXPRESSION IN THE ARCULATE NUCLEUS OF LACTATING RATS. H. Li, Wang and M.S. Smith. Department of Physiology, University of Pittsburgh, Pittsburgh, PA 15261.

The suckling stimulus alters hypothalamic function, resulting in suppressed GnRH and increased prolactin secretion. To understand mechanisms responsible for these effects of suckling, we assessed whether lactation was associated with changes in gene expression in the arcuate nucleus (AN). Animals were studied during estrus-1, and on day 10 postpartum with 8 pups suckling for 24 h after pup removal. In situ hybridization of AN was performed to assess mRNA levels for TH and NPY. For single label ISH, TH and NPY riboprobes were labeled with 35S. For double label ISH, TH riboprobe was labeled with 35S and NPY riboprobe with digoxigenin. TH mRNA (graft area/AN area) levels in lactating rats were suppressed to 60% in the rostral AN and were undetectable in the remainder of AN, compared to control lactating controls. In contrast, TH mRNA in the zona incerta did not differ between the two groups of animals. At 24 h, TH mRNA levels had increased to nearly 200% of controls. NPY mRNA levels were similar in diestrous and lactating animals except in the caudal area of the AN (at the level of the dorsomedial hypothalamic nucleus) where mRNA levels increased nearly two-fold in lactating rats. The change in NPY gene expression was reversed 24 h after pup removal. Using double label ISH, we found TH and NPY expressing neurons in close proximity in addition to TH positive, but NPY negative neurons for expression of TH and NPY in the same neurons. In summary, the suckling stimulus changes gene expression in specific subpopulations of dopamine and NPY neurons in the AN. These changes appear to be mediated by a change in the dynamics of the transmitter released. Supported by Grant HD14643.

392.10 FOS-RELATED ANGIOTENSINS AS MARKERS OF BASALINE NEURONAL ACTIVITY: EFFECTS OF LACTATION ON ARCULATE NUCLEUS DOPAMINE NEURONS. G.E. Hoffman*, W.J. Lee, A. Abd and M. S. Smith. Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

In many areas of the brain, neurons express Fos-related antigens (FRAs), but not cFos, under baseline conditions. These studies assessed whether FRA expression can serve as a marker for both decreased as well as increased basaline neuronal activity. To test this hypothesis, we examined FRA expression in tuberoneuroblastoplastic (TH) dopaminergic [DA neurons of the arcuate nucleus (ISH)] in cycling female rats and in pregnant and lactating animals. The TIDA neurons comprise the principal prolactin releasing system. TH neuron activity is known to increase in lactating rats, whereas DA neuron activity is decreased. Therefore, the suckling stimulus is a likely mediator of decreased TH neuron activity. This hypothesis was tested in the lactating rat, TIDA neuron activity is presumably inhibited, thereby facilitating prolactin release. Double label immunocytochemistry localized tyrosine hydroxylase (TH) and either FRAs or c-Fos. FRAs and c-Fos were distinguished using double antibodies generated against the common epitope region of FRAs (capable of recognizing most FRAs except c-Fos) and the c-terminal of c-Fos (selective for c-Fos). Under these conditions, c-Fos was expressed in the TIDA neurons. Animals were studied at 0-4 h after pup removal and at 24 h after pup removal and were restored to full expression by 24 hours. The changes in FRAs expression in the presence of the suckling stimulus and upon pup removal parallel changes we observed in TH gene expression in TIDA neurons of lactating animals. These data suggest that FRA expression can effectively serve as a marker of baseline activity in tonic neurons of the brain.
392.11
Rapid changes in oxytocin and vasopressin mRNA concentrations in the early postpartum period: evidence for a role of factors other than suckling. R.S. Crowley and J.A. Amico. University of Pittsburgh School of Medicine and VA Medical Center, Pittsburgh, PA 15261.

Oxytocin (OT) and vasopressin (AVP) gene expression are enhanced in the rat hypothalamus during gestation and during the second and third weeks of lactation. Increased OT gene expression during lactation is believed to be due to suckling, which is known to activate OT neurons resulting in coordinated stimulation of pituitary activity of the OT and AVP neurons and release of OT and AVP from the posterior pituitary. We hypothesized that other factors such as ovarian steroids might modulate responses to stimulation of these neurons. We therefore performed Northern analysis and in situ hybridization during the first ten days of lactation when rats are continuously suckling but ovarian steroid concentrations are known to change markedly. We report that during the first three postpartum days, OT and AVP mRNAs decreased dramatically reaching less than one fifth of peak gestation levels by day 2 postpartum in both suprachiasmatic (SCN) and paraventricular (PVN) nuclei. OT and AVP mRNA returned to levels comparable to late gestation on or about day 10 lactation, and remained elevated after 15 and 23 days of lactation. We have also compared OT mRNA isolated from lactating day 3 rats to cohorts which did not litter at the time of parturition. Lactating rats had significantly lower OT mRNA levels than their non-lactating cohorts. These data refute the hypothesis that lactation itself is not a factor in the increases in OT and AVP mRNAs produced as a result of continuous stimulation by suckling.

392.12
Oxytocin (OT) and vasopressin (AVP) gene expression in the osmotically-stimulated female rat. J.A. Amico, R.S. Crowley, S.M. Chalmers. Univ. of Pittsburgh Sch. of Med. and VA Medical Center, Pittsburgh, PA 15261.

Our finding that ovarian steroids, estradiol (E2) and progesterone (P), modulate hypothalamic OT and AVP gene expression in the lactating rat, led us to question whether similar effects occur in the osmotically-stimulated female rat. Sustained hyperosmolality (4-14 days of oral 2% NaCl) is reported to enhance OT and AVP mRNA concentrations in intact male rats. Similar studies have not been done in female rats. If E2 and P do influence OT and AVP mRNA expression in the osmotically-stimulated female rat, does hyperosmolality enhance AVP gene expression, as observed in the male, or does it decrease it? We have begun studies to address these questions. The responses of these genes to sustained hypernatremia in the female rat would likely be heterogeneous because of the differences between E2 and P in their actions as well as in their levels during the estrous cycle. More upregulation of OT and AVP gene expression should not occur in salt-loaded ovariectomized (OVX) rats. Adult female cycling Sprague-Dawley rats matched for age and weight were sham OVX (intact) or OVX (3 wks prior to study), administered oral 2% NaCl or tap H2O, and sacrificed on the 5th day of study. Salt-loaded OVX and salt-loaded intact rats developed comparable degrees of hypernatremia, depletion of posterior pituitary stores of OT and AVP, and weight loss (no significant differences, ANOVA). At sacrifice, E2 and P concentrations were non-detectable in OVX rats and varied among intact rats, depending upon the stage of the estrous cycle. Salt-loaded OVX rats (n=8) showed no upregulation of OT or AVP mRNAs, whereas salt-loaded intact, cycling rats (n=12), showed both up-regulated OT mRNA as well as decreased AVP mRNA expression. These data and others suggest that ovarian steroid-mediated mechanisms for up-regulation of OT and AVP gene expression are present during salt-loading.

TRANSPLANTATION I

393.1

Implanted chroaffin tissue alleviates some parkinsonism symptoms in humans, but not in experimental animals. Functional recovery could be due to the release of large amounts of both NE and DA from this tissue. Implantable biodegradable controlled-release microphreses containing NE or DA provide a novel means for the sustained restitution of subnormaal DA function. Rats were unilaterally 6-OH-DA lesioned in the MFB. Six to eight weeks later, a suspension of 3ml of DA- or NE-containing microphreses was implanted in 2 rats in each of 2 DA denervated striata. Contralateral rotational behavior induced by apomorphine was used as an index of lesion success and, following implantation of the microphreses, also as an index of functional recovery. Intact rats and NE microphre implanted rats displayed a 30-50% reduction in the number of apomorphine-induced rotations up to 6 weeks postimplantation. Following conclusion of the studies, immunochemical examination revealed growth of DA and tyrosine hydroxylase IR fibers in the striatum of DA and NE microphre implanted rats. Preliminary EM studies showed signs of axonal growth cones and of axonal sprouting in the vicinity of the injected microphreses. Thus, both microcapsulated NE and DA have the capacity to assure functional recovery and to promote DA fiber (re)growth in parkinsonism. This novel means to deliver these substances to the CNS could be of therapeutic usefulness in Parkinson’s disease.

393.2

Polymeric cell encapsulation may be a useful technique for investigating the mechanisms by which embryonic neural grafts ameliorate deficits in various animal models of CNS disease. Surrounding grafted cells with a biocompatible, impermeable membrane that allows diffusion of small molecules such as O2 and metabolic waste products promotes sustained cell viability but also, isolates the enclosed cells from the physical contact with cells of the host. This approach may reveal the relative importance of interaction between graft-derived molecular diffusion as mediators of graft efficacy. To test the feasibility of this approach, embryonic ventral mesencephalic cells were isolated from E17-19 day old rat embryos cultured in DMEM with 10% FCS either on polystyrene culture plates directly or after being combined, with an artificial extracellular matrix (Matrigel). Semi-permeable capsules containing fetal mesencephalic cells seeded in Matrigel were implanted within the striatum of normal adult male Sprague-dawley rats within three hours of isolation. Animals were sacrificed at two (n=5) and four (n=4) weeks and analyzed histologically. The in vitro culture systems contained non-neuronal and neuronal cells types which many of which stained positively for tyrosine hydroxylase (TH). Viable cells were present in all of the capsules in vivo explanted at two and four weeks which displayed morphological phenotypes similar to those observed in vitro cultures. Some of the cells stained positively for TH indicating that neuronal cells survived within the capsule over the four week period in vivo. Ongoing studies are aimed at optimizing neuronal cell survival and addressing functional efficacy.

393.3

The mouse mutation (Weave) induces a genetic nigrostriatal dopamine (DA) deficiency. Assays of ['H]DA uptake were carried out in vitro in striatal synaptosomal fractions from wild-type mice (+/+), and from the two hemispheres of weave mutant mice (wm/wm) that had received unilateral grafts of mesencephalic cell suspensions to the right side. Amphetamine-induced turning behavior was used to monitor graft survival. Recipient mice were ratied by an average of 22 turns to the left and 7 turns to the right in the non-grafted, and 10 in the transplanted striatum of weave mutants (n=15). Paired comparisons of right vs. left side in the striatum of the weave recipients showed a 38% increase on the grafted side [mean value (R)/L) in general, animals with a strong rotational bias to the left tended to have higher DA uptake values on the right. These findings attest to the functional effects of the grafts. Since DA uptake was measured in entire striatal preparations, the regional extent of DA effects in areas strictly associated with motoric activity may be underestimated. (Supported by USPHS R29-NS29283.)

393.4
Transforming growth factor alpha: A potential role in the efficacy of intrastriatal transplants. S. Loughlin, T. Lee, Y. Ibrahim, D. Teweld and J.H. Fallon. Departments of Anatomy and Neurobiology, University of California Irvine, CA 92717

Intrastriatal transplants of fetal mesencephalon reverse behavioral deficits associated with loss of dopaminergic innervation of the striatum. Transforming growth factor alpha precursor like immunoreactivity (TGFa-LI) is present in a subpopulation of astrocytes (Pallon, et al., 1990) which is increased by fetal transplants (Loughlin, et al., 1989). Transplants of adrenal medulla also ameliorate lesion induced deficits, even when dopaminergic cells do not survive (Bohe, et al., 1989). Adult adrenal medulla transplants are effective in treating striatal TGFa-LI astrocytes (Loughlin, et al., 1992). We therefore hypothesized that TGFa might play a role in the efficacy of transplants. To test this hypothesis, animals were given unilateral 6-OHDA lesions of the dopaminergic projection to the striatum and amelioration of apomorphine (0.2 mg/kg ip)-induced rotation behavior was quantified. One group of animals then received intrastriatal infusions of 200 at TGFa (0.05 ug/ul) in artificial cerebrospinal fluid (CSF) via an Alzet minipump (200 ul) over a two week period. A control group received infusions of CSF. Rotation behavior was quantified and animals were sacrificed. Brains were processed for localization of TGFa-LI. CSF infusions produced a modest increase in endogenous TGFa-LI, while TGFa infusions caused a dramatic increase in TGFa-LI. Rotation behavior was unchanged in animals which received CSF infusions (p>0.4). Infusions of TGFa, however, decreased rotation behavior by 40% (p<0.005). Thus, TGFa may facilitate recovery from 6-OHDA lesions. Whether such recovery reflects regeneration of dopaminergic afferents or other compensatory changes is not known. Since endogenous TGFa-LI is increased by transplants which have been shown to ameliorate lesion induced deficits, it is possible that the efficacious effects of transplants are mediated in part by upregulation of TGFa-LI. This may have important implications for the development of new treatments for Parkinson's Disease. Supported by NS 26761 and the American Parkinson Disease Association SCC.

SUPERPARAMAGNETIC CONTRAST AGENTS FACILITATE MAGNETIC RESONANCE IMAGING OF NEURAL TRANSPLANTS IN RAT BRAIN IN VIVO. Andrew B. Norman, Stephen R. Thomas, Ronald G. Pratt and Robert B. Norgren. Departments of Psychiatry and Radiology, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267.

Although transplants of rat fetal striatal tissue can be observed in vivo using magnetic resonance (MR) imaging, the transplanted tissue is approximately isointense with the host brain, making it difficult to distinguish from host tissue. We have used superparamagnetic ferrihydrate particles coupled to wheat germ agglutinin (WGA) to label and to visualize the transplant in vivo. Dissociated rat fetal striatal (E 15-17) was incubated with WGA-ferrihydrate particles for 2-5 min at 37°C and then transplanted unilaterally into rat striatum. Six days and 25 days following transplantation, rats were imaged at 0.14 T using a T2 weighted protocol (TR=500 ms/TE=30 ms). After imaging, the rats were perfused and brain sections stained with cresyl violet or hematoxylin for iron. The labeled transplant was clearly visible on MR images as a feature characterized by very low signal intensity within the host brain. At higher concentrations of WGA-ferrihydrate particles there was also a corona of high signal intensity, representing a susceptibility artifact surrounding the area of low signal intensity. Histologically, the ferrihydrate particles were observed to be mainly restricted to the area of the transplanted tissue and had a patchy distribution. The cells adjacent to the particles appeared to have normal morphology and cytochrome oxidase activity. These studies demonstrate that WGA-ferrihydrate particles remain associated with transplanted cells for at least 3 weeks and provide a means of monitoring the number of surviving transplanted tissue using MR images in vivo. (Supported by NSF Grant BNS9315733)

393.7

Eighteen rhesus monkeys are being evaluated quantitatively and qualitatively as to the effect of on-off transplantations using adrenomedullary/peripheral nerve grafts. The monkeys were trained on one of two different operant behavioral tests, involving quantitative measurement of disability produced by unilateral carotid ligation of MPTP. MPTP produced marked deterioration of performance in the affected arm. None of the operated monkeys demonstrated spontaneous recovery (M=4). Five to nine months after MPTP administration, a transcutaneous intraventricular catheter was placed in the caudate nucleus (M=2) or the surgical equivalent without tissue (M=4). Increased speed of performance on the task, and in some cases return to normal operant behavior, was observed in all acografted monkeys and only one of the surgical controls. The degree of recovery appeared to be directly correlated with the number of surviving cholinergic neurons and inversely correlated with the degree of deficit prior to grafting. Supported by NIMH, ROI NS24340 and NR-00165.

393.9

We have transplanted human embryonic mesencephalic tissue containing dopamine cells into the caudate and putamen of eight patients with advanced Parkinson's disease. Implants were unilateral in caudate and putamen (n=2) or bilateral into the putamen (n=6). Fetal tissue of 7 to 10 weeks of gestation was used. Alternate patients were immunosuppressed with cyclosporine A and prednisone. Results showed that at best, postural stability and walking were restored, hand movement became normal, and "off" episodes were eliminated. Drug doses were reduced as much as 50%. 18-F-F-D-Flurorodopa PET scans have been compatible with continued growth and survival of the transplant for up to 33 months. Both immunosuppressed and non-immunosuppressed patients improved, although improvement of some patients and some patients did not benefit. Fetal tissue implants may offer substantial long term clinical benefit to some patients with advanced Parkinson's disease.

393.10

SELECTIVE EFFECTS OF INTRAHIPPOCAMPAL LOCUS CORRELUS GRAFTS ON THE DEVELOPMENT BUT NOT EXPRESSION OF KINDLED SEIZURES. J. Renzi, Z. Kokaia and D. Lindahl, Reinsorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden.

Intrinsically noradrenergic locus coeruleus (LC) neurons strongly suppress the development of seizures in the kindling model of epilepsy. We have previously shown (i) that transplantation of fetal LC tissue to the hippocampus or the amygdala-paradox circumvent is 6-hydroxydopamine (6-OHDA) treated, hyperexcitable rats retards seizure development in hippocampal kindling; (ii) that kindling leads to a long-term decrease in basal hippocampal noradrenaline (NA) release from the intrinsically LC-seizored as monitored by intracerebroal microdialysis. We now report that this decrease in basal NA release can be reversed by LC grafts, but not by situatal tissue, implanted unilaterally into the previously kindled, non-derestricted rat hippocampus. However, the LC grafts had no effect on the spontaneous kindling convulsions despite a substantial noradrenergic overexpression of the host hippocampus around the grafts. Bilateral implantation of fetal LC tissue into the hippocampus of previously 6-OHDA treated, kindled rats resulted in a normal or supernormal noradrenergic fiber density in major parts of the hippocampal formation, had no effect on the severity of fully developed kindling seizures. Finally, implantation of fetal LC tissue into the intact brain, produced pronounced noradrenergic hypersensitivensaton of the hippocampus up to about 1 mm from the grafts, did not influence the subsequent development of hippocampal kindling.

In conclusion, these data show that a graft-derived, noradrenergic hypersensitivation of the hippocampus fails to affect both kindling development and established seizures. Furthermore, LC grafts have no anticonvulsant effect when implanted into the hippocampus of noradrenaline-depleted, kindled rats, in contrast to the powerful antiepileptic effect exerted by the grafts during seizure development. The data thus point to a marked selectivity in the effects of noradrenergic implants in the kindling model of epilepsy.
393.11
TRANSLATION OF HCN-1A INTO RAT BRAIN. B. Morgan, D. Pizzo, K. Werrbach-Perez, L. Hutton, Y. Lu, K.N. Westlund, C. Hultebusch, H.M. Eisenberg*, R. Perez-Polo. University of Texas Medical Branch at Galveston, TX 77555.

The HCN-1A is a human neural cell line that responds to the nerve growth factor (NGF) by fully differentiating and is a potential donor for transplantation into brain regions damaged by disease processes that have caused cell loss. It was developed from a child with megalencephaly. HCN-1A grown in 100% DMEM and 0.5% fetal calf serum with daily medium changes are differentiated in 10 ng/ml NGF, 1 mM forskolin, and 1 mM dibutyryl cAMP (NGF cocktail). We have evaluated the cells using immunocytochemical methods and found the cells to contain GABA, glutamate, VIP, somatostatin, and cholecystokinin-B. Immunoactivity of the cells for synaptophysin is increased with the differentiation of these cells. We have shown that these cells express p75NGFR mRNA using reverse transcription and the polymerase chain reaction (PCR) with primers for p75NGFR. The cells are also stained cytochemically with Me 20.4, an antibody to the human p75NGFR in preliminary experiments 5x10^6 HCN-1A cells were implanted into rat motor cortex. Surviving cells were demonstrated two weeks after transplantation of HCN-1A differentiated with NGF cocktail and/or acetyl-L-carbaryl amine into injured rat brain. Supported by a grant from the Mirt by Foundation and the Institute for Senescence, Pomezia, Italy.

393.13

Embryonic day 17 (E17) neurons transplanted adjacent to photolytically induced pyramidal neuron-deficient cortex (lamina III) of early postnatal mice have revealed preferential migration and pyramidal phenotype within the lesioned zone. These results support involvement of potentially altered expression of environmental cues in guiding grafted neurons toward partial restoration of normal cytoarchitecture. The present experiments assess whether these normally developmentally age-specific cues may similarly guide directed repopulation in selectively lesioned older mice at times when non-specific developmental cues would no longer be expected.

Donor neocortical neurons from E14 or E17 mice prelabeled with combinations of fluorescent nanospheres and [3H] thymidine were transplanted into photolytically lesioned 4 or 6 week old mice (n-14). Photolysis of targeted pyramidal neurons followed unilateral injection of latex nanospheres (230 nL) containing the cytoytic chromophore E, retrograde transport by cingulate projection pyramidal neurons in contralateral lamina III and V, and transectional laser illumination with a 670 nm continuous wave laser. After survival times of 1 to 6 weeks, serial sections were cut and processed for autoradiography, fluorescence, and routine histology. Preliminary results suggest that a subpopulation of transplanted neurons from both donor ages assume pyramidal morphology selectively within the neuron-deficient zone and extend processes. This suggests that E14 neurons "destined" to form deep cortical lamina may be influenced by a selectively altered environment to repopulate superficial laminae after normal development is completed. HUMAN COGNITION: BLOOD FLOW/METABOLISM

394.1

A positron emission tomography (PET) study of auditory processing was conducted using four classes of stimuli (syllables, words, tones, triplets) and two auditory task conditions. For each stimulus class, six different stimuli were presented ten times each. Activation of areas was assessed by defining areas of change on one group of subjects, and attempting to replicate these activations in other groups of subjects.

One set of subjects was instructed to listen passively to binaurally presented stimuli while fixating on a dot centered on a display monitor (passive task). Another set of subjects was trained to detect one of the stimuli within each set and to raise their left index finger whenever they heard the target stimulus, while also maintaining fixation (fixation task).

Activation patterns were assessed in a control condition for all tasks (fixation task). Areas which were more active during performance of the auditory detection task than control task included: primary and surrounding auditory cortex, left prefrontal cortex, and the medial frontal cortex. A set of areas localized bilaterally along the intraparietal sulcus were less active in the detection than control task. In contrast, none of the areas outside of auditory cortex were significantly changed during the passive task.

These results suggest that areas beyond the sensory processing regions are affected by task performance. Frontal regions might reflect processing necessary for activation of task performance, while parietal regions might reflect a reduction due to shifting of attention from the visual fixation task to an active auditory task.

394.2

A PET activation study was performed on 12 normal human subjects to examine areas related to working memory for verbal material. For the active tasks, subjects were serially presented 5 visual words or nonwords beneath a fixation cross prior to the start of the PET scan. Task instructions were to fixate while attempting to remember the items without verbalizing them or making mouth movements (monitored with EMG). Subjects recalled the items aloud when used after the scan. Stimuli used in the active tasks were: 1) categorically-related nouns, 2) unrelated nouns, and 3) nonwords. Two control tasks were used: simple fixation, and a recitation control (subjects silently and slowly repeated the digits '12345' while maintaining fixation).

All active conditions relative to fixation showed increased flow in midline structures and a right hemisphere, and decreased flow at or near Rolandic cortex. The activations in the recitation control differed from those of the activation tasks; only a left Sylvian-insular region was activated in the recitation control as compared to fixation. While there was cooling performance in the real word conditions, only half of the subjects recalled 100% of the nonwords. Activation differences found between good and poor performers included an increased activation of a left premotor area in good performers in contrast to an antememorial visual cortical area in the bad performers. There was a significant interaction between the two areas in the good vs. bad performers.

Several points are suggested in a representation of verbal material requires activation of certain areas (SMA, right prefrontal cortex) across many conditions; 2) inhibition of vocalization in these tasks produces decreases in Rolandic areas; 3) some areas differ with level of performance, suggesting a visual (bad performer) vs. phonological (good performer) strategy difference.
394.3 ACTIVATION OF LEFT POSTERIOR TEMPORAL CORTEX IN A VERBAL RESPONSE SELECTION TASK IS RATE DEPENDENT. ME Rauter*, JA Fiez, TO Vision, SE Peterson, Wash., U. Sch. Med., St. Louis, MO 63110. The cortical area in the left temporopolar boundary has been thought to play a significant role in word comprehension since the original observation of Wernicke in the 19th century. It was surprising, therefore, that event-related activation studies, in which subjects were asked to say aloud an appropriate verb for visually-presented nouns, failed to detect activation in this area of cortex. As a control state, subjects were asked to repeat aloud the visually-presented nouns, and the nouns were presented in both conditions at the rate of 1 per second. Five non-temporal areas showed significant activation: anterior cingulate, left prefrontal cortex and right cerebellum increased; while Sylvian insular cortex decreased bilaterally. A second study, using the same conditions, was performed at a rate of 1 word every 1.5 seconds. At this slower rate, there was a significant activation in the left posterior temporal region (x=9, y=-25, z=6); Taberach et al. (1997) accompanied by the previously noted changes. Several explanations are suggested by these results including: 1) the left posterior temporal region acts as a short-term verbal semantic buffer and is more active because the longer presentation time encourages longer storage times; 2) the region may be active because the slower presentation time allows more active and complete semantic processing before that demanded by the verbal presentation task, per se. Other investigators have also suggested that slower word presentation rates produce greater temporal activation (Marshall et al. Soc. Neurosci. 22, 1627). These data provide information into the role of left posterior temporal cortex in language processing, and also emphasize the crucial nature of paradigm design in the interpretation of imaging studies in the human brain.

394.5 FUNCTIONAL LOCALIZATION OF HUMAN Olfactory cortex with Position Emission Tomography. BJ Zatorre*, M. Jones-Gotman, A.C. Evans and E. Meyer, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B8. The cortical representation of human olfactory processing mechanisms was studied by examining regional cerebral blood flow changes with position emission tomography during olfactory stimulation. Eleven normal right-handed subjects were presented with a series of eight odorsants bilaterally during the activation phase; a baseline condition consisted of inhalation with no odor present. We used the paired-image subtraction procedure, averaging the responses across subjects; difference activated regions were plotted by matched magnetic resonance imaging. The principal result was strong activation (>3.6 in all cases) at the junction of the inferior frontal and temporal lobes bilaterally, corresponding to the prefrontal cortex, and unilaterally, in the right orbitofrontal cortex. The results agree with anatomical and behavioral data implicating these regions in olfactory processing, and indicate a functional asymmetry favoring the right orbital area in olfaction.

394.7 AGE-RELATED CHANGES IN REGIONAL CEREBRAL BLOOD FLOW (rCBF) ACTIVATION DURING VISUAL SELECTIVE ATTENTION. CL Greis*; B. Horwitz, J. France, G. Wagner, SI Rapoport, MB Schapiro, LG Ungerleider, IV Hasby. Lab. of Neurosciences, Nat. Inst. on Aging, Bethesda, MD 20892. Nine young (20 ± 3 yr) and 6 old subjects (67 ± 3 yr) performed visual tasks during position emission tomographic measurements of rCBF using [15O]water: face and location matching without selective attention (NSA), with stimuli differing between tasks, and with selective attention (SA), where stimuli were the same for both tasks but task demands differed. Young subjects showed no change in reaction time in SA vs. NSA, old subjects were slower in both NSA tasks than the young (p<0.001) and showed further slowing during SA for faces (p=0.02). Image data were analyzed using Statistical Parametric Mapping. Neither group showed significant rCBF increase in SA vs. NSA for either face or location matching. However, a significant age by condition interaction was seen for face matching, in which the old group showed a larger SA-NSA difference in rCBF compared to the young (p=0.003) in left hemisphere lingual, fusiform and inferior occipital gyr, and right hemisphere fusiform, superior and mid temporal, and inferior frontal gyri. Location matching, old subjects had a larger SA-NSA rCBF difference than did young subjects (p=0.005) in left hemisphere parahippocampal and superior temporal gyri, and only in hemisphere parahippocampal and fusiform rCBF. Our results indicate that the rCBF differences are task dependent. During SA for faces, old subjects show greater use of ventral occipital areas known to mediate face perception. During SA for location, old subjects show greater use of parahippocampal cortex, an area not previously identified in perception of location, which may indicate the use of memory systems by older subjects to perform spatial attention tasks.

394.4 REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING STORY LISTENING. D. Mason*, S. Dehane, N. Trehury, N. Murrinav, I. Cohen, O. Leverter, G. Salmamon, A. Sirota, J. Meckler, S.H. Joliot, CEA, Saclay, France, and L.S.C.P., C.N.R.S. and E.H.S. Paris, France. We have investigated regional cerebral blood flow (rCBF) changes during continuous speech listening. Healthy subjects listened in a resting state to the French texts read by a native speaker in an fMRI scanner. Each subject had six rCBF measurements using PET and [15O]water, a series of three conditions being replicated twice: rest, listening to a text in a language unknown to the subject and listening to a text in French (first protocol, N = 5); rest, listening to a list of French words, listening to a text in French (second protocol, N = 5). Auditory stimuli were presented binaurally over earphones. rCBF data were acquired with individual magnetic resonance images (MRI) and normalized CBF values within anatomically defined regions of interest were then compared across the three experimental conditions in each protocol (ANOVA). Both left (LST) and right (RST) superior temporal gyr were activated in all conditions of auditory stimulation (p<0.0005). They were the only active areas during listening to stories in 'Banul. A left inferior frontal gyrus activation (LIF, p<0.01) was found during word list listening. Listening to the stories in French in the first protocol activated the left and right temporal poles (LTP, p<0.0001; RTP, p<0.0005), and the left middle temporal gyrus (LMT, p<0.0005). These activations were replicated in the second protocol (LTP, p<0.0001; RTP, p<0.005; LMT, p<0.005). When pooling the two samples for this condition, extra-temporal activations were also found in LIF (p<0.05) and in left l Indochnis area (LIEN, p<0.05). These results indicate that, besides regions devoted to single-word comprehension, story-level processing activates additional areas. Experiments are under way to separate the putative role of syntactic parsing, verbal memory and semantic integration.

394.6 NETWORK MODELS FOR MAPPING COGNITIVE BRAIN FUNCTION USING POSITION EMISSION TOMOGRAPHY (PET) AND REGIONAL CEREBRAL BLOOD FLOW (rCBF). B. Horwitz* and P. Kirshna, Lab. Neurosci., Nat. Inst. on Aging, NIH, Bethesda, MD 20892. Understanding how the brain mediates cognitive behavior has been aided by the use of PET and fMRI to measure rCBF during specific cognitive tasks. However, given that multiple regions often are activated during specific tasks, the complex interrelationships that occur during cognition need to be understood in terms of neural networks. The starting point for such analyses is to use correlations among rCBF in different brain loci to investigate brain interactions (e.g., Horwitz et al., J. Cogn. Neurosci., in press; Friston et al., Proc. R. Soc. London B, 1991). However, the appropriate way to perform such analyses, and to use the results to generate network models to account for the cognitive behavior under study, is not clear. We recently have developed an explicit network model for simulating rCBF/PET data that allows one to examine brain functional interactions (Horwitz, Abstr. Soc. Neurosci. 17, 540, 1991). Here, we use this simulation model to determine some of the conditions under which two different correlational approaches (Horwitz et al., which is within-task design; Friston et al., which is an across-task design) produce similar or divergent results. Because the functional couplings between brain regions are specified in the model, we demonstrate for those cases with divergent results that the within-task correlational method better reflects the underlying functional configuration among the brain regions.

394.8 THE EFFECTS OF CLONIDINE ADMINISTRATION ON REGIONAL CEREBRAL BLOOD FLOW AND COGNITION IN THE ALCOHOLIC KORSakov Syndrome. E. Gundersen, A. Mathis, E.P. Daniell, N. Dougall, C. Murray, G.M. Goodwin, G. Fink*. MRC Brain Metabolism Unit, Royal Edinburgh Hospital, Edinburgh, EH10 5HF, Scotland, UK. McIntyre & Mair (TINS 1990 13, 340-344) reported that administration of the γ-agonist clonidine improved amnesia in the Alcoholic Korsakoff Syndrome (AKS). In an attempt to replicate and extend these findings, eighteen AKS subjects were recruited for a two phase trial. In phase 1, half the subjects received acute infusion of 150μg/kg of clonidine in a single dose, half received an infusion of saline. All subjects underwent functional neuroimaging using Single Photon Emission Computed Tomography (SPECT) before and after 30 minutes following infusion. Clonidine infusion resulted in a highly significant increase in anterior cingulate cortex blood flow and an associated improvement in verbal fluency. Subjects then entered phase 2, a chronic double-blind placebo-controlled cross-over trial of clonidine 0.3mg twice daily for 4 weeks, and maintained placebo for two weeks, incorporating an intervening two week wash-out period. Detailed neuropsychological assessments were carried out at the end of each two week treatment period, including the assessment of anterograde memory, attention, staff ratings of cognitive failures and 'frontal lobe' measures. Clonidine treatment had no significant advantage over placebo on any of the cognitive measures employed. We conclude that acute administration of clonidine activated the thalamo-anterior cingulate system, resulting in an improvement in selective attention in general, and target detection in particular. However, chronic treatment resulted in no cognitive enhancing effect, possibly as a consequence of receptor down-regulation.
394.11

To examine the role of genetic determination in the pattern of cerebral response to cognitive challenges, we used the oxygen-15 water method for measuring regional brain blood flow (rCBF) with PET to study five pairs of healthy monozygotic twins (two female and three male pairs: mean age 31 years, range 19 to 54). rCBF was measured while subjects performed neuropsychological tests including the Wisconsin Card Sorting Test (WCST), which is a sensitive indicator of the integrity of the dorsolateral prefrontal cortex in man, and Raven's Progressive Matrices (RPM), which is another complex abstract reasoning task that may involve more posterior cortical areas. Sensorimotor control tasks were designed to be similar to each neuropsychological task in visual characteristics and response mode (verbal for rCBF and finger movement for the WCST). rCBF values were normalized (i.e. expressed as a pixel-by-pixel basis as a percent of the whole brain mean). The similarity of regional brain function within twin pairs was assessed by determining the correlation between first- and second-born twins for each of a variety of brain regions.

Significant (p < 0.05) correlations were found: for WCS-right inferior frontal gyri (r = 0.98, p = 0.002), right anterior cingulate (r = 0.89, p = 0.04), and left thalamus (r = 0.91, p = 0.03); for the WCS control-none; for RPM-left inferior frontal gyrus (r = 0.89, p = 0.04), right temporal cortex (r = 0.96, p = 0.00) and for RPM control-right inferior frontal gyrus (r = 0.92, p = 0.02). left anterior cingulate (r = 0.97, p < 0.005), and right temporal cortex (r = 0.87, p = 0.05). These data may reflect the differential neural systems subserving the various cognitive operations involved in these tasks and may further suggest a high degree of heritability in cognitively related function in the implicated areas.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

394.12
SEX DIFFERENCES IN CEREBRAL BLOOD FLOW DURING SPEECH, S.Y. Bookheimer*, T.A. Zeffiro, W. Galliard, T.A. Blaxton, and W. Theodore, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

Gender differences in cognitive skills and aphasia patterns have led to the notion that the sexes differ in cortical language organization. To test this hypothesis, 16 adult males and female subjects underwent Positron Emission Tomography to measure cerebral blood flow while reading or naming objects. We found both general and task-specific differences in blood flow patterns. On all tasks, females showed greater activity in the posterior cingulate, while males showed stronger activation in motor areas. Females had greater left mid-occipital and angular gyrus activity during reading, while males showed increased mid-temporal activity. Left hemisphere area 44 (Broca's area) appeared more anterior among female subjects. Both groups showed strong left hemisphere dominance on language tasks. Contrary to some theoretical accounts, there was no evidence for relatively greater bilateral activity in either group.

DEGENERATIVE DISEASE: PARKINSON'S I

395.1

Human striatal extracts added to rat striatal homogenates (RTH) cultures stimulates dopamine (DA) neuron growth and neurite extension. This growth promoting activity (GPA) is elevated in Parkinson's disease (PD) striatal extracts, suggesting a compensatory trophic response to DA neuron loss. Initial findings suggest this activity is soluble and diffusible. Therefore, we postulated that human CSF may also contain GPA. Ventricular CSF from PD and non-PD patients (n = 11 for each group) was compared to normal and <10%CSF fractions using Cortico-ns microscopic cultures. Fractions from each patient were subsequently diluted (1:4) using Heat's Balanced Salt Solution and 50 μl added to freshly plated 1000 cells. Cells were growing in 200 μl defrosted media. 24 hr later, the number of neurons with processes (dependence of GABA) was counted in PD similar to the human tissue culture. CSF from PD patients consistently exhibited significantly higher GPA than non-PD patients as well as E5A treated (E5A: PD = 104, non-PD = 11, p = 0.01). Additionally, post-hoc comparisons revealed a significant difference in GPA between PD and non-PD and between PD and PD-BSA. GPA was only observed in >10%CSF. A >10%CSF sample from one patient with PD was separated into 7 fractions using FPLC and added to RTH cultures. GPA was significantly elevated in two of these fractions. These data suggest that 1) a factor(s) responsible for striatal GPA are also present in the CSF of normal patients, 2) CSF-derived GPA is not contained in an RTH-derived GPA, and 3) factor(s) > 10%CSF and may be amenable to further fractionation and purification. Studies are in progress to identify GPA using the appropriate chromatography and as well as the cellular specificity of CSF-derived GPA. Preliminary observations indicate that the cells that produce GPA are likely dopamine producing neurons of the nigrostriatal system. If confirmed, CSF-derived GPA may be a surrogate measure of nigrostriatal system function.

395.2

Extracts of adult human and rat striatal tissue stimulate the growth of dopaminergic (DA) neurons in primary culture. This growth-promoting activity (GPA) is elevated in patients with Parkinson's disease (PD). We have proposed that the increased GPA in the PD brain represents a compensatory response to the loss of DA neurons which could slow disease progression by stimulating sprouting. However, if striatal GPA is decreased in the aged brain, compensatory increases resulting from DA neuron loss may be inadequate to overcome PD progression. In an effort to determine if GPA varies with age, we evaluated striatal and cerebral extracts from 2, 16, and 24 month old rats (n = 16) on the growth of low cell density (3,500 cells/well), E15.5 rostral mesencephalic, dorsalized, primary cultures grown in defined media. Cells were treated with extracts from 24 month old rats possessed significantly more viable, neuron-specific enolase immunoreactive neurons with processes (263 ±) than cultures incubated with extracts from 24 month old animals (F = 0.06). Moreover, neuron viability in culture was inversely correlated with age (r = -0.69). In contrast, extracts of the cerebellum from these animals possessed very little GPA which was not correlated with age. If DA neurons in the aged brain exhibit decreased GPA activity for continued viability, the age related decline in this GPA may contribute to DA neuron loss. Furthermore, a compensatory increase in GPA brought about by the DA neuron loss of PD may be inadequate to overcome PD progression. If striatal GPA in humans exhibits a similar relationship to age. An age-related decline in striatal-GPA would therefore predispose older patients to PD.
395.3 MPTP INDUCED CHANGES IN STRIATAL D2-LIKE Dopamine receptors: a FINGER PRINT CHANGES IN MEGREX R-NAA. R. D. Tod*, J. Colvin, J. Carl, J. S. Pertelt*, Departments of Psychiatry and Genetics, and Department of Neurology and Neurosurgery, Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO 63110

MPTP induced destruction of dopamine producing cells has been used both as a model for Parkinson's disease and as a denervation agent for studying the role of dopamine receptors. In the present study we have determined the temporal pattern of receptor expression in MPTP treated primates. Baboons were unilaterally lesioned by intracardiac artery injection of MPTP resulting in a hemilateral Parkinsonian syndrome. Striata from injected animals were analyzed for titrated spiperone binding, messenger RNA levels for dopamine D2, D3, and D4 receptors and dopamine content. In both caudate and putamen there was an increase of two to seven-fold of eticlopride-displaceable titrated spiperone membrane binding which reached peak levels in about 5 days and declined to baseline levels by about 2 weeks following MPTP injections. These increases and decreases in binding site number occurred in the presence of 98% reductions in dopamine in the ipsilateral caudate and putamen. Putamen messenger RNA levels were quantified by reverse transcription coupled to polymerase chain reaction amplification using receptor specific oligonucleotides. In contrast to results for D2-like binding sites, there were no observable changes in the amounts of messenger RNAs for D2, D3, or D4 receptors. These studies suggest that MPTP induced changes in striatal D2-like receptors are secondary to translational or post-translational effects on receptor number.

395.5 MODELING CHAOTIC DopAMINERGIC NEURODYNAMICS. J. Sals, S.H. Price, A.D. Will and J.M. Toss*. Neurology and Psychiatry Services, Jerry L. Pettis Veterans Affairs Medical Center, Loma Linda, CA and Dept. of Neurology and Psychiatry, Loma Linda University School of Medicine, Loma Linda, CA 92350

A nonlinear dynamical model of the nigrostriatal dopaminergic system was proposed by King, Barchas and Huberman (PNAS 81:1244, 1984) who demonstrated the model's potential for explaining the rapid fluctuations in movement observed among certain Parkinson's patients following chronic treatment with L-dopa. We have explored the complex dynamics of a modification of this model. The modifications may be equated with biological variables involved in the pathophysiology of Parkinson's disease. We show that by varying one or both of two parameters, χ, representing mean firing rate of nigrostriatal neurons and γ, a variable proportional to postynaptic dopamine D2 receptor density, the system exhibited a wide range of dynamics. When the variable χ, representing the mean firing rate, was decreased we observed the appearance of a novel family of solutions which exhibited a decreasing incidence of chaotic states. Additionally, we observed the chaotic regime breaking up into a collection of discrete groups of firing states. When the variable γ, which is proportional to dopamine D2 receptor density, was decreased we observed a shift in dynamics from chaotic to nonchaotic states. On this basis we predict that premorbid nigrostriatal dopamine D2 receptor denatilization will influence sensitivity to chaotic dynamics and may influence susceptibility to Parkinson's disease and other movement disorders. We believe these findings may also have important implications in light of recent work being done in the area of experimental control of chaotic dynamics.

395.6 ON-OFF EFFECTS OF DIRECT Dopamine agonists in UNILATERAL NIAGRAL RATS. P.B. Silverman*, Dept. of Psychiatry, University of Texas Health Sci. Ctr., Houston, TX 77030

As Parkinson's disease and its treatment progress, the response to pharmacotherapeutic agents becomes increasingly erratic with the development of dyskinesias and "on-off" effects. In the unilaterally 6-hydroxydopamine lesioned rat, with respect to extent of dopamine depletion, a condition of advanced head-parkinsonisms exists. Here lesioned rats were tested repeatedly with selective direct-acting dopamine agonists and their rotational (circling) response recorded. A remarkable degree of real dose fluctuation was seen when the selective D2 agonist, bromocriptine, or one of the selective D1 agonists, SKF 82958 or SKF 72864, was administered a few days in. In consecutive daily sessions responses of individual animals varied from zero to hundreds of rotations per hour. When treated daily for 2 weeks, SKF 72864, some rats showed a pattern of response which appeared to be a 2 to 3 day cycle of response fluctuation. In others, as well as in the group as a whole, no consistent pattern of response fluctuations continued when treatments were spaced at 3 day intervals. This approach may prove useful for the study of "on-off" effects.

Supported by NIDA grant DA062169.

We are using a digitizing tablet based pointing task developed by Gordon and Ghez (CSH Symp Quant Biol 55:837-847, 1990) to examine the effects of sensory information and instructions influence basic task performance in normal middle aged adults and patients with Parkinson's disease. With arms hidden, 9 subjects (6 normals, aged 39 to 62, and 3 patients with Parkinson's disease (PD), Hoh and Yah ages 1 or II, aged 61-72) moved a cursor to 6 distances (2.4 to 26.4 cm) in an oblique right or leftward direction to match targets seen on a computer monitor. Without reaction time constraints, subjects were told to make uncorrected, straight movements. In 6 different session types, accuracy, brief movement time or both were stressed while we provided or withheld continuous feedback of hand position and/or knowledge of results. All subjects (45 sessions to date) reached different distances by scaling both velocity and duration, although velocity had a more consistent effect on performance (ascertained by multiple regression) in every session but one. Not only velocity and duration, but acceleration and time to peak acceleration were scaled to distance. PD patients had trajectory formulation similar to normals, but one patient (Stage II) had prolonged trajectories which further slowed and undershot distant targets if knowledge of results was unavailable. The PD group was also normal in the PD subjects while still revealing evidence of both bradykinesia (slowing) and excessive dependence on visual cues.

DEGENERATIVE DISEASE: PARKINSON'S I
WEDNESDAY PM

395.9 DEMENTIA IN PARKINSON'S DISEASE: CORTICAL INVOLVEMENT WITH A FRONTAL PREDOMINANCE USING THE IMMUNODETECTION OF ABNORMAL TAU PROTEINS. P. Vermersch 1, A. Delacourte 1, E. Lavoy-Angel 2, 3, J. Hasse 1, Y. Agid 2, 3 U 156 INSERM, 59045 Lille, 2 U 289 INSERM and Neurophysiology Research Unit, 75615 Paris, France.

The dementia, frequently associated with Parkinson's disease (PD), is generally considered to be of the subcortical type but the high frequency of Alzheimer pathology in dopa-treated patients indicates that dementia may be due to coexisting Alzheimer’s Disease (AD). In this study we analyzed the neurochemical changes in the lesioned dopamine pathway of PD patients.

Results: The frequency of immunodetection of the normal tau triplet was statistically higher in the demented subgroups than in the non-demented subgroup of PD in the prefrontal (p < 0.05), the temporal (p < 0.01) and the entorhinal cortex (p < 0.02) but not in occipital and circular cortex. A quantification of normal tau triplet by densitometry showed that, in opposition to the results obtained in AD patients, the intensity was higher in the prefrontal than in the temporal cortex of most of the demented PD patients.

Conclusion: This study: i) gives a biochemical evidence for the presence of AD changes in demented Parkinsonian patients; ii) suggests that lesions of the prefrontal cortex may significantly contribute to the occurrence of cognitive changes at least in some PD patients.

The aim of the study was to determine whether the speed of serial comparisons of sets of 2, 3 or 4 memorized digits with a target digit (Sternberg paradigm) is different in "on" and "off" states of levodopa and related to the levodopa plasma level. 18 parkinsonian patients (age 61.2; 10.1, disease duration 6.8; 3.1 years) were tested in the "on" and the "off" states of levodopa ("offs") and in states of optimal response to oral levodopa ("on"). Central processing time was not different in "on" and "off" (134.12; 129.51±18 sec) and significantly slower in "off" than in 13 age-matched normal controls (82±20 sec, Mann-Whitney U test). Central processing time was not related to the levodopa plasma level and the motor scores (Schwab rank correlation). In 3 patients significant improvement of arousal was observed under levodopa (affect-arousal scale of Bond and Lader) and in parallel marked acceleration of cognition suggesting that levodopa might have an activating effect on cognition in simple patients with deficient arousal in "off" states.

396.1 REFEEDING AFTER STARVATION INCREASES HYPOTHALAMIC NEUROPEPTIDE Y (NPY) MESSENGER RNA. R. Briones-Urbina 1, S.D. George 2, L. Schwartz 1. 1 Depts. of Medicine and Pharmacology, University of Toronto, Toronto, Ont., CANADA M5G 1A8.

NPY is a potent orexigen when administered into the CNS. Physiologically, it appears to be a neural factor regulating feeding behavior. Hypothalamic NPY gene regulation in response to starvation and refeeding was studied in male Sprague Dawley rats to assess a possible role of NPY not only in the regulation of feeding but also in the maintenance of feeding behavior and body weight. Animals weighing 180-200 g at the onset of the study were housed in environmental rooms in 12h dark/light cycles, with free access to water and food, handled and weighed daily. After an adjustment period of 2 weeks, groups of rats were starved for 12, 24, 48 and 72 h with free access to water. Weight losses of 10, 17, 23 and 30% occurred in each group respectively. Hypothalamic NPY mRNA levels were detected by Northern blotting analysis using a 32p labelled oligodeoxynucleotide probe complementary to bases 1632-1669 of the rat NPY gene. Increased NPY mRNA was detected as early as 12h, peaked at 48h and remained elevated until 72h. Groups of rats were then starved for 24 or 48h followed by free access to chow and water for a further 12, 24 and 48h. After 12 and 24h of refeeding following both 24 and 48h of starvation, there was a further increase in NPY mRNA levels coinciding with weight regain up to 80%, but no further increase was noted after 48h refeeding. We report time-dependent further increases in hypothalamic NPY mRNA levels in refeeding following starvation coinciding with the period of enhanced food intake, rapid weight gain and reversal of body weight to prestarvation levels. These results suggest a physiological role for NPY in the initiation and maintenance of feeding behavior and likely in the control of body weight as a reflection of energy balance.

Neuropeptides such as neuropeptide Y (NPY) and galanin may play a role in regulating circannual cycles of feeding in the golden-mantled ground squirrel (Spermophilus undulatus). To investigate this, we analyzed the distribution of NPY and galanin mRNA in ground squirrel brain using in situ hybridization histochemistry, in rats and mice, NPY mRNA was abundantly expressed in the hypothalamic arcuate nucleus and was also present in the cortex, hippocampus and reticular nucleus of the thalamus. Hypothalamic galanin mRNA was concentrated in the arcuate nucleus and the dorsomedial nucleus. Preliminary findings show that seasonal changes in feeding in ground squirrels is related to changes in the hypothalamic expression of neuropeptide mRNA. Thus, in hyperphagic (food intake = 29.8 ± 0.7 g/day; m4) we observed a reduction in NPY and galanin, whereas in a non-hyperphagic (12.1 ± 1.3 g/day; m4) animals, the reduction in food intake was paralleled by a decrease in hypothalamic expression of NPY and galanin, although a larger sample size is necessary to confirm this. Thus, golden-mantled ground squirrels expresses the genes encoding hypothalamic NPY and galanin in a distribution compatible to non-hibernating rodents. Seasonal changes in the expression of these neuropeptides may contribute to circannual cycles of feeding.

INGESTIVE BEHAVIOR: NPY, GALANIN AND INSULIN

Problem-solving ability in Parkinson's disease (PD) patients, elderly control subjects, and young control subjects was studied using the Halstead Category Test. The subjects were 61 PD patients, 40 age-matched elderly controls, and 46 young controls. Errors on the Category Test did not differ significantly (t tests) between the PD group (4.3±1.2), the elderly control group (4.4±1.4), and the young control group (3.9±1.2). The only indication of greater problem-solving difficulty in the PD group was the somewhat greater percentage of PD patients (58%) as compared to elderly controls (29%) who were impaired by ≥ 2 SDs from the young control group mean. However, an equal percentage of PD patients and elderly controls (26%) scored above the mean of the young control group. Our findings do not support previous reports of impaired complex problem-solving ability in PD patients.
396.4 NEUROPEPTIDE Y PROJECTION FROM ARCULATE NUCLEUS (ARC) TO PARVOCELLULAR DIVISION OF PARAVentricULAR NUCLEUS (pPV): SPECIFIC RELATION TO CARBOHYDRATE FEEDING. M. Hnasek-Unial*, B. Beck, Y.S. Hnasek, C. Burlet and S.F. Leibowitz. The Rockefeller Univ. New York, N.Y. 10021 and Faculty de Medicine, INSERM U.308, Nancy, France.

Neuropeptide Y (NPY) injection into the PVN stimulates food intake, specifically of carbohydrate (CARB). The pPV is particularly rich in NPY-containing terminals which originate primarily from the ARC. This study examines: a) the relationship between endogenous NPY and natural preference for CARB; and b) the specific importance of the ARC-pPV NPY projection in this relationship. Sprague-Dawley rats were perimortem hypophysectomized (CARB, protein, and fat), and daily food intake was recorded. Rats were sacrificed 3 ws later, their brains removed, and eight hypothalamic nuclei were microdissected and examined via RIA for endogenous NPY. The results demonstrate that: 1) High CARB eaters, compared to low CARB eaters, have significantly elevated NPY levels specifically in the pPV (p<0.01) but not the magnocellular PVN; in ARC (p<0.01); and in dorsomedial nucleus (DMN; p<0.05). 2) No such relationship was seen for fat or protein intake; 3) Endogenous NPY content is positively correlated with 24 hr CARB intake, in the pPV (r=0.71p<0.001), ARC (r=0.57p<0.001) and DMN (r=0.52p<0.01) only and 3) Endogenous NPY levels in ARC, where NPY cell bodies are concentrated, are positively correlated with NPY levels in the pPV (r=0.54p<0.001) and DMN (r=0.56p<0.001) to which the ARC projects. This demonstrates a close relationship between endogenous NPY, specifically of the ARC-pPV projection, and natural preference for CARB.

Since a large body of evidence shows that increased feeding under natural conditions is enhanced by enhanced NPY release in the PVN (PNAS, 88:1093, 1991), we evaluated the levels and patterns of in vivo and in vitro NPY release from the PVN of STZ-induced diabetic rats displaying hypophagia. Exp 1: NPY levels were measured by RIA in 7 microdissected brain nuclei of rats 18 days after STZ or vehicle treatment. STZ rats exhibited marked hyperglycemia, hyperphagia and elevated NPY levels in 4 hypothalamic sites including the PVN as compared to controls. Exp 2: NPY release from the microdissected PVN and ventromedial nucleus (VMN) of STZ rats was then studied in vitro. Both basal and KCl-induced NPY release were lower in the PVN of STZ-treatment rats than that of control rats. However, NPY release from the VMN of STZ-treated rats was unaffected. Exp 3: NPY release in vivo from the PVN of STZ-treated rats was assessed. Perfusions were conducted in the regions of the PVN and 1 wk later (18-20 days after STZ-treatment) the PVN was perfused via the PPC for 3-4 hours with artificial CSF. Compared to controls, NPY levels in PVN perfusates collected at 10 min intervals from STZ-treated rats were significantly enhanced in association with increased food intake. Cumulatively, these results show that NPY release is augmented in the PVN of STZ-treated rats. Since NPY is a potent, naturally-occurring orexigenic signal, our results support the hypothesis that increased NPY secretion, selectively in the PVN, may be the underlying cause of hypophagia in diabetes. (Supported by UP DSK KG 717 (AS) and NIH DK37275 (P3K & S3K), VA Merit Review (CAS)).

This study examined the relationship between hypothalamic galanin (GAL) levels and macronutrient intake in rats. Albinos (n=50) were maintained ad lib on diets of protein, carbohydrate, and fat. After 3 wk, the rats were sacrificed by decapitation, 10 hypothalamic nuclei and the posterior pituitary (PP) were microdissected, and GAL-IR was measured by RIA. Among the 10 hypothalamic areas examined, only the magnocellular paraventricular nucleus (mPVN) revealed a significant relationship between endogenous GAL and daily nutrient intake. In this region, where dense GAL cell bodies exist, positive correlations were observed between GAL levels and fat ingestion (r = -0.62, p<0.01), 24 hr feeding activity (r = -0.73, p<0.01), fat body weight (r = -0.62, p<0.01), and fat intake during the first 90 min of the feeding cycle (r = -0.68, p<0.01), and body weight gain (r = +0.37, p<0.05). While a small inverse correlation between mPVN GAL and carbohydrate intake (r = -0.41, p<0.05) was also detected, there was no apparent relationship between GAL and either protein intake, total caloric intake or body weight. GAL in the PP was similarly related to fat intake (r = +0.40, p<0.05), as well as to GAL levels in the mPVN (r = +0.40, p<0.05). No such correlations with the other hypothalamic areas were seen. This relationship, between natural fat ingestion and endogenous GAL specifically in the mPVN, agrees with studies of GAL mRNA and also with central injection studies showing the PVN to be the most sensitive site to the selective stimulatory effects of exogenous GAL on fat ingestion.

396.7 GALANIN IN THE CENTRAL NERVOUS SYSTEM OF LEAN AND OBSEZ ZUCKER RATS. Beck*, B. Burlet A. Nicolas, J.P. Burlet C. - INSERM U308 MRCA, 38 rue Capucine, 54000 Nancy (France)

Galanin (GAL), a 29 amino acid peptide, is widely distributed in the central nervous system and especially in the hypothalamus. It strongly stimulates food intake when it is administered in the paraventricular nucleus (PVN). The obese Zucker rat with a well-established hyperphagia is characterized by a general dysregulation of some important neuropeptides involved in the regulation of feeding behavior, such as GAL or CCK, but nothing is known about the central status of galanin in these rats. The aim of this study was therefore to measure GAL in different microdissected brain areas in lean and obese Zucker rats. As an index of the central status may modulate changes in the peptide, it was measured in ad libitum fed rats and in 48-h fasted rats. Bilateral arcuate nucleus (ARC) and paraventricular (PVN) and magnocellular (PVmN) parts of the PVN as well as the median eminence (ME) were microdissected and ionotropically perfused. GAL was measured by a specific radioimmunoassay. The two-way analysis of variance revealed a very significant effect of genotype in the PVN (p<0.001) and in the ME (p<0.02). No variation at all were noted in the ARC or in the PVN. Fastig did not influence GAL concentrations in any areas. GAL concentrations were more double in the ad lib obese rats when compared with controls (p<0.05). On the other hand, in the ME where GAL concentration was about 4-fold greater than in the other areas, there was a 20 to 30 % decrease in GAL concentrations in the obese rats (p<0.05). Opposite variations of GAL were therefore observed between obese and lean rats in two distinct areas. Increased PVN levels might be related to the hyperphagia of the rats but GAL did not behave exactly like NPY, an other orexigenic peptide with an ubiquitous action, so no effect on its levels. Its biological action might therefore be different.

396.3 EFFECTS ON FASTING ON GLUTAMIC ACID CARBOXYLASE (GAD) mRNA LEVELS IN RAT HYPOTHALAMUS. A.J. Spoel*, M.W. Schwartz and D.G. Baskin. Departments of Medicine and Biological Structure, University of Washington and Veteran Administration Medical Center, Seattle, WA 98108.

Evidence indicates that the inhibitory neurotransmitter γ-aminobutyric acid (GABA) plays a role in the central regulation of feeding behavior. Since food deprivation increases hypothalamic GAD activity, we proposed that fasting may influence GAD gene expression in the hypothalamus. To test this hypothesis, we measured the content of mRNA for two GAD isoforms (GAD65 and GAD67) using in situ hybridization. Following 24, 48 or 48 hr of food deprivation, coronal brain sections from male Wistar rats (initially weighing 275-300g) were hybridized with probes complementary to either GAD65 or GAD67 mRNA. Northern blot analysis revealed that these probes recognize separate mRNA transcripts. Film autoradiographs were quantified by computer image analysis (ICAy) in the arcuate nucleus (ARC), dorsomedial nucleus (DMN), and ventromedial nucleus (VMN). The VMN showed an increase in GAD67 mRNA expression while no change was observed in GAD65 mRNA. In fed rats, GAD67 hybridization was highest in DMN (0.177 ± 0.002) and ARC (0.170 ± 0.007) with lower values in VMN (0.118 ± 0.007). Food deprivation for 24 or 48 hrs did not alter levels of GAD65 or GAD67 mRNA in any area. However, we observed significant associations between GAD65 mRNA expression in ARC and plasma insulin (r = -0.61) and glucose (r = 0.54) levels. We conclude that: 1) GAD65 and GAD67 mRNA have identical quantitative distributions in hypothalams; 2) hypothalamic expression of GAD65 and GAD67 genes is not affected by food deprivation; and 3) GAD65 gene expression in ARC may be influenced by changes in circulating levels of insulin and/or glucose.
396.9 INSULIN TRANSPORT FROM PLASMA INTO THE CENTRAL NERVOUS SYSTEM IS SATURABLE IN VIVO. G.D. Baur, D.M. Foster, D. Perci Fr, R.N. Bergman and M.W. Schwartz*. Dept. of Bioengineering and Medicine, Univ. of Washington and Seattle VA Medical Center, 98108, and Dept. of Physiology and Biophysics, Univ. of Southern California, Los Angeles, CA 90033.

Circulating insulin enters the central nervous system (CNS) where it acts as a regulator of neurotransmitter and body weight. We have previously shown that the kinetics of insulin uptake into cerebrospinal fluid (CSF) from plasma can best be explained by passage through an intermediate compartment, hypothesized to be brain interstitial fluid. To determine if an insulin receptor contributes to this uptake, we infused anesthetized dogs (n=9) to 90 min euglycemic intravenous insulin infusions to obtain a wide range of plasma insulin levels (69-5046 μU/mL). Plasma and CSF samples were collected over 8 hr for determination of immunoreactive insulin levels, and the kinetics of CSF insulin uptake were analyzed using a mathematical model with three components (plasma→intermediate compartment→CSF). Frequent sampling during rapid changes of plasma and CSF insulin levels enabled the model to precisely identify rate constants (mean standard deviation): 14% characterizing the uptake of insulin from plasma, through the intermediate compartment and into CSF (k1,k2), and clearance of insulin from both intermediate compartment and CSF (k3). At physiological plasma insulin levels (8.3±μU/mL), k1,k2 was determined to be 11.5±1.0 min⁻¹. However, with increasing plasma levels, k1,k2 decreased progressively, being reduced seven-fold at supraphysiologic levels (5046 μU/mL). The apparent Km of this saturation curve was 500-800 μU/mL (3.5 μM). In contrast, the rates of insulin clearance from both the intermediate compartment and CSF did not vary with plasma insulin (k3=0.011±0.0001 min⁻¹ and k4=0.046±0.002 min⁻¹). We conclude that transport of plasma insulin into CNS is saturable. This mechanism is consistent with insulin binding to blood brain barrier insulin receptors and transcytosis through microvessel endothelial cells.

396.11 IVT INSULIN DECREASES RESPIRATORY QUOTIENT IN RATS. C.R. Park*, M. Chavez, S.C. Woods, Dept. of Psychology, University of Washington, Seattle, WA 98195

Centrally administered insulin decreases food intake and body weight in several species. In some studies the observed decrease in body weight appeared greater than what would be predicted solely on the basis of decreased food intake. It is therefore possible that central insulin affects metabolic rate independently of its behavioral effect. Male Long-Evans rats (n=6) received either insulin or saline vehicle into the third ventricle. Bolus injections (4μL in 4 μL) were given twice, 12 hours apart. Water, but not food was available. Respiratory quotient (RQ) was measured by indirect calorimetry. All animals were exposed to both conditions in a counter-balanced design. IVT insulin resulted in a statistically significant decrease of RQ from 0.79 in the vehicle condition to 0.72 in the insulin condition. This change of RQ was accompanied by a significantly greater weight loss during insulin treatment than during saline treatment. Peripheral injections of insulin at the same dosage and time schedule increased RQ. We conclude that centrally administered insulin affects metabolic activity and appears to do so by increasing the utilization of fat stores. These results further support the hypothesis that central insulin serves as a negative feedback signal in the central nervous system for body adiposity.

396.10 INTRAVENOUS INSULIN INFUSION INCREASES DIETARY FOOD INTAKE AND ENERGY EXPENDITURE IN RATS. A.E. Willing, H.S. Koopmans* and E.K. Walls. Dept. of Medical Physiology, Univ. of Calgary, Calgary, Alberta, Canada, T2N 4N1.

Chronic insulin treatment significantly increases daily food intake, but insulin has previously been found to both increase and decrease energy expenditure (EE). To study the relationship between feeding and EE in intravenous insulin, we used the veno cava of 12 Lewis rats (VC fixed and VC varied). In the VC varied group, daily food intake increased from a Ringer's baseline value of 71.5 ± 1.5 to 93.9 ± 1.3 and 112.2 ± 0.9 kcal/day at the 2 and 3 U/day insulin doses (p < .01). EE increased from a baseline value of 54.2 ± 4.1 kcal/day to 63.0 ± 4.9 kcal (p < .05). The 3 U/day insulin infusion and the rats gained weight rapidly. RQ increased from 0.83 ± 0.03 during baseline to 0.95 ± 0.02 at 2 U (p < .01) and remained constant. In the VC fixed controls, daily food intake increased from 73.5 ± 0.7 to 98.2 ± 1.4 kcal/day at 2 U/day (p < .01) which it remained constant. There was no significant increase in EE, but RQ increased from 0.87 ± 0.02 during baseline to 0.94 ± 0.02 (p < .01) at 2 U/day. Over time, RQ decreased to 0.79 ± 0.03 (p < .01). These results suggest that the observed increases in EE that are often obtained when exogenous insulin is administered are a result of the increased food intake that accompanies the insulin infusion. Insulin administration also shifts substrate utilization from fat to carbohydrate. This shift occurs even when there is little change in daily food intake.

397.1 REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING ACTIVE AND PASSIVE FINGER MOVEMENTS: A PET STUDY. T.A. Zeltzer* and M. Haliett. Medical Neurology, VA Medical Center, 10-9N226, NINDS, National Institutes of Health, Bethesda, MD, 20982.

Studies in subhuman primates have shown that many cortical neurons that modulate their activity in relation to voluntary limb movement also modulate their activity during passive movement of the same body part, suggesting a relatively tight relationship between a movement and its sensory correlate. In order to examine this in man, we used H215O positron emission tomography to record regional cerebral blood flow (rCBF) in 8 subjects during active and passive finger index movements. We studied 2 different tasks. In the active condition, each subject performed 4 finger abduction/adduction movements twice per second. In the passive condition, the index finger was moved with the same rate and range while the subject lay quietly. The control condition. Significant changes in rCBF were detected using co-variance analysis and the t statistic.

We found significant contralateral rCBF increases during both active and passive tasks in primary motor cortex, primary somatosensory cortex, supplementary motor area, cingulate motor area and putamen (p<0.1). In all these areas the rCBF increase was greatest in the active condition. Significant rCBF increases were detected in ipsilateral anterior cerebellar cortex, ipsilateral primary motor cortex, contralateral insula and contralateral superior parietal lobule. In many motor tasks, processing of repetitive movement is characterized by tight spatial coupling between activity related to active and passive movement of the same body part.
397.3

MOTOR SYSTEM CBF RESPONSES DURING FINGER MOVEMENTS ARE RATE INDEPENDENT. Scott T. Gratton, Roger P. Woods, Michael Pickles, and John C. Mazzeotta. U.C.L.A. School of Medicine, Los Angeles, CA 90024.

The goal of this study was to determine the effect of performance rate on the magnitude of regional cerebral blood flow (rCBF) responses in the human brain. Formal subjects performed a visually guided and mentally guided tracking task with their dominant index finger during serial position emission tomography (PET) imaging of rCBF. Target speed was set at 0.8, 2.6, 4.4, 24.6, and 32.8 cm/sec. Tracking at these rates spanned the physical limits of non-blastic finger movements. Significant changes of rCBF were identified using analysis of covariance and the t statistic after stereotactic normalization. Movement (versus no movement) was associated with significant (p<0.001) rCBF responses in the contralateral primary motor cortex, supplementary motor area, premotor cortex, and ipsilateral anterior cingulate. The magnitude of the responses in these areas was constant across tracking rates. No other linear or non-linear differences of rCBF associated with a rate effect could be identified in any other cerebral area. The results are in contrast to previous studies of the visual system that have shown a relationship between photic stimulus rate and the magnitude of rCBF responses in V1. Motor system rCBF responses, representing the integral of local neuronal activity, remain constant across performance rates. These results suggest that the observed longitudinal changes in the magnitude of motor system rCBF responses during skill acquisition and functional recovery are not secondary to a rate effect.

397.4

Using oxygen-15 labeled water and positron emission tomography (PET), we have found bilateral parietal increases in blood flow in normal humans performing both immediate and delayed visually guided and mentally guided reaches to visual targets. These increases are sufficiently robust that they are consistently seen in individual subjects. To determine which components of these tasks are required for parietal responses, we have varied the lateralization of visual input and motor output, dissociated the spatial and temporal information provided by the visual cues, and compared visual to auditory temporal cues. Restriction of targets to a single visual hemifield did not result in lateralization changes, but when subjects maintained central visual fixation and pointed to the targets with one hand, parietal responses were stronger contralaterally. When subjects pointed to locations that they chose at random, a robust contralateral parietal response was still seen. The timing of movements in this task was still cued visually by the disappearance of the central fixation target. Substitution of auditory for visual temporal cues resulted in a decrease in the parietal response contralaterally, but did not eliminate the response as compared to a motorless control state. A contralateral parietal response was even elicited by pointing to randomly chosen locations using auditory temporal cues in darkness with eyes closed. The contralateral parietal lobe plays an important role in movements to visible external targets and in movements to internally generated targets in the absence of any visual input. Because all of the movements were cued either visually or auditorily, we cannot say whether the role of the parietal lobe is more closely related to evaluation of the status of the cue or to the actual initiation of the motor output.

397.5

TASK-SPECIFIC CHANGES OF LOCAL BLOOD FLOW WITHIN THE HUMAN ANTERIOR CINGULATE CORTEX: RELATIONSHIP TO LEVEL OF PERFORMANCE. T. Paul, J. Petrides, A.C. Evans. Montreal Neurological Institute, McGill University, Montreal, Quebec H3A 2B4, Canada.

Overpractised and Reversal versions of Speech Colorator, and Manual tasks were used to study the role of the anterior cingulate cortex (ACC) in higher-order motor control. In two separate PET experiments, cerebral blood flow (CBF) was measured in 18 healthy volunteers, using the O-water-bolus method. For each subject, one "baseline" and six "task" scans were performed. Accuracy and latency of motor responses were also measured. On the basis of performance in the Reversal Speech task, subjects could be classified into two groups: "passed" and "failed". These groups did not differ in performance on the Overpractised Speech task. In both experiments, significant CBF changes within the ACC were obtained only in the reversal minus overPractised speech subtraction (Repl.: both groups, Expt. II: passed group only), but also in the overpractised minus baseline speech subtraction in the "failed" groups. The presence of ACC activation in a well practised speech task represents an atypical pattern of brain activity, the occurrence of which might signal failure in a more challenging task.

397.6

LOCALIZATION OF MOTOR AREAS WITH TRANSCRUTIONAL MAGNETIC STIMULATION AND MAGNETIC RESONANCE IMAGING IN HUMAN SUBJECTS. M. Daffertshofer, M. Syren, H. Henningsen, and M. Zimmermann. Departments of Neurology and Physiology, University of Heidelberg, Germany (Sponsor: EMA).

Transcranial magnetic stimulation (TMS) and magnetic resonance imaging (MRI) were combined to map motor fields of the human cortex. We used focal "eight-sided" coils (Novametrix 2 T) to stimulate the cortex as revealed by recording motor potentials by surface EMG electrodes over several muscles of the upper and lower limbs. Focal areas associated with distinct muscles were labelled on the skull surface with a cream rich in water, and numbers were assigned to these labels. Up to 80 sites of stimulation could be discerned. Subjects were then investigated by MRI (Siemens 2 T), and the labelled motor foci were projected to the image of the cortex.

In all 5 subjects studied so far the localizations of the points of motor excitations were consistent with precentral cortical motor fields associated with the limb muscles as were previously established by invasive electrical cortex stimulation. Thus, TMS enables the non-invasive mapping of motor fields with a rather high resolution. This method is valuable to detect changes in the topography of the motor cortex as might occur in amputees.

397.7

TMS can be used to map motor representations noninvasively, but it has not been possible to correlate these maps with brain anatomy. Ten TMS stimulations were delivered to each of a grid of points 1 cm apart on the left scalp while EMG was recorded and averaged from the right first dorsal interosseous muscle (FDI) in 4 subjects. EMG amplitude maps of the area surrounding FDI were roughly circular with a diameter of 1-2 cm for responses more than 60% of maximum response. In each subject the 3-D coordinates of the grid and about 300 points on the hemisphere were acquired with a magnetic digitizer. A sphere was fitted to the grid to determine the line perpendicular to the scalp at the maximum. The other points were used as a surface for registration with the subject's head surface on MRI. The parameters obtained from the registration were used to map the maxima into the MRI and to compute the intersection of the perpendicular line with each slice. The intersections were within about 1 cm of the precentral gyrus. This technique can also be used to map other types of electrophysiological data into images.

397.8

FAST MODULATION OF HUMAN MOTOR OUTPUTS DURING ISCHEMIC NERVE BLOCK IS MEDIATED BY UNMASKING OF INTRACORTICAL SYNAPTIC CONNECTIONS. I.P. Brasil-Neto, J. Valles-Sole, A. Pacual-Leone, A. Cammarota, E.V. Amassian, M. Hallett and L.G. Cohen*. Human Cortical Physiology Unit, Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892 and Department of Physiology, State University of New York Health Science Center at Brooklyn.

The amplitudes of motor-evoked potentials (MEPs) elicited by transcranial magnetic stimulation (TMS) in muscles proximal to a transiently ischemic limb segment increase for the duration of ischemia, and return to baseline level afterwards.

To determine the level in the central nervous system at which this fast modulation of human motor outputs takes place, we recorded H reflexes, maximal M responses, MEPs to transcerebral electrical stimulation (TES), MEPs to TMS, and MEPs to spinal electrical stimulation (SES) from muscles immediately proximal to an ischemic limb segment.

MEPs induced by TMS were larger during ischemia, whereas those induced by TES or SES were unchanged. Maximal H/M ratios were also unchanged, indicating that alpha-motorneuron excitability to segmental inputs was unaffected by ischemia.

Given the predominantly presynaptic activation of pyramidal tract neurons by TMS, as opposed to a more direct axonal activation by TES and SES, these findings suggest that intracortical unmasking of synaptic connections is the likely mechanism for short-term modulation in the human motor system during ischemic nerve block.
397.1

MOTOR NEURON CORRELATES OF DISHABITUATION AND SENSITIZATION OF THE GILL-WITHDRAWAL REFLEX IN APLYSIA
B.D. Hawkins1, T.E. Cohen1, R. Katsel2, & R. Kalil2. 1Swarthmore College, HAVEN, CT; 2University of Medicine & Dentistry of New Jersey, Newark, NJ.

We have developed a simplified preparation, consisting of the isolated mantle organs of Aplysia, which undergoes habituation, dishabitation, sensitization, and classical conditioning of the gill-withdrawal reflex (Hawkins et al., 1987, 1990). We previously established that the LE siphon sensory neurons contribute to the reflex in this preparation (Cohen et al., 1993). To investigate the role of different motor neurons, we hyperpolarized them and found that LGD1 contributes approximately 70% of the response. We have recorded correlations of habituation, dishabitation, and sensitization in LGD1. There is a decrease in evoked firing of LGD1 during habituation, and an increase 12.5 but not 2.5 min after shock during dishabitation and sensitization. Conversely, there is an increase in spontaneous firing of LGD1 2.5 but not 12.5 min after shock. To further analyze the mechanisms of these effects, we first hyperpolarized LGD1 and measured the area of the evoked complex PSP. As evoked firing, there is a decrease in PSP during habituation, and an increase 12.5 but not 2.5 min after shock during dishabitation and sensitization. We also measured the gill-withdrawal produced by a constant number of spikes in LGD1, and found an increase 2.5 but not 12.5 min after shock. These results suggest that habituation in this preparation is largely due to depression at central synapses, whereas dishabitation and sensitization are due to central and peripheral facilitation with different time courses. 2.5 min after shock there is a large peripheral effect, perhaps due to FIP at the neuromuscular junction, and probably because of competing transient inhibition. 12.5 min after shock there is no peripheral effect and significant central facilitation.

School, Boston, MA 02115.

Previous research has demonstrated that symmetric brain regions are larger than their asymmetric counterparts and that this difference resulted from a greater number of neurons in the symmetric brain (Galaburda et al., 1989). 

Neuropsychologia 28, 833-860, 1987). In this study, we tested the hypothesis that this relationship between cell number and asymmetry would be consistent for different studies as characterized by increased standard labeling.

Nineteen Wistar rats were sacrificed in adulthood by transection of the saline solution by 4% paraformaldehyde. The brains were post-fixed for 46 hours before being placed in buffered sucrose solution, sectioned coronally at 30 μm, and one series of every tenth section stained for Nissl substance with Thionin.

Adjuvant series were immunohistochemically stained for vasoactive intestinal polypeptide (VIP) or parvalbumin. The somatosensory/atomotor cortices of the right and left hemispheres were parceled on the Nissl-stained sections, their volumes determined, and the number of labeled neurons within these architectonic regions estimated.

Consistent with previous findings, symmetric brain regions are larger than asymmetric brain regions. In addition, there is a greater number of parvalbumin- and VIP-immunoreactive neurons in the larger of the two sides. These studies also appear to be greater cell packing density of parvalbumin-, but not VIP-immunoreactive neurons on the larger of the two sides. These results suggest that there may be asymmetric concentration of neuronal types associated with architectonic asymmetry. Because of the different proportion of parvalbumin-immunoreactive neurons in the larger side, the later may have different functional properties consistent with cerebral dominance.

CORTICAL NEURONAL PROTEIN SYNTHETIC CAPABILITY IN HYDROCEPHALIC AND DECOMPRESSED ANIMALS. C.L. Wolfgang1, J.P. McAllister II1, and J.S. Way1. Dept. of Anatomy and Cell Biology, Temple Univ. School of Medicine, Philadelphia, PA.

The biochemical etiology of neurological deficits observed in hydrocephalic neonates and the utility of surgical decompression remains obscure because of the lack of a sensitive marker of neuronal function. Therefore, the present study quantified cytoplasmic RNA and nucleolar volume in order to assess the protein synthetic capability (PSC) of neurons in the cerebral cortex of hydrocephalic kittens. The effects of decompression via ventriculoperitoneal (VP) shunt placement was analyzed using the same techniques. Hydrocephalus was induced in cats at 10 days of age by intracisternal injection of kaolin. Some hydrocepha-
ilic animals received "early" (7-8 days post-kaolin, moderate ventri-
culomegaly) and "late" (11-14 days post-kaolin, severe ventriculo-
mega) VP shunts; all animals were compared to age-matched controls.

Brain sections were stained with azure B for stoichiometric binding to
cytoplasmic and nucleolar RNA. Cytophotometric analysis revealed a 19-
48% depletion in the PSC from motor, association and visual cortices
of both moderately and severely hydrocephalic animals. After shunting,
PSC returned to control levels only after early treatment; late shunt
produced slight improvement, but PSC remained 25-52% below
control levels. Since the normal function of neurons is dependant on
the PSC, it follows that cerebrocortical neuronal function is adversely
affected by infantile hydrocephaly, and that surgical decompression
may restore function, but only if performed at early stages of the disorder.

IDENTIFIABLE CNS GILL MOTOR NEURONS OF APLYSIA: FINAL COMMON PATH OR HIDDEN LAYER? J. Leonard1, J. Edstrom1, M. Martinez2, R. Ferrus1, R. Goldmeier2, F. Lukowik3, M.K. Hartfield1 Science Center, Newport, OR 97365; Dept. of Med. Physiol., Univ. of Calgary, and Dept. of Zool. Univ. of Alberta, Edmonton, Canada.

The hypothesis that Aplysia gill-withdrawal behaviors could be
adequately explained by parallel monosynaptic reflex arcs between six
PGV gill motor neurons (PGNs) and the LE sensory cluster
(Kupfermann et al., 1974; review in Kandel 1978) made clear,
failable predictions that have stimulated experimental work for many
years. Results show that the hypothesis is incorrect, both in detail
(LE cells fire after Cohen et al., 1991; other cells active, Zecevic et al., 1989; etc.) and in principle (PGV
necessary for neither behavior nor learning, Petetz et al. 1976;
behavior not reflex, Leonard et al., 1989; behavior not necessarily
 correlated with MN acticity, Colebro & Lukowik, 1988; Leonard
et al., 1991; In press). Further experimental work requires a new
hypothesis consistent with the available data, i.e. that the CNS is
sufficient for these behaviors and that the CNS mediates behavioral
state and the two interact to produce the behaviors of the intact
preparation. We propose that the known CNS GPNs along with a set of
inhibitory GPNs, can vary in efficacy, both individually and in
concert, with learning and behavioral state and that the parallel CNS
pathways act to set the gain of the gill behavior and to phase shift the
int II network. The model suggests that the CNS GPNs are a biological
realization of the hidden layer of a neural network. Supported by MRC
(Canada), AMFHR, NIMH & NSF.

Previous studies indicated that habituation results in a decrease in the number of active neurons responding to the siphon touch and demonstrated the diversity of habituation effect on individual neurons. In the present experiments, a longer habituation training (up to 60 stimuli with 30 sec of inter-stimulus interval) were given. The habituation effects on both the overall neuronal response and the response pattern of individual neurons were examined. The overall neuronal response shows a good correlation with the decrease in gill contraction during habituation. They both have two phases: a rapid decrease at the beginning of habituation followed with a plateau (zero for the gill contraction). The plateau in the overall neuronal response indicates that the system maintains a constant response level (20-30% of control level) even after complete habituation was achieved. Additional analysis will aim at attributing these two phases to individual neurons or groups.

Supported by NIH grant #NS08437.

Two second messenger pathways, mediated by CAMP-dependent protein kinase A (PKA) and by protein kinase C (PKC), are known to contribute to the presynaptic facilitation of the gill withdrawal reflex in Aplysia (Braha et al., 1986; Sacktor and Schwartz, 1986; Sugita et al. 1992). We studied the relative contribution of each of these on STR-induced short term facilitation at nondepolarized, partially depressed (reduced to 40% of their initial level) and highly depressed synapses (reduced to 10% of their initial value) and on the spontaneous release. We used Rp-CAMP, a specific PKA inhibitor, and H7, a general kinase inhibitor that preferentially blocked PKC in intact Aplysia neurons. Our results show that the PKA inhibitor 1) completely prevents the facilitation of nondepolarized, 2) blocks a small component of the facilitation of highly depressed synapses and 3) has no effects on the modulation of spontaneous transmitter release by SHT. By contrast, H7 1) has no effect on the facilitation of nondepolarized synaptic connections, 2) blocks only partially the facilitation of moderately depressed synapses, 3) blocks a large component of the facilitation of highly depressed synapses and 4) blocks completely the enhancement of spontaneous release by SHT. Our results suggest that whereas activation of PKA is sufficient to trigger the facilitation of nondepolarized synapses, activation of both PKA and PKC is required to facilitate depressed synapses and that the contribution of PKC becomes progressively more important as synaptic transmission becomes more depressed.

The synaptic growth that accompanies S-HT-induced long-term facilitation of the sensory-to-motor connection in dissociated cell culture is associated with a down-regulation of cell adhesion molecules (αPCAMS) on the surface membrane of the sensory neuron (Mayford et al., Science, 1992). Down-regulation is achieved by a protein synthesis dependent activation of the endosomal pathway leading to internalization of αPCAMS (Bailey et al., Science, 1992). Unlike classical receptor-mediated endocytosis, the endocytosis of αPCAMS is triggered by the binding of ligand to a heterologous receptor, the S-HT receptor, and consequent internalization of αPCAMS. To explore the mechanisms of this novel form of transmitter receptor endocytosis in sensory motoneurons, we examined the effects of CAMP, a second messenger activated by S-HT, on the distribution of gold-conjugated mAb specific to αPCAMS. We found that a 1.5-h incubation in CAMP + IBMX (10 -5 ) stimulated the action of S-HT. It led to a 50% decrease in gold-labeled complexes on the surface membrane (10.8 ± 1.1) when compared to either untreated cells (22.6 ± 1.8; p < 0.001) or cells bathed in IBMX alone (122 ± 2.4; n = 5; p < 0.01). Accompanying the decrease in surface labeling was a sevenfold increase in the percentage of gold within the cell (31.6 ± 1.4 vs 4.3 ± 0.9; p < 0.001). These findings suggest the endocytic activation triggered by S-HT can be mediated through the CAMP cascade (either alone or in combination with other second messengers) and now allow us to track the steps within the sensory cells whereby S-HT binding to its extracellular receptor leads to the internalization and degradation of αPCAMS.

One characteristic feature of long-term memory to the tail-withdrawal reflex is that it requires both RNA and protein synthesis, accompanied by structural changes. In an attempt to identify the molecules involved in the process, we have cloned and sequenced one of the serotonin (S-HT)-induced proteins in the sensory neurons of the tail-withdrawal reflex of Aplysia. The protein sequence inferred from the cDNA clone demonstrated that it is the light chain of clathrin. 5HT mapping analysis showed that the steady-state level of clathrin light chain mRNA was increased by S-HT, suggesting that S-HT induces clathrin light chain mRNA expression. In addition, Northern blot analysis indicated that the Clathrin light chain is encoded by a single gene. This gene has all the important structural and functional domains of both light chain A and B of mammalian clathrin, suggesting that it may represent the original form from which the vertebrate chains developed. Serotonin increases the number of clathrin-coated vesicles and neurites in Aplysia sensory neurons. These coated vesicles are involved in the internalization of Aplysia cell adhesion molecules and probably contribute to the structural change of sensory neurons during long-term facilitation.

Tail shock-induced sensitization in Aplysia produces spike broadening and increased excitability in tail sensory neurons (SNs). Both of these effects are mimicked by serotonin (S-HT) but can be pharmacologically dissociated: cyproheptadine suppresses the S-HT-induced spike broadening but not increased excitability (Mercer et al., 1991). We report here that these two modal effects of S-HT can also be dissociated by their time course.

We recorded extracellular spike responses in tail SNs taken before sensitization and examined both spike broadening and excitability. A range of S-HT concentrations (0.5μM-5μM) produced significant increases in spike duration and spike broadening with no change in the duration of excitability (3.2 ms ± 0.3 repectively). However, at 9μM S-HT induced spike broadening lasted significantly longer than increased excitability (3.2 ms ± 0.25 ms; p < 0.01) and more. In contrast, the excitatory response was observed only under the 9μM S-HT concentration. This suggests that spike broadening may have a threshold level to produce excitatory action potentials. The time course revealed that both of these effects follow a discrete washout. At the lowest concentrations (0.5μM) only marginal differences were observed. However, at 2μM S-HT-induced spike broadening lasted significantly longer than increased excitability (3.2 ms ± 0.25 ms; p < 0.01). Thus, serotonin-induced spike broadening and excitability were dissociated in two ways: (1) spike broadening was preferential at carew (200μM) present during SHT applications (N=5); SHT increases in excitatory facilitation were blocked (0.55 ± 0.54%); however, increases in excitatory facilitation was still observed (increase = 73.1%, p<0.005). Moreover, a between-group analysis showed that, even though SHT facilitated the release of GABA, SHT-vegetative facilitation was significantly increased (70 ± 5%); in contrast, SHT facilitated the release of GABA, SHT-vegetative facilitation was still observed (increase = 73.1%, p<0.005). Moreover, a between-group analysis showed that, even though SHT facilitated the release of GABA, SHT-vegetative facilitation was significantly increased (70 ± 5%); in contrast, SHT facilitated the release of GABA, SHT-vegetative facilitation was still observed (increase = 73.1%, p<0.005). Moreover, a between-group analysis showed that, even though SHT facilitated the release of GABA, SHT-vegetative facilitation was significantly increased (70 ± 5%); in contrast, SHT facilitated the release of GABA, SHT-vegetative facilitation was still observed (increase = 73.1%, p<0.005). Moreover, a between-group analysis showed that, even though SHT facilitated the release of GABA, SHT-vegetative facilitation was significantly increased (70 ± 5%);

Protein kinase A (PKA) has been implicated in presynaptic facilitation in Aplysia. Four forms of the catalytic (C) subunit of the holoenzyme (R(C)C) are the products of a single gene: N1A1, N1A2, N2A1, N2A2 (Glabe et al., 1992). The A1 and A2 polypeptide units arise through alternative splicing of exon cassette encoding residues near the active site and exhibit different substrate specificities and affinities for a regulatory (R) subunit (Biochemistry 30, 15246 (1991)). The N1 and N2 forms arise from alternative promoters and contain complementary N termini originating at a point distant from the active site. Thus, the N termini may be involved not in the direct modulation of catalysis but in substrate targeting i.e. the binding of free C subunit of cellular locations in the vicinity of substrates. Evidence for this comes from in vitro phosphorylation of neuronal membranes using recombinant N1A1 or N2A1 subunits. The N1A1 form phosphorylates two polypeptides of ~30 kDa and ~10 kDa significantly more rapidly then does N2A1. In Aplysia neurons, there exist at least five forms of R subunit, four of which are homologs of vertebrate R (Neuron 8, 387 (1992)). We now provide evidence for R1 subunits in Aplysia neurons: (i) high molecular weight R1-binding proteins have been demonstrated by using 32P-labeled bovine filo to probe protein blots; (ii) rapid CAMP-independent phosphorylation of two ~50 kDa CAMP-binding polypeptides is stimulated by N1A1 or N2A1 subunits. By contrast, the recombinant Aplysia R1A1R1 (type I) subunit is not phosphorylated by C in vitro. R1-binding proteins may anchor PKA holoenzyme near selected substrates. (Supported by the NIH).

HABITUATION OF THE JUMP REFLEX TO OlfACTORY CUES IN NORMAL AND MUTANT DROsophILA. T. Tuyls* and S. Kos, Beckman Neuroscience Laboratory, Cold Spring Harbor NY 11724 and Department of Biology, Brandeis University, Waltham MA 02254

We are interested to know whether the molecular mechanisms of memory formation after nonassociative and associative learning are similar. Since learning through different sensory modalities may involve different molecular mechanisms and since our associative learning assay is based on odor-odor pairings (Tuyls & Quain, 1985, J. Comp. Physiol. A 157: 263), we have developed an assay for nonassociative learning based on olfactory cues. We found that flies would jump up - as if to fly away - when presented with a concentrated, noxious odor stimulus (10% benzaldehyde), as described by McKenna et al. (1989, PNAS 86: 8118). We then semi-autonomously the olfactory jump procedure to deliver 4x presentations of an airborne odor stimulus repeatedly to individual flies. With such a procedure, the flies eventually stopped jumping.

This response decrement in wild-type (normal) flies shows many definitive behavioral properties of vertebrate habituation: More stimulus trials are required for a fly to stop jumping if the interval of time between trials (ITI) is longer. Fewer trials are required for a fly to stop jumping if the odor concentration is lower. After habituating, 80% of flies will jump in response to the odor stimulus if they have been habituated by a novel, strong stimulus (75 s of violet). Analysis of the (associative) learning/memory mutants has revealed that a) acquisition of habituation is slower than normal, spontaneous recovery (memory retention) is faster than normal and dishabitation is normally low in dance mutants and c) acquisition, spontaneous recovery and dishabitation is normal in amnesic and lather mutants. In addition, acquisition of habituation is faster than normal in mutants with abnormal olfaction or locomotion. These results are consistent with the notions that a) the chocolate mutation affects memory, b) the dance mutation affects both memory and sensory or motor processes and c) short-term memory is normal in amnesic and lather.

MORPHOLOGICAL AND BEHAVIORAL DEVELOPMENT IN THE EMBRYONIC MEDICINAL LEECH. Shirley A. Reynolds, Andrew Baeder, and William B. Kristan, Jr.* U.C.S.D. Biology Dept., 0322, La Jolla, CA 92037

As a preliminary to studying the development of neuronal circuits responsible for different behaviors, we have been studying the normal course of behavioral development in the medicinal leech, Hirudo medicinalis. Most leech behaviors are first seen during embryogenesis. To establish staging criteria which cover the time of behavioral development, we have been tracking the development of several morphological features as well as the development of both spontaneous and mechanically-evoked behavior. We have found that behavioral responses to light mechanical stimulation vary among different body regions. At the anterior and posterior ends, the predominant response to mechanical stimulation is shortening. The predominant response at the midbody region early in development is circumferential indentation, which is replaced by local bending. A single mechanical stimulus will sometimes produce a combination of two simple behaviors, which can occur either sequentially or simultaneously. The percentage of mechanical stimuli which produce a behavior response reaches maximum at about one week after the animal first becomes responsive. Swimming develops as progressive refinements of the early swim-like behavior. In contrast, crawling is a complex behavior resulting from the successive integration of simpler behaviors, namely progressive elongation and contraction, rear sucker action, and front sucker action. Both crawling and swimming appear to be fully developed by the end of embryogenesis when the juvenile leech emerges from the cocoon. This work was supported by an NIH research grant (MH41390) and by Deutscher Forschungsgemeinschaft.

HABITUATION AND DISHABITUATION OF THE PROLEG WITHDRAWAL REFLEX IN LARVAL MANUCA SEXTA. D.E. Wiel* and J.C. Weeks, Institute of Neuroscience, University of Oregon, Eugene, OR 97403

Habituation was tested by repetitively deflection a single hair while measuring proleg retraction using either video analysis or a force transducer. Interstimulus intervals ranging from 30 s to 10 min produced significant response decrement. Dishabituation in response to a tactile stimulus delivered to the body wall of the habituated segment was also significant. These studies indicate that the proleg withdrawal reflex of the tobacco hornworm is capable of behavioral habituation and dishabitation. Studies of the neural correlates of these behavioral plasticities are underway.

A RETINA SPECIFIC PROTEIN EXPRESSED TRANSIENTLY ON ZEBRAFISH OPTIC NERVES. H. Chang and W. Gilbert*. Dep. of Cell. and Dev. Biology, Harwood Univ., Cambridge, MA 02138

We are interested in identifying molecules involved in neural development and axonal pathfinding in vertebrates. Zebraschiff provides an ideal system because it can be easily studied at early stage and its nervous system is relatively simple. We have generated a monoclonal antibody, 7A11, which recognized an antigen expressed specifically in zebrafish retina. Immunostaining showed that 7A11 Mabs first stains retinal ganglion cells around 38 hours after fertilization, later (3 days) it also stains inner plexiform layer (IPL) and inner nuclear layer (INL), at adult retina it only stains IPL and amacrine cells. Most interestingly, this optic nerve protein during the initial outgrowth of retina ganglion axons at embryonic stage, but no longer expressed at the adult optic nerve. The expression pattern of 7A11 antigen suggested it may involve in the development and guidance of optic nerve. Immunoblots showed that 7A11 Mab stained a single band at 28 KD, following SDS-PAGE of zebrafish retina sample. Studies are in progress to clone the gene for 7A11 antigen and to determine its role in retina development.

399.3

Mab E1 (SG-11) delineates neuronal cell classes in neuronal-glia interaction systems. A. Zimmermann* and A. Sutter. Institute of Zoology, Technical University, Schmittsplatz 3, 61 Darmstadt and Dept. of Immunopharmacology-Neuroimmunology Group, F. Merck, 61 Darmstadt F.R.G.

Axonal growth processes are controlled by neurotrophic factors as well as by neuronal contact. We describe a neural cell surface antigen E1, which appears to be involved in axonal growth regulation.

Mab E1 defines an early antigen of chick embryonic dorsal root ganglia (DRG). In the DRG E1 antigen is exclusively represented on neuronal cells until embryonic day 7 (E7). At later times it also appears on a fraction of DRG neurons. When antigen expression was analyzed in indirect immunofluorescence staining in single cell neuronal-glia cultures of chick DRG or in DRG explant cultures grown in the presence of nerve growth factor (NGF), it became apparent that E1 positive neurons displayed a growth-promoting effect on the DRG neurons. E1 negative neurons grew associated and became encephalized with E1 positive glial cells while E1 positive neurons did not. When Mab E1 was added to neuronal-glia cultures of chick DRG (E8), the NGF induced neurite outgrowth was blocked completely, suggesting a role of E1 antigen in neurite outgrowth which would appear to be glia mediated in this case of the E1 negative neurons. Also in the CNS the Epitope is widely distributed. Here, motoneurons of the spinal cord constitute one example for an E1 negative motoneuronal cell class growing out into the periphery in close association with E1 positive glial cells.

NEURITE OUTFLOW FROM CULTURED EMBRYONIC MOUSE RETINAL CELLS IS SUBSTRATE DEPENDENT. *C.F. Lapasset and I.M.H. Hankins.

*Univ. Pittsburgh, Pittsburgh, PA and Medical College of Ohio, Toledo, OH.

Is neurite outgrowth from mouse retinal ganglion cells (RGCs) of different development ages substrate-dependent? Previous studies indicate that RGC neurite outgrowth may be influenced by specific substrate molecules, but it is not clear whether the early developing RGCs show a preference for outgrowth on any particular substrate. To address this issue, we have monitored neurite outgrowth in vitro from dissociated E12-16) or early postnatal (P0-6) CD-1 mouse retinal cells on purified substrate molecules (L1, NCAM & laminin). RGCs from fetal retina were identified by staining with an antibody to neurotransmitter specific β-subunit (TuJ1), a specific marker for early differentiating RGCs (Watanabe et al., J Neurosci 22:85). RGCs from neonatal animals identified in vitro after emulsifying in tissue. This ability for given substrates to support neurite outgrowth was also compared with their expression in vivo.

Cultured embryonic cells expressed a variety of morphologies (unipolar, bipolar and multipolar), and all cells were TuJ1*. Neurite outgrowth on L1 was apparent shortly after cell attachment, and was vigorous after 18-24h (many cells with neurites exceeding 500 μm) (indicating a growth rate of about 1mm/day). Few neonatal RGCs survived beyond 24h, although RGCs survived on L1. Outgrowth from embryonic retinal neurons on non-L1 substrates was detectable only a few days later. The majority of RGCs on NCAM or laminin during one- to two-week cultures, elongation was seen. Neurite outgrowth from RGCs on laminin was seen only rarely. In contrast, cortical cells from the same embryos showed vigorous outgrowth on L1 and NCAM substrates. These data show that developing (E12-16) RGCs prefer to grow on L1 substrates; at some point between E16 and birth, RGCs lose their ability to survive and extend neurites on L1.

399.6

A NEW MEMBRANE PROTEIN ON CHICK SENSORY NEURONS. R.G. Perez*, Y.P.L. Yip, W. Halter, and J. Yip. Dept. of Neurobiology and Dept. of Physiology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

A 140 kD cell surface protein was identified by a monoclonal antibody (1A12) obtained from a mouse immunized with dorsal embryonic chick spinal cords. The protein is present on cultures of neurons in the CNS and PNS, but absent on glial cells and their axons. In spinal cord, the protein is present on a subset of primary afferents that project to the dorsal funiculi (DF). During early development, the 1A12 antigen is found in dorsal root ganglia, sensory components of peripheral nerves, and central projections in the DF. Later in development (E16-hatching), 1A12 ceases to be found in the DF and is present only in the lateral dorsal horn of spinal cord. In the visual system, 1A12 is present in the retina, optic nerve and optic tract in early stages of axon outgrowth. It is not present in the optic fiber layer of the tectum indicating that the expression of the antigen ceases in optic fibers reach this tissue. By E10, the antigen disappears entirely from the visual system indicating that expression of the antigen is developmentally regulated. The restricted spatiotemporal distribution of the antigen suggests that it is important for the development of different projections.

399.4

We have shown that a protease inhibitor of leupeptin analog, acetyl-Leu-Leu-Val-aldehyde (LLaAl) or benzoylcarbonyl-Leu-Leu-Val-aldehyde (ZllAla) induces neuronal differentiation in P12 cells. In an attempt to identify a target molecule(s), Leu-Leu-Val was immobilized and used as a ligand for affinity chromatography.

Proteins of 35, 35, and 160 kD were isolated from the membrane and cytoplasmic fraction of P12 cells. ZllAla had no effect to induce neurite outgrowth in P12 cells, and 35, 35, and 160 kD did not bind to the ZllAla-affinity column. Several lines of evidence suggest that these proteins are clathrin light chains (35kD and 35kD) and clathrin heavy chain (160kD), components of clathrin which is well known for its role in endocytosis. Separation of clathrin into its heavy and light chains showed the clathrin heavy chain had ability to bind to the ZllAla-affinity column directly. Furthermore, ZllAla but not ZllAla enhanced the rate of polymerization of clathrin triskelion to the coat structure. These results suggest that the role of clathrin should be incorporated into a model describing patterns during the initiation of neurite outgrowth.

**399.7** MODULATION OF LAMININ'S NEURITE-PROMOTING ACTIVITY. D. Muzi,* Developmental Neuro-Oncology Lab., Departments of Pediatrics and Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610

Purified laminin (LN) promotes neurite outgrowth by regenerating neurons and NGF-treated PC12 cells. Schwann cells secrete LN and other extracellular matrix molecules including proteoglycans (PGs) that bind to LN but do not affect its activity. In contrast, neurite-promoting activity is completely inhibited when LN is complexed with a Schwann cell-derived, high-density, chondroitin sulfate/heparan sulfate PG. The inhibitory PG appears to specifically address LN since it does not substantially inhibit the neuritic response of PC12 cells to other matrix molecules. Initially I observed, that in contrast to purified LN, LN activity in crude extracellular matrix extracts was not affected by the PG. Other LN-binding proteins including entactin and collagen type IV were not protective. In addition, when purified LN was first complexed with the inhibitory PG, inhibition was not reversed by the addition of LN-binding molecules including other PGs. Neurite-promoting activity was, however, restored (de-inhibited) by treating inhibited LN-PG complex with the metalloprotease stromelysin. Apparent, stromelysin selectively abolishes the inhibitory activity allowing LN to express its neurite-promoting activity. This mechanism for de-inhibition may be particularly relevant since PC12 cells secrete stromelysin at the onset of neurite-outgrowth.

These findings suggest that the neurite-promoting activity of LN is modulated by forming complexes with either protective or inhibitory PGs and this modulation is counteracted by protease(s) secreted during neurite outgrowth.

**399.8** DEGRADATION FRAGMENTS OF L1 ANTIGEN ENHANCE TYROSINE HYDROXYLASE-POSITIVE NEURITE OUTGROWTH IN MESENCEPHALIC CELL CULTURE. M. Pollrat,* J. B. Williams and W. F. Fried, NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20020.

The L1 antigen is implicated in axonal elongation during formation of major fiber tracts and promotes neurite outgrowth in cell cultures that during injury of brain tissue, neuronal surface molecules such as L1 antigen are shed, and degradation fragments may therefore be present adjacent to the damage. These L1 fragments might then influence regeneration and injury-induced growth. We have evaluated neurite outgrowth from tyrosine hydroxylase-positive (TH+) E13 mesencephalic neurons grown in vitro on intact mouse L1 antigen and three degradation fragments separated by molecular weight. Mouse MAG, laminin, fibronectin, poly-D-lysine, and total cell raft served as control substrates. L1 antibodies were added to one set of cultures (experimental), and compared to control cultures containing normal rabbit serum. After 3 days in vitro, the cultures were stained using an antibody against TH, and the length of the TH+ neurites was measured by computer-assisted image analysis in a double blind fashion. TH+ neurites were significantly longer when grown on intact L1 antigen, as well as on each of the three degradation fragments, as compared to the control substrates. As compared to control normal rabbit serum, L1 antibody blocked L1 immunoprecipitation and eliminated the neurite-promoting effect of the L1 substrate and of the L1 degradation products. These data suggest that the presence of L1 fragments in vivo might influence regeneration or synaptic restructuring.

**399.9** NCAM-POLYSIALIC ACID AND L1 EXPRESSION ON GROWING AXONS OF ISOLATED NEURONS. W. T. Kim, W. F. Collins*, and A. N. van den Pol.

Although NCAM has been considered to be a homogeneously distributed neuron adhesion molecule with a general role in development, NCAM expression at the cellular level may vary in molecular density and the amount of polysialic acid (PSA), thereby influencing adhesion and axonal growth. To study the relative densities of NCAM and PSA on the different surfaces of single isolated neuronal cells, we used immunogold cytochemistry and digitally-processed backscatter electron imaging in an Amray 1810 scanning electron microscope. Based on the gold particle density per membrane area from thousands of images representing all surface membrane domains of isolated cells, we found NCAM immunoreactivity distributed evenly throughout the plasmalemma, whereas PSA immunoreactivity different cells in the same culture dish varied as much as 222%. PSA, which may reduce the homophilic binding of NCAM, was strongly expressed on axonal growth cones and their filopodia. PSA immunoreactivity was found at higher densities (37% ± 12% S.E.) on axons than on dendrites of the same cell in 6 out of 7 neurons, and at higher densities (35% ± 11%) on the distal axon near the growth cone than on the proximal part of the same axon in all 7 cells. Since NCAM may influence the homophilic binding of the L1 molecule, we undertook parallel examination of L1. The presence of NCAM-PSA and L1 on the growth cone of axons, together with evidence of a strikingly heterogeneous distribution of these molecules in the cellular microenvironment, support the hypothesis that NCAM-PSA and L1 may participate in some aspects of axonal extension and guidance.

**399.10** DIFFERENTIAL MODULATION OF NEURONAL POLARITY BY EXTRACELLULAR MATRIX AND CELL ADHESION MOLECULES. A. Lochter* and M. Schachner, Department of Neuropathology, Swiss Federal Institute of Technology, CH-8093 Zurich, Switzerland.

The effects of extracellular matrix glycoproteins and cell adhesion molecules on neurite growth have been discussed mainly in the context of promotion of neurite initiation and elongation. Recently, however, there is growing evidence for inhibition of neurite growth into a number of different environments and substrates. The aim of these studies was to investigate the effects of extracellular matrix glycoproteins on the neurite growth of rat sympathetic neurons. Neurons were isolated and grown on polylysine-coated coverslips in standard medium containing 5% horse serum. After 2 days in vitro, the cells were processed for immunohistochemistry with antibodies against the cell adhesion molecule L1 and the lectin concanavalin A. The results of these studies suggest that the presence of L1 fragments in vivo might influence regeneration or synaptic restructuring.

**399.11** GROWTH CONE COLLAPSE INDUCED BY MEMBRANE-BOUND MOLECULES MAY BE MEDIATED BY PERTUSSIS TOXIN (PTX)-SENSITIVE GTP-BOUND PROTEINS. T. Kojima,* S. Yamanaka, S. Matsuura, S. Saitou, T. Varanasi, S. A. Stittmier, and M. C. Fishman, Developmental Biology Lab. and Cardiovascular Res. Ct., Massachusetts General Hospital-East, Charlestown, MA 02129.

Inhibitory signals to growth cones are crucial for the regulation of axonal pathfinding. The transduction mechanisms that mediate such "stop signals" are poorly understood. The collapse of growth cones in culture has been used to partially isolate inhibitory substances (Kumar et al., Science 257:702-705, 1992). We have recently demonstrated that G0 is one of the major proteins in growth cone membranes. In the present study, we examined the potential role of G0 protein in growth inhibition, using the growth cone collapse assay. CHAPS-solubilized collapsing activity of chick brain membranes causes growth cone collapse of both DRG and mouse cerebellar neurons, both in vitro and in vivo. The collapsing activity of DRG membranes is abrogated by octylglucoside-induced elimination of DRG growth cones in DRG neurons, and this effect is also inhibited by PTX. These results suggest that some of the membrane-bound inhibitory signals to growth cones may be linked to specific intracellular responses. However, the exact nature of this process is not fully understood and requires further investigation.

**399.12** PURIFICATION OF GROWTH CONE COLLAPSE-INDUCING GLYCOPROTEIN FROM ADULT CHICKEN GREY MATTER. Geoffrey M. W. Cook, Alan R. Johnson, Marina S. Gordon, Scott A. Akker and Roger J. Keynes.*

Department of Anatomy, University of Cambridge, Cambridge, U.K.

Adult avian grey matter contains a glycoprotein fraction that causes growth cone collapse in vitro (Abatr. Soc. Neurosci. 16: 77, 1990). We have also found collapse activity in mammalian central nervous system substrates. The collapse activity is not extracted with purified polyanionic carbohydrate, but is retained by treatment with proteinase K. In this study, we have purified this activity from chicken grey matter. The avian activity is removed by immobilized proteinase K (PNA), and may be related to a somite-derived, PNA-binding glycoprotein that is involved in the generation of a segmented pattern of spinal nerves. As a further test of similarity between brain and somite activities, chick CNS (E7 retinal) neurons have been grafted into the spinal region of E3 chick embryos; like growing spinal nerves, retinal axons avoid posterior half-somite and grow exclusively anterior half-somite. A purification schedule for the isolation of the glycoprotein from chicken (E9) has been devised. Upon filtration, activity is retained with a membrane of 100,000 M.W. cutoff. The macrosolute is then fractionated by chromatography on immobilized reactive dyes in combination with non-denaturating gel electrophoresis. Material electroeluted from a single band, running just behind a BSA marker on a 10% gel, induces growth cone collapse. We hypothesize that this component may inhibit growth of normal and regenerating axon terminals in the adult brain.
399.15
PURIFICATION AND CHARACTERIZATION OF INHIBitory PROTEINS FROM RAT CNS MYELIN. E. Keller*, R. Rubin, C. Bandlow and M.E. Schwab. Brain Research Institute of the University of Zürich, CH-8029 Zürich, Switzerland.

CNS myelin and mature oligodendrocytes are inhibitory for neurite outgrowth. When myelin proteins from rat CNS are separated by SDS-PAGE, inhibitory activity can be eluted from the 35 kD and 250 kD region. Two monoclonal antibodies (IN-1 and IN-2) were raised against the gel-purified inhibitory fractions and were found to neutralize the inhibitory properties of CNS myelin and oligodendrocytes (Carroll and Schwab, 1990). In addition, IN-1 was found to promote regeneration of transected corticospinal and septo-hippocampal axons in young and adult rats (Schneid and Schwab, 1990; Cadelli and Schwab, 1991). In Western blots of rat CNS myelin, IN-1 and IN-2 bind to a partially overlapping set of bands of approx. 35, 45, 55 and >200 kD. These bands appear to be specific for CNS myelin, since they are not found in PNS myelin. Interestingly, and in contrast to several of the major myelin proteins, some of these bands are resistant to extraction with nonionic detergents, and can only be solubilized with SDS. An immunofinity column was prepared by covalently crosslinking the IN-1 antibody to an IgG matrix. After adsorption of SDS-separated, CHAPS-dissolved CNS myelin to the column, part of the inhibitory activity was retained by the column and could be eluted by moderately increasing the salt concentration. This suggests that the activity binds to the column by means of weak interactions. The inhibitory fraction eluted from the column contained several protein bands between 35 kD and 250 kD that could not be identified. Other proteins eluted by lowering the pH did not show inhibitory activity, nor did they crossreact with the IN-1 (mAb).

399.16
ARE INDUCED ACTION POTENTIALS THE TRIGGER FOR GROWTH CONE COLLAPSE IN SYMPATHETIC PREGANGLIONIC NEURONS? C.P. MacCallum, J.J. Walker, R.I. Hanson. Department of Biogy, University of Michigan, Ann Arbor, MI 48109.

When growth cones of chick sympathetic preganglionic neurons (SPNs) contact dorsal root ganglion neurons (DRGs) in vivo, the growth cones exhibit rapid, oscillatory increases in calcium and collapse. One possible mechanism for this pattern of calcium change is that contact with DRGs induces the generation of action potentials in the SPN. The depolarizing phase of the action potential might create a brief, rapid influx of calcium that would oscillate with the frequency of induced action potentials. To test this hypothesis, SPNs were retrogradely labelled with Dil in vivo, dissociated into single cells, and plated at low density on a laminin substrate. After 16 to 32 hours, the culture medium was replaced with a standard recording medium and whole cell current-clamp recordings were made from SPNs. These neurons had stable resting membrane potentials and did not spike spontaneously. Once a stable resting potential was established, a DRG was manipulated onto the SPN growth cone and the SPN membrane voltage was monitored for the occurrence of action potentials. Our major finding was that in recordings made at either room temperature or at 33° to 37°C, we never detected voltage changes from baseline levels during the ten to twenty minutes of contact with a DRG. This failure to observe action potentials was not due to compromised cell integrity, since action potentials could be evoked in all cells studied. These results suggest that the previously observed calcium oscillations were not due to DRG induction of action potentials in the SPN and indicate that other mechanisms for increasing intracellular calcium should be explored.

399.17

CG4 is a permanent cell line of oligodendrocyte-type-2 astrocyte progenitor cells (O-2A) that can be continuously maintained in the proliferative stage or differentiated to oligodendrocytes (OC) (Louis et al., J. Neurosci. Res., 1992, 30:193-204). The availability of the CG4 line offers a unique opportunity to analyze which factors are produced by O-2A progenitors and their derivatives. Here, we report evidence that culture media conditioned by CG4 cells contian(s) i) an activity that inhibits their own proliferation and ii) an activity that modulates the neurite outgrowth of CNS and PNS neurons. The antiproliferative activity is present in the media conditioned by CG4 cells that are expanded as differentiated O-2A progenitors, as well as by CG4 cells induced to differentiate to OC. The inhibition of mitotic activity is readily complete and fully reversible, and is accompanied by the conversion of the CG4 cell phenotype to A2B5+ cell progenitors to A2B5+ A4+ pre-OC. The production of the growth inhibitory activity does not depend on the nature of the mitogen used to propagate the progenitor OC4 cells (medium conditioned by the B104 oligodendroblasts, PDGF or FGF) and similarly, is not dependent on which mitogen is used in the test CG4 proliferation assay. These observations indicate that O-2A cells constitutively secrete and remain responsive to an autocrine antiproliferative factor. Cultures of newborn rat hippocampal neurons and ER chick ciliary ganglion neurons, were used to determine that after conversion to OC, CG4 cells also release into the medium a polyvalent/ laminin-binding neurite-promoting activity for CNS as well as PNS neurons. A preliminary characterization by gel filtration and cation-exchange chromatography, indicates that the neurite-promoting activity resides in a heat-stable, strongly acidic fraction of Mr >50 kD. Supported by NINDS grant NS-16349.
400.1

To study signal transmission and processing in large assemblies of neurons, patterned networks in which connections may be localized or even specified would be advantageous. We have already developed a method for the formation of self-organized neuronal networks in culture (A. Kawana et al; Soc. for Neurosci., 1991). Here, we describe simultaneous multichannel recording of the extracellular electrical activity and intracellular calcium concentration in such simplified neuronal networks.

A silica glass substrate was employed with 16 or 64 transparent electrodes, each of which was connected to the corresponding metal bond. A metal mask with holes at positions corresponding to the substrate wells was used to locate haptocameral or cerebral cortex neurons selectively in each well. We typically monitored optical signals from 4-8 cells. Under low magnification, each optical signal was divided into three types of cells. From the optical signals, we could distinguish three types of cells: (1) a fast signal, (2) a slow signal, and (3) a signal identified as a fast signal. The fast signal reflected action potentials, and the slow signal revealed glutaminergic excitatory postsynaptic potentials. Based on these results, we have constructed maps representing the spatial pattern of the neural response, and we have suggested a possible embryonic origin of the functional organization of the nucleus of solitary tract in the embryonic chick midbrain, supported by The MESC of Japan and The Mitsubishi Foundation.

400.2
OPTICAL MAPPING OF NEURAL RESPONSE PATTERNS TO GLOSAPHYRGEAL NERVE STIMULATION IN THE EMBRYONIC CHICK BRAIN STEM: T. Sakai, Y. Momose-Sato, K. Sato, A. Hirotta and K. Kamino, Department of Physiology, Tokyo Medical and Dental University, 1-5-45 Yushima, Bunkyo-ku, Tokyo 113, Japan.

In an effort to understand the functional organization/architecture of the brain stem, we have used multiple-site optical recording in order to study the action of the glossopharyngeal nerve in the embryonic chick brain stem. The intact and slice preparations including the brain stem and glossopharyngeal nerve were dissected from 7- and 8-day-old chick embryos and stained with the dye. When a brief electrical stimulation was applied to the glossopharyngeal nerve, optical signals were evoked in the brain stem. They were recorded simultaneously from 127 contiguous sites using a 12 x 12 photodiode array. In the evoked optical signals, two components, a fast, phosphenic-like signal and a slow signal, were identified. The fast signal reflected action potentials, and the slow signal revealed glutaminergic excitatory postsynaptic potentials. Based on these results, we have constructed maps representing the spatial pattern of the neural response, and we have suggested a possible embryonic origin of the functional organization of the nucleus of solitary tract in the embryonic chick midbrain, supported by The MESC of Japan and The Mitsubishi Foundation.

400.3

Normal function of the mature visual system requires precise pattern and axonal connections between the retina and the visual nuclei. Development of this preci pattern involves formation of a rough pattern followed by refinement in the pattern. Evidence suggests this refinement process involves communication between the postsynaptic cell and the presynaptic elements. The neurotransmitter nitric oxide (NO) has characteristics that would allow it to participate in this retrograde communication. This study examined the expression of NO in the developing chick tectum to determine whether it might be present in cells upon which retinal axons terminate. Diaphorase histochemistry was used to reveal the presence of nitric oxide synthase (NOS), the enzyme responsible for NO production. The expression of NOS by cells in the developing tectum coincided spatially and temporally with the arrival of retinal axons in the tectum. NOS expression reached a peak in the tectum at the time that refinement of the initial pattern of connections is occurring. Anterograde labeling of retinal axons with WGA/HRP showed that the processes of NOS positive cells in the tectum were coincident with the region of retinal axon termination. Diaphorase histochemistry with anophthalmic chick embryos showed that NOS expression is dependent on the presence of retinal axons. Northern blot analysis using a cDNA probe for NOS from rat brain (Bredt et al., 1991) verified the histochemical results. These results in the developing chick suggest that retinal axons interact with tectal cells that express NOS which is consistent with the possibility that NOS has a role in the refinement of the pattern of retinotectal connections.

400.4

The topographic projection from the retina to the tectum is thought to be formed by two mechanisms. First, a gross topographic map is formed by axon guidance and position cues, and later a refined map is formed by correlated activity in the retina. We have simulated the formation of a topographic retinotectal map by constructing a two-dimensional neural network based on correlated activity. Hebbian modifiable synapses, and adhesive marker gradients. We first show that in a two-dimensional model of the retina and the tectum, two gradients of adhesive markers are necessary to establish the correct orientation of the map in both axes. The model also shows specificity as well as plasticity in the connections when retinal rotation and hemi retinal ablation experiments are simulated.

Recent evidence has shown that temporal retinal fibers are repelled by posterior tectal membranes while nasal retina shows no preference. To test whether a hemi-retinal adhesion difference is enough to generate a topographic map, we constructed a neural network without gradients which specified that the temporal retina is less attracted to the posterior tectum and the dorsal retina is less attracted to the medial tectum while the nasal and ventral retinas show no preference. We show that a topographic map is formed, and under certain conditions, the map can form more rapidly than the map formed using the two dimensional gradient model. Thus the retina and tectum need not be specifically labeled by two gradients. Instead, hemi-retinal and hemi-tectal differences in adhesion or repulsion that separate each surface into quadrants of differential adhesion/repulsion provide enough positional information to allow proper map formation.

400.5

The cholinergic feedback loop in tectum, which mediates a presynaptic augmentation of retinotectal transmitter release, was either removed using the cholinergic neurotrans AF64A or blocked using nicotinic antagonists. Intracranial injection (IC) of AF64A (30-130 nmoles) resulted at one week in the selective elimination of the cholinergic-mediated polysynaptic field potential following retinal nerve stroke with monosynaptic transmission unaffected, and in the loss of virtually all immunostaining for choline acetyltransferase (CHAT). CHAT staining later recovered in some deep cell bodies but not in the fibers of the SFGS, the retinal terminatory layer. IC injection of AF64A at 18 days postcrush, when regenerating retinal fibers are beginning to form synapses, resulted in unsharpened projections when mapped at 60-80 days. There was a robust topographic map but the multiple receptive fields (MRFs) recorded at each tectal point averaged 34° vs 11° in vehicle-injected control preparations. AF64A treatment before nerve crush also blocked sharpening, ruling out a direct effect on retina/greyness/axon or fibre, as AF64A rapidly decomposes.

IC injection of a Bungarotoxin (BoTX) during regeneration also failed to sharpen the MRFs (P< 0.04). Pure BoTX does not, however, subtractably block the polysynaptic component, the backcalchulation of the monosynaptic field potentials. Interestingly, BoTX has been shown in the goldfish retinotectal system to be a competitive antagonist of the NMDA receptor, blocking the polysynaptic component, but did not fully block the backcalchulation of field potentials. We are still determining if and to what extent sharpness is maintained by blocking the cholinergic system. Supported by NEI grant EY-03736.

400.6

The development of topographic maps has been studied in many regions of the CNS. For technical reasons, however, the development of maps of functional synaptic connections of the visual system has been an object of study. We studied this issue using the corticothalamo (CR) system of the cat as a model. CR axons elaborate their terminal arborizations during the first postnatal month, and adult-like topographic distribution of the axons within the red nucleus is observed only after postnatal day 51 (P 51, Yoshida et al., 1990). Here we carried out intracellular recording from rubrospinal neurons of P1-P28 kittens and examined monosynaptic EPSPs evoked from different sites of the sensorimotor cortex, under Nembutal anesthesia. As expected from the anatomical results, most (26/28) rubrospinal cells in kittens aged P13-P28 showed responses indicating the presence of adult-like functional maps: cells antidromically activated only from C1 and those both from C1 and C11 receive input from the forelimb and hindlimb cortical regions, respectively. However, against what is expected from the anatomical results, cells in kittens aged P1-P7 responded to both C1 and C11 (8/10). This suggests that the basic feature of excitatory connectional map in the CR system is established at birth, before the maturation of CR axons and before clear topography of the axons is observable.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
SENEGATION OF SPINOCEREBELLAR MOSSY FIBER TERMINALS IN +/-LC MALIGN MICE. M.W. Vogel* and J. Princic. MD Psychiatric Research Center, Baltimore, MD 21228.

Spinocerebellar mossy fiber afferents segregate during early postnatal development into sagittal columns. Studies of other mouse mutants and x-irradiated rats (Nunes et al., 1988. J. Comp. Neuro. 273:120-136) suggest that Purkinje cells provide cues for the parasagittal sorting of these afferents. We have examined the distribution of spinocerebellar mossy fiber terminals in the +/-LC mutant to determine if mossy fiber terminal segregation is affected by the death of +/-LC Purkinje cells during the early postnatal weeks of development.

The distribution of spinocerebellar mossy fibers in 1 juvenile (P13) and 4 adult (P6-P9) +/-LC mutants and 1 juvenile (P44) and 2 adult wild type mice (P>90) was visualized by injecting 2% WGA-HRP into the anterior lumbar region of the spinal cord (T13-L2). Cerebella were subsequently processed for TMB histochemistry.

Although the granule cell layer is reduced in size in +/-LC mutants due to increased granule cell death, the distribution of spinocerebellar mossy fiber terminals is similar to that seen in wild type mice. Lumbar mossy fiber terminals predominate in anterior and posterior vermis. While mossy fiber terminal columns are present, they are less distinct than in the wild type. In some areas of the granule cell layer there are clear gaps between regions of dense terminal fields. In other areas, terminal fields are separated only by regions with less dense staining. The poorly defined columns in the +/-LC mutant may be explained either by a failure to form well segregated columns due to +/-LC Purkinje cell death, or by the merging of well formed columns subsequent to granule cell death. (Supported by NARSAD and a NIH Shannon Award)

Part of the habenular projection to the interpeduncular nucleus (IPN) is cholinergic and therefore may be subject to regulation by NGF internalized via membrane bound NGF receptors. Immunocytochemical studies indicate that cholinergic habenular neurons innervate their target subnuclei in the IPN in the second postnatal week, the only period during which lesion induced sprouting can be demonstrated. This suggests that either NGF production or NGF receptors might be developmentally regulated in this system. We therefore used immunohistochemistry to examine the distribution and expression of low affinity NGF receptors (antibody 192, a gift from Dr. Eugene Johnson) during the development of the IPN in the rat. At postnatal day 4, NGF receptor staining is present on axons in the pathway from the habenula that innervates the IPN but is absent in the IPN. By 10 days, recognition of immunoreactivity appears in the intermediate subnuclei of the IPN, the subnucleus receiving densest cholinergic innervation from the habenula. This staining reaches its maximum by 14 days. Thereafter, the receptor staining decreases and is no longer detected by day 28. These observations indicate that habenular axons express the low affinity NGF receptor transiently during the time that they innervate their targets. Supported by NIH Grants NS16556 (MM) and NS28856 (FH).

Mature vertebrates have specific synaptic connections between muscle afferent fibers and motorneurons that innervate limb muscles. Motorneurons receive monosynaptic excitatory inputs from homonymous and synergistic muscles, and polysynaptic inhibitory inputs from antagonistic muscles. To determine whether specific sensory-motorneuron contacts are established during early synaptogenesis in the mammalian spinal cord, we have studied the pattern of these synaptic connections in embryonic (E20-22) and newborn rats (P0-4). Nine hindlimb nerves were stimulated and the evoked potentials were recorded intracellularly from motorneurons of isolated spinal cords. Monosynaptic potentials were distinguished from polysynaptic potentials by their shorter latency and resistance to high-frequency stimulation. Demyelinating CFSRs reversed at 50mV membrane potential. In the embryonic spinal cord, 20% of motorneurons received monosynaptic excitatory inputs from antagonistic muscles. These inappropriate connections persisted until at least 3-4 days after birth, suggesting that some reorganization of synaptic connectivity occurs during postnatal development. Supported by RCDA (NS01314) and NS23088.

TRKA; AN ALTERNATIVELY SPliced FORM OF TRKA EXPRESSED BY NEURONS. P.A. Basker, C. Lomen-Hoerth, S.O. Meynin, E.M. Gensch, E. M. Shooter, Department of Neurobiology, Stanford University School of Medicine, Stanford, California. 94305.

The product of the Trk proto-oncogene has been identified as a signal-transduction receptor for nerve growth factor. This tyrosine kinase receptor was originally cloned from human K562 cells, a human leukemic cell line. We have identified a variant of the TrkA receptor, TrkAn, which differs from originally cloned form of TrkA by virtue of a small insertion within the extracellular domain. Both forms of Trk receptors are found within rats and humans and the amino-terminal domain of the inserted region is conserved between species. The inserted domain is encoded by a distinct exon whose presence appears to be regulated by tissue-specific alternative splicing. Several nonsense mutations contain both forms of TrkA mRNA. However, only TrkAn is expressed within CNS and PNS neurons of rat and humans.

Rat TrkA and TrkAn have been expressed in Cos cells and shown to specifically bind NGF and display slow dissociation kinetics and tryptophan sensitivity characteristic of the slow NGF receptor. Although the functional role subserved by these distinct forms of the TrkA protein remain unknown, the evolutionary conservation of the inserted domain across species together with the tissue-specific expression of the alternative transcripts indicates some functional role.

401.4

In the retina of a different animal species including non-human primates a significant number of ganglion cells (RGCs) have been reported to express the low affinity NGF receptor (p75-NGFR). The finding that the axonality of the adult retina can be rescued from degeneration by intracocular administrations of NGF led to the hypothesis that RGCs represent a neuronal population of the central nervous system sensitive to the action of NGF. Since the biological activity of NGF is mediated by high affinity membrane-bound receptor, we have studied the immunochemical distribution of both the trk proto-oncogene product p140, which likely corresponds to the high affinity NGFR, and the p75-NGFR, in transverse sections of human retina, to determine if the human retina p75-NGFR immunoreactivity is restricted to Muller cells while a high number of neurons in the GC layer is immunopositive for the p140-trk. On the basis of morphological criteria at least part of these neurons can be classified as RGCs. Conversely, in the rat retina a sub-population of RGCs and Muller cells are immunoreactive for both antigens. Binding studies and affinity cross linking/immunoprecipitation experiments performed in purified in vivo preparations of RGCs from neonatal rat retina confirm the presence of the high affinity NGF receptor. These results suggest that RGCs in humans could be sensitive to the action of NGF and raise the possibility that NGF, or a closely related molecule, could represent a new therapeutic approach for the treatment of retinal neurodegenerative pathology.

401.5

NGF GENE EXPRESSION IN MOUSE AND MAN: ROLE OF RETINOIC ACID RECEPTORS(RARs). C. Jiang*, M. Cartwright and G. Heinrich, Biomedical Medicine, Boston University Hospital, Boston, MA 02118.

Retinoic Acid(RA) induces NGF mRNA in mouse L cells and high and low RA concentrations in NGF binding in L cells and high RA concentrations in NGF binding corresponding to embryonic sympathetic neurons, suggesting an important role in coordinating induction of neuronal NGF dependence, responsiveness to NGF and NGF production region. We have previously cloned the mouse, rat and recently the human NGF gene promoter regions. An intrinsic AP-1 element is conserved in the NGF promoter region of all species, but an upstream AP-1 consensus sequence is human specific. Gel shift analysis showed that the RAR-alpha can bind to the upstream AP-1 consensus sequence in the human NGF but not to the conserved intrinsic AP-1 elements in either human or mouse NGF promoters. Furthermore, the RAR-alpha suppressed binding of AP-1 complex to all AP-1 sites. Several RA response elements(RARE) like motifs are found within 1000bp upstream of mouse and human NGF promoters suggesting direct binding of RARs and transcriptional regulation of NGF by RA in vivo. We are analyzing the differential binding of additional RARs(beta and gamma) to mouse and human NGF promoters and their functional significance, also beginning to address the relationship between the structurally and functionally defined RAREs and the AP-1 consensus sequences.

401.6

NGF INDUCES C-FOS IN THE BASAL FOREBRANNEURS EXPRESSING NGF RECEPTOR (NGFR); A DOUBLE IMMUNOCYTOCHEMICAL STUDY IN THE RAT. Z. C. Papež, M. Fusco, M.G. Núñez* and M. Bentivoglio, Institute of Anatomy, University of Verona; "Fidia" Research Laboratories, Abano Terme, Padova, Italy. 30120.

In order to further elucidate the role of NGF in the brain we investigated the expression of C-Fos, a proto- oncogene product, in brain structures particularly vulnerable to NGF. Mice were injected with NGF (20 µg in 10 µl) into the interpeduncular nucleus, a site known to express NGF in the basal forebrain. The lamination of C-Fos immunoreactivity was assessed in several brain structures of the basal forebrain. Numerous double-labeled neurons were observed, and the latter were slightly more numerous on the side ipsilateral to NGF administration. After the injection of a higher concentration of NGF (20 µg in 10 µl) a stronger response was observed, and the neurons were more numerous. The data suggest that NGF exerts a direct and specific activation of the basal forebrain neurons which express NGFR.

401.7 LAR TYROSINE PHOSPHATASE RECEPTOR: EXPRESSION IN THE MAMMALIAN NERVOUS SYSTEM. F. M. Longo1,2 and J. M. Le Beau3.

Depts of Neurology, UCSF Sch of Med., S.F., CA 94143 & the Diabetes Institutes, Eastern Virginia Med. Sch., Norfolk, VA 23510

The Leukocyte Common Antigen-Related (LAR) gene encodes a transmembrane receptor with extracellular domain sequence similarity to N-CAM. Tyrosine phosphatase receptor activity is associated with the growth inhibition of female cell lines transfected with the LAR cDNA and expressing LAR. In situ hybridization of low affinity NGF receptor mice showed that LAR expression was restricted to the nervous system and was not detectable in adult skeletal muscle.

401.9 DISTRIBUTION AND REGULATION OF MEMBERS OF THE TRK FAMILY IN THE RAT BRAIN. I.P. Metello1,2,3, P. Enard1,2, J. Bengzon4, M. Jakob1, Z. Kolay1,2, B. Daras1, O. Lindvall1, and H. Persson4.

Laboratory of Molecular Neuroendocrinology, Karolinska Institute, S-104 01 Stockholm, 2Reproductive Neuroendocrinology Unit, University Hospital, S-221 85 Lund, 3UAB CNRS 1200-Laboratoire d’Histologie-Embryologie, Universite de Bordeaux II, F-33405 Bordeaux

Tyrosine protein kinases (TPK-1 and TPK-2) are signal-transducing receptors for the neuropeptides Nerve Growth Factor, Brain-Derived Nerve Growth Factor, neurophin-3 and neurophin-4. We have identified cDNA fragments encoding a part of trk-A and trk-B that are respectively and characteristically a full-length cDNA clone encoding rat trk-A. Cells expressing mRNAs for the different members of the trk family were identified in the rat central nervous system by in situ hybridization using oligonucleotide probes designed from the isolated cDNA sequences. The expression of trk-A mRNA was found to be restricted to neurons of the basal forebrain, caudate putamen with few magnocellular neurons of the subiculum. In contrast, cells expressing trk-B and trk-C mRNAs were widely distributed in many areas of the brain, including olfactory formations, neocortex, thalamic and hypothalamic nuclei, brainstem nuclei, cerebellum and spinal cord motorneur. Comparison between our data and previous analyses of cells expressing mRNAs for neurophin receptors shows that different modes of action and different combinations of receptor mediate biological responses to neurophins in the adult rat brain. Moreover, seizures induced by hippocampal kindling lead to a rapid and transient increase of mRNA in the hippocampus for trk-A, a function receptor for BDNF. No change was seen in mRNAs for trk-B or trk-C, counterparts of the high-affinity NGF or NT-3 receptors, respectively. The increase of trk-A mRNA was blocked by the AMPA receptor antagonist NBQX. The transient increase of trk-A mRNA showed the same time course and distribution as previously reported increase of BDNF mRNA. This suggests that BDNF and its receptor could play a local role within the hippocampus in kindling-associated neural plasticity.

Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591

The neurotrophins, NGF, brain-derived neurotrophic factor (BDNF) and neurophin-3 (NT-3), appear to bind with similar affinities to the LNGFR, but with markedly different affinities to the trk family of tyrosine kinase receptors. NGF binds to the product of the trk proto-oncogene (trkA), while BDNF and NT-3 are ligands for the related trkB and trkC receptors. While the relative contributions of the trks and the LNGFR to binding affinity and specificity and to signal transduction are now being elucidated in vitro, little is known regarding the co-distribution of LNGFR and trk receptors in vivo. We have examined the relative distribution of cells expressing these different neurotrophin receptors in the adult rat brain using in situ hybridization and immunohistochemistry. LNGFR message and protein are present in restricted subsets of neural and non-neural elements. trkA mRNA appears to be expressed predominantly if not exclusively in neurons, and shows a close correspondence in its neuronal distribution to that of LNGFR. However, non-correspondence of expression of trkB mRNA and LNGFR is apparent in some brain areas. In agreement with retrograde transport and binding studies, cells expressing trkB mRNA are much more numerous and widely distributed than those which express either trkA or LNGFR. Most neurons which express trkB did not contain detectable levels of LNGFR mRNA or protein.

401.11 DIRECTION OF NFG SIGNALLING PATHWAYS BY PERTURBATIONS OF LOW-AFFINITY RECEPTOR (gp75NGFR) INTERACTIONS. S.M. Dunfield1, L.A. Murphy2, R.A. Betteau1, A. Biopolis3, Queen’s University, Kingston, Ontario, Canada K7L 3N6, and 4University of Alberta, Calgary, Alberta, Canada, T2N 2T2.

Growth factors share many signalling events but different biological effects indicate that signalling routes diverge. NGF signal transduction selectivity likely begins at the receptor level because this growth factor interacts with two receptors. To address this suggestion, a peptide (RP3) identical to a cytoplasmic domain of gp75NGFR with predicted amphipathic properties (Myers et al., Soc. Neurosci. Abstr. 17, 1991) was covalently linked to a peripheral plasma target vector. In these NGF-mediated neuronal cell growth in a time frame consistent with its uptake into cells. The cDNA is used in a coexpression system of BDNF and the low-affinity NGF receptor immunoprecipitates. The increase of trk-A mRNA was measured in a number of different brain areas of an adult rat by in situ hybridization. In addition, the above protocols were used to analyze the distribution of LNGFR in vivo. In agreement with previous studies, cells expressing trkB mRNA are much more numerous and widely distributed than those which express either trkA or LNGFR. Most neurons which express trkB did not contain detectable levels of LNGFR mRNA or protein.

401.12 OVEREXPRESSION OF THE CYTOSOLIC DOMAIN OF p75NGFR RESULTS IN DOWN-REGULATION OF p75NGFR EXPRESSION. M. Benedetti1, I. Manni2, and M.V. Cecchini2.

Istituto di Neurobiologia, CNR, Rome, Italy (1997); Dept. of Cell Biology & Anatomy, Cornell University Medical College, New York, NY 10021

The low affinity p75NGFR receptor participates in the formation of high affinity NGF binding sites with the product of the trk gene-coding region. In the formation of NGF signal transduction pathways, a mutant p75NGFR gene was engineered, comprising the transmembrane and cytoplasmic domain of p75NGFR, an N-terminal signal peptide and a myc tagging epitope. This truncated receptor lacked the ligand binding domain. When stably transfected in PC12 cells, neuronal differentiated clones displayed altered responses to NGF. Most notably, in cells expressing this construct, trk tyrosine kinase activity was markedly lowered. This suggests that NGF binding sites, as well as the products of the various NGFR genes, are present in different NGF binding sites. In addition, NGF binding sites, as well as the products of the various NGFR genes, are present in different NGF binding sites. In addition, NGF binding sites, as well as the products of the various NGFR genes, are present in different NGF binding sites. In addition, NGF binding sites, as well as the products of the various NGFR genes, are present in different NGF binding sites.
401.13 EVIDENCE FOR KINASELESS AND ALTERNATE 5' TERMINAL FORMS OF TRKB AND TRKC IN CHICK. A.S. Ganem,* T. H. Large, Department of Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

The 5' flanking region of tyrosine kinase receptors mediate neurotrophin-induced responses such as proliferation, survival, and process outgrowth. Alternative splicing is one potential mechanism for generating diversity at the level of ligand binding and/or signal transduction. To identify possible splice variants and as a prelude to investigating the role of 5' trk receptors in the developing chick visual system, we have isolated cDNA clones of chick trk (trkB and trkC). An 1133 bp chicken brain cDNA library, screened initially with a mouse trkB cDNA probe, yielded a total of 22 trkB and 16 ch1c transcripts. From a 5' cDNA map and amino acid alignment of a full-length chtrkB clone with mouse trkB identifies conserved domains that are likely to be functionally important. Within the extracellular domain, the second immunoglobulin-like domain is strongly conserved (81%). The trkB juxtamembrane domain (between the transmembrane and kinase domains) is also highly conserved (98%) and may be the principal regulator of kinase activity and/or specificity, especially given the small size of the C-terminus (15 aa) and kinase insert (11 aa) domains.

Alternate 5' and 3' splice variants of chtrkB have also been identified. Similar to those reported for rat and mouse, a kinaseless chtrkB clone is truncated just after the transmembrane domain and the 11 alternatively spliced C-terminal amino acids are completely conserved. In alternate 5' terminal clones (chtrkB-Δ5'), the start AUG, signal sequence and first cysteine cluster are replaced with a sequence that contains an upstream stop signal. This sequence is also found in the 5' untranslated region of the full length clone and is flanked by a spliced donor site, indicating chtrkB-Δ5' results from the splicing of 5' untranslated sequence into the extracellular domain.

We have also identified full length, kinaseless, and alternate 5' terminal clones of chtrkC. As with chtrkB, chtrkC-Δ5' clones replace the start ATG, signal sequence, and first cysteine cluster with a novel sequence encoding an upstream, in-frame stop. Alternate 5' transcripts lacking a start ATG may represent an unusual mode of regulating expression. Alternatively, translation may be initiated at a downstream ATG or non-ATG codon, resulting in a trkB receptor with a truncated extracellular domain.

401.15 DORSAL ROOT GANGLION NEURONS EXPRESSING TRK ARE SELECTIVELY SENSITIVE TO NGF DEPRIVATION IN UTERO. S.L. Carroll, K. Ruiz, S.E. Frese, J. Milbrandt and W.D. Snyder*, Departments of Pathology, Laboratory Medicine, and Neurology, Washington University School of Medicine in St. Louis, Mo. 63110.

In utero immortalization of the neurotrophin-receptor nerve growth factor (NGF) receptors in the death of most, but not all, mammalian dorsal root ganglion (DRG) neurons. The recent identification of trkB, trkC, and trkA as the putative high-affinity receptors for NGF, brain-derived neurotrophic factor (BDNF), and neurotrophin-3 (NT3), respectively, has allowed an examination of whether their expression by DRG neurons correlates with differential sensitivity to in utero deprivation of NGF.

NGF deprivation in fetal rats was produced by injecting a specific, high affinity anti-NGF antibody into embryonic rats in utero (Ruit et al. Neurobytes 8:31, 1992). After 4 hr, the rats were perfused in situ and the DRG sections from control and experimental animals with proks for trk, trkB, trkC, and p75NGFR, the low affinity NGF receptor. We have found that more than 90% of DRG neurons expressing trk are lost when deprived of NGF in utero. In contrast, most, if not all, NGF-expressing trkB and trkC cells were preserved in this treatment. The low affinity NGF receptor, p75NGFR, is expressed in both NGF deprivation-resistant and -sensitive neurons.

These experiments show that DRG neurons expressing trk require NGF for survival and that DRG neurons which do not require NGF express the high affinity receptor for another neurotrophin. Furthermore, they provide evidence that trk, and not p75NGFR, is the primary effector of NGF action in vivo.

401.17 MAST CELLS EXPRESS TRK BUT NOT LOW AFFINITY NERVE GROWTH FACTOR RECEPTOR FACTOR RECEPTOR. J.C. Pryor, K. Horj Sunaj, and E.M. Johnson, Department of Molecular Biophysics and Biochemistry, Yale University School of Medicine, New Haven, Conn. 06511.

The physiological response to nerve growth factor (NGF) is best understood in sympathetic and sensory neurons and PC12 cells. Rat peritoneal mast cells (RPMC) release histamine in response to NGF when lysophosphatidylserine is present. We have determined the expression of trk in the RPMC and trk in a mast cell line to understand the receptor(s) mediating the physiological response to NGF in these cells.

Total RNA was isolated from RPMC, non-mast peritoneal cells (non-RPMC) and PC12 cells. Northern blots were done with probes to trk and LANGFR. These blots showed a perfect signal at the appropriate size in mast cells and PC12 cells, but a very low signal in the non-RPMC fraction. A strong message was detected for LANGFR in PC12 cells, but no signal was detected in mast cells or non-RPMC. RNA from mast cells, PC12 cells, and superior cervical ganglion sympathetic nerve culture (SCG) were reverse transcribed and PCR was performed using oligonucleotides specific for trk and LANGFR. Message for trk was stronger in the mast cell fraction than in PC12 cells; the strengthens of the two bands were detected in PC12 cells and SCG cultures, but none was seen in mast or non-RPMC fractions. Radioiodinated NGF was cross-linked to mast cells and PC12 cells; the same results were obtained in immunoprecipitated with polyclonal anti-NGF or monclonal anti-LANGFR. Bands consistent with LANGFR were detected with PC12 cells, but none were detected in mast cell cultures. Our results strongly suggest that mast cells have only one NGF receptor species, trk, yet are capable of responding to NGF with a physiologic response. This immunoreactivity appears to require dimerization between the trk proten- oncogene and LANGFR in mast cells. (Supported by NIH grants NS34670 and NINDS 5 T32 N012025-10, and the Sumanillo Chemical Company.)
401.16 EVIDENCE FOR THE EXPRESSION OF FUNCTIONAL LOW AFFINITY AND txa NGF RECEPTORS IN CULTURED HIPPOCAMPAL NEURONS. Y. L. Smith-Swintosky and M. P. Mattson. Sanders-Brown Research Center on Aging and Department of Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536.

There is considerable evidence that nerve growth factor (NGF) promotes the survival and maintenance of specific populations of sympathetic, sensory, and CNS neurons. Recent data suggest that NGF can protect/rescue CNS neurons from insults such as hypoglycemia and ischemia, including neuronal populations (e.g., hippocampus) previously believed to be unresponsive to NGF (Neuron 7:1031, 1991). Previous studies identified both a low affinity 75 kDa NGF receptor and a high affinity receptor which is identical to the txa proto-oncogene product. Both types of NGF receptors have been proposed to be important for the biological actions of NGF. Immunocytochemical and Western blot studies using polyclonal antibodies to the 75 kDa NGF receptor (REX) and txa (generous gifts from G. Westkamp, F. Lefebre, and L. Reichard) demonstrated the presence of these proteins in neurons in embryonic rat hippocampal cell cultures. In order to determine which NGF receptors might mediate actions of NGF in hippocampal neurons, we employed antiserum oligonucleotides (AO) directed against rat 75 kDa NGF receptor or txa (sequence provided by D. Clay). Levels of the 75 kDa receptor and txa were reduced in neurons exposed to the respective AO's. Administration of AO's for either NGF receptor resulted in neuronal death. However, neuronal death was more rapid in cultures exposed to txa AO (< 24 hr) as compared to 75 kDa NGF receptor AO (2-3 days). The NGF receptor AO's also eliminated the neurite outgrowth-promoting effect of NGF in glial-deprived cultures. Taken together, our data suggest that hippocampal neurons in culture possess both the low affinity NGF receptor and txa. Both NGF receptors may play a trophic role and protect hippocampal neurons against environmental insults. (NHI and Alzheimer's Association support).

401.21 INFECTION OF DISSOCIATED COCCHEAL GANGLION CELL CULTURES WITH HSV-1 and txa CHARGES THE SURVIVAL RESPONSE OF AUDITORY NEURONS TO EXTERNAL NGF. J. L. Van Der Wateren, F. P. Lefebre, L. J. Liu, K. Y. G. Moonen, J. A. Kessler, and H. Nakagawa. Dept. of Otolaryngology, Neurosciences, Medicine & Neurology, Albert Einstein College of Medicine, Bronx, NY 10461, Dept. of Physiology, University of Liege, B 4000 Liege, Belgium.

Auditory neurons in cell cultures of dissociated cochlear ganglia of the mouse after embryonic day 13 are not responsive to the survival promoting effects of nerve growth factor (Lefebre et al, 1991; Acta Otolaryng. 111:301-311). Transfection of PC12 cell mutants deficient in high affinity NGF binding site with full length rat txa cDNA restored the responsiveness of these PC12 cell line to NGF (Lueb et al, Cell 66:961-966, 1991).

A defective herpes simplex virus-1 vector (HSV-1) containing a gpt (HSV-txa) was used to infect cultures of dissociated cochlear ganglia that contained auditory neurons that were unresponsive to NGF. The expression of gpt 14OPT was driven by the HSV IE 6/5 promoter so that all infected cells of the culture would express the gpt 14OPT construct. When infected cultures were compared to uninfected ones, a significant enhancement of the survival of auditory neurons in the gptHSV-1 infected cochlear ganglion cell cultures treated with exogenous human recombinant NGF (1, 100 ng/ml) was evident in contrast to the uninfected control cultures treated with hGF.

402.1 EXPRESSION OF INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-4 AND -5 mRNAs IN ADULT RAT BRAIN. Kaye L. Steinhurt*, Michelle Gudjons, Ellen M. Zemlan, and Ronald腾 Chen. Salk Institute for Biological Studies neurobiology and Dept. of Medicine, University of North Carolina, Chapel Hill, NC 27599.

Insulin-like growth factors (IGFs) are believed to serve as neurotrophic factors in developing and adult rat brain. The IGPs are associated with a family of at least six IGF binding proteins (IGFBPs) which prolong the half-life of plasma IGFs and modulate IGF actions. Although high levels of IGF binding proteins are present in adult rat brain, their cellular sites of synthesis are still poorly characterized. To localize sites of IGFBP-4 and -5 mRNA expression, we performed in situ hybridization histochemistry using 35S-labeled antisense riboprobe to one of the IGFBP-4 and -5 mRNA provided by Drs. Nicholas Ling and A. D. Dufour, respectively. We examined fresh-frozen, post fixed sections of adult rat brain. Specificity of hybridization was confirmed by negative results in sections hybridized with sense riboprobe pre-treated with RNAse A prior to hybridization. The two IGFBP mRNAs were abundantly expressed within discrete regions of brain. Generally, the same expression patterns of the two mRNAs were non-overlapping. Notably, IGFBP-4 mRNA was highly expressed within hippocampal and cortical areas, whereas IGFBP-5 mRNA was not detected above background in these areas. Within hippocampus, immunoreactivity of the IGFBP-4 probe was detected in pyramidal neurons of a medial segment of the CA1 subfield and throughout the CA2 subfield of Ammon's horn. Strong immunoreactivity was also detected within the indusium griseum and subiculum. In cortex, IGFBP-4 mRNA was widely expressed in most cortical areas and layers. In contrast, IGFBP-5, but not IGFBP-4 mRNA was detected within fasciculus dentatus. The distinct expression patterns of IGFBP-4 and -5 mRNAs within brain suggest that these IGFBPs may mediate compartmentalization of the IGFs or paracrine/autocrine actions of the IGFs within the brain regions. Furthermore, expression of IGFBP-4 mRNA within hippocampal pyramidal neurons suggests a role for IGFBP-4 in modulating neuronal effects of the IGFs.

402.2 ASSOCIATION OF INSULIN-LIKE GROWTH FACTOR 1 (IGF1) ON BASAL FOREBRAIN CHOLINEURGIC NEURONS. A. Beauregard*, C. Desgrange, and M.-P. Faure. Neuroanatomy Lab, Montreal Neurological Institute, McGill University, Mil, Que, Canada H3A 2B4.

IGF1 was previously shown to stimulate the release of acetylcholine in adult rat brain slices. It is unknown whether IGF1 exerts its effects directly on central cholinergic neurons. To test the hypothesis that IGF1 receptors may be associated with basal forebrain cholinergic cells, we examined by double immunofluorescence, the labeling of IGF1 and ChAT in rat medial nuclei. Primary antibodies were reacted with secondary antibodies conjugated with FITC and Texas Red, respectively. In the medial septal nucleus, diagonal band of Broca and substantia innominata a large proportion of ChAT positive neurons exhibited IGF1 immunoreactivity. Reconstruction of serially sectioned images using confocal laser microscopy (CLSM) substantiated that IGF1 and ChAT immunoreactivity were present in a number of basal forebrain cells. Confocal microscopic analysis of this pattern of IGF1 was mostly membranous and took the form of highly fluorescent punctate dots. Hybrid cells derived from septal cholinergic neurons, produced by the fusion of basal forebrain cells with murine neuroblastoma cells, were used to characterize the biological effect of IGF1. The hybrid cells were treated for different times and concentrations with nerve growth factor, basic fibroblast growth factor, platelet-derived growth factor and IGF1. Stimulation with IGF1 (10 ng/ml) for 48 hours produced a change in cell shape and significant neurite outgrowth (15-25m) whereas none of the other factors produced any effect under these conditions. Moreover, fluorescence ChAT immunoreactivity was evaluated by CLSM and expressed a 10 fold increase following IGF1 stimulation. These results suggest that IGF1 may play an important role in the growth and function of basal forebrain cholinergic neurons and, consequently, that the impairment of its interaction with IGF1 may be involved in the degeneration of cholinergic systems such as occurs in Alzheimer's disease.
A RAPID INCREASE IN ACTION POTENTIAL FIRING RATE IN RESPONSE TO GROWTH FACTORS. R.H. Salwaye and L.A.C. Blair. Department of Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

The role of growth factors in the adult mammalian central nervous system is unknown. We have examined the rapid modulation of action potential frequency and ionic currents by growth factors known to be present in the central nervous system. Patch clamp recording techniques were used to indentify spontaneous electrical activity and ion channel events in GHSa-pituitary cells. It was found that culturing in serum-depleted conditions blocked the firing of spontaneous action potentials. Brief exposure to serum or to a pool of 14 growth factors normally contained in serum fully reconstituted electrical activity. Subsequent experiments demonstrated that addition of insulin, IGF-I and IGF-II are sufficient to restore normal action potential behavior. Specifically, using on-cell single channel recordings or whole-cell recordings in the current clamp configuration, the reconstitution of electrical activity was rapid (requiring 30 seconds to 5 minutes) and stable. Furthermore, preliminary whole-cell voltage clamp analysis suggests that both outward potassium currents and inward calcium currents are altered by the presence of growth factors. One of these growth factor-modulated currents is tetraethylammonium-sensitive but insensitive to 4-aminopyridine, indicating that Kv1 may be one of the potassium channels regulated by growth factors. Together, these experiments suggest that the insulin family of growth factors may be capable of inducing rapid changes in channel calcium and one or more potassium channels.

We have studied the presence of insulin like growth factor I (IGF) and its receptors in 22 day and 18 day gestation neuron cell cultures (NCC) from fetal rabbit brains. The 22 day NCC were incubated in IGF free/free serum free medium (ISFM) and the 18 day NCC in serum medium. The 18 day NCC died in an ISFM. The peroxidase anti-peroxidase method using rabbit anti-IGF antibody (R configuration) (1/100)(E.Lilly) showed IGF present. Antibody absorbed with IGF(E.Lilly) and rabbit serum lacked immunoreactivity. In situ hybridization using a 32P -biotinylated oligonucleotide revealed IGF mRNA. Electron microscopy using RIGF (1/10000) and anti-neuronfilament (1/10000) showed IGF in the neurons' endoplasmic reticulum, Golgi, cytoplasm and prolongations. IGF had enhanced neuron growth in ISFM. 10 day NCC from 18 day culture were transplanted into 15 day ISFM. We conclude: A) fetal NCC produce IGF, B) IGF promotes cell survival, and C) exogenous IGF may be needed in early brain development.

Recent studies have indicated that insulin like growth factor I (IGF-I) and IGF-I and IGF-I receptor mRNA are abundant in both the developing and in the mature rat brain olfactory bulbs (Ay-er Lieve et al., 1991; Wether et al., 1990, Bandy et al., 1992). By using the method of intracoriaral transplantation we were able to study effects of truncated IGF-I (IGF-I), antibodies against IGF-I and IGF-I binding protein on developing olfactory bulbs. 116 olfactory bulbs were grafted to the anterior chamber of adult host rats. Grafts were treated with either 20 µg/ml IGF-I, 1 µg/ml anti-IGF-I, 1 µg/ml IGF-I binding protein or vehicle solution alone prior to grafting. Similar results were obtained by intracoriaral injections S, 10, and 15 days postgrafting. Growth of grafts was monitored by direct observation and measurement through the cornea of the living animals. Grafts treated with IGF-I antibody showed growth similar to grafts receiving only saline treatment. When similar experiments were carried out on E16 and E17 partical cortex grafts, no enhancement in graft size was seen after IGF-I antibody treatment. However IGF-I has in previous studies (Gacubini et al. 1990) been shown to enhance growth of intracoriarally transplanted fetal partical cortex grafts. These results indicate that IGF-I is important in development in a regionally specific manner. Immunohistochemical studies of the olfactory bulb grafts are currently under investigation.

INSULIN-LIKE GROWTH FACTOR-I (IGF-I) INCREASES RATE OF FUNCTIONAL RECOVERY FROM SCIATIC NERVE CRUSH IN MICE. P. C. Contreras*, C. Steffler and J. L. Vaught. Pharmacology, Cephalon, Inc. West Chester, PA 19380.

IGF-I has been shown to stimulate several growth-associated processes and to support the survival of α-motor neurons in vitro. IGF-I has also been shown to enhance neuronal sprouting after sciatic crush in rats. The purpose of this study was to assess whether IGF-I also increases rate of functional recovery after sciatic nerve crush in mice. After Ski-Webster mice (25-35 g) were anesthetized, both sciatic nerves were exposed and crushed for 10 sec with a hemostat, covered with plastic tubing. Mice were injected with vehicle (1% BSA) or IGF-I (1mg/kg) s.c. after recovery from the anesthetic and for the next 15 days. Functional recovery from the sciatic crush was measured by 1) determining the number of times/5 trials the mice were able to grasp an inverted screen with both hindpaws; and 2) assessing changes in gait. Mice treated with IGF-I were able to grasp the inverted screen and return to normal running pattern but not the vehicle treated mice. There were also parallel improvements in several parameters used to measure gait, such as toe spread, in IGF-1-treated mice compared to vehicle-treated mice. These results indicate that IGF-I, which enhances survival of α-motor neurons, also enhances functional recovery. These data support the utility of rIGF-I for the treatment of ALS.
402.1 BASIC FGF AND FGF RECEPTOR-4 OCCUR IN CHICKEN. P. C. Evers and M. Bothwell*. Dept of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195.

The fibroblast growth factor (FGF) family presently consists of 7 members: aFGF, bFGF, Int-2, k-FGF, FGF-5, FGF-6, and KGF. These ligands bind, with specificity which is not fully defined, to mitogenic receptors of 4 genes: FGF receptor-1 (FGFR1), FGFR2, FGFR3, and FGFR4. Our previous results show FGFR1 expressed in the developing chick neurepithelium, where it is likely to have a role in proliferation and differentiation. To further explore the role of FGFs in neural development, we plan to describe the expression of the FGFs and other FGFRs in neural tube. Hence, we have sought to clone segments of each FGF and FGFR gene for use as in situ hybridization probes. Portions of six genes: aFGF, bFGF, FGFR1, FGFR2, FGFR3, and FGFR4 from chicken using PCR and degenerate nucleonucleotides. The sequences for two of these genes, bFGF and FGFR4, have not been reported previously. Sequence identity between the putative chicken bFGF and the mouse bFGF is 83% at the nucleotide level and 94% at the amino acid level. The nucleotide sequence identity between the putative chicken FGFR4 and the three known chicken FGFR genes is 72-79%, whereas the nucleotide sequence identity between the putative chicken FGFR4 and the human FGFR4 is 79%. Sequence comparisons suggest that the two cDNAs are portions of the bFGF and FGFR4 genes in chicken. The bFGF and FGFR4 cDNAs along with the cDNAs for aFGF, FGFR1, FGFR2, and FGFR3, will be useful in determining the roles of FGF in neural development.

Fibroblast growth factors (FGFs) are potent growth factors with roles ranging from development to adult plasticity in the brain. FGF-5 is a new member of the FGF family with a potential role in brain function and pathology. In order to evaluate a possible role of FGF-5 in the brain, we have examined the locus of synthesis of FGF-5 in the rat brain using in situ hybridization of S35-labeled RNA probe complementary to FGF-5 mRNA. FGF-5 mRNA was expressed in neurons in selected regions of the rat brain. FGF-5 mRNA in situ hybridization labelling was particularly intense in the olfactory bulb within periglomerular elements and granular cell layer. The primary olfactory cortex also showed strong FGF-5 mRNA labelling and mostly within cell layer II, throughout its rostro-caudal extent. In the hippocampal formation, the greatest intensity of FGF-5 mRNA labelling was shown in hippocampal pyramidal cells within subfields CA3 and CA2, and granular cells within the dentate gyrus. The cerebral cortex (neocortex) showed a modest labelling throughout its rostro-caudal extent, mostly within external layers. The entorhinal cortex showed a slightly higher labelling intensity as compared to the neocortex. The cerebellum, thalamus and striatum displayed light labelling. Gial-like cells scattered throughout the brain appeared to express low levels of FGF-5 mRNA. In general FGF-5 mRNA was mostly shown by limbic structures, suggesting the possibility that FGF-5 may play a role in limbic system function or pathology.

403.3 BASIC FIBROBLAST GROWTH FACTOR (bFGF) GENE EXPRESSION IN RAT BRAIN: AGE AND REGIONAL COMPARISON BY QUANTITATIVE RT-PCR. A. El-Hajjim, L. Apenten*, and R.P.C. Shih. Departments of Physiology and Anatomy, Faculty of Medicine, University of Manitoba, Winnipeg, Manitoba, Canada R3E 0W3.

Investigations in vitro have shown the importance of bFGF as a mitogen for astrocytes and as a neurotrophic factor for many neuronal types. This study was designed to compare bFGF gene expression in selected regions of the brain of rats at different postnatal ages. The reverse transcription-polymerase chain reaction (RT-PCR) was used to measure the levels of bFGF mRNA. These levels were quantitated relative to the levels of mRNA for glyceraldehyde-3-phosphate dehydrogenase, the latter being constant. We first compared the levels of bFGF mRNA in the cerebrum from male rats of ages 1, 3, 7, 14, 21 and 28 days and one year. Our results showed that by the end of the first month, the cerebral bFGF mRNA was about 10-fold that of the 1 day old rat, with the greatest increase occurring between the first and the second postnatal weeks. One year old cerebrum showed high levels of bFGF mRNA similar to that of 21 day old. Analysis of different regions of the 28-day old brains revealed that the lowest levels of bFGF mRNA occur in the cerebellum, and that the highest levels occur in hippocampus (7 times the levels in cerebellum, 7X), followed closely by cingulate cortex, occipital cortex, and inferior colliculus (4-5X). The highbathalumus and combined pons-medulla showed intermediate levels (2X). Preliminary studies of these regions from 1 day old rats showed there was a different pattern of regional expression at this age. Our results are consistent with the hypothesis of a role of bFGF in brain development.

Recently, it was shown that basic fibroblast growth factor (bFGF) is present in distinct neuronal subpopulations of the brainstem (Grothe et al J. Comp. Neurol. 323:119-121, 1991). Immunohistochemical analysis revealed a partial overlap of bFGF and neuropeptides (5HT, SP, CGRP) or tyrosine hydroxylase in some brainstem nuclei but no strict co-localization of bFGF with one of the neuropeptides or tyrosine hydroxylase.

To identify bFGF-responsive cells in the brain, immunocytochemistry and binding studies were performed. FGF-receptor could be localized in the cortex and, like bFGF, in neuronal subpopulations of several motor and sensory brainstem nuclei.

After colchicine treatment bFGF-IR disappeared in brainstem nuclei expressing the FGF-receptor and appeared or increased in nuclei lacking the FGF-receptor. Whether this change in the bFGF-IR is exclusively due to transported bFGF has to be clarified by in situ hybridization.

Supported by Deutsche Forschungsgemeinschaft GR 857/4-2

We have shown that bFGF-immunoreactivity (IR) is present in a neuronal subpopulation of postnatal and adult crest- and placode-derived sensory ganglia (Weise et al. Cell Tissue Res., 267: 125-130, 1992). In dorsal root ganglia (DRG) bFGF was strictly co-localized with the somato-statinIR subpopulation. Northern blots of total RNA from DRG and cortex revealed 3.7 and 3.9 kb mRNAs. In situ hybridization showed that the bFGF mRNA is present in nearly all DRG neurons. To identify neurons with putative bFGF responsiveness, FGF-receptor immunocytochemistry and binding studies were performed. The FGF-receptor IR was present in all bFGF-immunoreactive neurons suggesting that the protein mediates its effects in an autocrine and/or paracrine manner. The possibility that the distribution of the FGF-IR is different in the distribution of bFGF-IR and bFGF mRNA may include: 1) different translational regulation in distinct subpopulations; 2) different stabilities of mRNA and proteins.

Supported by Deutsche Forschungsgemeinschaft GR 857/4-2

Fibroblast growth factors (FGFs) are a family of related peptides which have been characterized by their ability to influence cellular differentiation and their mitogenic/angiogenic properties. We have observed the acidic and basic FGF mRNA and protein in sensory and motor neurons of the rat including the substantia nigra (SN). In contrast to the widespread distribution of basic FGF and acidic FGF expression is quite restricted. We examined the expression of aFGF and bFGF in the rat SN and dorsal root ganglia (DRG) from E16-18 to P90.

In DRGs, aFGF mRNA and protein were present at E18 and were observed through adulthood. bFGF mRNA was present in sensory and motor neurons of the rat. aFGF mRNA was first detectable in the SN at PN20 and was expressed through adulthood. The developmental expression of acidic and basic FGF in the SN may indicate different functional roles in this brain region.
403.7 BASIC FIBROBLAST GROWTH FACTOR (bFGF) PROMOTES THE SURVIVAL AND PROLIFERATION OF MESCENEPHALIC NEURONAL PRECURSORS IN VITRO. M.M. Bouvier1 and C. Mytilineou. Dept. Neurology, Mt. Sinai Sch. of Medicine, New York, N.Y., 10029.

We recently demonstrated that treatment with epidermal growth factor (EGF) results in the survival and proliferation of neuronal and glial stem cells from embryonic day 16 (E16) rat mesencephalon (Mytilineou et al., 1992). To determine whether dopaminergic neuronal precursors could also be induced to proliferate in vitro, we used ventral mesencephalic cultures from E12 rat embryos, a developmental stage that coincides with the beginning of the ventral mesencephalon. Mesencephalic cultures were treated with EGF (10ng/ml), bFGF (10ng/ml) or a combination of EGF and bFGF at the day of plating. Control and tropic factor-treated cultures were observed with phase contrast microscopy and analyzed at 7 days in vitro (DIV) by immunocytochemistry with antibodies to neuron specific enolase (NSE), tyrosine hydroxylase (TH) and glial fibrillary acidic protein (GFAP) to identify differentiated neurons, dopaminergic neurons and astrocytes, respectively. Some cell division, resulting in colony formation, occurred in the first 24-48 hrs after plating at all tropic factor-treated cultures, as well as in untreated controls. However, treatment with bFGF resulted in greater cell number and the formation of larger colonies. EGF had no apparent effect in these cultures. Cell loss was prominent in control and EGF-treated cultures after 7DIV, but it was less apparent in cultures treated with bFGF. At 7DIV the majority of surviving cells were positive for NSE while <1% stained with GFAP. TH immunocytochemistry revealed clusters of dopaminergic neurons in control and EGF-treated cultures, but their numbers were higher after treatment with bFGF. (Supported by NIH grant NS-23017 and the United Parkinson Foundation).

403.9 EFFECTS OF BASIC AND ACIDIC FGF ON GROWTH AND DOPAMINE NERVE FIBER PRODUCTION OF INTRAUTERINALLY TRANSPLANTED FETAL MESCENEPHALIC GRABS. S. Almqvist1, Z. Almqvist2,1, Y. Car1, R. Pettersson1, J. Olson1, Dept. of Histology & Neurobiology, Karolinska Institutet, Stockholm, Sweden, 2Fudan University, Shanghai, China.

Basic FGF has been shown to increase dopamine neuron survival in mesencephalic cultures (Ferrari et al. 1988) as well as inducing regrowth of damaged DA neurons in vivo (Otto, Unencer, 1990). We have followed the growth and survival of developing E14-E16 mesencephalic cultures under chronic intermittent treatments with either aFGF or bFGF in the anterior eye chamber of adult rat hosts. Pieces to be grafted were cultivated in either 25 μg/ml aFGF, 25 μg/ml bFGF or vehicle solution alone prior to grafting and 5 μl of similar solutions were injected intravitreally on days 5, 10 and 15. Host animals were sympathetically denervated 2 weeks prior to grafting enabling evaluation of catecholaminergic fiber outgrowth upon the host iris in whole-mount preparations by use of the Falck-Hillarp technique. Both aFGF and bFGF significantly increased the volume of transplanted mesencephalic grafts when compared to grafts treated with the vehicle alone. bFGF was a more potent growth stimulator than aFGF. Both bFGF and aFGF increased the area of the host iris innervated by graft-derived catecholaminergic containing fibers. Immunohistochemical evaluations of grafts are currently under study as well as studies of treatment of mesencephalic grafts using the described model with other growth factors.

403.11 THE COMBINED ACTION OF BASIC FGF AND SUBSTRA PROMOTES DIFFERENT CHROMAFFIN CELL FATE. C.H.Chu,1,2 C.O. Crabtree,1 A.M.Tolikovsky, Dept. of Human Anatomy, University of Oxford, South Parks Road, Oxford OX1 3QX, U.K.

Basic fibroblast growth factor (bFGF),like NGF, induces cell division and neurite outgrowth in adrenal chromaffin cells. In vitro, we found that 3H-thymidine incorporation of the adrenal chromaffin cells was increased by bFGF, unlike NGF, which promotes different neurite outgrowth responses on neural retinal chromaffin cells with different substrata. To determine the extent of chromaffin cell transformation into neurons, we counted the number of cells with tyrosine hydroxylase positive staining and neurites and cell division was assessed by 3H-thymidine incorporation of the chromaffin cells. The percent of cells expressing 3H-thymidine incorporation of the chromaffin cells was significantly reduced on laminin compared with collagen Type I. In contrast, cultures grown on collagen Type I, bFGF elicited little neurite outgrowth, and promoted the proliferation and survival of chromaffin cells. In addition, dexamethasone induced neurite outgrowth in response to bFGF on laminin and increased the proportion of surviving and tyrosine hydroxylase positive cells. These results show that bFGF and laminin act synergistically to promote sympathetic neuronal transformation, whilst on collagen Type I or in the absence of bFGF, bFGF acts as a mitogen and survival factor of chromaffin cells.

Basic FGF is expressed in catecholaminergic cells of substantia nigra and in sympathetic-adrenal system. We have recently shown that in adrenomedullary (AM) cells exogenous bFGF modulates expression of tyrosine hydroxylase and dopamine beta hydroxylase genes, suggesting that it may serve as an autocrine or paracrine regulator in catecholamine and norepinephrine biosynthesis. The present work was undertaken to determine subcellular localization of bFGF in AM cells and to examine whether bFGF expression is regulated by stimulus that affect synthesis of AM hormones. In cultured bovine AM cells stimulation with bFGF against recombinant bFGF, granular cytosolic and nuclear bFGF. Immunoreactivity (bFGF-IR) was observed. In majority of cells bFGF staining was more intense in the nucleus than in the cytoplasm. Incubation with exogenous 18 kDa bFGF (5x10^{-14}M) led to an increase in nuclear bFGF-IR within 10 min, which reached a maximum between 1-3 hrs. Incubation with forskolin produced a dramatic increase of nuclear bFGF-IR which peaked at a maximum after 12 hours. Lower pronounced increases in nuclear staining, were observed in cells treated with angiotensin II or with the depeolarizing agent, veratridine. Western blot analysis of total AM cells with antibodies against bFGF demonstrated that bFGF-IR was expressed in AM cells by hormonal (angiotensin) and neural (depolarization) stimuli, and by 2nd messenger (cAMP), supports the hypothesis that bFGF plays an active role in the plasticity of the adrenergic system. It also suggests that long-term genic effects of bFGF may be mediated directly in the nucleus.
404.3 MITOGENIC EFFECTS OF ACIDIC FIBROBLAST GROWTH FACTOR AND TRANSFORMING GROWTH FACTOR BETA ON BOVINE AND PORCINE ENDOTHELIUM IN VITRO. T.C. Ryken and V.C. Travenlis*. Department of Surgery, Division of Neurosurgery, University of Iowa College of Medicine, Iowa City, Iowa, USA.242.

The mitogenic effects of acidic fibroblast growth factor (aFGF) and transforming growth factor beta (TGF-beta) were assayed alone and in combination on cultured bovine and porcine endothelium. Triplicate growth-arrested cultures of each cell type were grown in the presence of aFGF (300 ng/ml) and/or TGF-beta (5 ng/ml) for 96 hours, renewing the media each 24 hours. The mitogenic effects were assayed by cell counting at the conclusion of the 96-hour period. Results are reported as a stimulation index of the initial cell number.

Both bovine and porcine endothelial cell cultures incubated with aFGF underwent a marked increase in mitogenic activity, increasing in stimulation index to 1.60 (± 0.05) for control (1.0 ± 0.0) and 3.81 (± 0.06), respectively. Endothelium incubated in the presence of TGF-beta underwent a decrease in mitotic activity with a stimulation index of 1.16 (± 0.10) and 1.17 (± 0.05) in the bovine and porcine cultures. Cells incubated in a combination of aFGF and TGF-beta demonstrated an attenuation of the mitogenic effects observed in the presence of aFGF alone, decreasing the stimulation index to 3.25 (± 0.11) in bovine endothelium and 1.80 (± 0.30) in porcine endothelium.

These results suggest that the mitogenic effect of aFGF in cultured endothelium can be antagonized by TGF-beta. The interaction of growth factors on endothelium is of interest to elucidate the mechanisms involved in angiogenesis and transformation.

Mac-Planck-Institut für biophy. Chem. P.O. Box 2841, 3400 Göttingen, Germany.

Basic fibroblast growth factor (bFGF) and nerve growth factor (NGF) are multifunctional proteins for neurons and astrocytes in culture. The mechanisms regulating the expression of bFGF and NGF in neurons and astrocytes of developing or injured rat brain are not well understood. Previous work demonstrated that hydrogen peroxide induces bFGF, NGF and c-fos in astrocytes. It has been shown that excitatory amino acids (EAA) induce calcium influx in hippocampal neurons.

In this study we demonstrate that EAA treatment increases c-fos and growth factor mRNA in a time dependent manner. When neurons and astrocytes were incubated in the presence of DNXQ and APV the expression of the mRNA was reduced. These findings suggest a possible interaction between glu-receptor activation and growth factor expression as an important aspect of neuronal-glial communication.

Effects of human recombinant acidic fibroblast growth factor (hhaFGF) on brain neurons of various regions in primary culture and hippocampal-lag long-term potentiation (LTP) in rat brains were examined. Dissociated cells from 8 regions of embryonic day 16 rats were cultured in medium containing 10% serum for 1 day and chemically-defined serum-free medium with hhaFGF for 3 days. 10-100 ng/ml hhaFGF enhanced neuronal survival in the cortex, hippocampus and substantia nigra, while 10 ng/ml CS23 (modified human basic FGF) was effective in all regions tested. Next, effects of hhaFGF and CS23 to the increases of the spike amplitude induced by tetanic stimulation were measured in the dentate gyrus of 24 hr fasted and non-fasted rats. Ten ul of drug was i.c.v. injected before the application of tetanic stimulation. hhaFGF (400 ng/ml) didn't influence the LTP induced by the tetanus of 100 pulses at 100 Hz in both fasted and non-fasted rats, but significantly facilitated the generation of LTP by tetanus of 20 pulses at 60 Hz only in fasted rats. However, 400 ng CS23 induced LTP when the tetanus of 20 pulses at 60 Hz was applied in both fasted and non-fasted rats. Protein kinase C activities of hippocampal cytosol fraction was decreased with the i.c.v. injection of 400 ng hhaFGF in 24 hr fasted rats but not in non-fasted rats. These results suggest that hhaFGF might be one of factors of feeding and memory and there might be different regulatory mechanisms on FGF receptors from those of basic FGF.

404.2 STAGE AND CONCENTRATION SPECIFIC EFFECTS OF RETINOIC ACID ON THE DIFFERENTIATION OF XENOPUS MINDRAIN AND EAR. T. Neary* and B. Fritzsch. Anatomy Div., Creighton University, Omaha, NE 68178.

Retinoid acid (RA) causes developmental defects of certain brain areas (Papapolu et al., Development 113 (1991) 1145) that could result either from abnormal inductive interactions between mesoderm and neuroectoderm or from direct effects of RA on the developing CNS. To discriminate between these possibilities we exposed Xenopus laevis embryos (stages 15-21; from completion of gastrulation to completion of neurulation) to 30 min. RA pulses (5 x 10^{-7} - 5 x 10^{-5} M RA). Reticulospinal projections, known to be altered by RA (Manns and Fritzsch, Neurosci. Lett. 136 (1992) 1) and connections of the inner ear were examined in later stages with fluorescent dextran amines. Effects on the reticular formation, (supernumerary Mauthner-like cells) were found with increasing concentrations of RA as late as st 21. In the ear, the separation of the utricular and saccular macula and the formation of the horizontal canal is suppressed with exposure to increasing concentrations of RA as late as st 21. Reductions in the numbers of sensory ganglia and efferent cells were concomitant with this effect. These data suggest that RA has a direct effect on the CNS and inner ear. 404.3
A MONOCLONAL ANTIBODY THAT RECOGNIZES A NOVEL POSITIONALLY-REGULATED EPITOPE IN THE RAT CNS
S. Tole*, J. Kapturik, S. Du, and P. H. Patterson
216-76, Division of Biology, Caltech, Pasadena, CA 91125

In an attempt to generate mAbs against downstream products of homologues expressed on neuronal surfaces, we employed NTD21
embryonic carcinoma cells. Retinoic acid induces homoblasts gene
expression and a neuronal phenotype in these cells. After the mouse's immune response to the NTD21 cell membrane is suppressed with
cyclophosphamide, membranes from the same cells treated with retinoic acid were injected. Hybridomas supernatants from this fusion were
screened on the NTD21 cell line and selected with specific hybridoma cell lines. mAb 5T6 (olfactory-tenectelephalic) staining is detected from E9 to E15 in the prosencephalon and part of the diencephalon.
The only other sites of staining are the nasal pits and the optic placodes. The rest of the nervous system and all non-neural tissues are
negative. At ED, staining also appears in the glomerular layer of the olfactory bulb, the olfactory epithelium, and the lateral nasal gland. From E16 through PI, limited staining is also detected in some regions of the
cortex and thalamus. In the adult, the entire brain is positive.

Immunoblotting identifies high molecular weight, proteoglycan-like antigens with a tissue distribution consistent with the
immunohistochemical localization at E14.5.

Arthur McCallum fellowship, a Markert internal grant in
Developmental Biology, and an individual NSRA.

404.4
THE MURINE HOX-1.2 GENE CONTAINS A CNS REGION SPECIFIC
REGULATORY DOMAIN.

The patterns of Hox gene expression during mammalian central nervous system development are remarkable for their spatial restriction, within a cluster of Hox genes, each gene has a more rostral extent than does its immediate 5' neighbor. We have begun a study of the homeostructures I gene to investigate mecha-
nisms of this intriguing spatial control of gene expression.

We have examined two lines of transgenic mice bearing 3.7 kbp of the Hox-1.2 gene upstream of the transgenic start site found on the B. coli 8.8 kb transgenic reporter gene. At embryonic day 12.5 there are high levels of reporter protein staining in the doral medulla, conforming to the endodermal. Staining appears to be localized to a small group of neuroblasts, which we have provisionally identified as the nucous nucleus solitus (NNS) which may be supported by labeling of this region by the carboxyanine dyel applied to the glossopharyngeal/vagal ganglia.
Interestingly, the vagus, trigeminal and facial nerves and ganglia are also stained. These latter nerves also have projections to the NTS, suggesting that Hox genes may participate in the specification of functionally integrated neural pathways.

The reporter gene is also expressed in the ventral horns of the caudal spinal cord and in a few lateral cells of the thoracic dorsal root ganglia. In one transgenic strain, at embryonic days 13 to 15, virtually the entire peripheral nervous system is stained, including the sympathetic chain and ganglia. In this same strain, reporter expression persists into adulthood, with prominent staining in the granular layer of the cerebellum, pontine nuclei and the dorsal horn but not the ventral horns of the spinal cord. Our results demonstrate that one Hox gene has temporally regulated expression in several distinct and nonoverlapping regions of the CNS. Therefore, expression of these genes is not confined to a single timepoint or single region of the neuraxis, although they may participate in positional or functional specification within these areas.

404.5
EVIDENCE FOR LINKAGE OF TES-1 AND DLX-1, TWO HOMEOBOX GENES EXPRESSED IN THE DEVELOPING MAMMALIAN FOREBRAIN.

Tes-1 and Dlx-1 are members of the Distal-less family of
homeobox genes and are likely candidates for regulating positional identity or cell differentiation in the developing forebrain. Tes-1 and Dlx-1 are both transiently expressed in the
cells of the embryonic ventral forebrain that give rise to the
temporal, entorhinal, thamic nuclei, and olfactory bulb. The present studies used pulsed-field gel electrophoresis (PFGE) to determine if Tes-1 and Dlx-1 are physically linked to each other, in the case for the Hox genes. Mouse thymus (A9) genomic DNA aliquots were digested with nine rare-
cutting restriction enzymes, subjected to PFGE, transferred to nylon filters, and sequentially hybridized to 32P-labeled Tes-1 and Dlx-1 cDNA probes. The probes co-hybridized to fragments generated by the four restriction enzymes: Nru I, Not I, Sal I, and BsuI. The physical linkage was further demonstrated by co-hybridization of the probes to DNA fragments generated by digestion with combinations of restriction enzymes.

The smallest DNA fragment (generated by digestion with Sfi I and Not I) that was recognized by both probes was approximately 45 kb. These results indicate that Tes-1 and Dlx-1 are physically linked within approximately 45
kb on the genome. These two genes may exist as part of a larger gene complex that acts in a coordinated fashion to regulate forebrain development.

404.6
GENETIC CONTROL OF SEGMENT-LIKE PATTERNS OF GENE
EXPRESSION IN THE MOUSE CEREBELLM.
Rockefeller Institute of Molecular Biology, Nutley, NJ 07110

We have previously shown that the gene for a Purkinje cell-specific
marker, L7, can be used to drive expression of β-galactosidase in
cerebellar Purkinje cells of transgenic mice. Although all Purkinje cells
in the adult express both the transgene and endogenous gene, early
developmental expression of both reveals a series of positive and
negative bands. The number of bands increases in the medio-lateral
direction during development until all Purkinje cells are positive.

Truncation of the promoter region of the transgene disrupts this normal developmental pattern. Animals carrying the truncated constructs show precocious lateral expression in early development. There is also a delay in the normal "filling in" of the bands. This suggests a series of positive and negative responders which are important for control of the banding pattern. In addition, these truncations have identified a minimal promotor sufficient for driving Purkinje cell-specific expression. This small promotor region contains a cluster of consensus binding sites for known families of developmental control
geneces and these sites can be footprinted by purified proteins from these families or by crude cerebellar nuclear extracts. By specifically
mutating these elements we are assayng their affect on cell-specific transgene expression. We are using a FCR strategy to identify the
cerebellar transcription factors themselves.

404.7
A MOLECULAR APPROACH TO CEREBELLAR
COMPARTMENTATION: THE CLONING OF ZEBRIN II
Calgary, Alb T2N 4N1; Alzheimer Res. Ctr., Cleveland, OH 44106.

The Zebrians are the first example that represent striking examples of the parasagittal organization of the cerebellar cortex. Zebrian staining by immunohistochemistry appears as sharp anterior to posterior border and like ventral and lateral (or less well registered bands) in the hemispheres. The bands have been likened to "compartmental" and probably reflect a basic organizing principle of the cerebellum. To study the molecular genetic basis of the Zebrian periodic pattern of expression, we have cloned Zebrian II, a 32 kd intracellular antigen, from a cDNA expression library of postnatal day 20 C57BL/6J mouse cerebellum. Several independent recombinants express a single class of cDNA recognizing by the Zebrian II monoclonal antibody. Partial sequence from these clones reveals a near identity to that previously published for rat and human aldolase C, one of the three
known aldolase isozymes. Aldolase is a glycolytic enzyme that hydrolyzes fructose 1,6-diphosphate, and previous reports show that the expression of aldolase C is heterogeneously restricted to Purkinje cells of the cerebellum; no higher-order organization of its expression has been previously recognized. To signal the whether the HAND pattern of Zebrian/aldolase antigen in cerebellum was due to differential transcription, in situ hybridization of horizontal sections of mouse brain was performed. Immunostaining appears in the cerebellar Purkinje cell layer, with regional heterogeneity. The registration of this heterogenous pattern with that of Zebrian II bands will be assessed.

Supported by NIH (N18189I-K0I: 27300M0755-11-A1) and PCR & AHPMR-8H.

404.8
FURTHER CHARACTERIZATION OF MEANDER TAIL, A GENETIC
MUTATION AFFECTING CEREBELLAR MORPHOGENESIS. C.

We have previously described the effects of a genetic mutation on the cellular and foliar structure of the mouse cerebellum (Ross et al., PNAS 87:4189, 90). We now present further analyses of this phenotype, including a three dimensional reconstruction of the mutant cerebellum. This analysis demonstrates that a rather large volume, comprising the "anterior" cerebellum, is completely missing. Thus, the meander cerebellum is a posterior half-cerebellum. We have also analyzed the meander tailed phenotype. There is a progressive failure of organization, with altered foliation and glial cell structure apparent at PO. The cells in the anterior external granule layer do not proliferate and the Purkinje cells never organize into a monolayer. By P7 the mutant phenotype is fully established. These results demonstrate the unique specification of the developing cerebellum.
404.10 NEURON SPECIFIC ENOLASE PATCHES IN THE DEVELOPING RAT STRIATUM. W.E. Silverman* and Y. Solomon. Unit of Morphology, Coro Center for Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.

One of the initial events signaling the development of patch and matrix domains in the embryonic striatum is the appearance of islands or patches of dopaminergic (DA) neurons in the neostriatum. Neurons in the cells in the patches subsequently produce opiate receptors and substance-P (SP). A complementary pattern, the matrix, is produced postnatally following ingrowth of fibers from the remaining DA cells into the area between the patches, followed by synthesis of neurotransmitter, calcium binding protein and other peptides by neurons there. This sequence of neuropeptide expression preceded by the ingrowth of DA terminals suggests an active role for the mesostriatal projection. We have examined the ontogeny of immunoreactivity for neuron-specific enolase (NSE), a metabolic enzyme-marker for synaptogenesis and neuronal activity with respect to that of tyrosine hydroxylase, SP and neurotensin in the striatum and ventral mesencephalon of the developing rat at the light and ultrastructural levels. The most striking findings were that NSE appeared exclusively in striatal patches until the 2nd postnatal day, when it co-localized with SP in neuronal perikarya; by P2 NSE also appeared in neurotensin-positive cells in the matrix. The data obtained support the hypothesis that DA fibers establish connections in the striatum, and induce metabolic activity and expression of neuropeptides, initially in the patches and then in the matrix. Supported by The Israel Ministry of Science and Technology.
GLIA AND OTHER NON-NEURONAL CELLS III

405.1 GLIAL CELL RESPONSE TO SUBSTRATE-BOUND ADHESION MOLECULES. H. R. Paun* and J. Lemmon. Department of Neuroscience, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

During neurogenesis and regeneration, both soluble and noninvasive molecules may act as cues for glial cell development. We examined the influences of purified extracellular matrix molecules and cell adhesion molecules on the development and proliferation of neuroglial cells from neonatal rat optic nerve. Dissociated optic nerve glia were plated on nitrocellulose-bound fibronectin, laminin, collagen type IV, L1, n-cadherin, and NCAM. Cultures were grown in chemically-defined medium to promote formation of oligodendrocytes. Other cultures were grown in 10% serum to support type-1 astrocytes and the differentiation of progenitor cells to type-2 astrocytes. Short term adhesion assays were used to measure cell affinity for the different substrates. In these experiments, glial cell types displayed characteristic patterns of substrate preference. The glial cells developed distinctive morphologies on different substrates after incubation for 4 days. Measurements of glial cell migration showed that the substrates did not significantly influence cell proliferation rates. Our results indicate that progenitor cells, oligodendrocytes, type-1 astrocytes, and adult astrocytes possess different compositions of receptors for the adhesion molecules in their environment. Transduction of this substrate-receptor binding signal may induce cytoskeletal alterations that produce the observed morphological differences in glial cells.

Rat primary olfactory neurites are localized in glomeruli and can be regenerated during adulthood. It has not been determined whether the unusual structure or the regenerative capacity of the glomerular system is due to unique growth properties of the olfactory sensory neurons (OSNs), to unique properties of the olfactory bulb (OB) glia that surround the OSNs and glomeruli, or both. However, the following: (i) the regeneration of two types of OB glia, OB astrocytes and ensheathing cells, suggest that the formation of neural circuitry in the OB, as in other areas of the nervous system, is controlled by glial-neuronal interactions. OB astrocytes resemble type-1 astrocytes, and some of the OB astrocytes extend the glomeruli and express the molecules J1 and chondroitin sulfate proteoglycan (CSPG) that have been associated with corticobasal and corticothalamic axons. Ensheathing cells resemble Schwann cells and ensheathe OSN axons from the glial lamellae to the glomeruli. Further, OB astrocyte cell lines with the characteristics of OB glia in the glomeruli-enriching glia promote very low neurite outgrowth by chick retinal ganglion neurons (CRGNE), as expected of glia which form barriers, while other OB astrocyte lines and the high OSN outgrowth, as expected of glia that form axon-growth permissive pathways. In this study, rat OSN neurite outgrowth was tested on both the same cell lines. The results are that neural OB astrocyte lines that express J1 and CSPG support very low OSN outgrowth, while other OB astrocyte lines and ensheathing cell lines support higher outgrowth, and adult ensheathing lines support higher OSN outgrowth than any OB astrocyte lines. Together, the chick and OSN outgrowth results are consistent with the following hypotheses: (1) outgrowth, some OB astrocyte lines may form corticobasal axons that delineate the glomeruli, while ensheathing cells guide the axons to the glomeruli, and (2) during adulthood, ensheathing cells and perhaps also some of the OB glia may permit OSN axon growth, allowing formation of the glomerular synapses.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
405.3 The NG2 proteoglycan inhibits neurite outgrowth from cerebellar granule cells in vitro. M. C. Lemos, Department of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794.

The NG2 antigen is a high molecular weight, chondroitin-sulfate proteoglycan. As a cell surface marker in vivo and identifies a population of developing glial cells in vivo, some of which differentiate into oligodendrocytes. Proteoglycans can play important roles in the regulation of axon elongation and provide a physical barrier to glial-restricted affinities of NG2 to either support or inhibit neurite elongation in vitro.

Tissue culture surfaces were coated with poly-L-lysine followed by either laminin alone (10μg/cm²) or laminin mixed with NG2 (5μg/cm²). Ceruleal granule neurons were isolated from postnatal day 5 and 6 rat pups on discontinuous Percoll gradients and seeded onto these surfaces in media supplemented with bFGF. After 24h, the cultures were fixed and the extent of cell attachment and neurite outgrowth quantified. The neurons attached equally well to both substrates, however, 66% of the cells extended neurites on laminin, while only 21% of the cells grew processes on the laminin plus NG2 coated surface. The extent of neurite outgrowth also differed between the two types of surfaces. On laminin, the mean neurite length was 92.5±11.4 microns whereas on laminin plus NG2, mean neurite length was 54±12.2 microns. Digestion of NG2 with chondroitin ABC did not remove the growth-inhibitory activity. When the laminin concentration was increased to 10μg/cm², NG2 no longer inhibited neurite outgrowth. The glycosaminoglycans, chondroitin sulfate and hyaluronic acid, each inhibited neurite outgrowth when used at 15g/cm² in this assay. These data suggest that NG2 is one of a number of proteoglycans that can inhibit neurite outgrowth. Calls that carry the NG2 proteoglycan on their surfaces within developing neural tissues may provide an unfavorable substrate for axon elongation.

405.5 Differential effects of median and lateral mesencephalic astrocytes on neuritogenesis. L.A. Cavalcante, V. Moura-Retei, J. Garcia, and E.L. Carlesso, Instituto de Fisiologia e Patologia, IPFBA, 21241 Rio de Janeiro, RJ, Brazil.

Sulcal glia in median and lateral sectors of the mesencephalon are heterogeneous in neurite response (Barradan et al., Glia 2:103, 1989). In this study, we have tested for regional differences in mesencephalic astrocytes on neuritogenesis. Dissociated cells from either median or lateral sectors of mouse embryo mesencephalic (MMG or LMG) for 2 days and co-cultured with an anti-MAP2 antibodies, (2) cultured onto poly-L-lysine in serum-free medium with addition of conditioned medium from MG or LMG. Both MMG and LMG on MMG grow long and varicose neurites whereas both MMG and MMG on MMG tend to aggregate and show extensive neurites. These features are also mimicked by conditioned medium from LMG or MMG. These results suggest (1) permissiveness vs. non-permissiveness of LMG vs. MMG on neurite growth, respectively; (2) mediation of effects, at least, partially by soluble factors. (Support: CNPq, FINEP, CEPID/GOBI)

405.6 Cultured ensheathing glia from adult rat olfactory bulb enfold olfactory neurites. A Ramón-Cueto, J. Pérez, P. Bovolenta* and M. Nieto-Sampedro, Cajal Institute, 37 Doctor Arce, 28042 Madrid, Spain.

Ensheathing glia of the olfactory bulb is a type of macroglia exclusively present in the olfactory bulb. To gain insight into the mechanisms underlying axonal regeneration in the olfactory bulb, we have studied ensheathing glia and their interaction with olfactory neurites in culture at the ultrastructural level. Three morphologically and ultrastructurally different cell types were identified in secondary cultures from adult rat olfactory bulbs. One of these cells is macrophage-like and showed a cell body with a round nucleus and a prominent nucleolus. The processes of these glial cells spread over the surface of the explant, which suggests that they are ensheathing glial cells. The other cells showed a neurofilamentous arrangement and were shown to be ensheathing glial cells. To examine the role of ensheathing glia in vivo, we used a lesion model of the olfactory bulb and found that ensheathing glia are present in the regenerating axons. These results suggest that ensheathing glia play a role in the regeneration of axons in the olfactory bulb, which is consistent with the presence of ensheathing glia in vivo.
405.9 GROWTH FACTOR INDUCED PHENOTYPIC CHANGES IN CULTURED SCHWANN CELLS INCLUDE ALTERED GAP JUNCTIONAL CONDUCTANCE. K.J. Chaudhuri, M. Chanson, D.C. Spray, J.A. Kessler. Albert Einstein College of Medicine, Bronx, New York 10461.

Schwann cell proliferation, morphology, and gene expression are altered after nerve injury. These changes are reproduced in vitro by agents which elevate intracellular levels of cAMP and by growth factors which are released after nerve damage. We have examined changes in gap junctional conductance in cultured Schwann cell pairs which occurred in association with other phenotypic changes. Antibody directed to reticulon (F2:~60kDa) and the perytanatory extract (BPE:~100kDa), the cells became more spindle shaped, and cell proliferation and low affinity nerve growth factor receptor (NGF-R) expression were increased. Gap junctional conductance was significantly elevated from 0.05±0.01(SEM, n=27) before treatment to 1.23±0.24(SEM, n=19) (p<0.01). By contrast, after exposure to transforming growth factor beta, (TGF-β, 10ng/ml) cells displayed a less flatten, multipolar morphology cell proliferation was not increased and NGF-R expression was decreased. Further, compared to control values, TGF-β significantly reduced cell coupling in a time dependent manner; after 48 hours of treatment, cell coupling was decreased to 20% of the control value. The results indicate that changes in cell coupling resulting from these treatments reflected the number but not the type of channels that were expressed. Electrical or chemical coupling may help to coordinate Schwann cell responses to injury and other stimuli. These observations indicate that the strength of intercellular communication between Schwann cells changes in response to alterations in the cellular milieu providing a possible mechanism for modulating functional interactions between Schwann cells and their environment.

Microglial responses in the rat spinal cord following a hemisection at T0 were examined at levels rostral and caudal to the lesion. Microglia were visualized histochemically using the Griffonia simplicifolia B-isolectin (USA). Expression of interleukin-1 alpha (IL-1 alpha) and tissue factor (TF) was determined in the central nervous system (CNS) using in situ hybridization with mxiRNA-GFAP staining. Lectin staining showed two distinct patterns of the microglial response. First, activated microglia appeared 1 day post-injury (DPI) and were widespread. This reaction was both the white and grey matter. A second pattern of microglial activation occurred 3-4 DPI in the grey matter (C4-C5, T4-T5, T12 and L1) to the level of the lesion. Activated microglia remained prominent for up to 2 weeks in the white matter and 4 weeks in the spinal gray zones. The second pattern of microglial activation was confined to the area of fiber tracts degeneration. The onset of this response was as early as 3 DPI and lasted as long as 2 months. In the dorsal funiculus rostral to the level of the lesion the microglial reaction was confined to the fasciculus gracilis (FG) of the lesion side involving without the adjacent corticospinal tract (CST). Caudally, the response was confined to the degenerating CST without involvement of the FG. By 5 days post-injury, a subpopulation of activated microglial cells showed expression of IL-1 alpha. The localized activation of microglia in regions of degenerating white matter (i.e. FG rostral to the lesion) and not in adjacent, intact regions (i.e. CST rostral to the lesion) suggests a non-directed triggering mechanism for the initiation of the degeneration-induced microglial response. The astrocytic reaction, on the other hand, showed a delayed onset (5 DPI), mostly in the degenerating fiber tracts, and the reaction was less intense than the microglial response during the early survival time. At longer survival times (>4 weeks), however, microglia and astrocytes displayed a largely parallel response in temporal and spatial distribution patterns. (Supported by NIH P01-NS 27511)

405.11 MICROGLIAL RESPONSES TO NEUROTOXIC ABLATION OF SEROTONERGIC AXON TERMINALS. M.A. Wilson* and M.E. Pollinger, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

Microglial cells are a heterogeneous class of non-neuronal cells in the CNS which respond to neuronal damage. Microglia exhibit a number of characteristic features which are altered in response to CNS injury. "Activated" microglia undergo morphologic changes, up-regulation or novel expression of macrophage/miyocyte antigens, and may proliferate and become phagocytic. The response of microglia varies depending on the nature of the particular injury, e.g., neuronal death vs. axotomy.

We have examined the response of microglial cells in the forebrain to the selective chemical ablation of 5-HT axon terminals induced by p-chloroamphetamine (PCA). Rats were treated with PCA (10 mg/kg, s.c., x2) and sacrificed 3 days, 6 days, 3, 6, or 9 weeks later. The dorsal raphe, a 5-HT source in the forebrain, but spares pretermninal 5-HT axons and cell bodies. Antiserum directed against 6-microglial antigens were utilized as markers for microglial activation in PCA treated rats, untreated controls, and rats with unilateral facial nerve transection. Morphologic changes in microglial processes and increases in staining for two of the antigens were detectable 6 days after PCA treatment. Three weeks after PCA, increased expression of four of the microglial antigens was detected, as well as increased branching of microglial processes and changes in the intracellular distribution of one of the antigens. By 6 weeks after treatment, these alterations were less marked; at nine weeks the microglia in treated animals resembled those in controls.

Recently, it has become clear that proliferation of microglial cells and hypertrophy of astrocytes may be a general component in association with the central processes of peripheral axotomy and sensory ganglion cells. For that purpose, by the use of a computerized scanning system, we have analyzed the time course for the microglial (antibody OX-42) and astroglial (antibodies to GFAP and in situ hybridization for mRNA-GFAP) cell reaction in the L4 dorsal horn, the column of Clarke and the gracile nucleus after sciatic nerve transection as well as after the transection of the trigeminal nucleus after infraorbital nerve transection. In all areas examined the microglial cell reaction started 24 to 48 hours and peaked one to two weeks postoperatively. The astrocytic reaction, on the other hand, showed a gradual decline in the reaction over a period of several months. The astroglial cell reaction seems to parallell the microglial cell reaction. These observations demonstrate that peripheral nerve injury induces a rapid and prominent response among microglial and astroglial cells in all the parallel primary sensory projection areas.

405.13 CALCIUM PERMEABLE CHANNELS IN MICROGLIA. M. Jia, M. X. Li, C. A. Colson, and D. L. Gilbert*. Lab. of Biophysics, NINDS, NIH, Bethesda, MD 20892 and Dept. of Physiology and Biophysics, Georgetown Univ. Med. School, Washington, DC 20007.

Cytosolic calcium is important for the activation of microglia. An influx of calcium through calcium-permeable channels may be a means of increasing cytosolic calcium. To study these channels, whole cell recording and single cell recording experiments were performed on cultured rat microglial cells. The calcium channel (in mM): 145 KCl, 1 CaCl2, 1.8 MgCl2, and 10 HEPES; the patch solution (in mM): 110 BaCl2 and 10 HEPES. Non-inactivating inward currents were observed at hyperpolarized membrane potentials. The single channel conductance was about 8 pS. The open probability was voltage-independent. We also report on a voltage-gated L-type calcium channel utilizing a whole-cell recording mode. The bath solution (in mM): 120 TEA-Cl, 15 CaCl2, 2 MgCl2, 10 TRIS-HEPES; the pipette solution (in mM): 120 CaCl2, 2 MgCl2, 5 EGTA, and 10 EDTA. Small long-lasting inward currents were activated with depolarizing pulses at a holding potential of -40 mV. The currents were enhanced with 1 μM Bay K 8644. Due to a lack of an outward K+ current, a slight activation could result in a sustained membrane depolarization. Surprisingly, at high extracellular potassium on microglial function. Using a cytochrome c reduction assay in the presence and absence of superoxide dismutase (SOD), we have measured the production of oxiradicals by resting and stimulated cultured neonatal rat microglia. In order to maintain a normal ionic strength and osmolarity, potassium was substituted for sodium in all experiments. When potassium concentration was changed from a normal of 5 mM to a high of 55 mM, there was no change in resting superoxide radical ion production. A significant increase was seen, however, when phorbi myristate acetate (PMA) was added to activate the microglia to produce the superoxide radical ion. In the presence of 5 μg/ml PMA, potassium concentrations of 25 and 55 mM initiated a 115 percent and a 127 percent increase, respectively, over the PMA stimulated release in normal potassium. This enhancement was partially blocked by 10 μM spiperone. These data indicate that changes in extracellular potassium at sites of injury may serve to modulate microglial release of oxiradicals.

Microglia are the resident CNS macrophages and are found at sites of trauma in the brain. Since injured cells release potassium into the extracellular fluid, we have examined the effect of high extracellular potassium on microglial function. Using a cytochrome c reduction assay in the presence and absence of superoxide dismutase (SOD), we have measured the production of oxiradicals by resting and stimulated cultured neonatal rat microglia. In order to maintain a normal ionic strength and osmolarity, potassium was substituted for sodium in all experiments. When potassium concentration was changed from a normal of 5 mM to a high of 55 mM, there was no change in resting superoxide radical ion production. A significant increase was seen, however, when phorbi myristate acetate (PMA) was added to activate the microglia to produce the superoxide radical ion. In the presence of 5 μg/ml PMA, potassium concentrations of 25 and 55 mM initiated a 115 percent and a 127 percent increase, respectively, over the PMA stimulated release in normal potassium. This enhancement was partially blocked by 10 μM spiperone. These data indicate that changes in extracellular potassium at sites of injury may serve to modulate microglial release of oxiradicals.

CHANGES IN LOCOMOTION AND NEUROMUSCULAR DEVELOPMENT IN THE NEONATAL RAT ACCOMPANY SIMULATED WEIGHT-LESSNESS. K.D. Walton1, J. Jacoby2, K. Ko1, S.A. Williams1 and R. Linas2, Depts. Physiology & Biophysics and Ophthalmology, NYU Medical Center, 550 First Ave., NY, NY, USA, 10016

Tail suspension of rat pups postnatal day 8 (P8) to P13 leads to abnormal swimming and wobbling (Walton et al., Neurosci. Soc. Abst. 16, 937, 1991). This study asked if: (1) irreversible deficits in motor skills result from an extended period of susp. and (2) susp. alters hindlimb HL muscle development. Pups were susp. P8-P13, P8-P21, P13-P21, or P13-P31. Each susp. (S) animal had a non-suspended companion (C). Free walking was videotaped with high speed camera (nac, 200 fps) and analyzed with Peak 20 motion analysis software. Swimming was unaffected in pups S on P13. Stepping in all S was slow with hyperextension of foot and ankle joints. Animals taken down on P13 or P21 recovered. Deficits persisted in those S until P31, e.g. in those S until P31, e.g. those S until P31, e.g. those S until P31, e.g. those S until P31.

406.3

A KINEMATIC AND ELECTROMYOGRAPHIC STUDY OF LOCOMOTION IN THE KITTEN. L. Girard1, T. Cabana1, and T. Drew2, Depts. Physiology and Biology, Université de Montréal, Québec, Canada, H3C 3J7.

To better understand the development processes of locomotion, a detailed kinematic and electromyographic (EMG) analysis has been undertaken in the kitten. Eight (8) kittens between the ages of 2 and 3 weeks were chronically implanted for the recording of EMG activity from flexor and extensor muscles of the fore- and hindlimbs. Video recordings were always made simultaneously with the EMG recordings. Most kittens were capable of steady treadmill locomotion at a slow speed (0.1 m s⁻1) at 3 weeks of age, but they had difficulty in supporting their weight, and the hindlimbs were placed in abduction. Analyses of the changes in joint angle, at this age, showed that there was a pronounced yield at the beginning of stance at the ankle and, to a lesser degree, at the elbow. By 6 weeks of age, joint angles resembled those measured in adult cats. Even at 3 weeks of age the EMG recordings resembled closely those seen in the adult with flexor and extensor muscles showing strict alternation, with little evidence of co-contraction. Although at 3 weeks there were some subtle differences in the relative timing of several of the muscles, in particular with respect to flexor muscles of the hindlimb, these disappeared by 6 weeks. These results suggest that kittens are capable of generating a normal pattern of locomotor activity at an early age, and that many of the differences in the locomotor capacities of young kittens, compared to adults, are due to their inability to fully support their weight. Supported by the FCAR and the FRSQ.

HINDLIMB SUSPENSION IN NEONATAL RATS LEADS TO PERMANENT DEFICITS IN AIR RIGHTING REFLEXES. Jane Skirina1, Kerry D. Walton2, Dan Hillman3 and Rodolfo Linas2, Depts. of Physiology and Biophysics and Otolaryngology, NYU Medical Center, 550 First Ave., NY, NY, USA, 10016

Unloading the hindlimbs (HL) of rats by tail suspension from P6 to P21 leads to reversible slowing of the air righting reflex (ARR) (Walton et al., IBRO Absts. 1991). In this study rats were suspended from P13 to P31 to find if the critical period for development of the ARR was the same as that for other motor behaviors and if extending the suspension period would lead to persistent deficits. The pups were suspended by their tails at 20°, and each suspended (S) animal had a non-suspended companion (C). The ARR, elicited by dropping the animals from 50cm onto a padded surface, was videotaped at 200fps. Righting of the head (HL), forelimbs (FL), and HL were measured. Righting of the HL was slower in S than C pups on P19 (341.8 ± 51 msec compared to 212.3 ± 11.9 msec, *p ≤ 0.004). On P31 the mean S and C HL righting times were significantly different at the p ≤ 0.0001 level (350±1.1 and 22±0.4msec) Righting times for the H and FL were not significantly different in the two groups. The differences in HL righting persisted at P60 indicating the existence of a critical period in the development of the central vestibular system (Dieter's nucleus and the vestibulo-spatial tract) beginning near P14 and ending by P31, a period different than that for swimming, but similar to that for walking. These data suggest the existence of a set of "critical periods" organized in a hierarchical manner corresponding to the acquisition of particular motor skills. Preliminary morphological results indicate that the density of neurotransmitters, specifically glycine, may be decreased in Dieter's nucleus in S animals. Supported by NASA.

406.4

Neonatal nerve injury leads to rapid changes in motoneuron synaptic excitation from afferents in the injured nerve (Navarrete, J. Physiol. 438:220P, '91). Here we have studied the distribution of primary afferent fibres around injured motoneurons using a monoclonal antibody to parvalbumin (PV) which preferentially labels large diameter primary afferent fibres (Zhong et al., J. Comp. Neurol. 302:715,'90). Motoneurons were pre-labelled by injection of fluorescent tracers into ankle flexor muscles at birth (P0). At P2, the common peroneal (CP) or the sciatic nerve was crushed unilaterally. At P7 and P14 spinal cords were processed for PV immunocytochemistry. In some cases, motoneurons were injected intrathecally prior to processing. At 7 and 14 days after sciatic crush, the density of PV staining in the ventral horn was markedly decreased on the lesioned side. After CP crush, decreased PV staining was largely confined to the area occupied by the CP motoneuron pool. On the injured side, PV immunoreactive fibres were found in close apposition to the soma and dendrites of labelled flexor motoneurons. We are mapping the distribution of PV-immunoreactive fibres on the somatodendritic surface of injured and uninjured motoneurons. These results show that (1) neonatal nerve injury causes a rapid decrease in PV-immunoreactive primary afferent fibres around lesioned flexor motoneurons. This may, in part, be attributed to death of dorsal root ganglion neurons.

CHRONIC SPINAL GAP TRANSECTION IN CHICK EMBRYOS: A KINETIC ANALYSIS. N.S. Bradley* and S.H. Chambers. School of Physical and Occupational Therapy, McGill Univ., Montreal, QC, Canada H3G 1Y5.

EMG (Bradley and Bekoff, J. Neurobiol. 92) and observation studies (Oppenheim, J. Cogn. Neurosci. 1990) suggested that the degree of motility is altered in the absence of descending neural inputs in chick embryos. Thus, a kinematic study was undertaken to examine these changes as part of a series of studies on embryonic spinal cord regeneration. The interaction of neural and extraneural factors in motor development.

Midthoracic spinal transections were performed on embryonic day 2 (E2) and continuous video recordings (1 hr) were made on embryonic day 9 for each of 9 embryos. Video records of entire movement sequences (40 s) for 2 embryos were computer analyzed at 60 Hz, the data filtered and corrected for movement out of plane, to measure concurrent wing and leg activity and to compare findings to data for 4 control embryos. Preliminary findings indicate that reduced buoyancy does not alter the overall motility. Linear trend analyses for experimental embryos suggest that relative timing of shoulder/elbow (r2=0.51) excursions and hip/knee/ankle (r2=0.43) are similar to controls (r2=0.47;0.44). While reduced buoyancy does not appear to alter primary features of motility, experimental embryos are not posturally displaced during movements or annomorphic contractions and their movements appear more orderly as compared to controls. This work was supported by FCAR and NSERC.

406.7

Previous results have shown that a spinal cord hemisection at C2 causes an increase in the number of multiple synapses (MS) contacting phrenic motoneuron profiles at the C3-C6 levels of the spinal cord. The reactive synaptogenesis is caused by lesioning the descending bulbo-sympathetic respiratory pathways to the phrenic nucleus or by the generalized effects of spinal cord injury (i.e., edema, ischemia, and the interruption of other inputs) in the immediate area of the phrenic nucleus. To evaluate these possibilities, we carried out a hemisection at either C2, C7, or T4 in 3 groups of rats and allowed a survival period of 7 days. The number of terminals forming multiple synapses and the number of synaptic active zones (SAZ) contacting HRP labeled phrenic motoneurons profiles were counted at EM levels in the spinal cord ipsilateral to hemisection. Seven days post hemisection the percent decrease in synaptic active zones was 86% (C2), 90.7% (C7), and 91.6% (T4) as compared to controls (100%). In order to decrease the decrease in SAZ, the number of multiple synapses increased after cervical hemisections (35.5 ± 5.2 (C2), 34.0 ± 7.4 (C7) as compared to controls (28.3 ± 3.3), but the number of multiple synapses decreased following the T4 lesion (22.8 ± 4.4).

These results suggest that the degree of reactive synaptogenesis in the phrenic nucleus is dependent upon the distance of the spinal cord hemisection site from the target neurons.

406.8

Previous studies have demonstrated a rather weak expression of the crossed phrenic reflex (CPR) in spinal hemisection and an immediate contralateral phrenicotomy in young adult rats (Exp. Neurol. 111:244-250, 1991). There is a significant increase in reflex activity, however, if there is a delay following C2 hemisection before contralateral phrenicotomy. The present study was carried out to determine if conditioning lesions at either the C7 or T4 levels of the spinal cord may also influence the CPR when a postlesion delay of seven days is allowed before the reflex is induced. There were 4 groups of rats: a control group (left C2 hemisection and right phrenicotomy with no preoperative delay), and 3 experimental groups each receiving a C2, C7, or T4 hemisection with a 7 day delay before induction of the reflex. Quantitative assessment of the CPR was accomplished by determining the mean integrated area of phrenic nerve compound action potentials under standardized recording conditions. The results showed that the CPR is significantly increased in the C2 hemisection group (97 ± 34mV, P<0.0003), C7 hemisection group (97 ± 14mV, P<0.01), and T4 hemisection group (31 ± 8mV, P<0.04) as compared to reflex activity in the control group (12 ± 2 mV).

These results suggest that a conditioning lesion in the spinal cord causes an increase in CPR activity. Furthermore, the amount of the increase is dependent upon the spinal cord level of the conditioning lesion.

ULTRASTRUCTURAL CHANGES IN THE RAT PHRENIC NUCLEUS 2 HOURS AFTER SPINAL HEMISECTION. N.A. Sperry and H.G. Goshergian, Dept. of Anatomy, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

This study extends our earlier analysis of injury-induced morphological changes in the rat phrenic nucleus (CJN, 284:519,1989) by examining the nucleus at 2 hrs. post-hemisection (p.h.). Phrenic motoneurons were identified at EM levels by horseradish peroxidase labeling. Micrographs were analyzed qualitatively and quantitatively in both normal and spinal hemisected rats. Our results showed a significant increase in the percentage of dendrodendritic appositions from a normal level of 4.73±0.8% to 8.40±5.4% at 2 hrs. p.h. Although there was not a significant increase in the mean percentage of single and multiple synapses at 2 hrs. p.h. (as first seen at 4 hrs. p.h. in our earlier study), a new finding showed a significant increase in the mean lengths of axonemes in a synaptic active zone from normal lengths of 0.37±2.009m and 0.044±0.07m to 0.41±0.10m and 0.51±0.03m respectively. The hemisected rats and synaptic active zones in the phrenic nucleus could enhance synaptic efficacy by increasing contact area, and从而使 movement direction in our spinal cord injury model.

Previous studies demonstrated that one of the main factors of normal formation and development of structure of central nervous system is afterrehabilitation of motor apparatus. In recent studies we used the local stimulation of the peripheral nerve-muscular system and polarization of the motor cortex. Using this data we developed a method of functional biocontrol (FBC) which aims to increase the rehabilitation of motor disfunctions. Application of this method had high clinical efficiency. We observed the reconstruction of movement, normalization of EEG, ENG, reflex responses of spinal motor neurons and normalization of the habituation process on long-term stimulation of sensory systems. We have shown that this method restores the functional asymmetry in the cortex and spinal cord. Using the method of FBC allows to provide rehabilitation and to decrease the period of treatments 1.5-2.5 time.

Despite its wide distribution in the central nervous system, the role of calbindin D-28k (CB), a calcium-binding protein, is still poorly understood. Recently, Laureo et al. (1991) have suggested a possible neuroprotective role for this protein, in the primate model of Parkinson's disease since tyrosine hydroxylase (TH)-positive neurons containing CB seem to be less severely affected by the toxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) than those who do not contain CB. The aim of this study was to investigate the ontological appearance of CB in neurons of rat substantia nigra and the degree of co-localization of CB with TH-positive cells in vitro. In serotonin, ventral midbrain tissue containing groups A9 and A10 was dissected from rat embryos at 14 days gestation, enzymatically and mechanically dissociated, then plated on 13 mm-culture dishes coated with poly-L-lysine as substrate. These cultures were grown from 1 hour to 10 days before being fixed by cold paraformaldehyde. The culture disks were then immunohistochemically reacted following standard procedures to reveal TH and CB-immunoreactive profiles.

TH-positive neurons are present in all cell cultures. In cultures grown for 1 hour, round to oval cell bodies without neurites display TH-immunoreactivity. Immunoreactive neurites appear in cultures grown 6 hours. The immunoreactive neurites form clusters and have the characteristic shape of dopaminergic neurons, being mostly polygonal and elongated with main processes arising at each pole of the cell body. In contrast, the immunoreactivity for CB appears in cultures grown for 6 days. CB-immunoreactive cells are oval, smaller than the TH-positive neurons and also tend to aggregate in the form of clusters. In double-labelling experiments in vitro, CB-positive cells were clearly distinct from the TH-positive cells. [Supported by FRSQ and MRC and Canadian Network of Centres of Excellence.]

406.13 THE EFFECTS OF NEONATAL CORTICAL OR CEREBELLAR LESIONS ON THE NUMBERS OF CORTICOSPINAL (CS) NEURONS IN ADULT RATS.

D.L. O'Donoghue, D.R. Humphrey and C.R.D. Poff. Dept. Anatomical Sciences, the University of Oklahoma Health Science Center, Oklahoma City, OK 73109;
*Lab. of Neurophysiology, Emory University, Atlanta, GA 30322.

Previously, we showed that 40000 cortical cells have transient spinal axons that are eliminated by the second postnatal week. The present study determined if increased numbers of CS cells could be retained into adulthood when the cortical fields for growing corticofugal axons are modified. Targets available to growing axons were expanded in the spinal cord by the ablation of the opposite cortex. Brain stem targets, such as the basilar pontine nuclei, were removed after cerebellotomy. Aspiration lesions were performed on postnatal day (PND) 1 prior to cortical lesions reaching the mid-cervical (CS) spinal cord or the development of corticopontine projections. The left frontal and parietal cortices or the cerebellum were removed from pups anesthetized by hypothermia. Pups matured to PND 30 when they were re-anesthetized with methohexital. Fast Blue (FB) soaked pledgets were inserted into the CS tract at CS of all animals. Serial section analysis of FB labeled cells indicate that neonatal cortical lesions do not alter the distribution or number labeled CS cells as compared to litter-mate controls. Cerebellotomy, although incomplete in cases, caused qualitative and quantitative decreases in the distribution and number of CS cells that could be labeled. These data indicate that spared spinal target areas do not result in more CS cells. By contrast, the loss of either the brain stem targets (i.e. basilar pons), or the ascending inputs from the cerebellum, resulted in an increased number of labeled CS neurons. Neonatal lesions anterior to or cerebellotomies result in similar alterations in microstimulation maps of evoked forelimb movements from the cerebral motor cortex. However, the present study indicates the substrate for these alterations in stimulation mapping are different. (Grant support by OU BRSG funds (DOC) & NIH NS01046 (DOC)).

407.1 REGENERATING FROG OPTIC NERVE AXONS: DO GLIA GUIDE THE GROWING TIPS. P.M. Orkand* and R.E. Blanco. Inst. of Neurobiology and Dept. of Anatomy, Univ. of Puerto Rico Sch. of Med., San Juan, PR 00961

Unlike those of mammals, injured optic nerves of frogs can regenerate and eventually form functional connections. Since frog retinal ganglion cell (RGC) axons are slow to degenerate after separation from their cell bodies, the regenerating tips may follow the course of the degenerating axons after a crush injury. In preliminary experiments aimed at studying the relationship of ganglion cells with regenerating axons in the absence of the degenerating ones, we looked at the structure of the proximal tip of the optic nerve 1-2 weeks following transection and deflection of the distal stump.

At early time periods, there is macrophage activity at the cut end, and gial cells are phagocytosing debris of retrograde degeneration in the nerve stump, where regenerating axons begin to appear. After 4 weeks, bundles of positive regenerating fibers lie along phagocytic cells and astrocytes that appear to have migrated into the cut end. Their identification will be confirmed by HRP fillings of RGCs.

Supported by NIH NS07464 and NSF EPSCOR II.

407.2 LEPTOMENIGEAL CELLS CAN INDUCE CHANGES IN ASTROCYTES IN VITRO. R. Moss and S. David*. Centre for Research in Neuroscience, Montreal General Hospital Research Institute and McGill University, Montreal, Canada.

Leptomeningeal (LM) cells rapidly migrate into penetrating wounds of the CNS. Astrocytes in the parenchyma of the CNS that interface with these LM cells transform to form the glia limitans. We have used an in vitro approach to study whether direct interactions with LM cells induce morphological and functional changes in astrocytes.

DiI labeled astrocytes purified from the neonatal rat cerebral cortex were plated onto monocultures of LM cells, astrocytes or polylysine coated glass coverslips. 16-20 hours later the cultures were fixed and the size of labeled astrocytes determined using an IBAS image analysis system. Astrocytes were smaller in size when plated on LM as compared to astrocytes or polylysine. When neurite outgrowth on these astrocytes was assessed by plateing purified cells on either glial cells, there was a 40% reduction in the ability of the astrocytes plated on LM to support neurite growth, compared to astrocytes plated on astrocytes monolayer. These results suggest that leptomeningeal cells can induce both morphological and functional changes in astrocytes, and may account for some of the astrocytic changes at the site of CNS lesions. (Supported by MRC, RHRMSL, FRSQ and PCAN)
407.3

We have developed a model to promote axonal regeneration in the unilateraly injured rat spinal cord (Adv in Neurosurg 3; 41- 44, 1991). Central neurons in the injured rat (female Wistar rat, 90-190 g body weight) spinal cord showed regrowth and remyelination in the autografted PNS bridge of peripheral nerve. HRP study demonstrated that the regenerant and remyelinated axons originated from the neurites of the spinal cord. In this paper, we examined the relationship between astroglia and regenerating nerve fibers in this model. The examination of the graft spinal cord interface revealed that GFA-P-positivie zone did not inhibit the regrowth of CNS axon into the graft. The A2B5 antibody-positive cells were less continuous developing a use of the spinal cord, whereas glial processes at the anotranlateral column located far from the grafted-inset side were clearly stained with the A2B5 antibody. Electron microscopically, in the graft close to the anotransplantation, a network of astrocytes was attached to the surface of basal laminae. Remyelination of regenerated axons was also observed in the spina cord of normal rats. The formation of a fibrous plate among the cells of the interstitial space were easily seen especially along the perivascular area. Astrocytic processes were closely apposed to the regenerant axons with or without giall basal laminae. These results indicate that astrocytic action does not impede the regeneration, rather astrocytes, especially type-1, might support the regeneration of CNS nerve fibers in the milieu of this model.

407.5

INTERACTION OF CENTRAL AXONS WITH SCHWANN CELLS OF PERIPHERAL NERVOUS TISSUE. W. K.D., CHAI, P. DOCKER, K.-F. SO* and K.-C. LAM, Dept. of Anatomy, University of Hong Kong, 5 Tsim Sha Tsui, Pokfulam, Hong Kong.

Optic nerve of 50 rat aged 6 weeks was cut intra-orbitally and replaced by a sciatric nerve graft. After 9 months, the graft was re-operated on and the regenerating optic axons were processed for electron microscopic examination. Various regenerative measurements were made on the myelinated fibers of the regenerating (n=6), age-matched normal optic (n=6) and sciatric (n=6) nerves. The relationship between myelin and axon was examined by plotting the myelin area against the axon area (based on perimeter). It was found that the mean slope of linear regression line for the regenerating group (0.54± 0.045) showed a closer resemblance to that of the optic (0.640±0.024) rather than to the sciatric group (1.29±0.081). The mean g-ratio (axon diameter/Fiber diameter), which indicates the relative sheathe thickness, was different among the three groups. However, there is a tendency for the regenerating group to overlap with the optic group (eg. 165, 64% and 98% of sciatric, regenerating and optic fibers respectively have a g-ratio above 0.68).

Thus, central axons regenerating in peripheral nerve environment seem to be able to alter the myelin production of the Schwann cells in such a way that it supports the idea of axon-dependence in the process of myelination.

407.7

Previous studies have demonstrated that a transected embryonic chick spinal cord loses its capability for axonal repair and functional recovery on embryonic day (E) 13. The onset of spinal cord myelinogenesis is coincident with this transition from permissive to restrictive repair period. To assess a possible inhibitory role of myelin in regeneration, we have delayed the onset of myelination (dysemelination). In such an myelinated embryonic cord, the subsequent assessment of spinal cord repair after a restrictive period transection (e.g. from E13) would serve as a test of whether myelin inhibits or permits axonal growth and functional repair. On E9-E12, direct injection into the thoracic spinal cord of a galactocerebroside monoclonal antibody with a source of spinal cord remyelination resulted in dysemelination until E17, as determined by myelin basic protein immunocytochemistry. A subsequent thoracic cord transection as late as E15 (i.e. during the normal restrictive period for repair) resulted in neurological repair and functional recovery (normally myelinated embryos showed no anatomical repair or functional recovery after an E15 transection). Retrograde labelling of brainstem regions, after regeneration, indicated that anatomical repair of brainstem-spinal projections in dysemelinated, transected chicks was indistinguishable from unoperated control animals. Behavioral (open field) as well as indistinguishable from unoperated control animals. This indicates that the myelination process is inhibitory to the repair of transected spinal cord in embryonic chick (supported by Canadian NCE for Neural Regeneration and Functional Recovery).

THE FUNCTIONAL PROPERTIES OF PURIFIED POPULATIONS OF CULTURED HUMAN SCHWANN CELLS STUDIED IN VIVO. A.D.O. Levie*, V. Guevadr, P. Aebersco, B.P. Bunge*. The Miami Project and Dept. of Neurosurgical Sciences, University of Miami School of Medicine, FL 33143 and Research, Provence, RI 02912.

Methods are now available to purify populations of Schwann cells (SCs) derived from adult human autographs. Two populations are seeded with 30:70 solution of Matrigel®/DMED (MD) with or without human SCs at a density of 80 million cells/ml. Channels were implanted within 8 mm gap of the transected sciatric nerve of male rats for a period of 6 weeks. The number of regenerated axons and cable surface area was uniformly greater in channels seeded with human SCs when compared to channels containing MD only. Survival of the transplanted human Schwann cells was established by demonstrating the regeneration process within 5 days in culture and immune staining for primates and rat specific nerve growth factor receptor and SI10. These results also indicated that the regenerated axons contained a mixture of human and rat (host) SCs. Myelination of regenerating SCs appeared to occur by both donor and host SCs. We are using immune staining for HNK-1, an antigen found in human but not rat myelins, to establish the presence of human myelin segments within the regenerating cable. These studies indicate that purified populations of cultured human SCs survive and enhance axonal regeneration when transplanted into the injured peripheral nervous system of the immune deficient rat. (Supported by NS 19923 NIH/NINDS, Glaxo, Inc., and The Miami Project. Dr. A. Levie is a Fellow of the Medical Research Council of Canada.)

407.6

Semipermeable guidance channels do not support the regeneration of ventral root axons across a large gap in adult rats. The guidance channel's luminal environment was changed by adding transplanted adult rat derived primary Schwann cells (SC) seeded in a laminin-containing gel (LCG) to provide an axonal outgrowth-promoting substrate. Adult Fisher rat-derived SCs were cultured and used based on 10-30% dissociation. Culture purity ranged from 94-46% SCs. Semipermeable channels were seeded with SCs (5-6 x 10^6 cells/ml) in LCG, or the LCG alone, and tested in a 250 mm gap injury model in adult male Fisher rats. Twenty-one rats received SC grafts and 8 rats received LCG grafts. Regeneration was assessed at 4 weeks post-implantation by counting the total number of axons on cross sections at the channel's midpt. Regenerated cables were found in 19 out of 21 of the SC graft recipients (mean total axons = 2630 ± 270), while only 2 of the LCG grafts resulted in cables containing a small number of axons (mean = 302 ± 225). Passage number and SC purity did not significantly affect the total number of axons in the regenerated cables. In order to delineate the role that the grafted SCs play in the regeneration process, a recombinant retrovirus encoding human placentual alkaline phosphatase (AP) was used to generate a population of AP-expressing primary adult innervated rat SC cultures which were then tested in the L5 ventral root model. Histochemical analysis of the regenerated cables at 4 weeks revealed the presence of AP-positive cells and demonstrated the ability of transplanted SCs to myelinate and ensheath host axons.

407.8

Previous studies in our lab have established that embryonic chick loses its capacity for substantial spinal cord regeneration among embryonic day (E) 13. Correlating with this transition, we have examined changes in protein expression using high resolution 2D gel electrophoresis (1992). We have identified sets of proteins; early neural proteins (ENPs) which are continuously present during spinal cord development (E10-E17) then decrease to relatively lower levels, and late neural proteins (LNNPs) which are only expressed at high levels after E13. Some of these ENPs and LNNPs may play direct or indirect roles in establishing permissive or non-permissive environments for the outgrowth of axonemuratorized fibers. Spinal cord myelin also appears at E13 and may inhibit axonal regeneration. We have also examined changes in the levels of these ENPs and LNNPs after 1) spinal cord injury (transsection) and 2) delaying the onset of myelination (dysemelination).

Embryos were subjected to complete spinal cord transections during the permissive (E10) and restrictive (E15) periods for axonal repair. Expression profiles of the ENPs and LNNPs changed between the E10 and E15 periods, at increments of 2 days, and compared with the up-regulated developmental expression profiles. Two of the ENPs appear to be up-regulated in response to spinal cord injury. In dysemelinated animals, the higher expression of some LNNPs was delayed until well after E13, suggesting that they are myelin associated. These preliminary studies have used high resolution silver staining to visualize the proteins. Currently, we are attempting to confirm and extend on these results with isotopic labelling techniques. (Supported by the MRC of Canada).
RESPONSES OF MACROPHAGES IN DORSAL ROOT GANGLION TO PERNERAL NERVE INJURY. X. Xu and P.M. Richards.. Div. of Neurosurgery, Montreal Gen. Hosp. & McGill University, H3C 3A4. The signals following peripheral nerve injury that induce a regenerative programme in the nerve cell body may involve cells in the vicinity of nerve cell bodies. Previously, the recruitment of inflammatory cells to a dorsal root ganglion was shown to correlate with macrophage regeneration in the corresponding dorsal root. More recently, immunohistochemistry with monoclonal antibodies to a cytotoxic T cell/macrophage marker (ED1), the lA antigen (OX-6), and the complement receptor (OX-42) were performed on cryostat sections of fifth lumbar dorsal root ganglia 0-16 days after sciatic nerve transaction. With all three antibodies, immunopositive cells were present in normal ganglia, the total number being several thousand per ganglion. Immunopositive cells had increased in number by 4 days after injury and were 1-8 times more numerous than normal after 16 days. The higher counts could result from recruitment of macrophages and/or increased immunoreactivity of resident macrophages. The modest inflammatory response surrounding sensory nerve cell bodies is a potential stimulus to regeneration of their axons.

SEAL FORMATION IN TWO TRANSPLANTED GIANT AXONS SUGGESTS TWO MODELS OF SEALING. Todd L. Krause, Harvey M. Fishman, Martin L. Ballinger, and George D. Bittner. University of Texas at Austin, 78712 and University of Texas Medical Branch at Galveston, 77555. Sealed axons could seal according to the following two models: MODEL 1. Constriction at a cut end reduces the opening and increases the resistance of the conducting path between axoplasm and external solution; sealing is accomplished if axoplasmic fusion occurs. MODEL 2. Injury-induced vesicles migrate to the cut end, occlude, and subsequently fuse with each other and the axolemma to form a complete seal. Previous studies have not distinguished between these two models; in fact, we now show they have not determined whether or not sealing occurs. To distinguish between these two models and to determine whether complete sealing has occurred, we have used several electrophysiological measures (membrane potential, complex impedance, and injury current) together with video-enhanced, light, and electron microscopic observations to assess sealing in giant (80-500 µm diameter) axons of squid (Architeuthis dux) and Sepia officinalis (cuttlefish). We found recovery of resting potential and input resistance (Ri) in both axons. However, injury current (i) persisted at a substantial level relative to precut level (background) in squid giant axon (GA) for 2.5 hr following transaction whereas i in earworm medial giant axon (MA) decayed to background within 20 min. Further, the decay of i to background in MAs correlated with the time course of Ri recovery. Morphological observations of the cut end, together with the electrical data, indicate that MAs seal completely by vesicle plugging of a slightly constricted end whereas squid GA constrict at the cut end to produce an increase in the resistance but the end remains open. Support: CNR (N0014-90-J-113), TX ATP, and NSF (ECR-891-5179).

PROTEINS FROM SCIASTIC NERVE CONTAIN A SIGNAL PEPTIDE THAT MEDIATES TRANSPORT THROUGH THE AXON TO THE CELL BODY AND INTO THE NUCLEUS. C. C. Huang, R. Schmid, R. T. Anrub, and C. Nolte. Anatomy and Cell Biology, Columbia University, New York, NY 10032. Axons undergo structural changes in response to environmental clues or injury. While these changes require transcription, it is not clear how the needs of the periphery are communicated, often over long distances, to the nucleus. Using organotypic culture systems, we discovered a pathway in Aplysia neurons that conveys protein precursors from the axon periphery to the nucleus (L. U. Nurney, in press). Access to the transport system depends upon a signal peptide (sp) H-Prx-Lys-Lys-Lys Arg-Lys-COOH. To obtain a probe that might be used to identify neuronal signal molecules that use this pathway, we coupled sp to keyhole limpet hemocyanin and injected the conjugate into rabbit. A polyclonal antiserum was then affinity purified using immobilized sp. When proteins extracted from sciatic nerves were separated by SDS-PAGE, a soluble 35 Kd peptide (sp55) was the major constituent detected by the antibody. Interestingly, when these soluble proteins were subjected to gel filtration on Sepharose S-200, the major immunoreactive fractions, detected by dot-blot assay, were found in a high molecular weight (105 Kd) fraction. However, Western blots showed that this fraction contains sp53. To look for transport, the 105 Kd proteins were coupled to rhodamine (TRITC) and microinjected into the Aplysia neuronal cell body. After 1 day, TRITC-protein was found in the nucleus. In contrast, sp53 extracted from a gel after SDS-PAGE was not transported after injection. These results indicate that endogenous sp-containing proteins exist in mammalian nerve, and suggest that these proteins must be in their native form, or complexed to a carrier molecule, in order to be transported.

RESPONSES OF RETINAL GANGLION CELLS TO AXOTOMY: DIFFERENCES WITH AND SIMILARITIES TO PERIPHERAL NEURONS. M. R. Weiler and U. Vaiyda. Nerve Regulation Research Laboratory, Dept. of Veterans Affairs Med. Center, Northport, N.Y. 11766 and Dept. of Neurology, SUNY, Stony Brook, N.Y. 11794. The reaction of retinal ganglion cells to intraocular crush lesions of the optic nerve was investigated over the first two weeks postlesion using the binding of [3H]Actinomycin D (Act. D) to nuclei of neurons in tissue sections. Changes in nuclear binding of Act. D reflect structural changes in chromatin associated with transcriptional activity. Adult male Wistar rats received intraocular crush lesions of the optic nerve and were utilized at 1, 2, 3, 4, 5, 7, 8, 9, 11, and 14 days after injury. Binding of nuclei for Act. D decreased sharply at one day after injury followed by a transient increase to above normal levels at days 2-3. The remaining pattern of response was characterized by both normal binding 4-7, 9 and 14 days, separated by increases to normal levels at 8 and 11 days after injury. Alterations of Act.D binding were also observed in the contralateral eye. Normal binding was observed at 3, 4 and 9 days and a primary increase in binding at 7 days after the operation. Except for magnitude, the basic pattern of response of surviving central and peripheral neurons to axon injury is similar, but the magnitude of the response is much less in central neurons.

IGNALS THAT INDUCT SPROUTING IN THE CENTRAL NERVOUS SYSTEM: SPROUTING IS DELAYED IN A MUTANT MOUSE EXHIBITING DELAYED WALKERIAN DEGENERATION. D. Stewart. Departments of Neuroscience and Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908. This study evaluates whether sprouting in the CNS is initiated by signals related to the degeneration of presynaptic axons. We evaluate the time course of sprouting of cholinergic septohippocampal fibers after unilateral entorhinal cortex lesions in a substrain of mice carrying a mutation which leads to a substantial delay in the onset of Walkerian degeneration. This is the "Oba" mutation, which has been characterized in detail by Perry and colleagues (Perry, V.H., Lune, E.R. Brown, M.C., Caluacs, S., and Gordon, S. Eur. J. Neurosci., 2: 408-413, 1990). It is thought that axonal degeneration is delayed because the mutation affects a signaling mechanism for macrophage activation. We assessed the time course of Walkerian degeneration after entorhinal cortex lesions using the Fink-Heimer technique. Cholinergic sprouting was evaluated using a histochimical technique for acetyl-cholinesterase (ACHE). In normal control mice, both the time course of Walkerian degeneration, and the time course of cholinergic sprouting after EC lesions occur with a time course that is comparable to that described in rats. Argyrophilic degeneration was prominent by 4 days postlesion, and increases in ACHE staining were well-developed by 8-10 days. In mice carrying the Oba mutation, however, argyrophilic degeneration was not detectable at 4 or 6 days postlesion, began to appear in the dentate gyrus by 8 days postlesion, and did not become prominent until 12 days. Increases in ACHE staining in the molecular layer of the dentate gyrus were not detectable even at 12 days postlesion, but developed gradually after 14 days. These results indicate that the signals which initiate at least one form of CNS sprouting are related to the degeneration of presynaptic axons. Supported by NIH grant NS12533.

THE APPEARANCE OF PRE-MITOTIC MICROGLIA ASSOCIATED WITH AXOTOMIZED MOTOR NEURON PERIKARYA IS INDEPENDENT OF AXON STUMP SIZE. T. G. Crawford M.D.* and J. W. Griffin, M.D. Johns Hopkins University School of Medicine, Baltimore, USA 21205. Following axonal injury tritiated thymidine labeled cells, identified as microglia, appear in the region of the perikaryon. These cells are implicated in the repopulation of the degenerated axon. The number of these cells has been seen following axotomy. We report that the timing and relative peak abundance of these labeled cells does not vary with location of the axonal lesion. At age 3 weeks both tibialis anterior muscles of Sprague-Dawley rats were injected with 1% fast blue. At age 8 weeks the left innervating nerve was severed, either by ventral root section of L4 and L5 (13 mm from the spinal cord) or the peroneal nerve at the level of the fibular head. One, and 4 days later, 4 hours following intraperitoneal injection of 5 pCi/ml tritiated thymidine, the animal was killed and labeled cells were counted, or within one perikaryal diameter to, fluoroescence labeled motor neurons were counted on each side. At day 2 neuron-associated labeled cells were abundant (0.59% neuron-associated axonal microglia, 1.17 neuron for distal axotomy). At 1 and 4 days labeled cells were less profuse, although variable for the proximal axotomy. Labeled cells on the control side were rare at all time points. These findings are consistent with the hypothesis that neuron-associated microglia are regulated by factors emanating from the terminal axon or target muscle.

COMBINATION OF INTRACELLULAR STAINING OF RETROGRADELY LABELLED NEURONS AND ANTEROGRADE FLUORESCENT TRACING: USE OF THE CONFOCAL LASER SCANNING MICROSCOPE.

C.J. Still and M.D. Cassebaum, Dept. of Anatomy, Univ. of Iowa, Med. College, Iowa, IA 52242.

This report describes a combined retrograde tracing, intracellular injection and anatomical fluorescence labeling method using the application of confocal laser scanning microscopy to simultaneously view the morphology of identified projection neurons and the distribution of retrogradely labeled fibers and terminals to characterize the anatomical relationship between these two elements.

With this approach, the retrograde tracer Fast Blue was injected into the bed nucleus of the stria terminalis (BNST) and anterograde tracer tetramethylrhodamine-conjugated dextran was injected into the insular cortex in adult rats. After one week survival time, the brains were fixed and sectioned on a cryostat. Immunofluorescent labeling of retrogradely labeled neurons identified in the amygdaloid complex on 120 μm thick sections were intracellularly injected with Lucifer Yellow under visual control and analyzed with confocal laser scanning microscopy. The results demonstrate that images from very thin optical sections can clearly show potential synaptic contacts between anterogradely labeled and intracellularly projecting neurons. Stacked images from optical sections show, in very great detail, the morphology of projection neurons in three-dimensions. In comparison with other combinations, the present method provides a more simple and efficient means to trace three successive components of a putative neuron chain.

THREE DIMENSIONAL IMAGING OF FACIAL NUCLEUS MOTOR NEURONS USING LASER SCANNING CONFOCAL MICROSCOPY.

The rat eye blink reflex is useful for neurophysiological studies of adaptive gain control. We have been interested in methods that might help elucidate the neurobiology of use-dependent plasticity in this reflex. For circuit tracing, one promising approach involves laser scanning confocal microscopy. In this technique, using a Bio-Rad MRC 600 LSCM system and a long-working distance (500 μm) objective (NA = 1.25).

The lid closure during a reflex blink is generated by a passive downward force plus active contraction of the orbicularis oculi (oo), whose motor neurons are located in the facial motor nucleus (FMN). The oo receives innervation from 2 branches of the facial nerve, the upper zygomatic and the temporal. In vivo injections of tetramethyl rhodamine or fluorescein into these 2 branches resulted in retrograde labeling of motor neurons in the FMN. After fixation, the FMN was transversely sliced (400 μm thick sections), mounted and covered. Optical sections were taken through the FMN at 0.5 - 1.0 μm intervals using a Bio-Rad MRC 600 LSCM system.

A total of 32 sections were analyzed. The data revealed that FMN was significantly larger than with conventional microscopy. Optimal sectioning enabled complete 3D imaging, which is important for cell classification, morphometric analysis, and dual labeling of pre- and postsynaptic elements. We are currently exploring other dyes that may be useful with LSCM in elucidating the reflex circuitry and its sites of modulation. In particular, we are examining projections to the amygdaloid complex, which has been implicated in conditioned potentiation of the eye blink reflex. Supported by an NIH grant (THB) and an NSF fellowship (BFL).

THREE DIMENSIONAL RECONSTRUCTION OF NEURONS USING CONFOCAL MICROSCOPY AND VOLUME RENDERING.

D. Bel, L. Arends, S.H. Creeds, S.H. Chandler' and N.A. Buchwald and M.S. Lepore, Mental Retardation Research Center and Department of Physiological Science, UCL, Los Angeles, CA 90024.

Our laboratory has been using confocal microscopy to visualize neurons in three-dimensions. Intracellular recordings and dye injection (Lucifer Yellow (LY) or biocytin) were performed in neurons obtained from brain slices of neonate or neonate motor nucleus of pinna. LY-filled cells were examined in whole mounts while biocytin-filled cells were examined at 40X in small sections processed by standard immunofluorescent techniques. Neurons were first optically sectioned with a laser scanning confocal microscope (BioRad MRC600). Sections were obtained at intervals of 1.5-μm (z-axis) with the confocal aperture at its minimal diameter. Dependent upon the numerical aperture and the magnification of the objective, optical section thickness varied from 1-4 μm. Three-dimensional visualization was obtained as a series of optical sections, stereo pairs or volume rendering. Volume rendering to permit three-dimensional imaging was performed with commercially available software (VoxBlast, VaxTec, Inc.) which uses alpha blending to create a three-dimensional projection. The software permits rotation around any axis, changes in the source of illumination and changes in the transparency of the image. Rotation around different axes provides a clearer picture of the three-dimensional characteristics of the neuron. Changes in illumination and transparency allow shadowing and surface landmarks to be visualized. Three-dimensional reconstructions permit perspectives to be reconstructed that were difficult or impossible to view in the serial optical sections or stereo pairs. Supported by USPHS HD 05958.
408.7 **IN-VIVO CONFOCAL MICROSCOPY OF THE RABBIT OPTIC NERVE**

**HEAD** Barry W. Thompson*, Selin Jin Chew, Roger W. Beuerman

LSU Eye Center, New Orleans, LA 70112

The tandem scanning confocal microscope (TSM) allows repeated, noninvasive examination of living tissue, in real-time, with the advantage of serial optical sections, superior contrast, lateral and vertical resolution. We used a new TSM to examine the optic nerve in the rabbit in two modes: as a scanning confocal microscope and as an ex vivo-imaging technique to investigate the human lamina cribrosa. Using a Noran TSM with a 25 mm water immersion lens, and a 60 mm magnification lens corrected for a cover slip, we examined the retina, optic disc and the optic nerve at the disc. At this magnification of 30X, we were able to ascertain the depth of the optic cup and to precisely identify the axons exiting the optic nerve. Using this TSM, we were able to perform a full thickness examination of the retina and optic nerve and the presence of a glial scar. We are currently working on this technique to investigate the human lamina cribrosa. Using a Noran TSM equipped with a 486 PC, we have been able to perform a full thickness examination of the retina and optic nerve. We conclude that Ca^2+ imaging in acute brain slices is feasible. This system may allow the investigation of intracellular-ion concentration dynamics under various experimental conditions.

408.8 **IN-VIVO MONITORING OF CORNEAL NERVE INJURY BY TANDEM SCANNING CONFOCAL MICROSCOPY**

Lauren W. Underwood*, Christopher Kelly, Selin Jin Chew, Roger W. Beuerman

LSU Eye Center, New Orleans, LA 70112

With its superior lateral and vertical resolution, the tandem scanning confocal microscope (TSM) allows repeated, noninvasive examination of the cornea in vivo. We used a new TSM to examine the nerves in the rabbit, following two modes of injury (mechanical and laser damage) and the image distributed neural activity in vivo.

408.9 **CONFOCAL FLUORESCENCE IMAGING OF [Ca^{2+}]_i-TRANSIENTS IN ACUTE RAT-BRAIN SLICES USING FLUO-3-AM AND A SMALL VOLUME SUBMERGED CHAMBER SYSTEM.**

Asthagiri, A. Vithoulka*, A. D. Yilmaz

Dept. of Neurology, University of Munich, 8000 Munich 70, F.R.G.

In order to establish a simple system for the imaging of intracellular-ion concentration dynamics in brain slices using fluorescent dyes we developed a small volume slice chamber. The chamber volume is ∼ 0.5 ml, affording rapid (< 5 s) exchange of the bathing solution by small amounts of dye. Imaging was performed with a confocal laser scanning microscope (Bio-Rad MRC 600; 488 nm), equipped with a Zeiss x60 NA 0.75 water immersion objective corrected for a cover slip. Images were obtained with minimal dye concentrations and loading time (1 μM, 15 min). The apparent diffusion coefficient, D*, was measured in cortex (Cserr et al. J. Physiol., 442: 277, 1991) but the 40 under a critical size that lies in the range 10-40 kDa. The diffusion of molecules above a critical size that lies in the range 10-40 kDa was also performed after image capture using a CCD camera. Eximer laser photorefractive keratometry was performed, with the ablation of the anterior 75μm of corneal stroma. The regeneration of epithelial nerve endings was observed with the TSM. Histology, using the gold chloride impregnation technique was used to confirm these observations. The epithelial nerves of human contact lens were compared with those of non-contact lens wearers.

408.10 **THREE-DIMENSIONAL ANALYSIS OF GRANULE NEURONS IN THE RAT DENTATE GYRUS LABELED WITH FLUORESCENT DYES.**

M. O’Boyle*, R. Gonzales*, T.J. Hahn*, R. Chabner*

Div. of Life Sciences, Univ. of Texas, San Antonio 78249, Department of Cellular and Molecular Physiology, Yale Univ., New Haven, CT 06520

Efforts to analyze the 3-D structure of fluorescently-labeled neurons have been hindered by the lifespans of the fluorochromes. Dense labels, which are more difficult to use, have been required. Here we report a technique that allows neurons labeled with DiI or Lucifer Yellow (LY) to be analyzed using a computer-microscope system equipped with epi-fluorescence optics. Glucose neurons in 400-μm-thick slices of the dentate gyrus were labeled either by retrograde transport of DiI in fixed tissue (Chabner & Chabner, J. Neurosci. Abstr. 17: 35) or by intracellular injection of LY in vivo or in fixed tissue (Pfau-Borg et al., Neurosci. Lett. 118: 289). To minimize bleaching of the dye, the intensity of the mercury excitation (Nikon H2A or Omega H2B) was decreased using neutral density filters, and the field of view was reduced to compensate for the decrease in fluorescence emission. We used a Hamamatsu C2400-08 camera and a Rolyn KG2 heat filter. We use this system to investigate the reliability of the system for 3-D analysis of fluorescently-labeled neurons. Supported by MABRS and ONR.

408.11 **QUANTITATIVE OPTICAL IMAGING OF THE DIFFUSION OF DYE TRANSPORTERS FROM DIFFERENT MOLECULAR WEIGHTS IN RAT CEREBRAL CORTEX.**

Kim, K.A*; Pardridge*, W.M.

Dept. of Physiology and Biophysics, New York University Medical Center, 550 First Ave., New York, NY 10016

Many permeable substances have molecular weights of 1 - 100 kDa and is important to know how they diffuse in tissue. We have developed a quantitative optical imaging system and analyzed the diffusion of 3, 10, 40, and 70 kDa dextran to determine molecular weights in the cortex.

Dextran labeled with the fluorescent dye Texas Red (Texas Red, Molecular Probes, OR) were pressure-injected into rat cortical slices maintained in a perfused chamber at 34°C and imaged as they spread in the tissue, using a confocal epifluorescence microscope with a 10X water immersion objective. About 20 images were taken with 2 - 10 second intervals and recorded by a cooled CCD camera (Photometrics, AZ) with 576 x 384 pixels and 14 bits and transferred to a 486 PC. The apparent diffusion coefficients, D, was determined by fitting an integral expression relating the measured 2-dimensional image intensity to the 3-dimensional dextran concentration. Measurements in dilute agarose gel provided a reference value of D. Values of the ratio, (D/D0)^0.5, for the 3 and 10 kDa dextrans were consistent with tortuositites derived from terephthalamide measurement in the range of 1.427 - 2.77, 1991) but the 40 and 70 kDa dextrans showed markedly larger ratios. This suggests that extracellular space may not be uniform but has consistencies that hinder diffusion of molecules that lies in the range 10 - 40 kDa. This implies that the concept of tortuosity, as a simple parameter describing the diffusion properties of the extracellular space, is valid only for molecules below this critical size. Supported by NIH Grant NS 28642.

408.12 **CCD-IMAGING OF VOLTAGE SENSITIVE DYE SIGNALS FROM WHOLE BRAIN OF LOWER VERTEBRATES.**

K.K. Delaney*, J.O. Kleinfeld* and D.W. Tank*

Dept. of Biocomputation, Princeton University, Burnaby B.C. V5A-1S6 & Biological Computation Research Dept. AT&T Bell Laboratories, Murray Hill NJ 07974

We used the fluorescent potassium membrane probe Di-4-ANEPES to image distributed neural activity in vivo and in isolated whole brain preparations of frog, lizard and turtle. These animal models were obtained with a CCD at a rate of 1 Hz and produced to process movies of the spatio-temporal patterns of voltage changes. Small arrays of diodes were used to measure voltage changes with high temporal resolution from selected regions. Simultaneous recording of optical and electrical signals was possible for periods >8 hours without light-induced toxicity.

Optical recordings reliably showed the onset, duration, and propagation of neural responses that were evoked by stimulation of cranial nerves or brainstem structures, by disinhibition with picrotoxin (PTX) and by light or odor stimuli. Optical signals generally differed from field potential recordings by the presence of long lasting slow components, that often persisted many seconds after a stimulus. In contrast, a close correspondence between the time course of optical signals and intracellularly measured voltage was seen suggesting the slow components are not glial in origin. Spontaneous activity induced by PTX originated in brainstem and propagated along several defined paths (e.g. anterior dural telencephalon to thalamus/ hypothalamus). Repeated initiation of these “epileptiform” events from the same sites was observed over the course of several hours. Telencephalon initiated events occurred more frequently and recovered faster than those in diencephalon, tegmentum, cerebellum or brainstem. Odors or olfactory nerve shock produced optically recorded oscillatory activity in olfactory bulb and activity extending into ipsilateral and contralateral caudal telencephalon.

SIMULTANEOUS KINETIC IMAGING OF INTRACELLULAR CALCIUM AND pH IN SINGLE MELANOTROPES. Stephen J. Morris*a, Diane B. Boyettφ, and Bibi M. Chromwell*. Div. of Molecular Biology and Biochemistry and TDIV, of Cell Biology and Molecular, Univ. of Missouri-Kansas City, Kansas City, MO 64110

There is a growing interest in the use of multiple fluorescence probes to analyze the relationships between [Ca2+]i and pH. We have designed an epifluorescence video microscope for calcium and four affording high resolution which simultaneously capture all four emission images at 405, 475, 575 and 640 nm from the two ratio dye indo 1 (for [Ca2+]i) and SNARF 1 (for pH) at video rates (SPIE Proc 1428:148,1991).

Popular dyes for measuring intracellular calcium, such as indo 1 and fura 2, have pH-dependent Ke and pH changes in pH, can be misinterpreted as changes in [Ca2+]i.

SNARF sensitivity to pH between 6.5 and 8.0 was unchanged by [Ca2+]i. The indo/Cr3+ Ke, examined at 390 and 37°C, shifted more than twice fold between pH 6.5 and 8.0. Rat primary melanocytes, grown in explant cultures, were double-labelled and Cr3+/pH interactions were examined during exposure to various stimuli. SNARF ratio maps were used to correct the pH-dependent changes in local cell calcium. Under most circumstances, pH correction modified the apparent [Ca2+]i: small changes in [Ca2+]i disappeared or were greatly attenuated and kinetics changed. Cells were later positively identified as melanotropes by immunohistchemistry.

K+-induced depolarization of murine fat produces increases in [Ca2+]i, which were closely coupled to reductions in pH, Chronically applied dopamine agonists suppressed this activity, which returned when the drugs were removed. Cells responded to both N’-isoflurane and subsequent acidification upon NH4Cl withdrawal with calcium transients from intracellular stores. We conclude that the new video microscope will be an invaluable tool for the study of intracellular dynamics.

808.15

Cells and cellular organelles can exist as the network of micros and therefore cannot be encompassed in a single thin section normally examined with conventional electron microscopy. Even with the use of high voltage electron microscopy, section thickness is limited to no more than a few microns. In an effort to overcome these limitations we have been exploring a method of linking serial thick sections by first extracting these three-dimensional information using tilting tomography and then aligning and linking the resulting serial volumes to form a single volume. We have used this method to investigate the 3D structure of the Golgi apparatus in dorsal root ganglion neurons. Briefly, four 2um serial sections were cut from an osmium stained, unperfused dorsal root ganglion (Lindsey et al., Neurosci. 12:3111, 1985). A tomographic reconstruction was created for each section of a single axis tilt series taken through 60um in 2um increments with a JEOL 100S electron microscope operated at 400KV. Alignment of the serial volumes was accomplished by slicing each volume into individual planes orthogonal to the depth dimension and registering the last slice of one volume to the first slice of the next with the aid of fiducial marks. The aligned slices of the 4 volumes were then merged into a single volume. The resulting volume was rendered and examined using the program ANALYZE (Rohrb et al., IEEE Trans Med Image, MI-8:217, 1989). The continuity of components of the Golgi apparatus could be observed through a depth of 10um with spatial resolution near to 100nm. This method appears promising for characterizing the 3D organization of subcellular structures over many micros while maintaining resolution sufficient to discern fine structural detail. While the alignment of the serial volumes appeared accurate, we are currently validating this technique by using a specimen of known 3D geometry. We are also exploring the use of this technique to investigate the continuity of neuronal endomembrane system components in bulging dorsal root ganglion and in cerebellar Purkinje cell dendrites.

808.17

In spite of high resolution obtained by modern imaging techniques it is necessary to supplement these data with histological and histochemical data from the microscopical examination of brain sections. In order to integrate these data we have created a 3-D human-brain-reference atlas. This atlas is based on one parafin-embedded brain (death to fixation interval: 2h), which was serially sectioned vertical to the intercommuncating plane. Cytomorphology and morphometric studies of this brain and correlations with immunohistochemical findings have been published by numerous authors. From 630 sections contournitures representing pit and ventricular surfaces, as well as subcortical nuclei and their subdivisions, were enzymatically cut manually. The contournitures were adjusted into a 3-D metric grid. Points of intersection between the contournitures and the grid were used for cubic spline approximation. The resulting curved panel was extrapolated to be manipulated after estimations of deformation and shrinkage due to tissue preparation. The smoothed contournitures were used for 3-D reconstruction. Contournitures of main thalamic subnuclei have been comparatively compared regarding to the interindividual variability, with those derived from paraffin-embedded brains (applying the same procedure of in-vitro - in-vivo transformation; 25 hemippheres) and MR imaging (18 hemippheres).

808.18

Past methodologies for analyzing cerebral microvascular system have employed single histological sections and stereotactical theory. Such approaches do not yield information on microvascular branching, length, and tortuosity. Since these parameters are suspect we suspect that some of these features vary among brain areas, three-dimensional reconstructions of local microvascular systems were made using serial histological sections and an image analysis system (MCID IM, Imaging Res. Inc) The results indicate that cerebral microvascular systems vary considerably in branching and tortuosity. For example, the capillaries in the hippocampus are fairly straight, long, and arise by simple division of the terminal arterioles, whereas those in the paraventricular nuclei form tortuous networks of many relatively short capillaries. Microvascular system organization, thus, seems to vary among brain areas, possibly in the liver.

**EFFECTS OF THE CALCIUM CHANNEL BLOCKER OMEGA-CONOTOXIN ON IN VIVO DOPAMINE EFFLUX IN RAT STRIATUM. C.A. Davy, C.D. Blaha* and A.O. Phillips, Dept. Psych., University of British Columbia, Vancouver, BC, Canada, V6T 2Z4.** The effects of omega-conotoxin (CTX, fraction GVI), an N- and L-type voltage-sensitive calcium channel (VSCC) blocker, on basal dopamine efflux was investigated in vivo using electrochemistry (chronamperometry, 1 s potential pulse/30 s). A 30 gauge cannula was positioned 0.5 mm adjacent to a stereotaxic graphite probe. The efflux electrode and was stereotaxically implanted into the dorsomedial striatum of urethane anesthetized rats. Following at least 1 hr of baseline recordings, injection of CTX (0.1, 1 or 10 pmol/ul 4 min) produced a dose-dependent decrease in basal DA efflux. A maximal decrease in DA efflux was achieved within 10 min of injection of 10 pmol CTX. This decrease was followed by a rebound in DA efflux which increased significantly above preinjection values within 1 hr of CTX injection. Additional CTX (10 pmol) injections during this rebound phase produced decreases in DA efflux that were similar in magnitude and time course as the first injection. These results provide some of the first in vivo evidence indicating that both N- and L-type calcium channels are involved in basal DA transmission and suggests that transient inhibition of these channels may lead to increased DA efflux. These findings are in contrast to in vitro studies which demonstrate an irreversible blockade of VSCCs by CTX. The mechanisms responsible for the transient and rebound effects of CTX are unknown at present, but may include a biphasic modulation of VSCCs or increased storage of DA at the presynaptic terminal.

409.2

**NOREPIPHRINE (NE) RELEASE FROM CARDIAC ADRENERGIC NERVE TERMINALS: AGE-RELATED DIFFERENCE IN OMEGA-CONOTOXIN INHIBITION. D.L. Snyder, V.J. Aloyo*, M.D. Johnson, and J. Roberts, Dep. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.** Cardiac sympathetic (SYN) preparations from hearts of 6 and 24 mo old male F344 rats were used to investigate the effect of age on omega-conotoxin (CTX) inhibition of NE release. CTX is a specific N-type Ca**2+** channel blocking agent. SYN were incubated in 3H-NE, placed in a superfusion system, and then perfused for 30 min with various concentrations of CTX. The SYN were then depolarized with a 2 min pulse of buffer at 75 mM K+ (concentration which produces maximum release) or 60 mM K+. The mean fractional release of NE (NE released/NE released+NE released, NE released=NE released after vehicle administration was significantly reduced in 24 mo old rats when compared to 6 mo old rats (N=5, see table). 6 mo old rats were more sensitive to CTX inhibition and showed a greater percent reduction in NE release at each level of CTX. These results suggest that the adrenergic nerve terminals of 6 mo old rats contain more CTX sensitive Ca**2+** channels than at 24 mo age. SYN from 6 mo old hearts contain more CTX binding sites than SYN from 24 mo old hearts. The loss of Ca**2+** channels with age may be responsible for the age-related reduction in NE release.

**Mean fractional NE release (% inhibition by CTX)**

**BLOCK OF MAMMALIAN CALCIUM CHANNELS EXPRESSED IN XENopus OOCYTES BY \( \alpha \)-AGATOXINS. A. Kondo, J. D. Mills* and M. E. Adams, Departments of Entomology and Neuroscience, University of California, Riverside, CA 92521.** \( \alpha \)-Agatoxins from Ageleoposis aperta spider venom are potent and selective blockers of voltage-activated calcium channels. We are using these toxins as probes in comparative studies of Ca**2+** channels expressed in Xenopus oocytes. Oocytes injected with mRNA prepared from rat brain, whole brain, and cerebellum displayed voltage activated currents through Ca**2+** channels using Ba**2+** as a charge carrier, TEA, 4-AP, and niflumic acid were used to block potassium and chloride currents. Oocytes expressing mRNA from heart muscle showed Ba**2+** currents with kinetics typical of L-type Ca**2+** channels. Exposure to 100-200 mM \( \alpha \)-AgA-III resulted in 30-90% block of high threshold current, with little or no effect observed on low threshold currents. Expression of mRNA from whole brain resulted in Ba**2+** currents that were blocked at 100-200 mM \( \alpha \)-AgA-II, but only 1-5% by 400 mM \( \alpha \)-AgA-IVA. In contrast, oocytes injected with cerebellar mRNA displayed Ba**2+** currents that were substantially blocked by both \( \alpha \)-AgA-III and \( \alpha \)-AgA-IVA. Based on the selectivity of \( \alpha \)-AgA-IVA, these results suggest that P-type channels are relatively more abundant in the cerebellum than in whole brain. Supported by NIH grant NS24472.

**A NOVEL PEPTIDE NEUROTOXIN SELECTIVELY BLOCKS MYOCARDIAL L-TYPE CALCIUM CURRENT. J.J. McArdle, Y.-F. Xiao, S.P. Aiken*, L.C. Sellin, J.J. Schmidt, and S.A. Weinstein, Dept. of Pharmacology & Toxicology, New Jersey Medical School (UMDNJ), Newark, NJ 07103-2714, and Dept. Toxicology, USAMRIID, Frederick, MD 21701-5011.** Peptide I (WTX-I) from the venom of Trimeresurus walgeri appears to act presynaptically with synaptic transmission (Pharr & Tox. 1992, in press). In order to explore the interaction of WTX-I with ion channels, we examined its effects on L-type Ca**2+** (\( I_{Ca} \)) and transient K**+** (\( I_{K} \)) currents, as well as Na**+** (\( I_{Na} \)) currents recorded from the atrial myocardial myocytes from the left ventricle of 10-11 week old rats. Ionic currents were recorded with the whole cell configuration of the patch voltage-clamp technique. Bath application of 6 to 20 mM WTX-I had no detectable effect on \( I_{Na} \) or \( I_{Ca} \). In contrast, 2, 4, and 6 M WTX-I reduced \( I_{Ca} \) to 68.4 ± 15.4 % (n=3), 47.7 ± 6.0 % (n=11), and 10.1 ± 10.1 % (3) of the respective control values. This inhibitory effect on \( I_{Ca} \) could not be reversed by applied to 5 mM nifedipine. Recovery occurred after washout of WTX-I containing solution. These findings suggest that WTX-I selectively blocks L-type Ca**2+** channels and that stimulation of \( \beta \)-adrenergic receptor-modulated phosphorylation of this channel may increase the inhibitory effect of WTX-I. Supported by grants from the NIAAA (AA008025) and the American Heart Association (90-G-27).

4.9.10 NEOMYCIN DISPLACEMENT OF \( [125] \) \( \omega \)-CONOTOXIN GVIA-A BINDING IS NOT UNIFORM ACROSS NEUROANATOMICAL REGIONS: EVIDENCE FROM AUTORADIGRAPHIC STUDIES. E. Filloux 1, B. M. Olivera 2, and J.M. McIntosh 3, Dept. Neurol., Pediat., Bio1, and Psychiatry, Univ. Utah, Salt Lake City, UT 84132.

Previous studies have demonstrated that neomycin (NEO) inhibits \( [125] \) \( \omega \)-Conotoxin GVIA (\( \omega \)-CTX) binding to brain membranes suggesting that NEO may block Ca channels. However, we have now characterized several new \( \omega \)-conotoxins which inhibit an expanded subset of mammalian CNS Ca channels. Oligonucleotide probes directed to conserved amino acids of the Ca channel-targeting 

4.9.11 Oligonucleotide probes directed to conserved amino acids of the Ca channel-targeting

4.9.12 The venom of fish-hunting cone snails contains potent peptide inhibitors of presynaptic neuronal calcium channels. However, previously characterized peptides such as \( \omega \)-conotoxin GVIA, target only a subset of mammalian CNS Ca channels. We used a molecular biological approach to derive new \( \omega \)-conotoxins which inhibit an expanded subset of mammalian CNS Ca channels. Oligonucleotide probes directed to conserved amino acids of the Ca channel-targeting peptides were used to identify cDNAs encoding two new Ca channel ligands. cDNA sequencing was used to guide synthesis of peptides MVIC and MVIB which inhibited synaptic currents in Purkinje cells and a subset of \( \omega \)-GVIA-resistant channels in CA1 hippocampal cells are sensitive to \( \omega \)-MVIC. In addition, in several systems, \( \omega \)-MVIC inhibits a component of neurotransmitter release that is resistant to \( \omega \)-GVIA or MVIA (see abstracts by Gaur et al., and Newcomb and Palma). Accordingly, these new peptides are of important new tools for the study of Ca channel subtypes.
409.11
CALCULUM CHANNEL ANTAGONISTS [125I]-Ag-Aga-III A AND [125I]-Ag-Aga-III B: A COMPARISON OF BINDING SITES IN RAT BRAIN. J.M. Mcintosh1, M.E. Adams2, B.M. Olivera3 and P. Filloux3, Departments of Psychiatry1, Biology3, Pediatrics4 and Neurology4, University of Utah, Salt Lake City, UT 84132, and Departments of Enzymology and Neuroscience5, University of California, Riverside, California, 92521.

Specific binding of the calcium channel ligands [125I]-Ag-Aga-III A and [125I]-Ag-Aga-III B to rat brain was performed as described earlier. [125I]-Ag-Aga-III A and [125I]-Ag-Aga-III B were compared autoradiographically using sagittal sections from rat brain. Binding patterns for these two ligands were generally similar, but notable differences were detectable particularly in the cerebellum and hippocampus. Specific [125I]-Ag-Aga-III A binding was greatest in the granule cell layers of the cerebellum and of the dentate gyrus. In contrast, binding of [125I]-Ag-Aga-III B was most intense in the molecular layers of these structures. 250 nM [125I]-Ag-Aga-III A inhibited less than 33% of [125I]-Ag-Aga-III A binding while 40 nM [125I]-Ag-Aga-III B inhibited greater than 92% of [125I]-Ag-Aga-III B binding. The P-type calcium channel antagonist, u-Aga-I-JVA (40 nM) blocked only 11% of [125I]-Ag-Aga-III A binding and 2% of [125I]-Ag-Aga-III B binding. These data suggest that [125I]-Ag-Aga-III binding sites are a subset of [125I]-Ag-Aga-III sites and that the combined use of agonists and conotoxins may be useful for discriminating between calcium channel subtypes.

409.13
([125I]-CONOTOXIN MVIA: A NEW, COMMERCIAL RADILIGAND FOR N-TYPE CALCIUM CHANNEL BINDING IN NEURAL MEMBRANES. J.J. Geer1, S.J. Shohr2, and D.J. Dooley1. Department of Neuroscience, Parke Davis Research, Warner Lambert, Ann Arbor, MI 48105.

The conotoxins GIVA and MVIA, isolated from the marine snails Conus geographus and Conus magus, are important tools for identifying and blocking N-type calcium channels in neuronal preparations. Although [125I]-GIVA is commercially available, its irreversible binding characteristics make true competitive binding studies difficult. We recently tested an experimental preparation of [125I]-MVIA (Amersham) and compared this ligand to [125I]-GIVA. We report here the methods for and characteristics of [125I]-MVIA binding. Synthesized MVIA (Peninsula) was iodinated by Amersham using an enzymatic method. Specific activity of the ligand was ~2000 Ci/mmol. Binding of [125I]-MVIA to crude rat neocortical membranes was carried out at 37°C in 0.5 ml buffer (50 mM HEPES-NaOH, 0.1% BSA, pH 7.4) for 30 minutes. Unbound ligand was removed by filtration through G-75 columns presoaked in 0.1% polyethyleneimine (PEI), followed by two washes with buffer supplemented with 0.2 M NaCl. Saturation analysis gave a Kd of 6 x 10^-14 M and a Bmax of 2 x 10^11 M. Dissociation rates were calculated from data obtained from 10-100 nM protein using [125I]-MVIA at 3 A. These results were comparable to those obtained with [125I]-GIVA (Kd = 0.6 pm; Bmax = 995 fmol/mg protein; 23°C). The association kinetics of both [125I]-MVIA and [125I]-GIVA were rapid (t1/2 = 2 min, 37°C at 3 A; GIVA, t1/2 = 4 min, 23°C). However, the dissociation rates were markedly different. [125I]-GIVA was readily dissociated by excess cold ligand (Bmax = 3 min). [125I]-MVIA was not significantly displaced by cold GIVA in 4 hours. Commercial availability of this highly-affinity, reversible radioligand will allow for direct competitive analyses of novel N-type calcium channel modulators.

409.15
Components of the electrically evoked increase in intracellular calcium in chick dorsal root ganglion and sympathetic ganglion neurons. Y. Zhao1 and W.D. Brenbon2. Department of Physiology, University of Minnesota, Minneapolis, Minnesota, MN 55455.

We measured changes in Fluor-3 fluorescence as an indicator of changes in intracellular calcium in primary cultures of chick DRG and sympathetic ganglion neurons. Ca2+ responses were evoked via trains of electrical stimuli delivered through the recording chamber. A 1-2 sec train at 10 Hz produced a rapid and reversible rise in internal Ca2+ in both DRG and sympathetic ganglion cells. The response was prevented by removal of external Ca2+ and by 300 μM 3,4-dichloroisocyanuric acid. This indicates that it is dependent on calcium influx and on the generation of sodium dependent action potentials. In DRG cells 89% (5±2%; n=15) of the Ca2+ response was prevented by brief incubation with omega Conotoxin. The block appeared saturated at a 1 μm solution. 10 μM Nifedipine blocked 138% (4±2%; n=23) of the [Ca2+]i increase induced by 3,4-dichloroisocyanuric acid. These data suggest that the calcium influx in chick DRG cells under these conditions is largely through N-type channels. Type channel appears to play a very minor role, since even relatively high concentrations of N-type channel blockers did not completely block the Ca2+ increase. These data appear to conflict with recent voltage clamp studies suggesting a significant role for T currents during the action potential. In sympathetic cells, Conotoxin blocked considerably less of the Ca2+ rise (63% ±4%; n=7). Very preliminary data suggest that Nifedipine and Amiloride may each block more of the Ca2+ rise in sympathetic cells relative to their effects in DRG cells. (Supported by NHlR T01 GM42829. We particularly thank Than for valuable advice and discussion.)

409.16
Toxins in Pleocyclus spider venom are potent blockers of vertebrate calcium channels. L.A. Newman, Y. Zhao, M.S. Rudnick, and W.D. Brenbon2. Dept of Physiology, University of Minnesota, Minneapolis, MN 55455.

We prepared a partially purified fraction of Pleocyclus trisius spider venom for assays on vertebrate calcium channel preparations. Size exclusion on Sephadex G50 and step elution from C18 with 30% and 60% acetonitrile (0.1% TFA) yields a relatively hydrophobic fraction containing peptides with masses of a few thousand daltons. This fraction has been found in various previous assays to be primarily inhibitory. This inhibitory fraction represents approximately a hundred fold purification from crude venom based on the mass, but it still contains many different peaks when analyzed on reverse phase by gradient elution. We assayed this fraction for activity in blocking electrically stimulated rises in internal Ca2+ in primary cultures of chick dorsal root ganglion (DRG) and sympathetic ganglion neurons. The change in intracellular Ca2+ induced by a train of brief electric voltage pulses was measured as an increase in the fluorescence of the Ca2+-indicated Fluor-3. The inhibitory fraction of the venom blocked 87% (5±8%; n=10) of the increase in fluorescence in DRG cells, and 64% (5±0%; n=15) of the increase in sympathetic ganglion cells. The block saturated at a 1:1000 or greater dilution of toxin relative to crude venom and was not reversible during the time course of the experiments. This toxin activity is similar to omega Conotoxin and likely represents a potent block at least of N-type calcium channels. Preliminary voltage clamp data on these toxins suggest that this fraction blocks Ca2+ currents. Purification and analysis of specific toxin components is in progress. (Supported by NHlR T01 GM42829.)

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

409.12
A POLYPEPTIDE FRACTION ISOLATED FROM CONUS MAGUS VENOM EXHIBITS NOVEL CALCIUM CHANNEL BLOCKING ACTIVITY. PREPARATIONS. S.J. Stroeh4, A.B. Giordano, R.R. Naughton, J.M. McIntosh2, D.J. Dooley1, B.M. Olivera3, and D.A. Downs1. Departments of Neuroscience1 and Chemistry, Parke Davis Research, Warner Lambert, and Departments of Psychiatry2 and Biology3, University of Utah, Salt Lake City, UT 84112.

Natural peptides purified from the venom of numerous poisonous organisms have become important tools for understanding neuronal ion channels. We have isolated two polypeptides from venom of the marine small Conus magus which interact with L-type Ca2+ channels. An aqueous extract from crude venom was tested in a [3H]-ipisodine binding assay to assess L-type Ca2+ channel affinity. The C. magus extract was at least ten times more effective at inhibiting [3H]-ipisodine binding to rat neocortical membranes than the extract from other Conus species (relative IC50 = 1/400,000 dilution). We used two reverse phase chromatography steps to isolate the active component, in each step, the inhibitory activity altered as a single peak (absorbance at 214 nm), resulting in a ~300-fold purification of the material. This material inhibited [3H]-ipisodine binding to both neocortical and crude skeletal muscle membranes. Intracerebroventricular injection of this fraction into mice resulted in anchored back and extended extremities, an effect similar to that seen with the L-type Ca2+ channel activator Bay K 8644. This fraction also blocked K+-induced Ca2+ flux into rat brain synaptosomes, indicating a functional interaction with presynaptic Ca2+ channels. When the fraction was further purified using reverse phase chromato-
409.17  

NEURAX Corporation, Menlo Park, CA 94025.

We have synthesized the conceptephide designated SNX-230 corresponding to a novel a-like conceptephide, M-VIIIC, predicted from a cDNA sequence obtained from a Cowan magus venom gland expression library (see abstract by Hillyard, et al.,). SNX-230 potently (20pm IC50) inhibits about 50% of release of radiolabeled noradrenaline (NE) from K+-depolarized rat hippocampal slices. It inhibits the remaining 50% with much lower potency (65mM IC50). In contrast, c-conceptephides SNX-111 (synthetic M-VIIIA from C. magus venom) inhibits a maximum of 65% of NE release and with much lower potency (0.5mM IC50). To understand the role of the conceptephide-sensitive components of NE release, slices were subjected to both peptides simultaneously: SNX-111 at a maximally (65%) effective concentration (30mM IC50) at which it exhibits only in high-potency (30%) inhibitory activity. Surprisingly, inhibition of NE release was not complete — being only about 85% complete. One explanation is that there are four conceptephide-sensitive components of NE release: total (50%), comp.1 (20%), comp.2 (20%), comp.3 (20%), comp.4 (10%).

SNX-230, 1mM 100% + + + +
SNX-230, 1mM 50% + + +
SNX-111, 100% 65% + +
SNX-230 + SNX-111 85% + + + +

These results indicate that the conceptephides SNX-111 and SNX-230 will be uniquely useful reagents in elucidating the roles of their calcium channel targets in neuronal function.

CALCIUM CHANNELS: PHYSIOLOGY II

410.1  

Release of caffeine-sensitive and IP3-sensitive intracellular Ca2+ stores are mediated by distinct proteins identified as ryoside receptor (RyR) and IP3 receptor (IP3R), respectively. RyRs in intracellular Ca2+ can induce release of Ca2+ from the caffeine-sensitive pool via the RyR, a process known as Ca2+-induced Ca2+ release. We have localized caffeine-sensitive and IP3-sensitive Ca2+ release channels in the brain using specific antibodies raised against purified brain RyR and IP3R, respectively. RyR was localized to pyramidal neurons at levels similar to low levels in the cortex. RyR was most enriched in the dentate gyrus and CA3/4 areas of the hippocampus, where IP3R was present at relatively low levels. In the cortex, RyR was localized to pyramidal neurons, some of which were not labeled by anti-IP3R antibodies. Antibodies to IP3R revealed the presence of RyR in axons and in dendritic spines receiving asymmetric synapses while IP3R was primarily identified in dendritic membranes forming symmetric synapses. These results suggest that the IP3- and caffeine-sensitive Ca2+ pools have roles in controlling intracellular Ca2+ levels that are in some cases distinct and that in other cases may interact in varying degrees depending on the neuron and the subcellular compartment within a given neuron. Supported by M01RR00933 to AHS, DA00074 to SLS, B-507-RR07062-26 to CA and Fitzger Fellowship to TMD. RPC is HHMI investigator.

410.2  
ACTION POTENTIAL-INDUCED ALTERATIONS IN CYTOSOLIC CALCIUM IN FURA-2-LOADED DISSOCIATED BULLFROG SYMPATHETIC NEURONS. T.J. Hepper and J.F. Fiekers, Dept. Anatomy & Neurobiology, College of Medicine, University of Vermont, Burlington, VT, 05405, U.S.A.

The kinetics of [Ca2+]i in response to direct electrical stimulation were examined in dissociated neurons from the 9th and 10th sympathetic ganglia of the bullfrog Rana catesbeiana. [Ca2+]i was determined in individual neurons using a ratiometric analysis with fura-2. Simultaneous recording of action potentials and passive electrical properties were recorded with electrophysiological techniques. Basal levels of [Ca2+]i ranged from 82 nM to 225 nM (n=19). Trains of action potentials (20 Hz) were evoked by depolarizing current injection. The rate of rise of [Ca2+]i was increased in a frequency-dependent manner. At each stimulus frequency, a maximal level of [Ca2+]i was obtained and maintained during the train. Basal levels were restored following cessation of stimulation. The addition of Co2+ (2 mM) to the extracellular solution abolished the stimulation-induced increase in [Ca2+]i. The [Ca2+]i response to afferent applications of ACh was decreased during train-induced elevations of [Ca2+]i. These results indicate that the origin of [Ca2+]i during action potential generation is extracellular and that these neurons are capable of buffering large changes in [Ca2+]i, during and following train stimulation. (Supported by NS 27319).

410.3  
SPONTANEOUS CALCIUM OSCILLATIONS IN CULTURED RAT CHROMAFFIN CELLS. A.R. Wakade, D.A. Przuvich, T.D. Wakade. Dept. of Pharmacology, Wayne State University, Detroit, MI 48202.

Rat chromaffin cells (RCC) of 8-day-old pups were used and were cultured to measure intracellular Ca2+ by Indo-1 dye method, to monitor membrane potential using patchclamp technique and to determine catecholamine release by labeling with [3H]NE. Almost all cultured RCC exhibited spontaneous oscillations (OSC) in intracellular free Ca2+ ([Ca2+]i). The OSC were random and varied in frequency, duration and magnitude. Neither calcium, caffeine, antagonist, ryoside, thapsagin nor tetrodotoxin or tetraethylammonium affected OSC. [Ca2+]i-free Krebs solution plus 0.5 mM EGTA completely blocked OSC and lowered [Ca2+]i in RCC. Spontaneous release of [3H]NE was reduced by more than 50% when Ca2+ was omitted from the external medium. Low temperature (2°C) caused maximum and sustained increase in [Ca2+]i. Whole cell current clamp recording showed that RCC had unstable resting membrane potentials (Em) and spontaneous action potentials (AP) which varied in frequency. Spontaneous AP were depolarized by TTX and blocked by TTX plus Ca2+ channel blockers. However, Em continued to fluctuate in the presence of these blockers. We have ruled out the possibility that Ca2+ OSC are due to voltage- or receptor-operated Ca2+ channels, or release of Ca2+ by intracellular mechanisms. Passive influx of Ca2+ could generate OSC and initiate exocytosis in RCC.

410.4  

We studied how [Ca2+]i relaxes after sudden changes in voltage-dependent Ca2+ entry, and uptake and release from a caffeine- and ryoside-sensitive store. High K+ (30-50 mM) depolarized Vm and caused a steady [Ca2+]i elevation, while caffeine (10 mM) produced a transient [Ca2+]i rise. Restoring K+ to 2 mM led to repolarization and a monotonic decline in [Ca2+]i. Caffeine removal produced a transient [Ca2+]i undershoot. Both relaxations are described by the sum of two decaying exponentials with the same t1/2 (3-5 s) and t1/2 (3-5 min) but with different amplitudes. This is consistent with a three-compartment scheme consisting of the external bath, the cytoplasm and an internal store, with pump and leak fluxes between compartments depending linearly on Ca2+ concentration, valid for small departures from the steady state. In this scheme, the r's reflect the dynamic properties of the system (transport rates, relative cytosolic and store volumes) while the amplitudes additionally depend on the initial conditions. To account for Ca2+ dynamics in the presence of caffeine, an internal Ca2+ dependent leak was introduced. The resulting flux functions exhibit periodic solutions resembling [Ca2+]i, oscillations in the presence of caffeine and high K+ (Friel and Tielin, 1992). Neurosci 8, 1-20: (1) tCa2+ " + frequency (f); (2) tCa2+ " + and amplitude, and (3) Ca2+ removal has phase-dependent effects on [Ca2+]i.

Therefore, a three compartment system with linear Ca2+ pumps and leaks and a single Ca2+-dependent leak in the internal store predicts [Ca2+]i oscillations like the observed ones; nonlinear pumps, etc. are not required. This provides a simple and testable model for caffeine-induced [Ca2+]i oscillations in sympathetic neurons, and may be useful in the study of caffeine- and ryoside-sensitive [Ca2+]i oscillations induced by agonists in non-neuronal cells.
410.5 DISTRIBUTION OF CALSKEQUIN, RYANOGEN AND IP3 RECEPTORS IN THE CHICK CEREBELLUM: A THREE-DIMENSIONAL IMMUNOCOLIZATION STUDY. M. E. Martone*, Y. M. Sappalagoni, T. Z. Dzczacka, J. A. Artzi†, L. J. Sztako†, and M. H. Hillman. San Diego Micromorphology Laboratory, UCSD, La Jolla, CA 92038; Pharmacology, Univ. of Nevada, Reno, NV 89557.

Many proteins involved in intracellular calcium regulation in skeletal or smooth muscle, e.g. the IP3 and ryano gen receptors, calskenein, Ca2+ ATPase, have been found to be abundantly expressed in the cerebellar perikarya (Vilin et al., J. Cell. Biol. 113: 739-745, 1991; Sztako et al., J. Cell Biol. 113: 739-745, 1991). While the muscle sarcolemmal reticulum is planar and ordered relative to the sarcomere, the neuron endomembrane system anastomizes in three dimensions (3D) presenting formidable obstacles to understanding the organization of calcium regulatory components. In the present study, the distribution of immunolabeled IP3 receptor (IP3R) and ryano gen receptor (RyR) was examined in chick cerebellum. Labeling for these proteins was determined in E18 to E17 chick cerebellum using laser-scanning confocal microscopy. Although labeling for all three proteins was extensively distributed within Purkinje cells, a unique pattern was found for each. Labeling for the IP3R was fairly evenly distributed throughout the cell body, dendrites and dendritic spines while labeling for RR and particularly CS was more discontinuous and not found in spines. The discontinuities in CS labeling appeared most prominent in older chicks. Preliminary analyses of double-labeled preparations suggest that the distribution of RR and CS labeling are not identical. In order to determine the structural basis for this difference, we have adopted a cryoimmunocytochemistry imaging method for 3D studies using thin sections and high voltage electron microscopy. Labeling for IP3R with 5nm gold was achieved through 0.25 um sections, with good structure preservation at normal cryo-conditions and elevated temperatures. Through the use of single and double-labeling, we expect to resolve how the spatial distribution of these proteins relates to the endomembrane system components thus providing important information to our understanding of the mechanisms by which these cells modulate intracellular calcium.

410.7 AN ALLOSTERIC MODEL FOR INACTIVATION OF VOLTAGE-DEPENDENT CHANNELS. Stephen W. Jones‡, Dept. Physiol. & Biophys., Case Western Reserve Univ., Cleveland, OH 44106.

Activation kinetics of L-type calcium channels can be described based on the Monod-Wyman-Changeux model, with movement of a voltage sensor corresponding to ligand binding, and channel opening corresponding to activation of the protein; the channel opens more readily with more voltage sensors moved (Marks & Jones, J. Gen. Physiol. 99, 367-390, 1992). A model where inactivation is also allosterically coupled to voltage sensor movement can explain (1) voltage-dependent macroscopic inactivation, (2) voltage-independent microscopic inactivation, (3) activation showing significant depolarized voltages, but rapid recovery from inactivation at negative voltages, and (4) Vv0 for inactivation more negative than Vv0 for activation. In its simplest form, where inactivation rates depend on how many voltage sensors have moved but not on whether the channel is open or closed (or on voltage), the model has 9 free parameters.

410.8 DETERMINATION OF THE 3-D CHANGES IN INTRACELLULAR Ca2+ ACTIVITY IN DISRUPTED RAT HICCUPPAL NEURONES USING RATIMOMIC FOCAL LASER SCANNING MICROSOPY. S. Jams, R. Perro, H. V. Wheel & J. E. Chaf, Dept. of Physiology and Pharmacology, Univ. of Southampton, SO1 3TU, UK.

The increase in intracellular calcium ion activity (Ca2+) within neurones is a powerful and potentially dangerous event for the regulation of neuronal activity and can lead to cell death. However, conventional investigative techniques have lacked the resolution to determine the true spatial and temporal extent of these changes. Confocal Laser Scanning Microscopy (CLSM) can resolve cellular morphology to a sub-micron level in three dimensions (3-D), revealing individual synaptic spines. This capability can be harnessed to the determination of changes in intracellular Ca2+ ion activity (within discrete volumes; focal plane) with the use of Ca2+ sensitive fluorescent dyes. We have used the acetyoxymethyl esters (AM) of the calcium-sensitive fluorescent dyes fluo-3 (10μM) and indo-1 (0.5μM), to load (60min,18°C) viable, dissociated rat hippocampal neurones. Indo-1 requires UV (360nm) excitation optics (argon ion laser), but can be used for ratiometric measurements. The Ca2+ responses of neurones to elevated K+ (20mM), caffeine (20mM) and glutamate (10μM) were tested (excitation lens Nikon 60 Plan Apo, NA 1.4). The experimental design was to record Z-series image data under control conditions, in the presence of the stimulus, after wash, in the presence of ionomycin, and finally with ionomycin and extracellular Ca2+ removed. The two last give a (maximal (saturated) and minimal Ca2+ loading of the dye. Caffeine gave the most consistent data, with apparently widespread elevations in Ca2+ (n=20/20 viable cells). Both glutamate and high K+ also produced increases in Ca2+ but less consistently. We are presently refining our techniques to unequivocally determine the subcellular localisation and extent of the changes in Ca2+ due to different stimuli.

410.10 ISOLATION OF NOVEL NEURONAL CALCIUM CHANNEL BETA SUBUNITS. E. Tunza and M. D. Uhler. Graduate Program in Neuroscience, Mental Health Research Institute and Department of Biochemistry, Mental Health Research Institute, Ann Arbor, MI 48105.

The dihydroxyproline-sensitive calcium channels in rabbit skeletal muscle consist of α1, α2, β, and γ subunits. The α1 subunits of these skeletal muscle subunits have been cloned. The β subunit has been further characterized and shown to have two genes that encode for homologous protein subunits. β1 is expressed in skeletal muscle and brain. In contrast, β2 is expressed in brain, heart and lung. In order to isolate splice variants of the β2 subunit, we screened a mouse brain cDNA library with a 900 bp DNA fragment corresponding to the first 900 nucleotides of the rabbit skeletal muscle β subunit coding region. Preliminary characterization of the isolated cDNA indicates that multiple splice variants of the β2 exist in brain. Sequencing of one clone demonstrated the existence of a previously undescribed splice variant. We have isolated a unique, new variant of the α1 subunit terminal sequence of this splice variant was found to diverge from the published α1 subunit sequence at amino acid 17. Initial characterization of the other clones suggests that additional splice variants of the α1 subunit exist in brain. In the future, crossexpression of these novel α1 subunit splice variants with mouse neuronal α1 subunits, currently being cloned in our laboratory, will be performed.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
410.11 ISOLATION AND CHARACTERIZATION OF THE P-TYPE CALCIUM CHANNEL FROM MAMMALIAN MUSCLE. B. Cherkesy, M. Sugimori and R. Linz. Dept. Physiol. & Biophys., NYU Med. Center, New York City, NY. P-type calcium channels, which are specifically blocked by the polyamine channel blocker "syntonic FTX", have been shown, both functionally (Linz et al, PNAS, 1989) and immunohistochemically (Linz et al, J. Histochem. Cytochem., 1991), to be present in different regions of the CNS. However, little is known about their distribution outside of the brain. The polyamine, l-arginyl-NO-,N′,N′-diisopropyl-1,4-butanediimine, which we have previously been employed to isolated synaptosomes of Sepharose 6B CL via a 1,4-Butanediol Dipycyl ether linkage. This affinity gel allowed the extraction of a protein from rat synaptosomal skeletal muscle homogenate (10% w/v). The functional activity of the resulting protein solution was assessed using the "up-down" bilayer technique. The electrical activity was measured in solutions containing: 80 mM BaCl2, 10 mM HEPES, pH 7.4 in the pipette; 0.25 M sucrose, 10 mM HEPES, pH 7.4 in the bath. Single channel activity was recorded under these conditions was characterized by a slope conductance of 55 fA. The current-voltage relationship was linear above -100 mV. The channel was rarely open at potentials more negative than -70 mV and opened with increasing frequency as the potential was made more positive. Single channels were blocked by the addition of Ca or Ca concentrations below 100 µM and by both a polyamine blocker synthetic FTX and by natural FTX. Ensemble averages of 60 ms steps from -30 to +30 mV showed that the channel activity did not inactivate during the 200 msec pulse duration. Analysis of the protein solution isolated using the polyamine affinity gel was performed using SDS-PAGE in polyacrylamide gels (only a single band (a doublet structure) at a molecular weight of 80-150 kDa was found when gels were silver stained. The results have shown that the protein isolated from mammalian skeletal muscle using an FTX affinity gel is a P-channel of similar structure and behavior to that found in CNS. Supported by NIH grants NS13742 and AG09480.

410.13 P-CHANNEL IS RESPONSIBLE FOR HIGH-THRESHOLD DENDRITIC ACTION POTENTIAL IN INFERIOR OLIVE NEURONS, AN FTX STUDY. A. Manfredi, B. Cherkesy, M. Sugimori, and R. Linz. Dept. Physiolology and Biophys., NYU Medical Center, 550 First Avenue, NY, NY 10016. Inferior olive cells have been shown to exhibit high-threshold and low-threshold calcium spikes (Linz et al, J. Physiol., 315:549,1981). The low-threshold spike is generated by a conductance consistent with the presence of T-type voltage-dependent calcium channels. The type of channel responsible for the high-threshold spike has not been determined. A histochemical study of the distribution of P-channels in the CNS using P-channel specific antibodies indicated that the inferior olivary neurons express P-channel (Manfredi et al, J. Neurochem., 68:7076, 1998). Since a polyamine purified from Agelopoge Aperta (FTX) has been shown to block P-channels (Linz et al, PNAS 86:1689, 1989) the effect of HPLC-purified FTX as well as whole venom of Agelopoge Aperta was tested in intracellularly recorded inferior oliver neurons in guinea pig brain stem slices. Both of these substances produced a clear block of the high-threshold calcium spike without affecting either the sodium action potential, the low-threshold calcium spike or calcium-dependent potassium conductance that generates the afterhyperpolarization. By contrast, the large high-threshold calcium dependent action potential and the afterhyperpolarization that follow were blocked. In addition, when the cell was depolarized, repetitive high-frequency sodium dependent action potentials could be obtained. The results indicate at least two calcium conductances are found in the inferior olive, a P-type conductance responsible for the high-threshold spike and the P-type channel responsible for most of the high-threshold spike. (Supported by NIH grants AG09480 and NS13742)

410.12 CHARACTERIZATION OF P-TYPE CALCIUM CHANNELS IN CEREBELLAR PURKINJE CELLS. M.M. Ussizig*, M. Sugimori, R. Cherkesy & R. Linz. Dept. of Physiology and Biophysics, NYU Medical Center, 550 First Avenue, New York, NY. There is good agreement between the pharmacological profiles of P-type Ca channels in cerebellar Purkinje cells, Ca channels expressed in Xenopus oocytes from brain homogenates, and the P-type Ca channel (see Tieson et al, TIPS 12, 349). However, it has been difficult to compare the biophysical properties of these channels, because the currents have not been recorded with the same Ba concentrations. Therefore, we have recorded P-type Ca channel currents carried by Ba ions ranging in concentration from 1mM to 100mM, and also by 2.4mM Ca. Cell-attached patch recordings were made at 22°C from the somas of adult Purkinje cells in thin cerebellar slices of the guinea-pig (Edwards et al, Piongues Archiv 414:600). The threshold of activation was carried linearly with the log of [Ba]; it was shifted towards positive potentials as [Ba] was increased, presumably due to screening of the surface potential by Ba ions. For instance, it was -40mV with 2.2mM Ba, -41mV with 5mM Ba and -23mV with 40mM Ba. Currents carried by 2.4mM Ca activated at around -41mV. Moreover, we found little difference in single-channel conductances measured with 10-100mM Ba; channel openings were to three conductance levels of 10pS, 14-16pS and 19-21pS (slope conductances). As [Ba] was reduced below 10mM, the unitary currents became progressively smaller and multiple levels could not be resolved. Single-channel currents carried by 2.4mM Ca were barely resolved. Supported by NINDS grant NS 13742 and at NESC/NOF Fellowship (MMU)

410.14 IMMUNOLOGIC AND KINETIC CHARACTERIZATION OF A Na+/Ca2+ EXCHANGER IN PRIMARY NEURONAL CELL CULTURES. G. Hoer, R. Pat, M. Herrbert, J. Wenzel. Dept. Pharmacology and Toxicology, and Center for Biomedical Research, University of Kansas, Lawrence, KS 66045. The plasma membrane Na+/Ca2+ exchanger is believed to play a role in regulation of Ca fluxes in neurons. We recently reported the development of Ab's against a 36 kDa synaptic membrane protein which immunoprecipitated an exchanger activity from purified dissociated membranes (J. Neurochem. 58:147, 1992). We have now used these Ab's to label primary neurons in culture with avidin-biotin conjugates to peroxidase. The antibodies produced significant labeling of axons, dendrites and cell bodies in neuronal cultures prepared from 18-day embryonic rat brain. Given the substantial amount of Ab labeling of the cells, it was of interest to see whether these cells exhibited Na+/Ca2+ exchanger activity with properties similar to those reported for adult brain synaptic membrane preparations. Points of contact between neurons stained quite heavily. Sodium-dependent Ca2+ transport was measured in washed homogenates of primary cortical neurons maintained for 3-6 days in serum-free, defined culture medium. Kinetic determinants of transport activity revealed that Ca2+ uptake was linear for at least 30 seconds at 23°C. Uptake was measured across Ca2+ concentrations using 50 sec incubations and the kinetic constants were determined to be: Km = 39 µM and the Vmax = 0.55 nmol/mg protein/sec. These values are quite close to those reported for other, somatic brain preparations. (Supported by grant AA04732 and MDM Sci. Educ. Partnership.)

ACETYLCHELORINE: CNS I

411.1 AFFERENTS TO THE MESOPONTINE CHOLINERGIC NUCLEI FROM THE PERIPHERAL BULBARY IN THE RAT. T.L. Steininger and B.H. Walker, Comm. on Neurobiology, and Dept. Pharm. and Phys. Sci., The University of Chicago, Chicago, IL 60637. A large body of evidence suggests that the mesopontine cholinergic groups, the pedunculopontine tegmental (PPT) and laterodorsal tegmental (LDT) nuclei, participate in mechanisms of behavioral state control; specifically in arousal and the rapid eye movement sleep. Previous retrograde tracing studies have identified putative afferents to the PPT from numerous regions, including the brainstem, olfactory bulb, striatum, hypothalamic area, dorsal raphe nucleus, and the periaqueductal gray (PAG). Furthermore, the ventrolateral region (Steininger et al., J. Comp. Neurol., in press). In the present study, we have utilized anterograde tracing with PHA-L coupled with choline acetyltransferase immunohistochemistry to examine the PAG innervation of the mesopontine tegmental nuclei. At the light microscopic level, a dense innervation of PHA-L labeled fibers was observed in the region of the PPT and LDT. At higher magnification, the fiber terminals were observed between anterogradely-labeled boutons and cholinergic neurons. The functional implications of these connections are unclear, but may be involved in mediating the physiological and behavioral correlates of arousal that are features of the "defense reaction" elicited experimentally by ventralpial PAG stimulation. (Supported by NS 17661 and MH 09919)

411.2 MEDIAL PREFERENCES CORTEX PROJECTS DIRECTLY TO CHOLINERGIC NEURONS OF THE MESO-PONTINE TEGMENTUM. R.S. Reves*, S.R. Grant. Dept. of Biological Sciences, Psychology and Program in Neuroscience, University of Delaware, Newark, DE 19716. Stimulation of the medial prefrontal cortex (MPFC) reliably activates neurons in meso-pontine nuclei including the laterodorsal tegmental nucleus (LDT) and rostral locus coeruleus (rLc). Although anatomical studies report direct projections from the MPFC to the LDT it is not clear if these cortical afferents directly and/or selectively innervate cholinergic neurons in the LDT. In order to resolve this question we used Phaeusolus leucogatullin (Phal.) injected into the rat MPFC to labelafferent fibers, and NADPH-diaphorase histochemistry to identify cholinergic neurons. Later, both cholinergic and non-cholinergic neurons in the LDT were contacted by numerous branched and varicose affenter fibers. The fibers were densely at rostral levels and formed a continuous plexus that extended from the LDT to the adjacent dorsal raphe (DR), but avoided the intervening dorsal tegmental nucleus of Gudden. Some fibers swept laterally into the dorso medial portion of the pedunculopontine tegmental nucleus, and extended ventrally into the reticular formation. Laterally, fibers generally spared Barrington nucleus, but Phal. positive fibers occasionally entered the rLC. Fibers in the LC appeared thicker than fibers in other regions. The relative number of Phal. labeled fibers in the LDT and LC was related to the domino- ventral positioning of the injection. This study is consistent with our stimulation and pharmacological studies suggesting a monosynaptic excitatory amino acid projection from the MPFC to the LDT. Studies combining NADPH- diaphorase immunohistochemistry are in progress to verify the cortical transmitter. Supported by NIMH, the State of Delaware, and ICI Pharma.

ACETYLCHOLINE: CNS I

411.4

The descending cholinergic projection from the laterodorsal tegmental (LDT) and pedunculopontine tegmental (PPT) nuclei to the pontomesencephalic reticular formation is thought to be implicated in the regulation of the rapid-eye-movement (REM) sleep phase. The fluorescent triple-labeling technique combined choline acetyltransferase (Chat) labeling by fluorescent (AMCA) immunohistochemistry with the use of two different fluorescent retrograde tracers, fluoroscan- and cholodin-conjugated latex beads. The retrograde tracers were injected into the entire side of the pontomesencephalic reticular formation and adjacent structures in 13 rats. In each case, triple-labeled neurons were found in the LDT and PPT nuclei, indicating Chat immunopositive neurons with bifurcating axons. Overall, there was a contralateral projection in about 22% of all ipsilaterally projecting neurons in the pons and 15% in the medulla for the PPT. Furthermore, for contralaterally projecting PPT neurons, there were ipsilateral branches in 38% in the pons and 22% in the medulla. LDT percentages were less in both cases. Quantitative volumetric measurements indicated that all injections of retrograde label occupied less than 3% of the reticular nuclei; despite this small volume of injection, bilaterally projecting cholinergic, an oxytocinergic, and a vasopressinergic neuron population was found. In summary, our data support the idea that a substantial number of cholinergic neurons in the pontomesencephalic reticular formation project bilaterally, and that cholinergic neurons are involved in the regulation of the rapid-eye-movement sleep phase.

411.5

Intracellular recordings were made from laterodorsal tegmental nucleus neurons in the in vitro brain slice preparation. Recordings were obtained from 95 cells which had mean input resistances of 160 (+/- 45) MOhm and action potential overshoots of at least 10mV. Virtually all cells, regardless of their cholinergic or non-cholinergic nature, responded to the application of carbachol (1-10μM) with a membrane hyperpolarization and increased decrease in input resistance. Under voltage clamp conditions this response was shown to be due to an outward current that was strongly inward rectifying and had a reversal potential near the equilibrium potential for potassium. The carbachol response was partially blocked by cesium (2nM) and fully blocked by barium (100μM) providing additional evidence for the activation of an inward rectifying potassium conductance by carbachol. The carbachol effect was not blocked by low concentrations of the M1 antagonist pirenzepine, indicating that the response was due to the activation of non-M1 acetylcholine receptors. Supported by the Dept. of Veteran's Affairs and N.I.M.H. grant MH39863.

411.6

NORADRENALINE HYPERPOLARIZES CHOLINERGIC NEURONS IN RAT LATERODORSAL TEGMENTUM IN VITRO. J.A. Williams* and P.B. Reiner Kinsmen Laboratory of Neurological Research, Dept. of Psychiatry, University of British Columbia, Vancouver, B.C. Canada, V6H 1Z1.

Inhibition of brainstem cholinergic neurons by noradrenergic neurons of the locus ceruleus has long been suggested as one mechanism of behavioral state control. While there is anatomical evidence for a noradrenergic innervation of cholinergic neurons in the rat laterodorsal tegmentum (LDT), the direct inhibitory influence of noradrenaline on cholinergic neurons has never been demonstrated. The purpose of the present study was to characterize the effect of noradrenaline upon cholinergic neurons in the rat LDT. Using whole-cell patch clamp recordings in slices, 26 cells were studied during bath application of 50 μM noradrenaline (NA). Cholinergic neurons were positively identified by intracellular labelling with biocytin and subsequent NADPH-diaphorase staining. 93% (13/14) of identified cholinergic neurons hyperpolarized with an increase in conductance in response to noradrenaline. In contrast, non-cholinergic neurons exhibited mixed responses to NA (25% (3/12) hyperpolarized, 33% (4/12) depolarized, 42% (5/12) no response). Bath application of 1μM isoproterenol blocked the hyperpolarizing effect of NA on cholinergic cells. To test whether the response to NA was a direct effect, some slices were bathed in low Ca2+, high Mg2+ ACSF solution. The responses of cholinergic cells to NA in this condition were identical to those in normal ACSF. These results demonstrate for the first time the direct hyperpolarization of cholinergic neurons by NA, and that this is an oxy-mediated effect.

411.7

EFFECTS OF SEROTONIN UPON BASAL FOREBRAIN NEURONS IN VITRO. Natalia A. Gorelova* and Peter B. Reiner, Kinsmen Laboratory of Neurological Research, Department of Psychiatry, University of British Columbia, Vancouver, BC V6T 2Z3 Canada.

Neurons of the basal forebrain project to the hippocampus and cerebral cortex and are thought to be intimately involved in the control of cortical arousal. Anatomical studies have demonstrated the existence of serotonergic afferents to the basal forebrain. Moreover, there is considerable evidence that serotonergic inputs to the medial septum are involved in generation of some types of hippocampal theta rhythm. In order to understand the role of serotonergic afferents in control of cortical arousal, we studied the responses of basal forebrain neurons (medial septum, diagonal band) to serotonin using whole-cell patch clamp recordings in an in vitro slice preparation. Basal forebrain neurons exhibited heterogeneous physiological properties, with a mean resting membrane potential of -52 ± 4.8 mV and input resistance of 350 ± 152 MΩ. In accord with the variable electrophysiological properties of basal forebrain neurons, differential, of twelve cells studied, 6 cells depolarized, 2 cells hyperpolarized and 4 cells showed no response. Current efforts are directed towards correlating transmitter status with responses to serotonin.

NUCLEUS BASALIS STIMULATION ELICITS NEOCORTICAL ACTIVATION AND FACILITATES THALAMOCORTICAL SYNAPTIC TRANSMISSION: INTRACELLULAR AND EXTRACELLULAR RECORDING IN RAT AUDITORY CORTEX. Paul Medrano* and John H. Ashe, Departments of Neuroscience and Psychology, University of California, Riverside. CA 92521.

Neocortical activation (EEG) during basal nucleus stimulation) reflects a state of behavior and cortical information processing. Through largely undetermined cellular mechanisms, the neurotransmitter acetylcholine (ACh) is thought to be involved in neocortical activation. Since nucleus basalis (NB) neurons are a primary source of cortical ACh, these cells may mediate EEG activation. We have examined this hypothesis, and the implications of cortical activation for thalamocortical transmission, by stimulating the NB and the auditory thalamus (medial geniculate, MG) during intracellular and extracellular recordings in the middle to deep layers of auditory cortex in urethane-anesthetized rats.

Electrical or chemical stimulation of the caudal NB desynchronized the local EEG recorded in auditory cortex; this action was blocked by cortical application of the muscarinic receptor antagonist atropine. Simultaneously with its effect on the EEG, NB stimulation elicited depolarization (-10 mV) of cortical neurons and subthreshold membrane potential fluctuations from large amplitude, slow (1-5 Hz) oscillations to low amplitude, fast (25-40 Hz) oscillations. MG stimulation elicited a discharge in auditory cortex and afferent volley (peak latency ca. 2 ms) followed by an afterhyperpolarization (ca. 3 ms onset, 7 ms peak) by a negative-going field potential, or intracellularly, an excitatory postsynaptic potential (EPSP). NB stimulation did not alter the thalamocortical afferent volley, but facilitated the slope and amplitude of the negative-going field potential via a muscarinic action. NB stimulation also enhanced MG-evoked EPSPs, producing a hyperpolarization that was followed by a slow afterhyperpolarization.

These data suggest that one function of ACh-mediated neocortical activation is to facilitate thalamocortical transmission.

411.9 Ca²⁺-CALMODULIN KINASE MEDIATES MUSCARINIC BLOCKADE OF GluCa and ENHANCEMENT of Ca²⁺ CHANGES IN HIPPOCAMPAL CA3 PYRAMIDAL NEURONS. W. Muller*, J.J. Petrozzi,* L. Griffith,* W. Danhof* and J.A. Corporan* Dept. of Neurosciences, Roche Center, Hoffmann-LaRoche, Inc., Roche Research Center, Nutley NJ 07110

An important intrinsic control of excitability in pyramidal neurons of the hippocampus is represented by adaptation of discharge during constant-current flow afterhyperpolarization following repetitive discharge. This negative feedback is mediated by Ca²⁺ dependent K-conductances GluCa and is subject to down-modulation by extracellular muscarinic agonists. Muscarinic suppression is of particular interest for its important role in synaptic plasticity and learning. This input uncouples intradendritic Ca²⁺ from synaptic activation and thereby potentiates intradendritic Ca accumulations, a factor that possibly underlies facilitation of synaptic plasticity during muscarinic activation.

Using new peptide inhibitors of Ca²⁺-calmodulin dependent kinase (CaM kinase) and PKC we found that muscarinic modification of GluCa and Ca²⁺-changes relies on CaM kinase activation, but the converging effects of serotonic and glutamatergic agonists are mediated either through other kinases or by different intrinsic mechanisms. We summarize that these large part separate pathways include also different branches that are relevant for distinct functions of these neurotransmitters.

W. Muller was supported in part by a Helmholtz-Stipend from the BMFT.

411.11 CHOLINERGIC SLOW SYNAPTIC ACTIONS ON RAT NEOCORTEXAL NEURONS IN VITRO. J.H. Asher*, C.L. Cox, R. Mehler and E. Jaber. Deps. of Neuroscience and Psychology, Univ. of California, Riverside, CA 92521.

Acetylcholine (ACh), exogenously applied, can produce lasting modifications of functional characteristics of cortical neurons. However, the actions of synaptically released ACh upon neuronal excitability and synaptic transmission in neocortex are not clearly understood. These experiments investigated the action of cholinergic agonists and endogenous ACh upon auditory cortical neurons.

Tetanic stimulation of deep cortical gray matter (10-100 mA; 8-40 pulses, 20-80 Hz) elicited a voltage-dependent long-lasting slow membrane depolarization (tonus of seconds) to many microelectrodes. This slow depolarization persisted in the presence of amino acid antagonists (DNQX, APV, picrotoxin). Tetanic stimulation also produced voltage dependent 1) decreased spike frequency accommodation, 2) decreased slow afterhyperpolarization, and 3) facilitated spike afterdepolarization. The effect of the tetanic stimulation were mimicked by exogenously applied cholinergic agonists, ACh and mecameline (Mecamylamine, mecamylamine), and antagonized by the muscarinic antagonists atropine or pirenzepine. These data suggest that synaptically released ACh produces multiple voltage-dependent actions via muscarinic receptors.

A subpopulation of neurons has been identified as "thyroid-bursting" neurons due to their low frequency rhythmic (5 Hz) bursting discharge to a depolarizing current pulse. These cells have an intermediate firing pattern identified by layer 5 pyramidal neurons following bicuculline injection. In these cells, tetanic stimulation reduced the number of bursts and increased the number of higher frequency (10-15 Hz) single spike discharge in response to a depolarizing current pulse, independently of membrane depolarization. This effect was enhanced by exercise, blocked by atropine and mimicked by muscarinic agonists, Mecamylamine and Carbachol.

These data suggest that synaptically released ACh, acting via muscarinic receptors, can modulate the excitability of neocortical neurons. Modulation of the excitability of these neurons may influence the neurons response to subsequent afferent and efferent information and may serve as a potential mechanism of synaptic plasticity. Supported by NSF BNS 9008618.

Neocortical cells recorded from cat association areas 5 & 7 display an oscillation around 0.5 Hz, consisting of depolarizing and hyperpolarizing sequences, time-locked to a similar EEG oscillation (Steriade et al., this meeting). Here we report the modulation of this novel type of slow neuronal oscillation by shifting the EEG synchronization (high-amplitude and slow waves) to activated patterns. We used intracellular recordings of cortical cells under urethane anesthesia to examine the effect of the EEG state by a brief stimulation (pulse-trains at 30 Hz lasting for 1 s) of pedunculopontine tegmental (PPT) and locus coeruleus (LC) nuclei. In most cells, PPT stimulation produced a depolarization (1-5 mV) associated with tonically increased firing and lasting for 10-20 s. The slow oscillation was blocked for 5-10 s and resumed thereafter. This cellular effect was voltage-dependent, as it could not be obtained at a membrane potential more negative than -45 mV. In some neurons, in which the oscillation mainly consisted of rhythmic hyperpolarizations superimposed by depolarizing waves, PPT stimulation interrupted the oscillation by selectively suppressing the hyperpolarizing episodes. The time course of the PPT-induced blockage of slow oscillation was similar to that of EEG activation. The PPT effect was suppressed by systemic administration of a muscarinic blocker, scopolamine. LC stimulation produced qualitatively similar effects on cells and EEG activity, but less pronounced and durable. After clonidine administration, the effects of LC stimulation were no longer observed. The similarity between the cholinergic and noradrenergic effects suggests that the major mechanism underlying the blockage of the slow cortical oscillation, and especially of the rhythmic hyperpolarization, is the reduction or suppression of potassium conductances. Supported by NRC of Canada (grant M3869).

411.13 SERIAL SECTION ANALYSIS OF THE ACETYLCHOLINE (ACH) INNERVATION IN ADULT RAT PARIETAL CORTEX. D. Unbom*, K.C. Watkins*, D.H. Hart* and S. Czerny CRSN (Départements de pathologie et de physiologie), Université de Montréal, Montréal, Qc, CANADA; Instituto Biologia Cellulaire CNR, Roma (ITALY), and Department of Psychiatry, University of Minnesota, Minneapolis (MN).

We have now completed the electron microscopic examination in serial thin sections of 795 portions of adult rat parietal cortex (ParI), immunostained with monoclonal antibodies against purified rat brain choline acetyltransferase (Soc. Neurosci. Abstr. 16:300, 1990). This material from 4 rats was initially fixed by perfusion of a paraformaldehyde (2.5%) - glutaraldehyde (0.1%) mixture, and processed with the ABC method. 140 varicocities of layers I, II, III, IV and V, 517 of layer IV, 199 of layer V, 216 of layer VI were photographed from end to end and examined at a final magnification of 8000 (average of 11 pictures for varicosity). The maximal transverse diameter of these varicosities was similar in every layer (0.49 ± 0.15 μm s.d.). Both large and small varicosities could be observed on the same fiber. The average proportion of the varicosities exhibiting a synaptic membrane differentiation (9.3% in layer I; 13.8% in II-III; 11.6% in IV-V; 26.2% in VI), which reaches a maximum of 14.5%. These 118 synaptic junctions were almost invariably symmetrical (98.2%). A majority were found on dendritic branches (80.7%), some on spines (22.8%) and none on cell bodies. The varicosities located on the same fibers. There were only 4 varicosities with dual junctions and the 2 asymmetrical junctions were on spines in layers I and II-III. These data indicate that the ACh nerve terminals form an punctate, with a junctional, with a slightly higher proportion of synaptic varicosities in layer V. Identification of receptive elements will be needed to determine the functional targets of such an innervation. [Supported by the FCAR and grants MT-3544 (MRC) and NS 12311].

The cholinergic innervation of the human amygdaloid complex was studied using choline acetyltransferase (ChAT) immunohistochemistry. CHAT-positive fibers and varicosities were observed throughout the amygdaloid complex. In parts of the amygdala the density of this cholinergic innervation was higher than in any part of the cerebral cortex. The highest level of ChAT-positive varicosities was seen in the basolateral nucleus, the lateral nucleus of the amygdaloid complex. The basomedial, accessory basal and cortical nuclei, the amygdaloparietal area, and the amygdalopeduncular transition areas and anterior amygdaloid areas showed a lower density of CHAT-positive varicosities and fibers. The lateral nucleus displayed the highest level of innervation and there were only rare CHAT-positive fibers in the medial nucleus. The two lateral nuclei together displayed a low level of innervation in comparison to the other amygdaloid nuclei. The amygdaloid complex is approximately equivalent to that of entorhinal cortex, which receives one of the heaviest of all extrinsic innervations in the cerebral cortex. The pattern of differential staining was maintained throughout the anteroposterior extent of the amygdala. The cholinergic innervation of CHAT-positive fibers and varicosities within the various nuclei and their subdivisions was by and large homogenous, with a given level except for some patches in the central nucleus. The distribution of CHAT-positive fibers was determined using the post-mortem sections as studied by CHAT immunohistochemistry and was comparable to that observed with ACHE histochemistry. These results confirm that, as part of the limbic system, the human amygdaloid complex receives a dense and differentially distributed cholinergic innervation.
411.15 ULTRASTRUCTURAL EVIDENCE FOR DISTINCT CHOLINERGIC AND VIP-ERGIC MODULATION OF INTRACRANIAL BLOOD VESSELS. A. Chebat*, D. Umirović*, B-K. Hartman* and E. Hamel*. Montreal Neurological Institute, McGill Univ., Univ. de Montréal, Montréal, Québec, Canada and Dept. of Psychiatry, Univ. of Minnesota, MN, USA.

Acetylcholine (ACH) and vasoactive intestinal polypeptide (VIP) exert potent vasoactive effects within the cerebral cortex. The relationships of ACh and VIP terminal profiles with cortical microvessels were evaluated at the ultrastructural level after immunocytochemical labeling for choline acetyltransferase (ChAT; MCAT-1C; Cozzari et al., Soc. Neurosci. Abstr. 16: 200:1990) or VIP (Pabst 4P8) with 4% paragamneldehyde (PF) and 0.025% glutaraldehyde followed by PF alone. Vascular terminals (section thicknesses 60 µm) were immunostained for ChAT or VIP by the ABC method with DAB-nickel as the chromogen. An equal number (> 80) of ChAT and VIP terminals located close (0.3 µm) to blood vessels were photographed and analyzed in single thin sections (Bioquant II). These terminals were respectively located at an average distance of 0.62 ± 0.05 and 0.75 ± 0.07 µm from the vessel wall (capillaries or arterioles). Of these, 26% (ChAT) and 20% (VIP) were separated from the basal lamina by a thin glial leaflet only, irrespective of the distance, VIP (0.56 ± 0.05 µm) were significantly larger than ChAT terminal (0.34 ± 0.03 µm; p < 0.001). Membrane specializations were never observed at the neuro-vascular interface even in serially-sectioned ChAT (n = 20) and VIP (n = 5) terminals. Together with our previous data showing that 59% of cortical neurons stain for VIP, 28% for ChAT and 13% only colocalize both transmitters, the present results strongly suggest that intracortical vascular functions are primarily influenced by distinct ACh and VIP nerves. Supported by the MRC of Canada.

NBOX (2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo[f]quinoxaline), a selective antagonist of the AMPA subtype of glutamate receptor, has antispastic effects in monoamino-depleted rats and MPTP-treated primates (Ann. Neurol. 1991; 30:717-723). In the present study, NBOX was administered to normal rats and primates to determine if it produced any apparent side effects. In rats, various doses of NBOX (0, 5, 10, 20 mg/kg; i.p.) were evaluated (n=9/dose). Each rat was tested measuring horizontal activity and stereotypies. There were no apparent side effects in rats treated with 0, 5, 10 mg/kg NBOX. However, there was a slight but significant (p<0.05) narcotic effect observed in rats treated with 20 mg/kg NBOX. In the primate testing, 3 normal older (approximately 12-16 years old) female rhesus monkeys were administered doses of 0 and 1 mg/kg (i.m.) NBOX on alternate days. Each primate was subjected to 1 week of testing. Data were gathered by videotaping and computerized cage activity monitoring in which the number of times an animal crossed an infrared beam was recorded. These data were analyzed using a Clinical Rating Scale consisting of 4 measures of parkinsonian features (posture, gait, bradykinesia and balance), 3 measures of drug-related side effects (dyskinesias, vomiting and psychomotor disturbance) and 1 measure of overall level of activity. There were no apparent NBOX related side effects seen in any of the primates. Supported by a grant from the Motor Neuron Foundation.

Excitatory amino acid receptors can be classified by pharmacological and electrophysiological selectivity for the ligands NMDA, AMPA, kainic acid and t-ACPD. The present report characterizes the effect of antagonism of the AMPA subtype, NBOX, on local cerebral glucose utilization (LCGU). NBOX has been previously shown to have neuroprotective effects. NBOX was administered at doses of 3 to 90 mg/kg i.p. 30 minutes prior to the administration of 60 uCi [14C]-2-deoxyglucose i.v. in conscious rats. NBOX (3 to 30 mg/kg) selectively increased LCGU in the lateral heperula, raphe, superior and inferior colliculus and vestibular nucleus. NBOX at 60 mg/kg decreased LCGU in 47 of the 62 brain regions examined. NBOX at 90 mg/kg decreased LCGU in 60 of the 62 brain areas examined.

NBOX did not increase LCGU in limbic brain areas at any of the doses examined. In fact, NBOX at ≥60 mg/kg decreased LCGU in limbic areas. These data suggest that antagonism of the AMPA receptor subtypes with NBOX results in changes in LCGU different from those previously reported for non-competitive antagonists (i.e. PCP, MK 801), further suggesting that NBOX may not be associated with PCP-like effects.

412.3 KAINATE-INDUCED EPILEPSY LEADS TO AN INCREASE IN GLUTAMATE-STIMULATED PHOSPHODIESTERASE METABOLISM IN THE HIPPOCAMPUSS. M. Maya*, M. Emin-Matal, N. B. DallaMora, and R. Recasens*. INSERM U239, Hopital St-Charles, INSERM U248, CNRS UPR 8402, 34000 Montpellier, FRANCE.

Intrahippocampal injections of kainate (KA) ultimately induce status epilepticus associated with neuronal loss in local and distant structures. In the hippocampus, a mossy fiber sprouting occurs in consequence of this seizure-related damage. Since glutamate metabotropic receptors (mGLU-R) may be involved in synaptic plasticity, we examined the agonist-induced inositol phosphates (IP) formation in hippocampal slices of rats subjected to an intrahippocampal KA injection (2.5 mol in 1 µl). After 24 hours, no significant effect of KA application on IP accumulation was observed. However, 1 week following injection, significant increases of the metabotropic responses mediated by quisqualate (QX; 1µmol) and ibotenate (IBO; 1µmol) and trans-aminoacycloptene- dioxobutylate (t-ACPD) were noted in hippocampal slices. In control animals, the IP formation (IP synthesis) for buffer, QA, IBO, t-ACPD and carbachol were 28,028±491, 41,544±1051, 5,497±411, 7,508±5, 4,164±757 pmol/mg protein respectively whereas in KA treated animals they were 3,125±709, 11,071±1054, 13,196±228, 15,117±13, 5,664±119 pmol/mg protein. Significant increases were also obtained 2 and 6 weeks after injection. For carbachol, there was no significant increase at all times except after 6 weeks following KA treatment. This specific dramatic increase of the mGLU-R response in the hippocampus following seizure-related damage suggests that mGLU-R may play a role in the molecular mechanisms leading to brain plastic changes.

Glutamate receptors (GluR) are thought to play a role in epilepsy. We examined GluR gene expression in adult and 15 day rat brains after induction of status epilepticus by kainate (15 or 4.5 mg/kg i.p.). In situ hybridization was used to measure levels of NMDA1, GluR1, GluR2, and GluR3 mRNAs in corona sections from control and KA-injected animals 6 to 14 h after seizure onset. In adults, damage to amygdala, entorhinal cortex, and selective thalamic nuclei was evident at 6-12 h, while CA3/4 selective cell loss was not evident until 48 h. Autoradiography of adult brain sections indicated significant increases in GluR2 and GluR3 expression (50-100%) in the dentate gyms (DG) and subiculum (50%) and a comitant decrease (40-60%) in CA3/C4 hippocampal subfields at 24 h. GluR1 expression was unchanged. Emulsion-dipped sections revealed that the observed changes were in mRNA content per neuron. After 12 h adult NMDA1 mRNA levels were greatly reduced (CA3:60-80 %) but unchanged in DG suggesting a specific role for genomic expression of glutamate receptor subtypes in seizure activity. In 15 day pups, an age when KA does not induce neurodegeneration in limbic structures, GluR1 and GluR2 dentate mRNA levels were elevated in DG by 50-100% 24 h after seizure onset with no changes in GluR3 mRNA. The three transcripts were unchanged in CA3/C4. In conclusion, changes in adult mRNA expression occur prior to obvious CA3/4 pyramidal cell loss, but after afferent denervation from limbic structures. There are maturational differences in GluR mRNA expression that may be explained by the presence or absence of associated structural lesions.
412.5  CELL-ATTACHED RECORDINGS OF NMDA CHANNELS IN CHRONICALLY EPILEPTIC (KINDLED) NEURONS. G. Köhn* and I. Modéy. Center for Molecular Biology, Univ. of Heidelberg, F.R. Germany and Dept. of Neurology & Neuroscience, Univ. Sch. of Med. Stanford, CA.

Our studies in hippocampal slices and acutely dissociated neurons have shown that kindling-induced epilepsy increases synaptic activation of NMDA receptors. These changes are obtained in a whole cell, NMDA remained and alteration of the activation/inactivation kinetics of HVA Ca" currents. We have now examined if long-lasting changes can be detected at the level of single NMDA channels.

Cell-attached recordings were obtained in acutely dissociated control and kindled dentate gyrus granule cells in Mg-free medium containing 3 μM glycine using NMDA as an agonist (1, 5 and 10 μM). Single open times and the conductance of single channels were comparable in control and kindled neurons. Kindled channels differed from controls by having a longer burst duration and a higher +pwm at low NMDA concentrations (1 of 5 μM).

Following kindling, the combined effect of the longer burst duration and the higher +pwm was a 23-fold and a 3.6-fold increase in the charge carried through NMDA channels at 1 and 5 μM NMDA respectively. As a result of a reduced +pwm at 10 μM NMDA the charge through kindled channels was 57% of that recorded in control cells. On-cell dose-response studies, according to a double-fil method (A. Auerbach, Biophys. J., 60:660, 1991), were done by allowing NMDA (25 μM) to gradually diffuse to the channels over a period of 15:30 min. These experiments confirmed the higher affinity and augmented desensitization at high NMDA concentrations of kindled channels.

The chronic enhancement of NMDA receptor channel function may result from a covalent modification during kindling; the outcome for neuronal excitability conceivably contributes to epileptogenesis.

412.7  DELAYED PHENCYCLIDINE EFFECTS ON NMDA SENSITIVE HGLUTAMATE BINDING X.-M. Gao* T. Kakati, C.A. Tannmisa, University of Maryland, MPRC, P.O. 21247; Baltimore, MD 21228.

Phencyclidine acts in a psychotomimetic way, which has a prolonged potomimetic effects in humans, hence it has been used as psychotomimetic model. We have previously demonstrated that single doses of PCP in rat produces an increase in +pwm than a prolonged decrease in cerebral glycose metabolism (rCMRGlu) lasting longer than 24 hours. This effect is prominent in rat limbic structures. Moreover, schizophrenia studies have shown a high degree of functional changes in limbic structures and postmortem pathologic changes in limbic and paralimbic regions. Therefore, we have begun to explore the neurochemical correlates of this delayed PCP action, especially in the limbic system. Here, we report the 24 hour effect of PCP (8.6 mg/kg) on the NMDA sensitive H-glutamate binding sites and other glutamate receptors. NMDA and AMPA glutamate receptors were quantified according to the method using H-glutamate and H-AMPA, respectively. Our results show an increase of more than 40% in NMDA binding in limbic structures like hippocampus, and in limbic related neocortex, like dorsolateral frontal, medial prefrontal, and posterior cingulate cortex, 24 hours after a single dose of PCP. This effect is significant in CA1 region of the hippocampus (dorsal: PCP=92.6±22.9, control=64.6±13.9 fmoles/mg tissue; ventral: PCP=86.0±15.0, control=62.8±11.8), Means±SD, n=6, P<0.05), and dorsolateral prefrontal cortex (PCP=52.0±16.3, control=26.8±5.6, P<0.01). No change in AMPA receptor density was found. These data suggest that the psychotomimetic effects of PCP, particularly of those delayed effects may be mediated by limbic glutamatergic synaptic selective for NMDA. These observations may suggest direction of study in schizophrenia.

412.9  Interactions of EtOH and Glycine with the NMDA Receptor-Linked Ion Channel Complex in EtOH Withdrawal Seizure-Prone and Resistant Mice and Rats. C.C. Crabb* and J.C. Crabbe. VAMC and Oregon Health Sciences Univ., Portland, OR 97201.

We have characterized the assay conditions that are required for equilibrium binding of [3H]MK-801 to the NMDA receptor-linked ion channel complex. Results of our experiments indicate that radioligand binding to a well washed tissue preparation (10 μM EtOH) includes glycine (10 μM) and NMDA (10 μM) requires 24 hrs to reach equilibrium. In addition, the dose response curve for the glycine-induced increase in the affinity of the binding sites is not altered after 24 hrs incubation at 25°C, with Hill coefficients increasing over time.

Under these conditions, EtOH (3 - 100 mM) has no effect on the characteristics or radioligand binding, on the glycine-induced increase in affinity for radioligand binding. In addition, there appears to be no difference in the density of [3H]MK-801 binding sites but there was a dose-dependent increase of EtOH withdrawal seizure-prone (WSP) and resistant (WSR) mice, which differ in handling-induced convulsion severity. Acute administration (24 hr inhalation) of the dose did not alter the density or affinity of binding sites in either mouse line. Thus, under well defined equilibrium binding conditions, EtOH does not directly interact with either the glycine or [3H]MK-801 binding sites on the NMDA receptor-linked ion channel complex. Differences between the effects of EtOH on radioligand binding under equilibrium and non-equilibrium conditions, and EtOH-induced altered behaviors will be discussed. This work was supported by NIAAA and the V.A.

Etanol is a selective inhibitor of the function of NMDA glutamate receptors. To assess changes in NMDA receptor function after chronic ethanol exposure, we measured NMDA-stimulated increases in intracellular Ca" in primary cultures of cerebellar granule cells. The cells were obtained from 8-day-old rats and exposed in vitro to 100 mM ethanol for two or more days or 30 mM ethanol for three or more days. In the ethanol-exposed cells, there was an increased maximal response to NMDA in the presence of glycine and glycine (in the presence of NMDA), with no change in the EC50 values. There was also no change in inhibition of the NMDA response by competitive or non-competitive antagonists or by ethanol added acutely. Chronic ethanol exposure apparently produced an increase in the number of NMDA receptors, with no change in their properties. Western blot analysis of membrane proteins using an antibody raised against the recently-cloned 70 kDa-glutamate-binding protein, believed to represent a subunit of an NMDA receptor, revealed a 50% increase in the amount of this protein in cells exposed to 100 mM ethanol for 2 days and a 30% increase for 4 days. These results are compatible with an ethanol-induced increase in synthesis, or decrease in degradation, of the glutamate binding subunit of an NMDA receptor. 411.16 THE SPASTIC HAN-WISTAR RAT AS A MODEL OF GLUTAMATE
EXCITOTOXICITY: ELECTROPHYSIOLOGICAL ANALYSIS. B.W. Cohran,
J.F. Marqués, J.B. Watton, N.A. Buchwald, and M.S. Levine.
Mental Retardation Res. Center, UCLA School of Medicine, Los Angeles, CA 90024.

Our laboratory has been studying a mutant strain of the Han-Wistar (HW) rat which
carries an autosomal, recessive gene causing spastic paraplegia characterized by ataxia,
tremor, and hind limb rigidity. Morphologically, starting about 30 days postnatally,
progressive cell death occurs in the Purkinje cell layer of the cerebellum and the CA3
layer of the hippocampus. Currently, we are investigating the hypothesis that
the cerebellar and hippocampal degeneration may be induced by glutamate (Glu)
excitotoxicity. Evidence was first obtained from Xenopus oocytes expressing HW rat
glutamate receptors following injection with mRNA from normal wild type (cont.
DNA injected controls). Oocytes injected with mutant HW cerebellar mRNA (45-50 days of age)
displayed significantly larger current responses to GLU and kainate (KA) than controls.
The dopamine in this disorder was studied by comparing mRNA of oocytes injected
with 32P-Glu and KA. These results showed a 40% increase in the maximum amplitude of the
response in the mutant cerebellum. This work suggests that enhanced presynaptic
release of glutamate is needed to evoke a response. These findings provide more evidence for abnormal,
glutamate neurotransmission in the cerebellum of HW rats which may underlie the
cellular degeneration observed in this mutation.
413.1

GABA A-receptors activate Ca 2+ entry into cultured spinal cord neurons via voltage-gated Ca 2+ channels (Wang et al., Neu. Abs. 17:977, 1991). Patch techniques were used to test directly if the activation of the GABA A-receptor depolarizes embryonic dorsal horn neurons and by what ionic mechanism. Membrane voltages responses to 10 μM muscimol, a GABA A-receptor agonist, were recorded in current-clamp mode using perforated patch recording. Pipettes contained (mM): K 2SO 4 75, KCl 100, HEPES 10 and 100 μg/ml tetrodotoxin (TTX) and 5 mM BATH. Next, 65 neurons tested during the first week in culture, 10 depolarized to between -30 and -40 mV, 26 to between -40 and -50 mV and 24 to less than -50 mV. 5 cells were hyperpolarized. To test the ionic basis of the depolarization, cells with depolarizing responses were identified, the perforated patch electrode was pulled out, then whole cell recording was established using a second pipette to control [Cl -]. Lowering [Cl -] to 40mM led to a depolarizing shift of +25 ± 2 mV (mean ± SEM; n=5) in the measured reversal potential. A +30 mV shift is predicted if Cl - is the only permeating extracellular anion. Reducing NaCl to 0.1 or 0.3 mM led to slightly depolarized reversal potentials (n=5) suggesting that Na + is not responsible for the depolarizing responses. These results demonstrate that GABA A-receptor activation can significantly depolarize a high percentage of embryonic cultured dorsal horn neurons and that an anionic conductance is mainly responsible for this effect, possibly due to a high [Cl -] (supported by EUKf and NIH).

413.2
GABA-INDUCED Ca 2+ TRANSIENTS IN TYPE 1 ASTROCYTES IN PRIMARY CULTURES. Michael Nilsson 1, Peter S. Eriksson 1, Lars Riemerks 1,2,3 and Elisabeth H. Hansson 1. 1Institute of Neurobiology and Department of Neurology, University of Göteborg, Göteborg, Sweden.

By using the Ca 2+-sensitive indicator fura-2/AM, the cytosolic Ca 2+ levels of type 1 astrocytes in rat cortical astroglial primary cultures, after stimulation with GABA, muscimol (GABA A–agonist) or baclofen (GABA B-agonist). We report that stimulation of both GABA A and GABA B receptors evokes Ca 2+ transient in type 1 astrocytes. In some cells, the responses after GABA stimulation were blocked to baseline levels after exposure to bicuculline (GABA A-antagonist). In other cells, bicuculline only slightly reduced the GABA-evoked responses, and the addition of phaclofen (GABA B-antagonist) did not amplify this inhibition. However, the muscimol-evoked rises in [Ca 2+] i were completely inhibited after exposure to bicuculline, while the responses after baclofen could only be partly blocked by phaclofen. GABA evoked rises in [Ca 2+] i lower than 50 μM; which alternatively were inhibited (mostly) or persisted in Ca 2+-free buffer. The rises in [Ca 2+] i persisted, but were reduced, in Ca 2+-free buffer after stimulation with muscimol, but were the contrary inhibited after baclofen stimulation. The results suggest that type 1 astrocytes in primary culture express GABA receptors which can elevate [Ca 2+] i directly or indirectly via Ca 2+ channels and/or via release from internal Ca 2+ stores.

413.3

In order to investigate the mechanism of action of Flupirtine, we tested its effect on cultured neurons from rat brain using the "whole-cell" configuration of the patch-clamp technique. The currents were measured using asymmetrical chloride concentrations, Flupirtine induced a dose-dependent, reversible depolarization. This was suppressed in the presence of bicuculline indicating that Flupirtine has GABA A-agonistic properties. With threshold concentrations of Flupirtine, the GABA-effect was enhanced in an over-additive manner. Experiments performed at voltage-clamped neurons demonstrated, that the action of Flupirtine is dependent on the membrane potential. At potentials more negative than -50 mV, the drug caused a monophasic chloride inward current. At more positive membrane potentials, the application of Flupirtine induced an additional transient outward current. Probing the effect with voltage-jump protocols showed, that this current is not carried by chloride, and thus is not mediated via the GABA A-receptor.

413.4

In previous work, stimulatory effects of diazepam (DZP) on free Ca 2+ were demonstrated using the membrane-permeant acetoxyethyl ester of the fluorescent dye fura-2 (fura-2/AM) in rat brain synaptosomes (Martín et al., 1991, Brain Res. 548:222). As an approach to evaluate the relative presynaptic and postsynaptic contributions to the observed effects of DZP on Ca 2+ metabolism, we compared the effects of DZP on Ca 2+ in synaptosomes and synaptic neuroneosomes from rat brain. A freshly dissected brain (without brainstem or cerebellum) was divided equally as starting material for the two preparations. Synaptosomes were made by the Percoll step gradient method of Dunkley, et al. (1986, Brain Res. 352:220). Both preparations were maintained in buffered salt solution in which NaCl was replaced by isomolar choline (136 mM choline chloride, 5.6 mM KCl, 1.3 mM MgCl 2, 11 mM glucose, pH 7.4) and incubated with fura-2/AM for 55 min, followed by extensive washing, so the only fluorescent response was due to fura-2 generated inside the organelles by endogenous esterases. In all cases, depolarization with 45 mM potassium increasing 1.2 mM CaCl 2 increased the level of cytoplasmic free Ca 2+. While DZP increased the levels of synaptosomal Ca 2+ in a dose-dependent fashion which was synergistic with the effects of depolarization (as before), there was no effect of DZP as high as 110 μM on synaptosomeroal Ca 2+. Since synaptosomeroal membranes are primarily post-synaptic in origin, these findings support the idea that effects of DZP on Ca 2+ may be selectively mediated (with a presynaptic mechanism. Supported by the Busch Fund and Rutgers University Research Council.)
413.5 EXCITOTOXIC LESIONS IN NEOSTRIATUM/GLORUS PALLIDUS CAUSE AN INCREASE IN IRON STAINING AND GLIAL CELL NUMBERS IN GLOBUS PALLIDUS AND SUBSTANTIA NIGRA. S. Sarty, G.W. Arnould, R. Richardson. Dept. of Biology and Institute for Biocomputational Science, University of Victoria, B.C., Canada, V8W 3P6.

The substantia nigra (SN) and globus pallidus, two iron-rich brain areas, receive a dense GABAergic innervation. This anatomic relationship suggests that GABA is important in iron metabolism. Therefore, we investigated the effects of iron accumulation after excitotoxic lesions of striatal/pallidal GABA inputs to globus pallidus/SN on iron staining and correlated histochemical and immunohistochemical markers with those results. Adult male Sprague-Dawley rats were divided into three groups. The first group received four intracerebroventricular infusions (5 μl of each) of saline; the second group received four infusions of bicuculline (10 μM); and the third group received four infusions of bicuculline (10 μM) and 6-OHDA (10 μM). Animals were sacrificed 1 week after surgery. The only lesion involved the substantia nigra/pallidus in the other two groups. Significant increases in iron staining and iron-positive cell counts were seen in the SN of the 6-OHDA lesions compared to saline- or bicuculline-injected rats. These results indicate that excitotoxic lesions compromising GABAergic innervation to SN and globus pallidus increase iron levels in areas, supporting a regulatory influence of GABA on brain iron.

413.7 GABA-INDUCED MEMBRANE CURRENTS IN DISSOCIATED MEDIAL SEPTUM/DIAGONAL BAND (MS/DB) NEURONS. D.R. Pytte and W.J. Griffith. Dept. of Med. Pharmacol. & Toxicol., Texas A&M Univ. Coll. of Medi- cine, College Station, TX 77843-1114.

Anatomic and electrophysiological data indicate that cells in MS/DB are GABAergic. Virtually all cells in these regions respond to GABA in a GABAergic synaptic contact. In the present study we present a significant fraction of spontaneous postsynaptic potentials recorded in vitro in MS/DB neurons. A large negative inactivation state (GABAA-induced membrane currents in all cells examined (rats, n=10; Guinea pigs, n=7)). Rapid application of GABA (100 μM) evoked a large negative inactivation state in all cells examined (50-100 μM). Whole-cell patch clamp recordings in acutely dissociated, adult MS/DB neurons identified GABA-induced concentration-dependent currents from a holding potential of -60 mV that reversed near 0 mV. Reponses to GABA (100 μM) significantly decreased in the presence of GABA (100 μM) which decreased an average of 42 ± 1.3% during the application. The effects of combined application of GABA with pentobarbital, midazolam or ethanol are currently being investigated. Supported by AA07005 (WHG); AA06322 and RD3A AA00101 (GDF).

413.9 MDA-RECEPTOR CHANNELS ARE SPECIFIC SOURCES IN THE SUPPRESSION OF GABA RECEPTOR FUNCTION BY INTRACELLULAR CALCIUM. N. Shi and A. Stolzen. Dept. of Pharmacology, SUNY Brooklyn, Brooklyn, NY 11203.

Elevation of intracellular calcium [Ca2+]i leads to a suppression of GABA receptors in freely dissociated CA1 pyramidal cells (cf. Chen et al., 1990, J. Physiol.). In the same preparation, we examined the contribution of various sources of [Ca2+]i elevating systems in the regulation of GABA receptors. Under whole-cell patch clamp recordings, two different calcium currents were elicited by voltage commands from -70 to +10 mV. One of these currents was blocked by calcium channel blockers. Alternatively, GABA responses were elicited by pressure application followed at similar intervals by GABA chloride current. GABA responses were measured at +10 mV under both experimental conditions. GABA responses generated through MDA-receptor channels were blocked by 200 μM bicuculline hydrochloride. In contrast to this, MDA-activated calcium currents were not blocked by bicuculline hydrochloride. Recovery from excitatory responses generated through MDA-receptor channels was slower than recovery from bicuculline hydrochloride-sensitive calcium currents. Therefore, it seems likely that two different types of calcium dependent GABA receptors exist. One type is calcium activated and the other type is calcium independent. The slower recovery from bicuculline hydrochloride-sensitive currents may be due to the presence of a calcium independent GABA receptor.

With the emergence of multiple GABA receptor subunit variants and many possible combinations in the brain, it has become a challenge to determine, from receptor binding studies, the number and pharmacological characteristics of the sites present. A major weakness has been the use of fairly nonselective radioligands. Critical to the determination of receptor heterogeneity is using curve-fitting programs such as LICAND, is the [H] of the radioligand must be determined at each putative site present, as the [H] of each competing ligand is dependent on this value. We have found that [3H]RO15-1788 is not sufficiently selective to clearly distinguish different receptor types using LICAND, however, its absolute nonselectivity cannot be assumed. We have been exploring a powerful new method to determine the Kd and receptor density of the ligand in several rat brain regions. This method, a Fourier-derived affinity spectrum analysis (FASA), (Anal. Biochem. 157(21), 1986), transforms receptor binding data (free and bound ligand conc.) into a probability-density function and solves it numerically, providing an affinity spectrum, as a function of affinity. No assumptions are made as to the number of binding populations. We have used this method to investigate the affinity of [3H]RO15-1788 at BDZ sites in several tissues, including the rat cerebellum and olfactory bulb. In each tissue, the radioligand [3H]RO15-1788 was competitively displaced from 0 to 20-fold. This information will greatly help the analysis of competitive binding data using LICAND, by determining the number of binding sites, and by providing initial and final guesses for the analysis. The use of the FASA method, along with data analysis using LICAND, should enhance our understanding of BDZ binding sites in the rat brain.

413.6 EFFECTS OF EXCITATORY AND INHIBITORY NEUROTRANSMITTERS ON WHOLE CELL RECORDINGS IN GUSTATORY ZONE OF NTS. L. Wang, M. S. King and R. M. Bradley. Dept. of Biologic and Materials Sciences, School of Dentistry, University of Michigan, Ann Arbor, MI 48109.

The gustatory zone of the NTS consists of the lateral and terminals immunoreac- tive for substance P (SP) as well as GABA-ir neurons. Therefore, SP and GABA may have important influences on rostral NTS neurons. We investigated the effects of these transmitters on neurons recorded from the gustatory zone of the NTS using whole cell recording in slices of the rat medulla. Superoxions of Nm concentrations of SP transiently depolarized 54 of 88 neurons (61%) and increased input resistance, while GABA (10 μM) hyperpolarized 105 of 166 neurons (67%) and decreased input resistance. Since they could be elicited when synaptic transmission was blocked, these effects were due to direct postsynaptic action on the recorded neurons. GABA acted on both GABA and non-GABA neurons because both GABA (10 μM; GABA agonist) and bicuculline (10 μM; GABA antagonist) mimicked the effects of GABA. In addition, the GABA antagonist bicuculline (10 μM) and the GABA antagonist picrotoxin (10 μM) strongly suppressed the neuronal responses to GABA. Bicuculline also suppressed sympathetically in- duced IPSPs evoked by electrical stimulation of the solitary tract. Of 34 neurons tested, 15 (44%) responded to both SP and GABA, suggesting inhib- itory and excitatory modulation of single NTS neurons. The integra- tion of these excitatory and inhibitory influences may be important in process- ing gustatory information. This possibility is currently being investigated through the analysis of the effects of GABA and SP on single neurons in the gustatory zone of the NTS. [Supported by NHI DCOO28].

Modulation of GABA-mediated 36Cl influx into microsacs by ligands binding to the benzodiazepine (BDZ) site on GABA_A receptors is a potentially useful approach for the design of agonists and inverse agonists. To develop reliable conditions for assessing such actions, we have studied the effects of a prototypic agonist flunitrazepam (FLU 1μM) and inverse agonist DMCM (1μM) in rat cerebellar and cortical microsacs. In both tissues, most of GABA-mediated 36Cl influx occurred in the first 3 of 5s. Significant enhancement of this effect by FLU and reduction of it by DMCM was achieved in both tissues when the drugs were applied in the presence of 36Cl and GABA for 3s. The DMCM effect was in part due to a reduction of flux in the nominal absence of GABA. Although reproducible, the effects of these BDZ ligands are modest (-20%), and may be due to not all GABA mediated CI channels being sensitive to BDZs. To approach this problem, we have performed these studies in the presence of zinc (100μM), known to preferentially inhibit GABA_A receptors that are insensitive to BDZs because they lack a γ subunit. The presence of Zn substantially reduced GABA (100μM) mediated 36Cl flux in cortex (61% and) in cerebellum (51%+) suggesting a significant proportion of the CI channels are likely insensitive to BDZs. Under these conditions FLU increased dramatically to 273% from 42% without Zn. These results indicate that optimum conditions for measuring the effects of BDZ agonists and inverse agonists on GABA mediated 36Cl flux involves measuring the effect within 3s of addition of GABA, but with the ligands in prior contact with the GABA receptor. Addition of Zn appears to enhance the effect of these ligands by allowing the measurement of CI flux only through BDZ sensitive GABA channels.

3. MSL 26479 MEDULATES GABA RECEPTOR ACTIVATION: SINGLE CHANNEL CURRENTS FROM CULTURED RAT HIPPOCAMPAL NEURONS. C.J. Rogers and K.M. Giesler, Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

GABA receptor complex chloride current is gated through the integral ion channel by GABA, receptor activation and mediated via allosteric receptor interactions. MSL 26479, may act via a benzodiazepine-like binding site as an inverse agonist. In vivo, MSL 26479 displaced [3H] Ro 15-1788 binding consistent with a benzodiazepine-like interaction. Extracellular recordings from the hippocampal slice enabled enhanced sensitivity to MSL 26479. [3H]-butyrylcholine-3 binding was increased with MSL 26479 suggesting a benzodiazepine-like agonist-like action. Behavioral studies indicate MSL 26479 enhanced respiration. To determine whether MSL 26479 modulates GABA-activated CI current and the mechanism by which it may do so, we used the single channel patch clamp recording technique. Single channel recordings were obtained from cultured rat hippocampal axons in response to the positive application, from 1-5μs across diameter accessibility, of GABA (2μM) alone or GABA (2μM) plus MSL 26479 (10, 100, or 300μM). Single channel currents were pooled from up to 80 different recordings for each of the different conditions tested. MSL 26479 modulated GABA-activated CI current in a concentration dependent manner. Total CI current, comparing GABA (2μM) alone versus GABA (2μM) plus MSL 26479 (12μM) was decreased by 38%, decreased by 49% at 120μM, but increased by 134% at 300μM. The mean open duration of the channel for the 30 pS conductance state was concentration dependent: 2.42 μs, GABA (2μM) (6.3 μs, GABA (2μM) plus MSL 26479 (2μM)); 3.16 μs, GABA (2μM) plus MSL 26479 (10μM), and 1.47 μs, for GABA (2μM) plus MSL 26479 (300μM). Further investigations are underway to better understand this concentration dependent response and to determine whether this compound selectively activates specific receptor subunit configurations.

4. A COMPARISON OF THE ACTIONS OF THE BENZODIAZEPINE (BZ) PARTIAL AGONIST, Ro16-6208, WITH "FULL AGONIST" BZs ON THE GABA_A RECEPTOR COMPLEX (GRC). D.A. Finta and K.V.G. Dept. Pharmacology, College of Medicine, Univ. of California, Irvine, CA 92717.

Ro16-6208 (Bretazenil) is a relatively new imidazo-diazepine derivative with a pharmacological profile characteristic of a BZ partial agonist. Ro16-6208 exhibits potent anticonvulsant and anticonvulsant effects with minimal psychomotor impairment or development of physical dependence. The present study utilized modulation of [35S]-butyrylcholine binding and enhancement of GABA-stimulated 36Cl- (chloride) uptake as measures of GRC function to further assess Ro16-6208's partial agonist profile. Ro16-6208 was the most potent of the examined compounds (concentration at which half-maximal inhibition of specific [35S]- butyrylcholine binding occurs) of 1.1mM, compared to 2.7mM for diazepam (DZP), 4.3mM for clonazepam (CLON) and 47.4mM for flunitrazepam (FLU). However, Ro16-6208 was less efficacious in that it produced 27% inhibition of specific [35S]- butyrylcholine binding, compared to DZP (49%), CLON (34%) and FLU (41%). In the presence of 3mM DZP, Ro16-6208 antagonized the inhibition of DZP alone. These data provide further support that Ro16-6208 is acting as a partial agonist at the BZ receptor in modulating [35S]- butyrylcholine binding. (Supported by NIH grants NS25986 and NS24645).

A range of biochemical markers of GABAergic and dopaminergic (DAergic) neuronal activity were examined in the CNS of Roman high-avoidance (RHA/Ver) and Roman low-avoidance (RLA/Ver) rats. The dopamine transporter (DAT) was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver. RHA/Ver rats had a lower DAT density than the corresponding RLA/Ver rats. In addition, the dopamine level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The serotonin transporter (SERT) was measured in the nucleus accumbens and the raphe nuclei. RHA/Ver rats had a lower SERT density than RLA/Ver rats. In addition, the serotonin level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The binding affinity of [3H]-GABA to the GABA_A receptor was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver rats. RHA/Ver rats had a lower binding affinity than RLA/Ver rats. In addition, the GABA level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The binding affinity of [3H]-flunitrazepam to the GABA_A receptor was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver rats. RHA/Ver rats had a lower binding affinity than RLA/Ver rats. In addition, the flunitrazepam level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The binding affinity of [3H]-35s-TP5 to the GABA_A receptor was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver rats. RHA/Ver rats had a lower binding affinity than RLA/Ver rats. In addition, the 35s-TP5 level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The binding affinity of [3H]-DAMGO to the opioid receptor was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver rats. RHA/Ver rats had a lower binding affinity than RLA/Ver rats. In addition, the DAMGO level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The binding affinity of [3H]-naloxone to the opioid receptor was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver rats. RHA/Ver rats had a lower binding affinity than RLA/Ver rats. In addition, the naloxone level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum. The binding affinity of [3H]-dextrorphan to the opioid receptor was measured in the striatum and the nucleus accumbens in RHA/Ver and RLA/Ver rats. RHA/Ver rats had a lower binding affinity than RLA/Ver rats. In addition, the dextrorphan level in the nucleus accumbens of RHA/Ver rats was lower than that of RLA/Ver. A similar, but less marked, difference was observed in the ventral pallidum.
414.1

A cis ELEMENT IN THE NEUROPEPTIDE Y GENE MEDIATES STIMULATION BY NERVE GROWTH FACTOR

Neuropeptide Y (NPY) gene expression, in rat PC12 cells, is stimulated by nerve growth factor (NGF) at the level of transcription. To investigate the mechanism by which NPY expression is enhanced by NGF, we report an NGF-responsive, cis-acting sequence, the NGF response element (NRE).

414.2

TRANSCRIPTIONAL CONTROL OF HIPPOCAMPAL NEUROPEPTIDE Y EXPRESSION

Hippocampal neuropeptide Y (NPY) expression is predominantly localized to neurons in the dentate gyrus hilus and stratum oriens. In the current study, we identified the affected promoters by transfection experiments with and without NPY expression in the absence of NGF. We report that the NPY expression is increased by NGF in the presence of NGF, but not in the absence of NGF.

414.3

SECOND MESSENGER AND RECEPTOR-MEDIATED REGULATION OF SUPERIOR CERVICAL GANGLION NEUROPEPTIDE Y (NPY) EXPRESSION AND SECRETION, V. Mys and K.M. Bras, Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Superior cervical ganglion (SCG) neurons synthesize and secrete calcitonin gene-related peptide. We have learned that calcitonin gene-related peptide is released in response to a variety of stimuli. We have studied the regulation of neuropeptide Y (NPY) expression and secretion in primary rat SCG neuronal cell cultures. Enzymatically dissociated SCG cells from newborn rats were treated with 10 μM cAMP or 10 μM cGMP to increase the intracellular concentration of calcium.

414.4

Gene expression of neuropeptide Y (NPY), an important neurotransmitter and neuromodulator, is regulated by neural activity via neural activity by transduction of intracellular signals. The effect of neural activity on NPY gene expression was measured by a new method that uses calcium imaging and transduction of intracellular signals. The effect of neural activity on NPY gene expression was measured by a new method that uses calcium imaging and transduction of intracellular signals. The effect of neural activity on NPY gene expression was measured by a new method that uses calcium imaging and transduction of intracellular signals. The effect of neural activity on NPY gene expression was measured by a new method that uses calcium imaging and transduction of intracellular signals. The effect of neural activity on NPY gene expression was measured by a new method that uses calcium imaging and transduction of intracellular signals.
414.5 NEUROPEPTIDE Y EXPRESSION IN TARGET SPECIFIC NEURONS IN THE RAT SUPERIOR CERVICAL GANGLION. A.E. Elsheikh, K. Hentschel, and L.L. Wright, Dept. Anatomy/Neurobiology, BUSHM, Boston, MA 02118.
This study was to compare the pattern of neuropeptide Y-like immunoreactivity (NPY-ll) in adult and developing rat sympathetic superior cervical ganglion (SCG) neurons projecting to purely vascular targets, and those projecting to "mixed" vascular and glial elements. Adult and postnatal day 1 (P1), P5, P25, and P60 rats were used. The retrograde tracer Fluorol Gold (FG) was injected into the temporals muscle or frontal cortex to label SCG neurons projecting to a "purely vascular" target, and into the submandibular gland, to label neurons projecting to a "mixed" target. In each case, FG was utilized to compare the relative proportions of each population of SCG neurons that contained NPY-ll. Analysis of the results showed that nearly all (98%) of temporals projecting neurons contain NPY, most (76%) of cerebral blood vessels projecting neurons contain NPY, and few (9%) of submandibular projecting neurons contain NPY. The results were similar at P5, P15, and P25, in that most of the SCG neurons projecting to the cerebral blood vessels and temporals muscle contained NPY-ll, while significantly few of those projecting to the submandibular gland contained NPY-ll. From these data, we conclude that the population of neurons projecting to these target organs differs significantly in the percentage of neurons displaying NPY-ll in adult and that this pattern is present after the fifth postnatal day of development. This work has been supported by a B.U. GSRA to AFE.

The neuronal localization of vasopressin (VP) mRNA was carried out using digoxigenin-labeled oligonucleotide complementary DNA probes 908-943 of the VP cDNA. Vibratome sections of rat brain fixed by perfusion with 4% paraformaldehyde and 0.1% glutaraldehyde were processed for in situ hybridization or with triton X-100 and hybridized with the digoxigenin-labeled probe. Following the washing steps, the digoxigenin was detected using an anti-digoxigenin antibody and the ABC-peroxidase method. The peroxidase was revealed with DAB enhanced with NiCl2, the sections were postfixed with osmium tetroxide and embedded in epoxy resin. This method allowed us to label the perikarya of magnocellular neurons of the rat hypothalamus. In addition, its high sensitivity was demonstrated by the labeling of VP neurons of the suprachiasmatic nucleus, where VP mRNA concentration is known to be low. At the electron microscopic level, the well preserved morphology allowed for precise subcellular localization of VP mRNA. 1. MAGNOCellular PERIKARYA. In the perikarya, the label was mainly associated with the membrane of the rough endoplasmic reticulum (RER), but not its lumen. This labeling was localized to discrete areas along the RER, suggesting a compartmentalization of VP mRNA within the RER. The Golgi apparatus, as well as neurosecretory granules appeared to be devoid of label. 2. AXONAL COMPARTMENT. Some axonal swellings in the median eminence, containing secretory granules, were highly labeled. These positive swellings were more abundant in salt-loaded rats. Some positive swellings were also observed in lactating rats and much more rarely in control animals. Within these swellings, the labeling was diffuse and therefore the precise localization of VP mRNA could not be ascertained. This limitation may be overcome through the use of colloidal gold probes.

414.7 ARGININE VASOPRESSIN (AVP) GENE EXPRESSION IN DISCRETE AREAS OF THE RAT BRAIN FOLLOWING PRE-TREATMENT WITH AVP. P. Pouliot, P. Scoy, D.J. Pitman and D.M. Dorog, GREC, VA Medical Center, Seattle, WA 98108.
It has been shown that AVP enhances its own release and enhances (sensitizes) the responses of the rat brain to subsequent AVP exposure. One possible mechanism for these effects may be by AVP-induced alteration in AVP gene expression. The level of cytoplasmic AVP mRNA was quantified autoradiographically in discrete areas of male Sprague Dawley rat brain 24 hours following AVP (100 pmol iv) or vehicle (physiological saline iv) pretreatment. Following decapsulation, brains were frozen and 20 pm sections were hybridized with a [35S]labeled probe for AVP mRNA, emulsion coated, developed and analyzed for the number of labeled cells and/or for dotdensity. Preliminary results show that while AVP pretreatment enhanced the number of hybridization positive neurons in the Bed nucleus of the stria terminalis increases from 62 (control) to 35 (AVP pre-treated), the number of AVP mRNA expressing cells in the mediodorsal (16 control; 18 AVP pre-treated) and the paramentric nuclear (rod. 284 control; 283 AVP pre-treated) was not enhanced by AVP pre-treatment. These results suggest that pre-exposure of the rat brain to AVP results in discrete alterations of the expression of AVP messages. Studies are now in progress to evaluate AVP mRNA levels in discrete areas of rat brain 1, 3, 6, and 12 hrs following AVP (100 pmol iv) or vehicle (physiological saline) pre-treatment. This work was supported by Savoy Foundation (PF) MRC (OJP) and VA medical center and NS 20311 (PS and DMD).

414.8 CCK mRNA EXPRESSION, PRO-CCK PROCESSING AND REGULATED SECRETION OF CCK IMMUNOREACTIVE PEPTIDES BY THREE ENDOCONE TUMOR CELLS IN CULTURE: A VALID MODEL FOR BRAIN CCK?
M.C. Benoit-Deloze, Dept. Pharm. & Physiol. Sci., St. Louis Univ. School of Medicine, St. Louis MO 63104.
Subclones of three common endocrine cell lines At-T20, rat insulinoma (RIN 5f) and a thyroid medullary carcinoma, both express a single CCK mRNA species the same size as that found in rat brain. The WE cells contained levels of immunoreactive CCK comparable to rat cerebral cortex (about 4 ng/ mg protein). While the other cell lines contained significantly less CCK. Like the rat brain, they were able to correctly process pro-CCK to a form which co-eluted with CCK 8 on Sephadex and HPLC. All three cell lines secreted CCK as well as CCK 33, and this secretion was significantly enhanced by cAMP, but not by tumor-promoting phorbole esters. When transfected with a eukaryotic expression vector containing the rat CCK cDNA behind the CMV promotor, the At-T20 cells expressed about 500 times as much CCK as the wild type. These cells still correctly processed pro-CCK to CCK 8, which suggests that either the expression of the processing enzymes is coordinately regulated with expression of the proenzyme or that the enzymes are present in a considerable excess. In summary, these cell lines appear to be a good model for studying pro-CCK processing in the brain and should facilitate future studies of CCK expression, biosynthesis, processing, and secretion. Supported by NIH 18667.

414.9 HALOPERIDOL-INDUCED NEUROTENIN GENE EXPRESSION IN STRIATAL NEURONS IS REDUCED BY CHRONIC TREATMENT. R.S. Merchant, D.J. Dobie and D.M. Dorog, Grec, VA Medical Center, Dept. of Psychiatry & Behavioral Sciences and Pharmacol., Univ. of Washington, Seattle, WA 98195.
Expression of neurotensin/neuromedin N (NT/N) gene in dorsolateral striatal (DLS) neurons appears to be under the regulation of dopamine D2 receptors such that acute blockade of D2 receptors by neuroleptics (e.g., haloperidol) raises the level of NT/N mRNA by 1000%. The present study investigated the responses of the NT system to chronic haloperidol administration, a treatment which has been shown to attenuate the expression of D2 receptors. Male Sprague Dawley rats were treated s.c. with saline or haloperidol (1 mg/kg/d) using osmotic minipumps and sacrificed on day 28. A separate group of rats was treated similarly followed by removal of the pumps on day 28 and was challenged 24 hr later with a single dose of saline or haloperidol. Expression of NT/N mRNA was examined by in situ hybridization. Neuronal mRNA localization was revealed using NT/N mRNA expression in DLS was significantly lower in rats which received chronic haloperidol when compared to those which received acute haloperidol following chronic saline treatment. The tolerance in NT/N mRNA expression was not modified by an acute haloperidol challenge to chronically treated with haloperidol. It is likely that the decreased sensitivity of NT/N cells in the presence of haloperidol reflects a compensatory post synaptic response to upregulation of D2 receptors. (Supported by Scottish Rite Schizophrenia Foundation, the VA, and NS 20311)

414.10 REGULATION OF SOMATOSTATIN GENE EXPRESSION IN DISOCIATED CULTURES FROM CEREBRAL CORTEX. G.L. Coopers, and C.B. Choi, Dept of Pediatrics, The Kennedy Krieger Institute and Johns Hopkins Medical Institutions, Baltimore MD 21205
Somatostatin (SOM) is a small peptide transmitter which is found in the cerebral cortex. The two biologically active forms SOM-14 and SOM-28 are both derived from the same inactive precursor molecule preprosomatostatin (pPSOM). Within the cortex, SOM is localized to a small subset of neurons and comprises about 2% of the total neuronal population. These neurons have been implicated in the pathogenesis of a variety of diseases (Down's syndrome, Epilepsy and hypoxic-ischemic encephalopathy). Previous studies have demonstrated that the pPSOM gene can be regulated by such diverse stimuli as second messengers (cAMP, neurotransmitters, electric field) and other factors. To further study the effects of cAMP, primary cultures of dissociated cerebral cortex were made from E15 mouse brain and grown for 7 days in MEM, with 10%FCS/10%HS in 95% air and 5% CO2. Cultures were stimulated with cAMP (2.5 x 10-5 M) at days 3 and 10. All cultures were stimulated with cAMP at day 10. At day 10, total RNA was isolated at 4,8,12 and 24 hours. Changes in pPSOM mRNA abundance was measured using Northern blot analysis. Stimulation with 2.5 x 10-5 M cAMP resulted in an (10-fold) increase in pPSOM mRNA by 4 hours and a (50- fold) increase by 8 hours. When cultures were stimulated with BcAMP increased pPSOM mRNA was also seen at 4 hours (2-fold), 8 hours (5-fold), 12 hours (9-fold), 24 hours (7-fold) compared to unstimulated controls. Our results support previous findings which demonstrate that pPSOM gene expression is regulated via cAMP mediated signal transduction pathway and extends the observation to neurons in the developing cerebral cortex. Supported by CIDA 1-K08-NS01466-01A1.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

Somatostatin (SRIF), a neuropeptide produced by C cells in the thyroid gland, has been implicated in the modulation of thyroid hormone function. In the present study, we have assessed whether SRIF gene regulation is regulated by calcium or triiodothyronine (T3). Since cyclic AMP is a known modulator of SRIF secretion, we also evaluated the effect of forskolin or a cyclic AMP analog on SRIF production. Rat medullary thyroid carcinoma cells (MET-6-23) were grown in DMEM and 15% horse serum, and serum-deprived cells were incubated in DMEM 0.05 mg/ml heparin. The media content of SRIF and calcitonin was determined by radioimmunoassay. Northern blot analysis (20 μg total RNA) was used to assess SRIF mRNA levels. Forskolin (10 μM) or the cyclic AMP analog (10 μM) increased SRIF mRNA levels and SRIF as measured by intracellular SRIF mRNA levels (p<0.05 vs. 0.5 μM calcium). However, T3 (10 μg/mL) had no effect on SRIF mRNA levels or media content. These results indicate that calcium acts to increase calcitonin release as well as cause increases in both SRIF secretion and steady state SRIF mRNA levels. Since SRIF has been shown to inhibit calcitonin secretion, SRIF may act in an autocrine fashion to limit calcitonin production in response to a calcium challenge. (Supported by WVU Med.Corp. and NIH BRG No.2.507 RR05433-29).

414.13 DOPAMINERGIC REGULATION OF TRANSCRIPTIONAL ACTIVITY OF ENKEPHALIN GENE IN RAT BASAL GANGLIA. S. P. Swain and A. L. Chaudhari. Department of Pharmacology & Toxicology, Indiana University School of Medicine, 3400 Broadway, IN 46202.

This study examined whether a deficiency of dopamine during neonatal developmental period will induce permanent alterations in the rate of transcription of enkephalin gene. Dopamine deficiency was induced in Sprague-Dawley rat pups, by intracerebral administration of 100 μg of free base of 6-hydroxydopamine (6-OHDA) on the third day after birth. The animals were sacrificed 60 days after the 6-OHDA lesion. Striatal tissues were used for the determination of preproenkephalin (PPE) mRNA by Northern blot analysis, Met5-enkephalin (ME) levels by radioimmunoassay and amines and metabolites by HPLC. The rate of transcription of PPE gene was determined by a nuclear run-on assay using nuclei isolated from fresh or frozen tissues; the 32P-labeled run-on transcripts obtained from a run-on transcription reaction were hybridized to a slot-blotted nitrocellulose or nylon membrane containing a plasmid with rat cDNA for PPE. As expected, dopamine-denervated animals exhibited a significant loss of dopamine (>90% of control), an increase in PPE-mRNA and an increase in ME levels. The rate of transcription of PPE gene as evidenced from the run-on transcription assay was increased in lesioned animals. The increase in the rate of PPE transcription gene coupled with an increase in PPE-mRNA and its translation product ME indicate an enhanced rate of biosynthesis of enkephalin in lesioned animals. The results suggest a crucial role for dopamine in the development and regulation of enkephalin neurons of the basal ganglia. Supported by USPS grant NS29603.

Dexamethasone (DEX, 10^-7 M) increased [Met5]enkephalin (ME) secretion from cultured striatal and hippocampal cells 2-fold over basal release after 24 hrs and 4 days exposure, an effect comparable to stimulations with the adenylate cyclase activator forskolin (FSK, 10^-5 M) and the protein kinase C activator phorbol myristate acetate (PMA, 10^-7 M). DEX strongly potentiated the stimulation by FSK (to > 8-fold over basal) at 4 days, but not after 24 hrs. DEX did not increase the response to PMA or to the Ca2+ ionophore ionomycin (10^-6 M). The potentiation of DEX was mimicked by corticosterone and competitively blocked by the anti-glucocorticoid RU486. Surprisingly, progesterone pretreatment abolished the DEX effect. Stimulated ME release at 4 days reflected synthesis of peptide, being much greater than cell ME content, and increased preproenkephalin (PPE) mRNA was observed in situ hybridization studies. In hippocampal cultures, PPE mRNA and ME and precursor peptides appeared restricted to a subpopulation of type-I astrocytes. In striatal cultures, neurons may also contribute to the observed effects of DEX on ME.

We have previously reported that long-term exposure of BAM cells to nicotine increases both the secretion of ME and the expression of proENK gene. In order to elucidate the molecular mechanisms underlying these long-term effects of nicotine, studies were undertaken to determine whether continuous activation of nicotinic receptors was required for both the delayed increase in ME secretion and proENK mRNA. Cholinergic receptor antagonists, hexamethonium (1 mM) and atropine (0.5 μM), were added to the incubation media at different time points (0.5, 1, 3, 6, 9, 12, and 24 hr) after nicotine treatment and aliquots of incubation medium were taken at each time point for ME determination and the cells were washed and incubated 24 hr for proENK mRNA measurements. Nicotine (10 μM) stimulated both distinct phases of ME secretion; a short-term rapid phase, followed after 9 hr by a sustained increase in ME release. Hexamethonium and atropine added 0.5 to 6 hr after nicotine treatment significantly inhibited the long-term phase of ME secretion and the expression of the proENK mRNA levels measured after 24 hr of nicotine treatment. Unexpectedly, these antagonists were ineffective in blocking the nicotine-induced responses when added 9 hr before treatment. Nuclear run-on assays showed that the transcriptional rate for proENK mRNA was increased by nicotine for at least 9 hr after drug treatment. Our results suggest that the long-term (at least 9 hr) nicotine effect on ME secretion and proENK mRNA is mediated by the long-term stimulation of the ME increase in proENK mRNA levels induced by nicotine reflects an increased transcription of the proENK gene. Currently, we are comparing these effects of nicotine with effects of this drug on the expression of tyrosine hydroxylase mRNA and the short- and long-term secretion of catecholamines.

The promoter region of the preproenkephalin gene contains elements for regulation by a number of transcription factors and second messenger systems. In striatum and glia, cAMP and CREB appear important for regulating ME. In rat adrenal, there is evidence for AP-1 binding as a primary regulator, and in spleen NFκB has been reported to regulate enkephalin expression. Nicotine stimulates adrenal medulla and sympathetic and parasympathetic ganglia. Chronic nicotine (3mg/kg bidally) was no more effective than saline injections at increasing adrenal ME in agreement with reported findings. However, acute repeated nicotine injections (3mg/kg every 30 minutes for 3 hours) produced a significant 2-fold increase relative to saline injections when measured after 2 days. Adrenal medulla AP-1 binding was decreased by nicotine and the decrease was long lasting (12 hrs) after acute repeated injections. Adrenal NFκB binding was increased by nicotine. In spleen, repeated acute nicotine injections also increased ME by about 2-fold after 2 days. Both AP-1 binding and NFκB binding were increased in spleen by nicotine. Our data indicate differential regulation of ME in peripheral tissues by nicotine.

EFFECT OF NICOTINE ON RELEASE OF CALCITONIN GENE-RELATED PEPTIDE FROM THE RAT TRACHEA

S. JINNO, Y. Y. HU, A. IWAI & T. Y. YASHI
Dept. of Anesthesiology, Univ. of California, San Diego, CA 92093

Calcitonin gene-related peptide (CGRP) exists in the peripheral terminals of sensory C-fibers which innervate the airway. Topical nicotine is known to stimulate these terminals. Given this excitatory effect, the present study assessed whether nicotine could evoke the release of C-afferent CGRP from the rat trachea. The rat trachea (from large to carina) was dissected free and incubated in oxygenated Krebs solution kept at 37°C. After 30 min equilibration time, the trachea was sequentially incubated in tubes containing 2 ml of: 1) Krebs (baseline); 2) Krebs + drugs (nicotine or capsaicin); and 3) Krebs (control) for 10 min. CGRP levels in each test tube was analyzed by RIA. Nicotine (5x10⁻⁶ to 5x10⁻⁵M) caused a concentration-dependent increase in the levels of CGRP in the perfusate. Forty minutes after the first exposure to nicotine, a second challenge with nicotine revealed a concentration-dependent desensitization of CGRP release. The releasing effect of capsaicin (10⁻⁴M) was unaffected by nicotine desensitization. Pretreatment, however, with capsaicin (10⁻⁴M) blocked nicotine (10⁻⁵M)-induced peptide release. The result suggests that nicotine activated the peripheral terminals of capsaicin-sensitive primary afferents in the trachea and released CGRP.

CYSTEAMINE PRETREATMENT ENHANCES INHIBITORY ACTION OF S₈S IN THE DENTATE GYRUS

T. W. J. Watson & L. Borg
Research Neuroscience Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1

We have previously reported that both S₈S and S₈S₄ act as an inhibitory action on the evoked ECFP pop spike recorded from the dentate gyrus (DG) and cause direct postsynaptic hyperpolarization of dentate granule cells. These experiments were designed to examine the effects of the somatostatin-depleting agent cytoxamine on responses to S₈S and S₈S₄ in DG. 500 µm thick transverse rat hippocampal (HPC) slices were completely submerged and continuously superfused in a recording chamber with oxygenated pH buffered ACSF. Three to four week old Sprague Dawley rats were pretreated with a single injection of 200 µg/kg of cytoxamine given 15 to 20 hours prior to preparation of brain slices. All recordings were carried out in 10⁻⁴ M bicuculline. Cysteamine pretreatment resulted in selective increase in the inhibitory action of S₈S₄ on the DG ECFP. Threshold of inhibitory effect was noted at 0.1 µM with complete and reversible suppression of evoked activity being observed at concentrations of 3 to 5 µM. Interestingly, inhibitory action of S₈S was reduced in the cytoxamine pretreated slices. When cytoxamine was added to the perfusate (100 nM) a gradual increase in amplitude and number of evoked pop spikes was observed and this increase in activity persisted during the wash. These findings indicate that cytoxamine pretreatment results in selective enhancement of the response to S₈S with relative down regulation of S₈S₄ response and suggests the possibility of a differential effect on receptor subtypes. The increased amplitude and repetitive firing observed during bath application of cytoxamine supports the concept that somatostatinergic neurons in the DG play an inhibitory role in controlling the firing of DG granule cells and that loss of these neurons may be involved in the pathophysiology of certain seizure disorders.

KEENOPROTECTIVE AND LTP-ENHANCING EFFECTS OF CHOLESTORBININ 18 Hippocampal slices, K. Yasui, M. Fushiki, Y. Nakazawa, W. Li, H. Shinya, A. Ando, and T. Araki, Kinki Medical College, Osaka, Japan

Cholescolystokinin octapeptide (CCK-8) is densely distributed in the hippocampus, however its functional significance in this area is still unclear. Here we demonstrate neuroprotective and long-term potentiation (LTP)-enhancing effects of CCK-8. CCK-8 dose-dependently enhanced the magnitude of LTP induced by tetanic stimulation of Schaffer collateral-axosomatic synapses in the CA1 region of guinea pig hippocampal slices. This enhancing effect was antagonized by pretreatment of CCK-8 receptor antagonist. Furthermore, desulfated CCK-8 showed a similar action on the LTP. The late negative component of evoked response, which was induced by a K⁺ channel blocker and by elevation of extracellular K⁺, was reduced by CCK-8. In vitro ischemic insult (hypoxia & hypoglycemia) induced a transient disappearance of evoked response followed by a short hyperexcitability period and a long-lasting dysfunction of CA1 pyramidal neurons in hippocampal slices of stroke-prone spontaneously hypertensive rat. CCK-8 reduced spreading depression-like depolarization and shortened time for the early disappearance of evoked potential as well as that for recovery of population spike. This neuroprotective action was also mediated by CCK-8 receptors. These results suggest that CCK-8 plays a positive role in the muscle system and shows neuro-protective effects possibly by closing K⁺ channels via breakdown of phosphoinositide in the hippocampus.

VASOPRESSIN ELICITS A LASTING INCREASE IN EXCITATORY POSTSYNAPTIC POTENTIALS (EPSPs) IN VENTRAL HIPPOCAMPUS NEURONS, J. L. Urban and P. L. French, Rudolf Magnus Institute, University of Utrecht, The Netherlands.

(Vanop: EDA)

Vasopressin (VP) is a neuropeptide which is synaptically released in several brain structures, including the lateral septum (LS) and ventral hippocampus (VH). Small amounts of VP, applied centrally, altered acquisition and extinction of various conditioned behaviors as well as the activity of brainstem. In LS slices, pH concentrations of VP for hours enhanced EPSPs in LS neurons, without affecting the resting membrane potential (RMP), input resistance (IR) and other properties of these neurons. We used conventional microdialysis (3M KAc) and studied in brain slices the effect of VP on the EPSPs in neurons in the CA1/subiculum region of VH, evoked by stimulation of the stratum radiatum. Application for 15 min with 10⁻⁴ M VP had little effect on either RMP (before VP: 60.67±5.7 mV; 35 min after VP: 60.73±5.3 mV), IR (before VP: 46.84±6.5 MΩ; 35 min after VP: 49.28±7.4 MΩ) or the threshold for action potential was little changed by VP (before VP: 50.5±3.4 mV; 35 min after VP: 48.76±4.9 mV). In 14 of 20 neurons studied, EPSPs commenced to increase during and after VP application. At 35 min after the peptide application the amplitude of the EPSPs obtained on average 137.5% of the control values and remained at this level for the rest of the recording (max 2.5 hr). In the remaining 6 neurons EPSPs either did not changed (n=4) or decreased (n=2) after the VP treatment. Thus, VP concentrations of 10⁻⁴ M can for many hours enhance the excitability of the excitatory, presumably glutamatergic, transmission in CA1/subiculum neurons of the VH presumably by augmenting the glutamate release and/or the sensitivity of postsynaptic glutamate receptors. This VP effect was presumably different from the short excitatory action on the hippocampus, LS and other brain regions that required much higher VP concentrations, may be of physiological significance and could be related to the behavioral effects of this neuropeptide.
415.5 EFFECTS OF CEREBROLYIN ON SYNAPTIC TRANSMISSION IN THE RAT HIPPOCAMPUS. L.M. Wolkowicz, S. Wang and A. Basiky. Department of Physiology and Clarke Inst. of Psychiatry, Univ. Toronto, Toronto, Ont, MSS 1A8, Canada.

Cerebrolysin (CB) is a brain tissue-derived mixture of polypeptides and amino acids that is widely used in treatment of dementias. To understand how CB exerts its therapeutic actions we applied it acutely to the rat hippocampal slices from 3-5 week old Wistar rats. CB was dissolved in saline and applied to slices for 5-10 minutes. CB inhibited the evoked field potential (F1) responses in the CA1 region of the hippocampus. The threshold of the effect was observed at 2μM/L and a maximal inhibition at 10-20μM/L. At 10μM/L FPs were inhibited by 59% (S.E. = 9.5, n = 11). In 5 out 11 experiments a long-lasting increase (28%, S.E. = 12.7) of FPs followed the inhibition. The effects were not associated with changes in the presynaptic fibre volley or paired pulse facilitation. Addition of 10μM bicineulid did not affect the CB action on FP, suggesting independence of GABA Receptors. Similar effects were observed in CA3 area of the hippocampus but not in the dentate gyrus where smaller inhibition (16%, S.E. = 1.5, n = 4) followed by 18.5% increase was noted. Given complex, albeit unknown composition of CB, it appears to have remarkably specific action on synaptic circuits in the hippocampus. Further studies are needed in order to elucidate the active ingredient(s) of CB. Supported by EBEWE, Austria.

Since somatostatin (SS) and gamma-aminobutyric acid (GABA) are co-localized in some neurons, the interactions between the actions of SS and GABA-ergic inhibitory postsynaptic potentials (IPSPs) in the CA1 pyramidal neurons of the pig hippocampal slices are investigated. SS (5S-14, 2 μM) induced a hyperpolarization of the CA1 neurons associated with a reduction in the input resistance of the CA1 (n=16). These effects were not blocked by picrotoxin (25 μM) (n=24) or phaclofen (1 μM) (n=16). Chelation of intracellular Ca2+ (Ca2+-EGTA) with BAPTA (5 μM) or inhibition of protein kinase C (PKC) with sphingosine (30 μM) (n=4) had no significant effects on the hyperpolarizing action of SS. The peptide suppressed the GABA Receptor-mediated fast IPSPs and the GABA Receptor-mediated slow IPSPs, but had no significant effect on the excitatory postsynaptic potentials (EPSPs) (n=16). SS-induced depression of IPSPs was not due to the hyperpolarization of the neurons. SS-induced hyperpolarization of the CA1 neurons was greatly reduced in the presence of baclofen (20 μM, n=6), an effect that was not due to the hyperpolarization by baclofen. The presence of QX-314 in the CA1 neurons, prevented the hyperpolarization of the neurons by SS and baclofen (n=12). QX-314 blocked the depressant effect of the peptide on the fast IPSP but not the depressant effects of baclofen on the IPSP and the fast IPSP (n=12).

These results indicate that SS depresses GABA-ergic IPSP without affecting the GABA receptors. The peptide suppresses the fast IPSP through a QX-314-sensitive postsynaptic mechanism. SS can modulate IPSPs if the peptide receptors and the postsynaptic GABA Receptors are coupled to the same channels or the peptide and the amino acide act through the same intercellular second messengers. (The authors are grateful to Astra Pharmaceuticals for the gift of QX-314.)

Human galanin is a 30 amino acid peptide which differs significantly from porcine, bovine and rodent galanin both in regard to sequence in the carboxy-terminus and extent of the peptide and its terminal amidation. Synthetic human galanin, prepared using a solid phase peptide synthesiser and purified to homogeneity using high pressure liquid chromatography, was administered to rats and humans in order to assess the biological activity of human galanin. Intravenous bolus administration of synthetic human galanin to conscious rats during glucose infusions produced blood glucose elevation and reduced circulating insulin, consistent with established effects of native galanin in the rat. Synthetic human galanin was infused for 90 min into healthy human volunteers at low and high levels (50 and 100 pmol/Kg/min, respectively) for 90 min or saline control (n=8). A 25g intravenous glucose bolus was administered 30 min into the galanin infusion. There was a small drop in systemic blood pressure and an increase in heart rate during the infusion. All subjects reported a metallic taste and hypersalivation. No significant effect of human galanin on plasma glycose, serum insulin (basal or stimulated) or C-peptide levels was observed relative to control. Plasma growth hormone levels rose even in the face of a glucose load in both low and high dose infusions. Thus, human galanin is an ineffective β-cell suppressant in humans, compared with rats, but significantly increases growth hormone secretion.

415.10 PASSIVE IMMUNIZATION TO GALANIN ALTERS BIOGENIC AMINE METABOLISM IN MALE RATS. S.M. Gabrieli and P.J. Krout. Dept. Psychiatry, Mount Sinai School of Medicine, New York, NY 10029 and Bronx VA Hospital, Bronx NY 10468.

Galanin is found in biogenic amine-containing neurons. In the present study, male rats were implanted with lateral ventricular cannulas. After surgical recovery, the absence of cerebral, prefrontal cortex or a specific anti-galanin serum were administered intraventricularly to freely-moving, conscious rats. Animals received two morning injections, 24 hours apart. Hypothalamic tissues were harvested 4 to 6 days after the second injection for analysis of biogenic amine and metabolite concentrations by HPLC with electrochemical detection. Concentrations of the serotonin metabolite, 5-hydroxy-indol-acetic acid (5HIAA) were significantly elevated 32% and 39% in anti-galanin and preimmune-treated rats in the medial basal and preoptic hypothalamus, respectively. Concentrations of 5HIAA were unchanged in the paraventricular and supraoptic hypothalami. Presumably, passive immunization sequesters released peptide. Thus, these data suggest that galanin plays an ongoing inhibitory influence on serotonergic neurotransmission, perhaps subsequent to increased serotonin release or monoamine oxidative activity. This indicates that a novel biological interaction exists between galanin and serotonin.

W-Acetyl-Aspartyl-Glutamate Potentiates Inward Currents in Rat Dorsal Lateral Geniculate Nucleus Neurons

By Scott R. A. Malaney* Department of Biology, Georgetown University, Washington, DC 20057.

W-acetyl-aspartyl-glutamate (WAG) is an endogenous dipeptide found throughout the brain and is proposed to have a neurotransmitter or neuromodulatory role in the central nervous system. In the visual system, high concentrations and a calcium-dependent release (Hoffett et al., Brain Res 538:86-94, 1991). Among the highest concentrations noted was that of the dorsal lateral geniculate nucleus (dLGN). Since retinogeniculate transmission is thought to be mediated by glutamate, and WAG has been reported to activate glutamate receptors, its effect was studied on dLGN neurones in the rat. 20 Hz pulses were used to whole cell patch clamp electrophysiology on 300 micron thick thalamic slices containing the dLGN. When WAG was applied via a pressure pipette (9 mM in ACSF, pH 7.3) on the recording site, cells clamped at the resting membrane potential (typically -60 to -75 mV) exhibited increases of inward current (as much as -1.14 pA) for varying periods of time before returning to baseline current values. Similar responses were elicited in glutamate (10 mM in ACSF, pH 7.3) applied in the same manner, suggesting that responses to WAG were mediated by glutamate receptors. These results suggest a role for WAG as a neurotransmitter in the dLGN.

416.1

We evaluated the role of endogenous neuropeptide Y (NPY) in the suppression of baroreceptor reflex (BRR) responses by locus coeruleus (LC), using adult, male Sprague-Dawley rats anesthetized with pentobarbital sodium (40 mg/kg, i.p.). Under an electrical stimulation condition (10 train of 1-ms rectangular pulses, at 10-20 μA and 10-20 Hz) that did not appreciably alter the basal systemic arterial pressure and heart rate, the LC significantly suppressed the BRR responses induced by an intravenous injection of phenylephrine (5 μg/kg), bilateral microinjection of NPY (4.65 pmol/20 μl), or an antiserum against NPY (120, 20 μl), into the nucleus tractus solitarii (NTS), the terminal site of baroreceptor afferents, elicited respectively a reduction in, and an enhancement of, the BRR response. Direct application of the NPY antiserum into the NTS also attenuated the suppressive effect of the LC on the BRR response. Treatments with normal rabbit serum, and heat-inactivated NPY or NPY antiserum, on the other hand, were ineffective. These results suggest that neurons in the brain that contain NPY may exert a tonic reduction in the BRR sensitivity. Furthermore, the endogenous NPY may participate in the modulation of the same reflex by the LC. Both these actions may possibly take place at the NTS.

416.2

EFFECT OF NEUROPEPTIDE-Y (NPY) ON BLOOD FLOW IN THE RAT TAIL AND FOOT. M. E. Heath and J. B. Thomas*, Navy Medical Research Institute, Bethesda, MD 20889.

The purpose of this study was to assess the effect of i.v. administered NPY on superficial cutaneous microcirculatory blood flow in the tail and foot (by laser doppler flowmetry), and on total blood flow in the tail (via venous occlusion plethysmography). Male 300 g Long-Evans rats, with jugular catheters, were anaesthetized, placed in a tubular plexiglass holder, and allowed to equilibrate for 25-30 min before experiments. NPY, norpinephrine (NE), [Leu]4, Pro36 NPY, NPY[13-36] or saline control was administered i.v. following 5 min of baseline data. Increasing doses of NPY, from 16 to 64 μg/kg, induced an immediate, marked, and long lasting decrease in superficial cutaneous microcirculatory blood flow in both foot (max=50%) and tail (max=25%). In contrast, total blood flow in the tail either showed no change or increased (max=25%). In addition, the volume of blood in the tail usually increased in response to NPY, thus suggesting relaxation of and reduced resistance in the larger tail vessels. NE and the specific Y1 receptor agonist, [Leu]4, Pro36 NPY, produced effects on superficial foot and tail blood flow and on total tail blood flow similar to that of NPY, although smaller in magnitude. NPY[13-36], a specific Y2 receptor agonist, did not appear to modulate blood flow in either the foot or tail. These findings suggest that NPY Y2 receptors do, and Y2 receptors do not, participate in the cutaneous microvascular blood flow response of NPY.

416.3

The regulatory peptides, VIP and NPY, are present in autonomic nerve fibers innervating the blood vessels. Exogenous VIP exerts vasoactive effects resulting in a decrease in blood pressure (BP), while NPY has vasocostricton effects resulting in increased BP. To study the role of endogenous VIP and NPY in the regulation of BP, we passively immunized rats against these peptides. Anti-VIP serum (AVS-1) and anti-NPY serum (ANS-1) were generated in rabbits against synthetic porcine VIP and NPY, respectively. VIP monoclonal antibody (VIP-1b) was supplied by J.C. Porter (Univ. of Texas). AVS-1 has a Bmax of 491nmol/Kg and Kd=0.83 nM for VIP and does not crossreact with any of 17 other peptides tested, including peptide histidine isoleucine. ANS-1 has a Bmax = 1.99 nmol/Kg and Kd=0.47 μM for NPY and does not crossreact significantly with rat peptide YY, rat pancreatic peptide or any of 8 other peptides tested. Arterial BP was continuously measured in anesthetized (ketamine & pentobarbitale) Sprague-Dawley rats (males, 220-250g) for 45 minutes beginning 5 min before treatments. BP was not changed after ANS-1 administration (1 ml, iv) when compared to BP in control rats (saline or normal rabbit serum). In contrast, when AVS-1 (1 ml, iv) was given, BP increased (144%, p<0.01). Heart rate was not changed. Similarly, VIP-1b (0.2 mg/kg) injected IP in a dose dependent manner (up to 138%, p<0.01). These results suggest that VIP may function as a tonic vasoconstrictor and be involved in the physiological regulation of BP in the rat, whereas the involvement of NPY in the maintenance of normal BP is not evident. (Supported by NSF DCB-900470).

416.4

Hypothalamic neuropeptide Y (NPY) has multiple behavioral and physiological functions and has been shown to produce both increases and decreases in neuronal activity. To determine the possible contributions of NPY receptor subtypes to these responses, the effects on neuronal activity of NPY and the presumed Y1 and Y2 agonists (Pro34)-NPY and C2-NPY were examined. Coronal slices of rat hypothalamus were maintained in vitro and extracellular single unit recordings have been obtained from paraventricular nucleus (PVN) neurons and 7 perifornical area (PFA) neurons. Cells in the PVN had a spontaneous firing rate of 3.2 spikes/sec; spontaneous firing rate for cells in the PPH was 7.8 spikes/sec. In the PVN, microtopical application of NPY and [Pro34] NPY produced a repeatable decrease (11/16 at 1.5 μM and 6/11 cells at 0.15 μM) on average, to 20% of spontaneous rates. The reduction lasted from 3 to 20 min. Similar responses to NPY were evident in the PPH. In contrast, C2-NPY (0.15 μM) application in the PVN predominantly increased firing rate an average of 79% in 59 cells. Excitation lasted an average of 4 min and most cells returned to their baseline firing rates. The present findings suggest that the NPY agonists have differential effects on neuronal discharge rate; perhaps via actions on different NPY receptors. Supported by NSF BNS 9008818 and NIH NS 24268.
415.6 NEUROPEPTIDE Y MODULATION OF MELATONIN SECRETION FROM RAT PINEALOCYTES. V. Simonneau, S. Bichet and P. Pévet. Lab. of Neurobiology of Rhythmic and Seasonal Functions, URA-CNRS 1332, 12, rue de l'Université, 67000 Strasbourg, France.

Pineal gland of mammals receives a noradrenergic input indirectly from the retina. The day/night rhythm of noradrenergine (NE) release, the major neurotransmitter of the day/night rhythm of melatonin synthesis and release with high nighttime values. NE added to cultures of rat pinealocytes increases melatonin secretion by pinealocytes previously stimulated with or not by the α2-adrenergic agonist isoprenaline (ISO). This study was performed on 2-day-old pinealocyte cultures of one month-old rats. NE alone induces a small stimulation of melatonin secretion. Together with ISO, NE displays a clear potentiation effect on melatonin secretion especially at low ISO concentrations. The most efficient concentration of NE in stimulating pineal activity is 10 nM.

In conclusion, this study demonstrates that NE stimulates melatonin secretion at a postomnic level in the rat pineal gland.

VIP acts on many cell types through mechanisms which are not fully understood. In the pineal gland, VIP increases CAMP accumulation and N-acetyltransferase (NAT) activity, the rate-controlling step in melatonin synthesis. It is known that stimulation of these parameters by noradrenergine (NE) is strongly dependent upon α1-adrenergic elevation of [Ca2+]i. Accordingly, in this investigation we determined whether [Ca2+]i, is also elevated by VIP, this was examined using computer assisted single cell analysis of pinealocytes in primary culture. VIP (1-100 nM) produces a rapid and sustained increase in [Ca2+]i, in more than 85 % of the cells, as does NE. This indicates that both agonists act on the same population of pinealocytes. The VIP-induced increase in [Ca2+]i is absent when [Ca2+]i is less than 1 J/m. In contrast, the NE response is reduced to a transient increase in these conditions, suggesting that VIP and NE may act in part through different mechanisms. The VIP-induced increase in [Ca2+]i is not abolished by classical voltage-gated Ca2+ channel inhibitors, such as nicardipine, D-600 and omega-conotoxin. The effect of VIP was mimicked by PPACK 1-28.

These studies indicate that VIP can elevate [Ca2+]i, and that it acts by opening plasma membrane channels which are distinct from classical voltage-gated channels.

VAGUS TUBE INTESTINAL PEPTIDE (VIP) IS A NEUROMODULATORT, GROWTH REGULATOR AND SECRETAGOGUE FOR NEUROGENAL SURVIVAL FACTORS (COXES AND BRENNER, 1989, NOL. NEUROBIOL. 3, 1-3).

416.10 ANTAGONISTIC PROPERTIES OF CORTICOP. 37 ON NEUROCHEMICAL EFFECTS OF HUMAN CALCITONIN GENE-RELATED PEPTIDE. D. Ménard, A.L. Drumheller, A. Pouinier, and F.B. Jolicoeur. Departments of Psychiatry and Pharmacology, Faculty of Medicine, University of Sherbrooke, Sherbrooke, Quebec, Canada J1H 5N1-RNS-Saml, Point Claire, Que, Canada.

Pre-administration of the C-terminal fragment hCGRP37 antagonizes some but not all neurobehavioural effects of hCGRP. In the present study, we investigated the effects of hCGRP administered alone or following pre-treatment with hCGRP on brain regional concentrations of noradrenergine (NE), dopamine (DA), DOCA, HVA, as well as somatostatin (S-ST) and 5-HIAA. Peptides were administered ICV in a dose of 20 µg and 20 min later, brains were removed and dissected for neurochemical analyses. No neurochemical changes were found in striatum or thalamus. However, hCGRP enhanced DA and increased HVA concentrations in the nucleus accumbens. Increased concentrations of all amines and metabolites were found in the globus pallidus, amygdala and frontal cortex. The hippocampus, except for HVA, all neurochemical parameters were elevated by hCGRP. In the hypothalamus, hCGRP significantly increased and decreased DOCA and HVA respectively without affecting other neurochemical parameters. In the substantia nigra, marked decreases in DA and HVA levels were the only significant changes found. Pre-treatment with hCGRP either significantly attenuated or completely abolished all neurochemical effects of hCGRP in the substantia nigra, amygdala, nucleus accumbens and globus pallidus. In the frontal cortex, except for the increase in NE, all neurochemical effects were blocked by hCGRP. In the hypothalamus, hCGRP induced increases in hippocampal DOCA and 5-HIAA concentrations were also not affected by the fragment. Finally, hCGRP37 did not alter any of the neurochemical actions of hCGRP in the hypothalamus. Together, these results reveal pervasive but heterogeneous neurochemical effects of hCGRP and point to the existence of pharmacologically distinct receptors mediating these effects. Supported by the Medical Research Council of Canada.

PHARMACOLOGY OF THE EFFECTS OF BRADYKININ AND SEROTONIN ON THE RELEASE OF CGRP FROM THE RAT TRACHEA  
X-Y. HUA, S. HEDLEY, S.M. BACK & T.L. YAKSH  
Dept. of Anesthesiology, Univ. of California, San Diego, CA 92030-0818  
Depolarization of peripheral terminals of C-fiber afferents in the rat trachea can induce a local release of CGRP. In a previous study, application of bradykinin (BK) into the tracheal perifusate induced a dose-dependent increase in CGRP release, while serotonin (5-HT, 10⁻⁶M) with no effect along, facilitated CGRP release by capsaicin (10⁻⁶M), but not by a BK antagonist: [Des-Arg⁹, Leu⁵]-BK. The facilitatory effect of 5-HT on CGRP release appeared mediated by activation of the 5-HT2 receptor and subsequent PG formation. The sensitization effect of 5-HT on the releasing function of primary afferent terminal is apparently mediated by a 5-HT3 receptor and prostaglandin synthesis.

416.12  
ANATOMICAL DELIMITATION OF A NEW ANIMAL MODEL OF DEPRESSION USING CALCITONIN S. Soud and R. De Beersteine*, Laboratory of Pharmacology, CHU Côte de Nacre, 14032 Caen, France  
Calcitonin is a peripheral peptide hormone which has several functional, behavioral, and hormonal effects when injected into the rat cerebral ventricles or into specific brain sites: calcitonin decreases food intake, locomotor activity, intestinal motility, produces sleep disorders, increases cortisol secretion, and inhibits sex hormones secretion and TRH-induced TSH secretion. On the other hand, these calcitonin effects mimic the symptoms of the human depressive syndrome. Moreover, the anergic effect of calcitonin can be reversed by specific antidepressants. We therefore proposed that calcitonin is a mimic of the animals a new model of depression. Previous experiments have shown that many of the effects of calcitonin listed above are related to an effect on the periventricular nucleus of the hypothalamus. Calcitonin has also marked anergic and hyperthermic effects which are not common symptoms in depression. To clarify possible anatomical grounds for our model, we studied the brain sites involved in the anergic and hyperthermic effects of calcitonin.  
We tested the effects of intracerebral injections of salmon calcitonin (150g in 0.5μl) on heart rate, body temperature, and justification rate. The results show that the sites involved in calcitonin induced anergies and hyperthermias are the preoptic area, the dorsal-medial and posterior nucleus of the hypothalamus, the suprachiasmatic nucleus, the ventro-medial nucleus of the thalamus, and an area in the internal part of the zona incerta. The ventro-medial and the periventricular nucleus of the hypothalamus are not involved in calcitonin-induced multiple and hyperthermia.  
We conclude that calcitonin-induced anergies and hyperthermia can be excluded from our model of depression which may fit more specifically with a selective action of calcitonin on the periventricular nucleus of the hypothalamus.

416.13  
DYNORPHIN A (1-17) INDUCED DEPRESSION OF VENTRAL ROOT POTENTIALS IS MEDITATED THROUGH KAPPA OPIATE RECEPTORS. H. Rats and L. Isaac*  
Department of Pharmacology, University of Illinois College of Medicine at Chicago, IL 60680  
Intrathecal application of dynorphin A (1-17) (DYN) results in a dose-dependent hindlimb paralysis of 30-60 min duration which may be mediated through kappa opiate receptor interaction. Additionally, repeated injection of DYN at 2 hr intervals results in desensitization to paralysis. Finally, direct application of DYN to the spinal cord results in a dose-dependent depression of the ventral root potentials (VRP) of 30-60 min duration. To investigate this apparent parallelism we determined whether the VRP depression is kappa receptor mediated and whether it is subject to desensitization.  
Rats were surgically prepared, under urethane anesthesia, to record VRP monosynaptic and polysynaptic reflexes. The kappa opiate receptor antagonist nor-binaltorphimine (nor-BNI 20μm) was applied directly to the spinal cord 60 min prior to DYN application and in separate experiments DYN (10μm) was applied at 2 hr intervals to the spinal cord.  
Nor-BNI resulted in a partial shift of the dose-response curve for DYN-induced depression of the VRP. With nor-BNI the ED₅₀ was 8 μm and with saline it was 4 μm. Repeated application of DYN resulted in desensitization to depression of the VRP of about 50%.  
These data suggest that DYN-mediated depression of the VRP is mediated through the kappa opiate receptor. Because both DYN-induced paralysis and depression of the VRP are mediated through kappa receptor interaction they may be causally related. Although the mechanism of these effects remain to be investigated they both involve desensitization. Supported by NSF BNS-8916983 and NIH NS-30295.

416.14  
COMPARISON OF BEHAVIORAL EFFECTS OF DYNORPHIN A (1-17) WITH DYNORPHIN A (1-13) AFTER INTRATHecal INJECTION IN THE RAT. Z.X., Q.T. J. Marczynski* and L. Isaac Department of Pharmacology, Univ. of Illinois College of Medicine at Chicago, IL 60680  
Previously, we reported that dynorphin A (1-13) administered intracerebroventricularly to rats resulted in a reversible hindlimb paralysis and an irreversible inhibition of the tail-flick reflex. These effects follow a dose-response relationship with identical ED₅₀ values.  
In the present investigation, we report the influence of dynorphin A (1-17), the peptide configuration of the endogenous substance, on these same behaviors after i.t. injection in rats. Injection of this substance results in a reversible hindlimb paralysis and an irreversible inhibition of the tail-flick reflex. These effects follow a dose-response relationship with an ED₅₀ value for paralysis of 7 μmole and a value for inhibition of the tail-flick reflex of 18 μmole whereas the value for the (1-13) configuration is 10 μmole for both behaviors.  
With (1-13), paralysis and inhibition of the tail-flick reflex always occur together; on the other hand with (1-17), some animals paralyze while their tail-flick reflex remains intact suggesting that different mechanisms may be involved with the different peptide configurations.  
These data demonstrate a fundamental difference between dynorphin A (1-17) and dynorphin A (1-13). In conclusion, it appears that use of the (1-17) peptide to study the physiologic and pathophysiologic role of dynorphin in spinal cord function is preferred over the use of the (1-13) configuration.

EVIDENCE FOR A DIRECT ACTION OF MET-ENKEPHALIN ON GABAergic TERMINALS IN ORGANOTYPIC SLICE CULTURES OF THE RAT HIPPOCAMPUS. J.C. Bechlin#, Institute of Neurophysiology, University of Copenhagen, DK-2200 N. Denmark  
Intracellular recordings from pyramidal cells in organotypic slice cultures of the hippocampus were performed with 1 M KCl containing extracellular solution. Spontaneous IPSPs were blocked by 20 μM NBQX, APV and synaptic transmitter release due to sodium-dependent action potential was blocked by TTX. Under these circumstances a tonic bombardment of miniature IPSPs were seen. The IPSPs were blocked by 20 μM bicuculline and thus were GABAergic.  
Application of 10-20 μM met-enkephalin reduced the frequency of spontaneous IPSPs by up to 50% and this effect was reversed upon wash: for 20 min.  
These observations point to the conclusion that pyramidal cells cultured in vitro and hippocampal are exposed to tonic GABAergic inhibition, which is not the result of propagating sodium-dependent action potentials, and that this tonic inhibition can be reduced by met-enkephalin through a direct action of met-enkephalin on the presynaptic terminals.

EVIDENCE THAT PITUITARY ADENYLATE CYCLASE ACTIVATOR PEPTIDE (PACAP) IS A PRESYNAPTIC NEUROTRANSMITTER IN THE BOVINE ADRENAL MEDULLA. J.C. Wray, V. Hendrick and D. Martin  
The Department of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77030  
VIP has been shown to stimulate catecholamine (CA) synthesis in isolated bovine adrenal chromaffin cells. One of the peculiar aspects of this stimulation is the high concentration of peptide (μM) required, if VIP is mimicking the action of other peptides that act endogenously at lower concentrations. Accordingly, we tested the effect of PACAP, a VIP-like peptide, on the CA synthetic pathway in bovine adrenal chromaffin cells. These studies revealed a potent interaction of either PACAP-27 or PACAP-38. At a high concentration PACAP-38 stimulated 4.5-fold with a 1/2 max concentration of 20 nM. Tyrosine hydroxylase (TH), the rate limiting enzyme in CA synthesis, is phosphorylated selectively on serine 40 by both PACAP and VIP. At these points, TH mRNA synthesis and levels are elevated, followed by increased TH protein and activity. Morphological studies using perfusion-fixed, intact bovine adrenal medulla showed PACAP-27 immunoactive axons innervating BAC. Labeled axons and terminals were found throughout the medulla but were particularly dense near the adrenal cortex and around blood vessels. The labeling was unaffected by synthetic 1 μM VIP but completely abolished by synthetic PACAP-27. These results support the conclusion that PACAP is a presynaptic neurotransmitter in the bovine adrenal medulla and a promising candidate for the endogenous ligand of the "VIP receptor" described previously. Supported by USPHS grant NS311061 & BY06472.

PITUITARY ADENYLYL CYCLASE ACTIVATING POLYPEPTIDE (PACAP) REGULATION OF AIT-20/16V CORTICOTROPE CELL FUNCTION. K.M. Brasar, I.M. Koropka, C.A. Brandenburg and V.M. May. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405, and Department of Biological Psychiatry, Hines VA Medical Center, Hines, IL 60141.

The α-aminated hypothalamic peptides, pituitary adenylate cyclase activating polypeptide (PACAP) and PACAP27, share considerable amino acid homology with vasoactive intestinal peptide; however, the physiological roles of the PACAP peptides remain unclear. PACAP alters the functions of anterior pituitary gonadotropes, somatotropes and a small number of corticotropes. To investigate the roles of PACAP on corticotropes, we examined PACAP-mediated regulation of ACTH/endorphin secretion and membrane depolarization using AIT-20/16V mouse pituitary corticotrope cells. The basal secretory rate for AIT-20 cell ACTH was approximately 3% of cellular hormone content. Treatment of AIT-20 cells with 100 nM PACAP38 for 3 to 6 h stimulated hormone release approximately 1.5- to 1.8-fold. PACAP27 elicited a similar stimulated secretory response, suggesting that the PACAP peptide exerts functional responses on corticotropes cells by increasing action potentials; occasionally, these action potentials led to the initiation of sustained depolarizations (SD) (< 3 sec), followed by hyperpolarizations (< 1 sec). The input resistance significantly decreased during the plateau of the depolarizations. 100 nM PACAP38 increased the rate of SD approximately 2-fold, suggesting a possible correlation with increased hormone release. (Supported: NSF grant 9010444 to KMB, HD-27468 to VM and VA RAG 0001 to LMK)

THE PENETRATION OF DYNORPHIN-1-13 ACROSS THE BLOOD BRAIN BARRIER. J.L. Browning*, T.P. Turner, M.A. Widmayer and D.S. Baskin Dept. of Neurosurgery, VAMC Houston and Baylor College of Medicine, Houston, TX 77030.

The opioid peptide dynorphin 1-13 has been shown to increase survival and decrease neurologic deficit and infarct size in a feline model of focal cerebral ischemia (FCI). The ability of (Ile-His-Pro)1-13-dynorphin 1-13 (DYN) to cross the blood brain barrier (BBB) was studied in rats, cats and cats with FCI. The brain uptake index (BUI) was measured by a modified Oldendorf technique showed that the BUI of DYN was not significantly different from sucrose (vascular space reference) in the rat. Peptide inhibitors had no effect. In contrast, the BUI of DYN in the cat was significantly greater than that of sucrose in hippocampus, cortex and cerebellum. In addition, the BUI of DYN was even greater in cats with FCI, such that the BUI of DYN was significantly greater in hippocampus, cortex, brainstem and hypothalamus. These results suggest that DYN does cross the BBB of cats and may act centrally in ischemia to mediate its neuroprotective action.

**416.2**

We have previously demonstrated that β-endorphin (BEND) content is lateralized in the medial preoptic and caudal arcuate areas of the male rat brain, and that this lateralization is differentially modulated by left vs right hemispheric injury. To investigate the bases for these differences, we recently initiated a series of studies to further investigate the mechanism of this apparently lateralized control. In this first study we investigated lateralization of peptidic markers of the medial preoptic and arcuate; preproenkephalin (PENK) and neuropeptide Y (NPY) mRNA content. These studies were consistent with a demonstration that left caudal MBH BEND content is greater than right, and suggest greater forebrain opiomelanocortinergic activity originating in the left vs right MBH. We have previously demonstrated that MBH MAG mRNA content is correlated with MBH tyrosine hydroxylase (TH) mRNA content, suggesting interaction between MBH opiomelanocortinergic and dopaminergic activity (Neuropysiociology, in press). Consequently we are further investigating whether MBH TH mRNA is also lateralized and whether this lateralization is correlated with that of POMC mRNA.

TWO DIFFERENT OPIODYT CELL GROUPS IN LAMINA X OF RAT LUMBOSacRAL SPINAL CORD. A.P. Nicholas, Z. Xu and T. Hikata*. Department of Histology and Neurobiology, Karolinska Institute, Stockholm, 10401, Sweden.

Using a three-color immunofluorescence technique, the coexistence of enkephalin-like immunoreactivity (ENK-LI) with immunoreactivities for other peptides was examined in neurons of lamina X in the lumbosacral spinal cord of conscious, untreated rats. Briefly, animals were anesthetized, the lumbosacral laminae were removed, the dura mater excised and colchicine soaked gelatin pads were placed under the dorsal roots for 1-2 h and then removed. After a 48 h survival time, the animals were perfused with formaldehyde/glacial acid and the lumbosacral cord removed, frozen and cut (14 µm) on a cryostat. These sections were incubated overnight in 1:20 mouse anti-ENK, plus either a combination of 1:400 rabbit anti-cholecystokinin (CCK) and 1:200 guinea pig anti-gallamine (GAL), or a combination of 1:400 rabbit anti-neuronenrich (NT) and 1:400 goat anti-neuropeptide Y (NPY) antisera. Secondary antiserum (1:40; Jackson Immuno Research) consisted of a combination of AMCA (blue) conjugated donkey anti-mouse and FITC (green) conjugated donkey anti-rabbit, plus Lissamine Rhodamine (red) conjugated either to goat anti-guinea pig or to donkey anti-goat antibody. ENK was shown to coexist with CCK and GAL in adjacent large lamina X neurons from L1 to L5, while ENK coexisted with NPY in almost all smaller lamina X neurons from L5 to S2. In this caudal region, a few ENK/GAL/peptide cells were primarily a separate cell group. Thus, the present study showed that in lamina X of the lumbosacral spinal cord, there are at least two major populations of opioid neurons: a rostral group of large ENK neurons that are CCK and GAL positive and a caudal group of smaller ENK neurons that are primarily NPY (and sometimes PENK) positive. Previously, others have shown that CCK/GAL and ENK cells in lamina X of the lumbosacral cord project to higher brain centers and it has been suggested that they are involved with pain transmission.

ULTRASTRUCTURAL LOCALIZATION OF ENEKPHALIN AND GABA IN RAT SUBFORNICAL ORGAN. J.M. Pickett* and J. Chan Division of Neurobiology, Department of Neurology and Neuroscience, Cornell University Medical Center, New York, N.Y. (9021)

We examined the ultrastructural localization of Met₂-enkephalin (ME) and GABA in the rat subfornical organ (SFO). ME-like immunoperoxidase labeling was intensely localized to large dense core vesicles (DCVs) in axon terminals. These terminals formed symmetric synapses primarily on unlabeled dendrites and also were seen within perivascular spaces and in the parenchyma adjacent to fenestrated capillaries in the central and caudal portions of the SFO. GABA labeled soma, dendrites and terminals were numerous throughout the SFO. In dual labeled sections, immunoperoxidase labeling for ME was detected in a few terminals forming synapses with cells showing gold silver labeling for GABA, but most of the targets were without detectable immunoactivity. Other types of associations between ME and GABA included: colocalization within single axon terminals, convergence of separately labeled terminals on common targets, and appositions between separately labeled terminals. Single as well as dual labeled terminals formed symmetric synapses with unlabeled dendrites throughout the SFO. These results suggest that in rat SFO, GABA and opioid peptides may be released from separate, or sometimes the same, axon terminals to inhibit (symmetrical junctions) local neurons. Moreover, the release of one or both putative transmitters may be modulated by circulating hormones or axonal associations. The findings suggest that GABA may be involved in the inhibition of renal water, sodium and potassium secretion by oocytes at the level of the SFO (Grant support: MH00078, DA04600, HL18794).
**411.5** VENTRAL TEGMENTAL AREA NEURONS RECEIVE CONVERGENT GABAERGIC AND ENKEPHALINERGIC INPUT FROM THE SAME AND MORPHOLOGICALLY DISTINCT TERMINALS S.R. Sesack* and V.M. Pickel Dept. Behavioral Neuroscience, Univ. Pittsburgh, PA 15260 and Neurology & N. Med. Coll., NY 10036, NY 10021

We examined the ultrastructural basis for functional interactions between enkephalin (ENK) and γ-aminobutyric acid (GABA) in the rat ventral tegmental area (VTA), using dual immunoperoxidase-gold methods. Immunoreactive labeling for ENK or GABA, which were dually labeled for both substances. Immunoreactivity for ENK was intensely associated with dense-core vesicles localized along non-synaptic portions of the plasma membrane, while ENK immunoreactivity was associated with small clear vesicles, some of which aggregated at presynaptic specializations. GABA-labeled terminals, with or without ENK-immunoreactivity, formed synaptic symapses on unlabeled dendrites, while singly ENK-labeled terminals formed either symmetric or asymmetric synapses on unlabeled targets. Separately labeled GABA and ENK-immunoreactive terminals frequently converged on common dendrites, or were in direct apposition to one another. These results suggest that GABA and ENK (1) are colocalized in a subset of VTA terminals; (2) are differentially released from distinct vesicle populations, regardless of their co-distribution; and (3) may have opposing actions on common VTA neurons following their release from the same or different terminals, which would be consistent with the idea that GABA and opioid peptides may interact to modulate the activity of dopaminergic and non-dopaminergic VTA neurons. This work was supported by USPHS grants: NS08193, MH04392, MH00078, DA04600.

It is well established that, in the striatum, biosynthesis of the opioid peptide dynorphin (Dyn) increases following activation of D1 receptors and decreases following D1 receptor blockade. In the present experiments, we were interested in examining some of the molecular mechanisms which may mediate, or interact with, the dopaminergic regulation of Dyn biosynthesis in the striatum. We treated (twice daily for 7 days) rats with the dopaminergic agonist, apomorphine (APD; 5 mg/kg), caused a small but significant increase in Dyn-in the striatum; this increase was accompanied by increases in the immediate early gene products, c-fos and/or fra. Pretreatment of animals with a low dose (125 mg/kg) of MK-801, a non-competitive antagonist of NMDA receptors, blocked the increases in both Dyn and fosf/ra immunoreactivity. In a subsequent experiment, animals received unilateral 6-hydroxydopamine lesions of the substantia nigra (destroying the dopaminergic innervation of Dyn-containing neurons in the substantia nigra) and were injected with APD alone or together with MK-801. APO treatment alone caused a 4-fold increase in Dyn-in the striatum and an intense immunostaining of fosf/ra peptide expression in the lesioned striatum. However, in contrast to its effects in intact animals, MK-801 did not appear to have any effect on the APO-induced increase in fosf/ra expression in 6-OHDA lesioned rats although it did reverse the increase in Dyn. These data demonstrate that changes in fosf/ra expression are sometimes dissociated from Dyn and suggest that other factors in addition to fosf/ra may be involved in the nigrostrial regulation of Dyn expression.

Increases or decreases in transynaptic activity in the RA activate c-fos induction and Penk gene expression in a sequential manner. We investigated whether c-fos induction and Penk gene expression can be dissociated in RA. Increases in transynaptic activity by a neurosteroid (a metabolite of 5α-3β-SDH) converted a sequential induction of c-fos and proenkephalin (Penk) mRNA in RA. In hypophysectomized RA, the MTD-induced increase in Penk mRNA, but not c-fos mRNA was significantly reduced. In normal RA, ACTH treatment blocks the MTD-induction of c-fos mRNA and Penk protein without a significant effect on the MTD-Induction of Penk mRNA. Removal of transynaptic activity by adenral medullary explantation also produced a sequential induction of c-fos and Penk mRNA. However, in contrast, the induction of Penk mRNA was blocked by cycloheximide (2 mg/ml). Porcine c-fos mRNA was not a factor in the induction of Penk mRNA at 1 hr. In contrast, the drug-induced increase in Penk mRNA at 24 hr. These results demonstrate that the Penk gene is an independent gene and c-fos induction does not always result in Penk gene expression and Penk gene expression can occur in the absence of c-fos induction. (Supported by DA01457 and DT07243.)

We have previously reported that ventral tegmental area (VTA) microinjections of the selective opioid receptor agonist DAGO produce increases in extracellular nucleus accumbens (NAs) dopamine (DA), DOPAC, and HVA, assayed with high performance liquid chromatography with electrochemical detection. Interestingly, VTA microinjections of the selective μ-antagonist CTOP also produce increases in NAs DA and metabolites. The dose-dependent changes in NAs DA and metabolites was evaluated, and the μ-receptor selectivity of the response to CTOP (a substitution of the COOH-terminal amino acid) was compared with the response to a structurally dissimilar μ-antagonist, flunoxadrenaline (B-FNA: a furamate methyl ester derivative of naloxone). VTA microinjections of CTOP in the dose range 0.03 - 3.00 nmol/inject produced dose-dependent increases in NAs DA and metabolites. VTA 8 - FNA (1.0 μmol) produced increases in NAs DA and metabolites which were statistically similar to the increments produced by an equimolar microinjection of CTOP. One possibility is that these effects of CTOP and B-FNA may be mediated through actions at μ receptors located on GABAergic afferents to the VTA. Release of these afferents from opioid-inhibition could result in increased GABA-mediated inhibition of GABAergic interneurons intrinsic to the VTA. This increased inhibition of GABAergic interneurons would then produce a disturbance of mesolimbic dopaminergic neurons, resulting in the observed increases in NAs DA and metabolite concentrations. Therefore, under physiological conditions, GABAergic afferent to the VTA and GABAergic interneurons within the VTA may interact in a complex manner to modulate mesolimbic dopaminergic activity.

**411.8** REGULATION OF C-FOS and 28 K CALIBINDIN mRNA IN RAT CEREBELLM IN RESPONSE TO ACUTE AND CHRONIC MORPHINE. P.S. Tsujimula and R.D. Howell*, Department of Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ 07103.

The cellular and biochemical adaptations which underlie the addictive state are poorly understood. Since it is likely that changes in gene expression accompany the development of addiction, we are examining changes in the expression of candidate genes. In this study, the effect of acute and chronic morphine administration on expression of the proto-oncogene, c-fos, and the calcium-binding protein, calbindin, was examined in rat cerebellum and rat brain (minus the cerebellum). Adult male Sprague-Dawley rats were injected with morphine (10 mg/kg) daily for 15 days. Rats were sacrificed 45 min after the last injection, the cerebellum and remaining brain minus the cerebellum were removed, and total RNA was extracted using the acid guanidium thiocyanate/phenol chloroform method. RNA levels were quantified by Northern blot analysis. In addition, other rats received a single injection of morphine (10 mg/kg) and were sacrificed after 45 min, 4 hr, or 24 hr later. The effect of naloxone-precipitated withdrawal on gene expression in morphine-addicted rats was also analyzed 45 min after naloxone (1 mg/kg ip). Levels of c-fos mRNA were increased 2.5-fold in cerebellum and brain 45 min after a single dose of morphine compared to saline-injected controls. Calbindin mRNA levels in cerebellum were decreased to 30%-40% control at 45 min and 4 hr after a single morphine injection. Tolerance developed to these effects in that levels of c-fos and calbindin were not altered 45 min after morphine injection in morphine-addicted rats. Unlike the cerebellum, calbindin mRNA was increased 3.5-fold compared to controls 45 min after morphine injection in chronically injected animals in the remainder of the brain. Naloxone-precipitated withdrawal caused a 30% decrease in c-fos levels in the brain minus the cerebellum. Differential effects on c-fos and calbindin gene expression following either acute or chronic morphine administration may be important aspects of the adaptation of the nervous system to morphine. Supported by DA 05819.

**411.10** MU-OPIOID ENHANCEMENT OF NMDA AND AMPA RESPONSES IN HORIZONTAL Versus CORONAL SECTIONS OF RAT LOCUS COERULEUS. R. Miczek and J.T. Williams, The Vollum Institute, Oregon Health Sciences University, Portland, Oregon, 97201.

The μ-opioid receptor agonist DAGO was recently reported to selectively enhance the NMDA component of the glutamate response in spinal trigeminal neurons via activation of protein kinase C (Huang, 1991). We have investigated this modulation by μ-agonists in rat locus coeruleus (LC) neurons where μ-agonists elicit inhibitory effects through augmentation of a K+ conductance. Intracellular voltage clamp recordings were performed on LC neurons (holding potential of -70 mV) in horizontal or coronal brain slices. All drugs were applied by superfusion. Following pretreatment with diazepam (1 μM) and picotinin (100 μM), the responses to NMDA (100 μM) were increased by DAGO (1 μM) by a factor of 1.9 (167 - 12 versus -370 ± 30 pA). This enhancement was observed in horizontal sections of the LC (n=10) but not in coronal sections (n=6; factor of 1.1) nor in horizontal sections treated with 2 mM barium (n=3; factor of 1.1). The specificity of the DAGO-modulated enhancement was tested following application of AMPA (100-300 mM). The DAGO-enhanced current (factor of 1.2 ± 0.3) was potentiated by a factor of 2.3 by DAGO (275 ± 68 pA) in horizontal sections (n=4) but not in coronal sections of the LC (n=4; factor of 1.6). Current-voltage relationships from horizontal and coronal sections indicate a convergence of the AMPA and AMPA/DAGO regression lines. A lack of voltage clamp control of the dendritic arborization may explain the enhanced responses to DAGO and the following DAGO application. (Supported by FRSQ and NIH DA04523.)
411.13 CHRONIC MORPHINE INDUCES A PERMANENT INCREASE IN RAT STRIATAL CALBINDIN D28K IMMUNOREACTIVITY VIA AN NMDA RECEPTOR-DEPENDENT MECHANISM. M.M. Garcia* and R.E. Harlan, Dept. of Anatomy, Tulane University Medical School, New Orleans, LA 70112.

Calbindin D28K (CBD) is an intracellular calcium-binding protein which acts as a Ca++ buffer, thus protecting cells from the damaging effects of high intracellular Ca++. As chronic morphine (M) has been reported to cause increased Ca++ levels in striatal synaptosomes, we studied its effect on CD immunoreactivity (IR) in rat brain, using immunocytochemistry. In the initial series of experiments, male rats were made tolerant and dependent by sc implantation of 75 mg M pellets (1/day for 5 days); controls were implanted with vehicle pellets. Using a monoclonal antibody to CD, we found CD IR in control brains in the matrix compartment of striatum but not in patches. In the brains of M-treated rats, there was a dramatic increase in CD IR in matrix, with the appearance of intense CD IR in patches. When M treatment was discontinued, the increased CD IR in patches persisted through day 14 post-pellet. Because striatal patches receive glutamatergic (GLU) input from cortex, we studied the interactions between M and GLU in a second series of experiments using the NMDA antagonist, MK-801. Rats were injected daily for 5 days with saline/GLU, 5/M (10 mg/kg), MK (2 mg/kg)/GLU, or MK/GLU. Levels and patterns of CD IR in brains of S/30% MK/5 rats were as found in controls from the previous study, while the S/30% MK rats resembled the pattern seen in the M-treated brains. CD IR in the MK/GLU brains, however, resembled control patterns, with CD IR absent from patches. We suggest that chronic morphine increases glutamatergic transmission in striatum, increasing Ca++ and CD levels. These findings are consistent with reports that MK-801 inhibits tolerance to morphine, and provide a possible mechanism for this inhibition. (Supported by the National Institute on Drug Abuse)

411.14 MORPHINE REGULATES EXPRESSION OF JUN FAMILY MEMBERS IN RAT BRAIN. R.E. Harlan, O. Prakash* and M.M. Garcia, Department of Anatomy, Tulane Medical School (REH, MMG) and Division of Research, Ochsner Medical Foundation (OFC), New Orleans, LA 70112.

Members of the Jun family of immediate-early genes dimerize with c-fos or fos-related antigens, to form a protein complex which binds to the AP-1 promoter sequence, activating or inhibiting expression of a variety of genes. We have used immunocytochemistry with antibodies to c-jun (Oncozyme Science AB-1 and AB-2) and to Jun-B and Jun-D (gift of R. Bradski) to study the cellular distribution of these proteins, and their regulation by morphine. In untreated rat brains, the four antibodies reveal four distinct distributions, suggesting that they may recognize four Jun family members. The distributions of cells recognized by the c-jun AB-1, Jun-B and Jun-D antibodies are very similar to recent reports on distributions of cells expressing the c-jun, Jun-B and Jun-D genes. Since the distribution revealed by the c-jun AB-2 antibody is strikingly different, with immunostaining of neurons only in the nucleus accumbens, striatum, olfactory tubercle and central nucleus of the amygdala, this antibody may recognize a Jun-related antigen. In the striatum, the AB-2 antibody recognizes neurons in the matrix, leaving patches unstained. Chronic morphine treatment (one 75 mg morphine pellet, sc, daily for 5 days) greatly increased the number of neurons stained by the AB-2 antibody, especially in the patch compartment. Acute 30 mg/kg or chronic treatment with morphine greatly increased the number of neurons stained by the Jun-B antibody in the nucleus accumbens, striatum and frontal cortex. These results extend previous work demonstrating morphine-regulated induction of immediate-early gene expression (c-fos) in the striatum and further suggest that the activated mu-opiate receptor may be coupled to stimulatory as well as inhibitory cellular events. Supported by DA-06194, NS-24148 (REH) and DA-05411 (MMG).

411.15 HYPERTHERMIA INDUCED BY INTRAPEPTIC MICRODIALYSIS OF A SELECTIVE μ OPIOID RECEPTOR AGONIST IN RAT. L. Xu*, E.B. Geller and M.W. Adams, Department of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140.

Previous studies from this and other laboratories have shown that the hyperthermic response of the rat to opioids are mediated by μ receptors. To investigate the role of the opioiic area (POA) in the hyperthermia, the present study used the selective μ receptor agonist, PE-301 (7 mg/kg sc). The temperature change was measured in the POA (superior hypothalamic area) and the thermoregulatory areas (anterior hypothalamus). The rats were exposed to continuous subcutaneous infusions of PE-301 for 6 hr. The results showed that PE-301 produced a significant increase in body temperature.
418.1 ELECTROPHYSIOLOGIC EVIDENCE THAT VENTRAL PALLIADAL (VP) DOPAMINE MODULATES VP RESPONSES TO AMYGDALA STIMULATION.
The VP is a dopaminergic brain region that also receives amygdaloid (AMN) efferents. Receptor subtypes involved in dopamine (DA)-mediated VP responses and the effects of DA on AMN inputs to VP are unknown. Thus, the present study determined whether VP responses to AMN stimulation could be modulated at the level of the VP by exogenous DA (microlithophoretic application) and/or endogenous DA (stimulation of midbrain dopaminergic regions; mDA).

Single, spontaneously active VP neurons, recorded in vivo in male Sprague-Dawley rats and anaesthetized with chloral hydrate, were assessed for convergent responses to AMN and mDA single pulse stimulation. Most VP neurons tested responded to both. Seventy percent of the short latency inhibitory VP responses to activation of the mDA were attenuated by microlithophoretically applied SCH23390 (61.6% vs. 30.5%), and with a greater magnitude (61.7% vs. 30.5%). AMN-evoked short and long latency inhibitory effects of VP neurons were attenuated by DA within the VP (84% and 80%, respectively), and by prior mDA stimulation (10 pulse train; 85% and 78%). The results suggest a monosynaptic inhibitory influence on VP neurons by mDA that is often mediated through DA receptor activation. DA within the VP and mDA activation produce a similar modulatory influence on AMN efferents to the VP. Thus, the VP may be an integrative site of limbic (AMN) and motor (mDA) systems. Work supported by MH45180.

418.3 MOTRIC ANALYSIS OF DOPAMINE RECEPTOR SUBTYPE ACTIVATION WITHIN THE VENTRAL PALLIADAL AND DORSAL GLOBUS PALLIDUS.
T. C. Nagler* and F. Rehahn. Department of Pharmacology, Loyola University Chicago, Stritch School of Medicine, Maywood, IL, 60153.

Dopamine (DA) projections ascending to forebrain striatal regions are known to mediate a complex repertoire of motor-related behaviors. Recent work demonstrates that pallidal regions also are dopaminergic, responding to both D1 and D2 DA receptor activation. Thus, the present study investigated the effects of DA-mediated motor functions, and whether the contribution of the dorsal globus pallidus (DOP) differs from that of the more medial ventral pallidus (VLP), were examined.

Under pentobarbital anesthesia, male Sprague-Dawley rats were implanted bilaterally with guide cannulae to allow i.c.v. microinjection of treatments into the DOP and VLP. Experimentation began 1 week after surgery and various motor effects were quantified for 1 hr following i.c.v. treatments. Intrapallidal DA (0.01 to 100 ng/5 µl) induced a dose-related increase in locomotion and rearing/wall climbing. Quinpirole (QUIN, D2 agonist) elevated these behaviors only when injected into the DOP. In the VLP, such effects were mimicked by SKF82958 (SKF, a full D1 agonist). SKF also produced robust "mouthing movements" that remained intact in rats with complete lesions of endogenous DA (in contrast to the other behaviors). Thus, DOP and VLP regions contribute a distinct profile to dopaminergic modulation of motor function. Since the magnitude of the locomotor and rearing/wall climbing measures was less than that observed in these animals with 1 mg/kg ip amphetamine, pallidal structures serve as constituents of an engaged system for these behaviors. Whereas, mouthing movements resulting from VP D1 receptor activation, without the involvement of endogenous DA (and thus, D2 receptor) induced a response that was greater than any other treatment assessed, suggesting that VP D1 receptors play a critical role in this behavior. Supported by MH45180.

418.5 EXCITATION OF RAT CAUDATE NEURONS BY INDIRECT AND DIRECT ACTING DOPAMINE AGONISTS.
The effects of dopaminergic (DA) drugs were evaluated for effects on neuronal firing rates of DA neurons in the substantia nigra pars compacta (SNPC) and the caudate nucleus (CN), the major projection area for SNPC DA neurons, in choroidal hydrate anesthetized rats. Using dye-filled glass microelectrodes, DA neurons in substantia nigra pars compacta (SNPC), Bursten et al., JPTT 155:560, 1973) and caudate neurons were identified by classical electrophysiological/neuroanatomical criteria. Cells were located in central caudate and were selected for spontaneous activity and large positive-negative waveforms (Type II, Life Sci 25:419, 1979). Intravenous injections of the indirect DA agonist, amphetamine (AMPH, 1-3 mg/kg), excited spontaneously active CN neurons and inhibited SNPC neurons by a HAL-sensitive mechanism. Similarly, quinpirole (QUIN, 0.3-3 mg/kg), a D2 agonist, and apomorphine (3 mg/kg), a D1/D2 agonist, excited spontaneously active CN neurons by HAL-sensitive mechanisms. However, much lower doses of apomorphine were effective in inhibiting SNPC neurons. SKF38395, a D1 agonist, did not alter CN firing rates or responses to QUIN. The data is consistent with the view that, while apomorphine inhibited CN and apomorphine inhibited SNPC neurons by direct autoreceptor activation.

418.6 ELECTROPHYSIOLOGICAL STUDIES OF (-)-STEHODILENE ON SNC AND VTA DA NEURONS.

(-)-Stepholidine is a novel DA receptor agonist, but it possesses agonistic action on rotational behavior in the 6-OHDA-lesioned rats. It is presumed that D2 receptors in the SNR are involved in this agonistic action. The present work attempts to elucidate whether SFD exhibits the agonistic or antagonist action on extrastriatal firing recorded from SNR and VTA DA neurons in the anesthesized, the reserpinized, and the 6-OHDA-lesioned rats.

It has been shown that SFD had antagonistic effect only to D2 receptors in the SNR and VTA on anesthetized rats. However SFD was an antagonist on both D1 and D2 receptors in the reserpinized rats. Interestingly, SFD had the characteristic of depolarization inactivation in VTA, not in SNR, of the anesthetized rats. This action is the characteristic of atypical neuroleptic. Thus SFD would exist the potential possibility of atypical neuroleptic. Furthermore, when firing was recorded from the SNR in the 6-OHDA-lesioned rats, SFD showed the D1 agonistic action. This result would be compatible with the rotational behavior.
418.7 DIFFERENTIAL INTERACTION OF DOPAMINERGIC D-1 AND D-2 RECEPTORS WITH GLUTAMAMERIC AND CHOLINERGIC TRANSMISSION IN THE 6-HYDROXYDOPAMINE MODEL OF PARKINSON.
M. Morelli, S. Fenu, A. Coroglio, A. Pini, and G. Di Chiara, Dpt. of Toxicology, University of Cagliari, Cagliari, Italy.

The interaction of dopaminergic D-1 and D-2 agonists with antagonists of N-methyl-D-aspartate (NMDA) or muscarinic receptors, was examined after a unilateral 6-hydroxydopamine lesion of the dopaminergic nigrostriatal system. Blockade of NMDA receptors by MK-801 increased the contralateral rotational behavior induced by the D-1 agonist SKF 38393 and inhibited the rotation induced by the D-2 agonist LY 171558. Blockade of muscarinic receptors by scopolamine, like MK-801, potentiated D-1 mediated contralateral rotation but did not influence D-2 mediated rotation. D-1 dependent activation of the proto-oncogene c-fos in the lesioned caudate-putamen (CPu) was increased after both treatments. 2DPC utilization studies evidenced an increased metabolic activity in the entopeduncular nucleus and substantia nigra reticulata after these treatments, indicating that the behavior observed is associated with specific biochemical modifications in the CPu, reflected by functional modifications in striatal afferent areas. The results suggest that administration of NMDA or muscarinic receptor antagonists might improve the therapeutic efficacy of D-1 agonists in the treatment of Parkinson’s disease.

6-OH dopamine (6-OHDA) is known to selectively destroy nigrostriatal pathways in the brain. In this study, we have investigated the effects of 6-OHDA lesions on G protein levels in the rat striatum. Male Sprague Dawley rats were treated with unilateral lesions of 6-OHDA and striata were removed from both hemispheres 1, 4, 8, or 16 days post-lesion. Quantitative immunoblotting of western blots, using specific antisera, was used to assess relative levels of Goα, Gβγ, and Gαq subunits. Both Gαq and Gβγ levels were found to be depressed in striata ipsilateral to the lesion relative to non-lesioned striata, and this effect was most pronounced by day 16. Although both Gαq and Gβγ levels showed similar patterns of alteration, Gαq levels consistently showed the greatest difference for each day post-lesion, suggesting that alterations in Gαq levels may follow changes in Gαq activity. Gαq levels showed no significant alterations in lesioned relative to unlesioned striata at any day post-lesion. Given that the molecular basis of many human neurodegenerative diseases are not at present well established, we have begun attempts to relate these results to healthy individuals and to the alterations in human neurodegenerative conditions. This work was supported by grants from the Parkinson’s Foundation of Canada and NIH.

Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Indirect dopaminergic agonists, such as amphetamine, typically increase motor-related, but suppress nonmotor-related neurons in rat striatum (Har et al., Brain Res. 489:365, 1989). In an initial attempt to assess the mechanisms by which dopamine regulates striatal activity, we monitored the effects of quinpirole (171558), a dopamine agonist that has a high affinity for D2 and, especially, D3 receptors, and SKF-38393, a D1 agonist, on single unit activity in the striatum of awake, behaving, male rats. Like amphetamine, quinpirole (1-5.0 mg/kg) alone, or administered 30 minutes after the D1 agonist SKF-38393, inhibited nonmotor-related neurons in the striatum. Unlike amphetamine, quinpirole also inhibited motor-related neurons located in the lateral and central striatum. In medial striatum, however, neurons were particularly sensitive to the animal's state of arousal. After quinpirole, these cells showed complex changes in firing rate that may, in part, reflect behavioral activation induced by the drug. In contrast, SKF-38393 (5mg/kg sc) alone had no effect on the firing rate of striatal neurons. Nor did its effects differ from control when administered 30 minutes after quinpirole. Collectively, these results suggest an important role for D2 and/or D3 receptors in regulation of striatal activity. Supported by USPHS Grant DA 02451.

418.10 SOME STUDIES ON DA D1 & D2 ANTAGONIST-INDUCED CATALEPSY IN RATS. D.M. Jackson1, J.A. Watson2, A. Bengtsson1, and M. Lindner.

Arcus Astra AB! and Astra Parn Control AB/2, Södertälje 151 54, Sweden.

Catalepsy (C) is produced in rats by either DA depletion or by blockade of DA D1 or D2 receptors with antagonists. While C is a useful & predictive model, the measure itself is sensitive to environmental manipulations. In this test study we investigated the method of testing on SKF38393 (SKF) and raclopride (R)-induced C. C was determined on a steel grid at an angle of 60° +2° & the time each rat spent before moving 1 of its 4 paws determined. 3 experiments are described. 1) 2 methods were used to measure C after agonist injection. First, the C time for each rat was determined 0.5, 1, 2, 4, 8, and 24 h after injection. Secondly, the C time was measured only once on each rat at 0.25, 1, 2, 4, 8, and 24 h after injection. With the first technique, both SKF & R produced dose dependent C that peaked 2 to 8 h after R & 0.5 to 1 h after SKF, peak time depending on dose. With the second technique, C was measured only once on each rat at 8 h after injection. In contrast, R produced weak C when each rat was tested once. 2) Rats were injected with R (60 μmol/kg). Half were injected 10 min later with saline & the remaining remained untreated. All rats were then tested repeatedly beginning 0.5 h after saline injection for 24 h. The time course curve for C was altered by the saline injection. 3) Rats were given R (60 μmol/kg) & half handled each 5 min, & half not handled, before determining C 0.5 h through 24 h after injection. Less C was evident in the handled group. It is clear that D1 & D2 induced C depends upon markedly different mechanisms, as proposed earlier. Some form of conditioning, which is extremely sensitive to environmental influences, seems to play a major role in D2, but not D1, induced C.

Rats deprived of REM sleep 96 hours using a water tank procedure; group L/S resided on larger (control) pedestals for 72 hrs, then on small pedestals for 24 hrs; control group remained on large pedestal for 96 hrs; and group CC remained in the home cage. The striata were analyzed for dopamine D1 and D2 receptor density and affinity using [3H]SCH23390 and [3H]YM-09151-2 as ligands, respectively. Group REMD showed increased in Bmax for D1 and D2, and increased Kv for D2, compared to group TC. Group L/S had increases in Bmax and Kv for D1 and D2, compared to group CC. Group TC showed decreased Bmax for D1 and D2 and decreased Kv for D2, compared to group CC. Thus, stress caused different receptor types, whereas REMD had an opposite effect. These data suggest that differences in D1 and D2 receptor binding may be used to distinguish the effects of stress from the specific effects of REMD. (Supported by Dept. of Army)

COMPARATIVE STUDIES OF F-18 LABELED BENZAMIDES AND [F-18]MNETHYLPSIPERONE: R1 Mace, 1 G. Greenberg, 1 P A. Pavlik, 1 D. Evens, 1 B. Ehrenkranz, 2 R. Landeck, 2 CD Unsworth, 2 K. Jones, 2 S. Childers, 2 RB Molinoff, 1 and M. Stylik. 1 1Univ. of Pennsylvania and 2Bowman Gray School of Medicine.

A series of imaging studies using PET were carried out on a baboon comparing the uptake and retention of 2,3-dimethoxy-N-(p-fluorophenyl)piripendol-4-yl benzamide (MIBP) and 2,3-dimethoxy-N-0-(p-fluorophenyl)9-aracyclohexyl-3,3,1 nonas-8-yl benzamide (MABN) with that of N-methylpsiperonine (NMSP). All three compounds displayed a high accumulation in the basal ganglia (BG) with NMSP exhibiting the lowest rate of washout from the cerebellum (Cb). MIBP reached a 40% BG uptake at 40 min post-injection. Washout of MIBP after maximal accumulation occurred with a half-life of 140 min. MABN and NMSP did not washout from the BG and a linear increase in the BG/Cb ratio was seen over the three hour data acquisition period. The rapid washout of MABN from the Cb resulted in a BG/Cb ratio twice that of NMSP. A series of in vivo binding studies were conducted in order to determine the selectivity of each analog for D2 vs 5-HT2 and D2 receptors. The radioligands and tissue sources used were: D2, [3H]NC-298, rat striatum, 5-HT2, [3H]II-LSD, P11 cells, and [3H]Rauwolscine, rat cortex. The results of the in vivo study indicate the MIBP and MABN possess a higher 5-HT2/D2 ratio than NMSP. All three analogs possess a low affinity for D2 receptors. The results of these studies suggest that MIBP and MABN may be superior to NMSP for PET studies of D2 receptors.

REVERSED RELATIVE EFFICIENCIES OF QUINPIROLE (QUIN) AND (+3-PPP AT DOPAMINE (DA), D. RECEPTORS (D, R) IN STRIATUM AND ANTERIOR PITUITARY (AP); E. Meier, 1 J. Pizz, 2 J. Diamond, 1 and K. Bohmaker, Dept. Psychiatry, NYU Medical Center, New York, NY 10016.

Previous studies have shown that D3R on striatal DA nerve terminals and AP luteocorticol mediating, respectively, inhibition of transmitter synthesis and prolactin (PRL) release, both display a similar large receptor reserve (RR) for full agonists. Both effects involve receptor coupling to pertussis toxin (PTX)- sensitive G protein(s); consequently, the efficiency of receptor coupling (i.e., RR), is likely to be related to the ability of agonists to induce ternary complex formation. Treatments which reduce the amount of receptor or G protein are therefore expected to reduce the RR. Treatment of AP cultures with 17-estradiol (EST; 10, 3 days), recently shown to reduce PTX-sensitive G protein levels in AP, shifted the dose-response curve (DRC) for DA-4-propylnorapomorphine (NPA) to the right (14-fold; receptor inactivation is PTX-sensitive; 1 μM, 30 min) showed that EST treatment abolished the RR for NPA. Surprisingly, EST had nearly identical effects on the DRCs for QUIN and (+3-PPP (4.3-fold shift), although differential effects were expected since (+3-PPP has been found to be a much weaker agonist than QUIN in striatum. Treatment of cultures with PTX (10 ng/ml, 24 hr) produced shifts in the DRCs for NPA, QUIN and (+3-PPP which did not correlate with their previously determined relative efficacies; the PTX DRCs were also significantly shallower (P < 0.001). Receptor inactivation experiments revealed that maximal response in AP for QUIN and (+3-PPP required 25 and 9.6% receptor occupancy, but 6.2 and 3.0%, respectively, in striatum. "Promiscuous" coupling of D3R to different G proteins in the two tissues may underlie the reversal of relative efficacy, as recently predicted (Konakini and Morgan, Mol. Pharmacol. 1989). Supported by NS 23618.

LOCALIZATION AND BINDING ANALYSIS OF [3H]BTPC: A DOPAMINE UPTAKE SITE ANTAGONIST. M.E. Hunt1, P. Filloux, 2 H. Marang, C. Johnson, and J.R. Wamsley1. 1Research Institute, Fargo, ND 58103 and Western Institute of Neuropsychiatry, Salt Lake City, UT 84106.

The phenylpiperidine analog, [3H]-BTPC: (4-(3-benzoylphenyl) piperidine) has recently been made available in tritiated form ([3H]BTPC) for use as a radioligand. Specific binding of [3H]BTPC in striatal tissue was maximized at a pH ranging from 6.8 to 7.0 and a NaCl concentration between 145 and 220 mM. Nonlinear regression analysis of association and dissociation experiments yielded a Kd = 0.008 min^-1 and a Ka = 0.023 min^-1. The calculated Kd is equal to 30.22 min^-1 which is in agreement with the k_d derived from nonlinear regression analysis of the dissociation isotherm for a single high site model. However, two site modeling of the saturation isotherms proved to be significantly better than one site model and revealed high and low affinity binding sites with k_d’s of 1.3min and 79.7min respectively. Autoradiographic localization showed high binding in the caudate putamen, nucleus accumbens, and olfactory tubercule.

**ELECTROPHYSIOLOGICAL ACTIVITY MODULATES THE LEVEL OF ENDOGENOUS ADENOSINE IN THE HIPPOCAMPAL SLICE.** \*J.B. Mitchell* and T.W. Dunwiddie. University of Colorado Health Sciences Ctr. and VA Medical Ctr., Denver, CO 80262

Adenosine is a potent inhibitory neurotransmitter within the CNS. An increase in adenosine levels accompanies hypoxia, ischemia and seizures, but it is not known if elevating adenosine has a role in non-electrophysiologic function. We have found evidence for the activity-dependent release of adenosine from in vitro hippocampal slices maintained under physiological condition. Bipolar stimulating electrodes were positioned in the Schaffer collateral-commissural fiber layers of areas CA1 and CA3, and test fEPSPs were recorded from a single recording electrode positioned in the stratum radiatum of CA1. A train of conditioning pulses was applied to one stimulating electrode, and then a response evoked by applying a test pulse to the second stimulator. A train of 6 conditioning pulses (100 Hz) beginning 250 ms prior to the test pulse decreased the amplitude of the test fEPSP to 78 ± 1.9 percent of control. Antidromic firing of the CA1 pyramidal cells, evoked by an electrode positioned in the alveus, decreased the amplitude of the test fEPSP by 81 ± 2.6 percent of control. The decrease in fEPSP amplitude induced by either conditioning stimulus could be prevented by superfusion with an adenosine antagonist. When 2 conditioning pulses were used, the decrease in fEPSP amplitude lasted 500 ms and the maximum decrease occurred at 250 ms. Superfusion with the adenosine uptake inhibitor, dipyridamole, (50 μM) lengthened the duration of the decrease. Threogenesis adenosine levels can be increased in response to activation, and that this adenosine can then decrease excitatory neurotransmission in the hippocampus.

**NMDA- AND NON-NMDA-EVOKED ADENOSINE RELEASE: DISTINCT PURINERGIC SOURCES AND MECHANISMS OF RELEASE.** \*C.G. Craig* and T.D. White. Dept. of Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7.

Activation of excitatory amino acid receptors releases the inhibitory neurotransmitter adenosine from superfused rat cortical slices. Here we investigated the source of adenosine and its mechanism of release. Inhibition of the nucleoside transporter with dipipyridamole greatly enhanced adenosine release evoked by glutamate, NMDA, kainate receptor activation, and electro-shock of cortex-nucleus tractus solitarius with α,β-methylene ADP and GMP had no effect on either kainate- or AMPA-evoked adenosine release but decreased glutamate- and NMDA-evoked adenosine release by 23% and 68%, respectively. NMDA-evoked adenosine release, but not kainate- or AMPA-evoked release, was Ca2⁺-dependent. These results indicate that activation of non-NMDA receptors releases adenosine per se in a Ca2⁺-independent manner. In contrast, NMDA receptor activation evokes a Ca2⁺-dependent release of a nucleotide which is subsequently converted extracellularly to adenosine. Although neither NMDA- nor non-NMDA-evoked adenosine release occurs via the nucleoside transporter, this transporter does appear to be a major route for removal of adenosine from the extracellular space. (Supported by the MRC of Canada)

**BLOCK OF NMDA-EVOKED ADENOSINE RELEASE BY IBMX IS NOT DUE TO INHIBITION OF PHOSPHODIESTERASE I OR IV.** T.D. \*White* and C.G. Craig. Department of Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7.

Activation of NMDA receptors in rat cortical slices evokes a Ca2⁺-dependent release of a nucleotide which is then degraded extracellularly to adenosine. To test whether the released nucleotide might be cAMP, we examined the effects of PDE inhibitors on adenosine release. IBMX (IBMX), a non-selective PDE inhibitor, blocks NMDA-evoked adenosine release but this was not accompanied by enhanced cAMP recovery in the medium. However, it seemed possible that cAMP might be degraded intracellularly to 5'AMP which is subsequently released to adenosine. To test this possibility, we measured the breakdown of cAMP to 5'-nucleotidase, PDE I, II and IV have been isolated in the cortex. Inhibitors of Ca2⁺/calmodulin-dependent PDE I (8-methoxymethyl-IBMX, W-7 and calmidazolium) and cAMP-specific PDE IV (rolipram) did not mimic the effects of IBMX on NMDA-evoked adenosine release. It appears that IBMX decreases the NMDA-evoked release of purines from cortex both by inhibiting PDE II or by acting at a site other than PDE. (Supported by the MRC of Canada)

419.4

Adenosine transport inhibitors have been suggested for the treatment of neuropsychiatric disorders. Heterogeneity of adenosine transporters has been described with differential sensitivity to dipipyridamole (DPR) and nitrobenzyl-xanthosine (NBI) in the brain of some mammals. Preparation of crude membranes from human parietal cortex and [3H]DPR as well as [3H]NBI radioreceptor assays were performed as described. [3H]DPR and [3H]NBI revealed approximately the same number of binding sites with a Bmax of about 100 fmol/mg protein and Ki's in the low nanomolar range. They displaced each other completely from their respective binding sites with Ki's equivalent to their respective Ki's. In conclusion, the data obtained so far in human brain makes the development of CNS-specific adenosine transport inhibitors on the basis of DPR- and NBI- sensitive transport unlikely.

419.5

**CHARACTERIZATION OF ADENOSINE UPTAKE SITES IN CULTURES OF CHICK EMBRYO RETINAL CELLS.** \*R. \*Pase-de-Carvalho* and E. \*Brassard*. Neurobiol., Univ. Fed. Fluminense, Niterói, RJ 24000, Brazil.

The presence of a specific uptake system for adenosine that can be inhibited by nitrobenzyl-xanthosine (NBI) or dipiridamole (DPR) was previously demonstrated in cultures of chick embryonic retina cells. Here we showed that (±)-NBI binds with high affinity to adenosine uptake sites on intact retinal cells. Cultures obtained by disassociation of 8-day-old chick embryonic retinas and incubated in BME with 5% fetal calf serum for 6 days at 37°C were washed and incubated in Hank's with 2-50uM (±)-NBI in the absence or presence of unlabeled NBI (10uM) to determine nonspecific binding. The binding was blocked approximately 70% in the presence of unlabeled NBI or DPR and attained equilibrium after 10 min at 37°C. The addition of NBI or DPR after equilibrium completely displaced specific binding, indicating the binding to surface sites rather than (±)-NBI uptake into cells. The data indicate that adenosine uptake sites labeled with (±)-NBI can be directly studied in living intact retinal cells and that primary cultures of chick embryonic retinal cells are excellent models for the study of these sites and their regulation by external factors.

419.6

**[3H]ADENOSINE TRANSPORT IN POSTMORTEM HUMAN BRAIN.** J.G. \*Guu*, G. \*Kalls*, and J.D. \*Geiger*. Dept. Pharmacology, Univ. of Manitoba, Faculty of Medicine, 700 Bannatyne Avenue, Winnipeg, Manitoba, R3E 0W3.

The kinetics of [3H]adenosine transport was characterized in cerebral cortical synaptosomes prepared from postmortem human brain. For this assay, it was determined that the adenosine transport inhibitors dimethylxanthine and diltiazem were instantaneously and completely effective in blocking adenosine transport. For 5 sec incubations, two kinetically distinguishable processes were identified; the Ki and Vmax values for high affinity adenosine transport were 89 nM and 0.98 nmoles/min/mg protein and for low affinity adenosine transport were 4.5 nM and 15.2 nmoles/min/mg protein. With incubation of 1 min [3H]adenosine accumulation was at 5 sec and 10 sec at 600 s; hence adenosine transport was not a concentrative process. For 5, 15, 30, 60 and 600 sec incubations, 12, 23, 34, 43 and 80% of transported [3H]adenosine was metabolized mainly to its phosphorolated derivatives AMP, ADP, and ATP. The concentration (μM) of total accumulated radiolabeled purines at these times was 0.3, 0.5, 1.0, 1.3 and 5.6, respectively; hence the accumulation of radiolabeled purines was constant only when extensive metabolism was present. In the presence of 10 μM EHNA, an adenosine deaminase inhibitor, and 10 μM toadalin, an adenosine kinase inhibitor, metabolism was 14, 14, 16, 14, and 38% of the transported [3H]adenosine and total radiolabelled purine accumulation was 0.3, 0.5, 0.5, 0.7, and 1.8 μM; hence concentrative accumulation of radiolabeled purines can be inhibited by the inhibition of adenosine metabolism. Thus, adenosine transport in human brain synaptosomes is via a facilitated diffusion system that exhibits low affinity for adenosine.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

Intracellular microelectrodes were used to characterize the adenosine receptors of 102 myenteric neurons. Biocytin was injected from the microelectrodes to characterize the morphology and sensitivity to adenosine receptor agonists. Superfusion of adenosine, the A2 agonists 5'-N-ethylcarboxamidoadenosine and CGS 21680 or the A1 selective agonist N6-cyclopentyladenosine and 2-chloro-N6-cyclopentyladenosine (CCPA) evoked an inhibitory response in 93 of 102 AH/Type II neurons (93.1%). The response consisted of membrane hyperpolarization, associated with a decrease in firing rate, increase in the hyperpolarizing after-potentials, inhibition of spike discharge and a decrease in cell input resistance. The latency profile for inhibition of cell input was CCPA > CGS 21680 > ADO (N=40); the EC50 for CCPA (15.1±2.17 μM) was 1000 fold lower than that of CGS 21680 (5.60 ± 2.54 μM). This effect was reversible with the A1 selective antagonist 8-cyclopentyl-1,3-dimethylxanthine (10-0.10-6 μM). Of 30 responsive neurons, 27 neurons (90%) had Dogiel Type II and 3 neurons (10%) had Filamentous morphologies. It is concluded that inhibitory A1 adenosine receptor exist mainly on myenteric AH/Doigiel Type II neurons. (Supported by NIH R29 DK44417 to FLC and ROI DK 37328 to JDW).

PC12 (GGt) is a putative transcription factor that regulates the synthesis of growth hormone (GH) and prolactin. Hormones and other agents regulate PI-3' kinase by various mechanisms, including effects on adenylate cyclase (AC). Since AC activity can be increased or decreased by a number of adenosine (Ado) via A1 or A2 receptors, respectively, we studied the effects of these ligands on mRNA synthesis under the control of the PI-3' promoter. GH-producing rat pituitary tumor cells (GH4C1) were transiently transfected with a chimeric reporter construct containing part of the 5'-flanking sequence of the PI-3' gene and linked to the coding sequence for chloramphenicol acetyl transferase (CAT). After 24h, various concentrations of forskolin (Fosk), a direct activator of AC, R-R-phenylisopropyladenosine (PIA, an A1 agonist), 8-cycloptensylnucleotide (CPT, an A3 antagonist) and/or Ado deaminase (ADA) were added. Cells were harvested 24h later and lysates were assayed for CAT activity. ADA altered both the magnitude and dose-dependence of Fork-stimulated CAT activity, suggesting a role for A1-Ado. In the presence of 2 U/ml ADA, the Forsk concentration giving half-maximal increase in CAT activity was increased 2- to 3-fold, and CAT activity was stimulated 25- fold by 0.5 μM Forsk. PIA (0.1 or 1 μM) consistently inhibited the expression of this construct to 40-60% of the basal value in the presence of 0.25 μM Forsk and 2 U/ml ADA. The effect of 0.1 μM PIA was completely blocked by 1 μM CPT. In the absence of ADA, responses to PIA were variable, e.g. 10 nM PIA stimulated construct expression 2-fold in some experiments. Our results indicate that adenosine should be added to the growing list of neurotransmitters and hormones which regulate pituitary hormone production at the transcriptional level. (Supported by NIH grant DK16638 and the Cohen Fund)

We have previously shown that specific adenosine A1 receptor activation in the rat medulla induces a motoneuronal excitability decrease and increases input resistance (RI). This decrease in excitability is due in part to an adenosine-mediated increase in afterhyperpolarization (AHP) amplitude. In order to understand better the mechanisms underlying A1 receptor effects, we recorded intracellularly from vagal motoneurons using a rat brainstem slice preparation before and during sub intrusion with either adenosine (10 μM-1 mM) or a specific A1 receptor agonist, cyclopentyladenosine (CPA, 10 μM). Synaptic blockade with either TTX or a permeant containing Mg2+ (10 μM), low Ca2+ (0.5 mM) blocked the CPA-induced increase in RI. Blockade of Ca2+ entry with 10 μM-3 mM Ca2+ abolished the CPA- and AHP amplitude, and increased excitability. Interestingly, no effect was seen with exogenous adenosine itself, unless adenosine uptake had been blocked with diphenhydramine (25 μM). We conclude that the CPA-induced RI increase, and possibly the AHP increase as well, is due to A1 receptor actions on presynaptic mechanisms, 2) the ion channel mediating the increase in AHP amplitude is sensitive to both but not 4AP or ampin, and 3) the ion current system in the vagal motor nucleus effectively buffers extracellular adenosine.

The accepted binding mode for a xanthine within the A1 receptor superimposes N1,N2,N3, and the N of the xanthine with the 4 identical xanthine base. This mode does not overlap the xanthine C6-N or the adenosine C8-R positions, the positions which impart potency and selectivity to xanthine-based antagonists and substituted adenosine agonists. With superimposition of N1,N2, and N of adenosine and N1,N3 and N of the xanthine, the C6 and C8 positions are in close proximity. MOL 102,234 (MDL) 1R-1,3-dipropyl-8,8-(1-phenylpropyl)xanthine) is a C8 substituted xanthine with the same stereochemistry as the C8-N phenylisopropyl substitution of the A1-selective agonist R-PIA. MOL 102,234 has Ks values at the adenosine A1 and A3 receptors and 0.86 and 0.53 μM, respectively. The compound is a very weak phosphodiesterase inhibitor with IC50 values against PDE Type III and PDE Type IV of 104 μM and 28.3 μM, respectively. This is 10,000-fold weaker than its potency at the A1 receptor. In guinea pig ileum, MOL 102,234 induced weak negative chronotropic and inotropic responses. At a concentration of 10 μM has no effect on heart rate or diastolic blood pressure. In conclusion, MOL 102,234 is a selective A1 antagonist and supports the new binding mode of xanthines to the A1 receptor.

IN VIVO ACTIVATION OF AD1 RECEPTOR ENDOCYTOSIS BY CCQA 

The effect of 2-chloro-N6-cyclopentyladenosine (CCQA), the most selective A1, adenosine receptor agonist, was studied on 3'S-TBP binding measured "ex vivo" in the mouse brain. In fact, the increased decrease of 3'S-TBP binding in the rat and mouse brain homogenate reflect a reduction and an enhancement in the expression of the GABAa receptor-coupled chloride channel, respectively. CCQA (0.5 mg/kg i.p.), like negative modulators of GABAAergic transference, elicited a 30-40 min rise in the close-dependent increase of 3'S-TBP binding in the mouse cerebral cortex, hippocampus, striatum, but in the cerebellum. The effect of CCQA lasted for more than 4 hrs. Saturation studies revealed that the effect of CCQA on 3'S-TBP binding was abolished by the concomitant administration of the specific A1 receptor antagonist DPCPX (3 mg/kg i.p.). Moreover, apecsin (0.5 mg/kg i.p.), an anticoagulant and anticonvulsant benzodiacepine receptor ligand, completely abolished the increase of 3'S-TBP binding induced by CCQA. In spite of its capability of interacting with the site of GABA coupled chloride channel, CCQA (1-3 mg/kg) completely antagonized the convulsant activity of pentylentetrazol and iozanol, two GABA function inhibitors, while failed to antagonize kainic acid and strychnine-induced seizures.

EXPRESSION OF ADENOSINE A1 AND A2 RECEPTOR SUBTYPES IN PRIMARY CULTURED NEURONS FROM FETAL RAT FOREBRAIN. J. L. Deval*, F. Nicolas, J. Billet and V. Koziel. INSERM U373 30 rue Lhomme, 75754 PARIS, FRANCE.

The expression of both adenosine A1 and A2 receptors, which are physiologically coupled to adenylyl cyclase via a G protein, was investigated by radioligand binding methods in primary cultured neurons isolated from fetal rat forebrain and grown in serum-free medium for 8 days. A1 receptors were labeled by incubating intact neurons in 50 nM Tris-HCl buffer (pH 7.4) for 120 min at 25°C with 2 nM adenosine deaminase and increasing concentrations of [3H]d,l-N6-cyclopentyladenosine (CCPA), using cytochrome-cytochrome c, for the determination of non-specific binding. A2 binding sites were analyzed by incubating the cells for 15 minutes at 25°C with 2 nM [3H]CGS 21680, a specific ligand. Both radioligand bound specifically and with high affinity to a single population of sites. Scatchard plots yielded Kd values of 2.9 nM (for [3H]CCPA, 1.7 nM for [3H]CGS 21680 and 33 nM for [3H]Forskolin. Maximum numbers of sites were 160 ± 14, 104 ± 15 and 254 ± 2 fmol/mg protein for CCPA, CGS 21680 and forskolin, respectively. The addition of 1 μM Gpp(NH)p, a GTP analogue, increased significantly Kd values for both CCPA and CGS 21680, suggesting that receptors are, at least partly, linked to G proteins.

We have previously reported the expression of the human adenosine receptor (A2R) on human chromosome 22, suggesting an important role in motor function and extrapyramidal disorders. Complementary DNAs (cDNAs) for the A2R have been isolated from dog (B & B 173,1169) and rat (Mol Br Res in press). These A2D cDNAs exhibit substantial nucleic acid and amino acid homology in the transmembrane (TM) domains of the two species. To further understand the functional significance of sequence divergence at the carboxy terminus of the A2R, we have begun to characterize the human A2R gene. A panel of somatic cell hybrids containing various human chromosomes on a rodent background was screened with a 540 bp fragment of coding sequence for the rat A2R. Hybridization was detected with the cDNA 22 containing cell line. Localization on chromosome 22 proximal to a breakpoint at 22q11 was then established by hybridization with hemizygous somatic cell hybrids. A human chromosome 22 cosmid library was screened with the same probe and two clones were isolated. Southern analysis of one of the cosmid clones which selectively hybridized to the rat probe was subcloned and sequenced. The predicted amino acid sequence of this fragment is 89% homologous to the dog and 84% to the A2Rs (70% overall identity and greater than 90% identity in the transmembrane domains). We conclude that A2-like sequences homologous to the dog and A2 Rs reside on human chromosome 22.

NUCLEOTIDE RECEPTORS IN PHALEOCHROMOCYTOMA (PC12) CELLS. L. de Souza, S. Baba, A. Lange and J. K. Reed. Depts of Biochemistry, Zoology and Chemistry, University of Toronto, Brindille College, Mississauga, Ont. L5I 1S6.

The effect of extracellular ATP was studied in PC12 cells, a neurosecretory line that co-releases ATP with catecholamine upon stimulation. We have examined the effects of ATP by monitoring both cytosolic free Ca$^{2+}$ concentrations [Ca$^{2+}$]i and inositol phosphate (IP) levels. NMDA and kainic acid (KA) evoked a transient increase in [Ca$^{2+}$]i as measured with the Ca$^{2+}$-sensitive dye fura-2. The increase was eliminated by DTA. ATP and IP were not detected in PCs and ATP had little effect. A variety of ATP congeners were screened to identify the purinergic receptor subtype involved. The rank order potency of these analogues is not consistent with either P2X or P2Y purinergic receptors. The effect of ATP on IP levels was determined using [3H]-inositol IP levels increased in response to ATP and other nucleotides such as UTP and TTP, but not GTP. The rank order potency for agonist-induced stimulation of IP production followed closely the rank order potency for the calcium response. We propose that PC12 cells express a P2X nucleotide receptor that is distinct from classical purinergic receptors.

420.2

ATP increases intracellular Ca$^{2+}$ in glial cells from the spinal cord and other regions of the CNS by activating P2Y purinergic receptors. Signal transduction mechanisms of this effect of ATP were investigated by measuring Ca$^{2+}$1 in individual cells and delivering agents intracellularly by whole-cell patch clamp electrophoresis. Glia were studied in primary dissociated cultures prepared from the dorsal spinal cord of neonatal rats (2-14 days). Ca$^{2+}$1 was measured using the fluorescent dye, Fura-2. Cells were loaded with the dye by incubating with the cultures in the permeant form, Fura-2 AM (2 μM). The standard intracellular solution used for whole-cell patch clamp work and the solution stored in reagents and ATP had no effect on the response to ATP. These results lead us to conclude that ATP elevates Ca$^{2+}$1 in PC12 cells by a mechanism independent of the PC12 cell Ca$^{2+}$1 stores.

420.3

Intracellular recordings were made from myenteric neurons in vitro to study the actions of ATP applied by superfusion (10 nM-10 μM). ATP showed pre- and postsynaptic actions in a concentration-dependent manner. ATP produced a membrane depolarization associated with an increase in input membrane resistance in 5 cells and a hyperpolarization accompanied by a fall in input resistance in 1 cell. Both responses were reversed in polarity near the K$^{+}$ equilibrium potential and were markedly reduced or abolished in Ca$^{2+}$-free/high Mg$^{2+}$ solution. These responses suggest that ATP may interact with K$^{+}$ currents and the ATP-induced depolarization and hyperpolarization were nullified by manual clamp method. It should be added that ATP at lower concentration (<100 nM) did not affect ACh-synaptic release of ACh. Thus, it is concluded that ATP may act pre- or postsynaptically or both and may regulate synaptic transmission in the myenteric plexus. This study was supported in part by a Grant-in-Aid from the Ministry of Education, Japan.

420.4

Receptor-mediated cytosolic Ca$^{2+}$ mobilization studies readily adapted in the rat parotid acinar cell model, where at least five different neurotransmitter receptors participate in Ca$^{2+}$ elevation. Previously, we observed that extracellular ATP at high concentrations (10 μM) stimulated a Ca$^{2+}$ influx without IP formation in cell suspensions, and that the concentration-response curve was biphasic. Fluorescence microscopy ratio imaging methods were used to study ATP-induced calcium responses in perfused, single acinar cells loaded with Fura-2. All cells (93%) which respond to muscarnic and Substance P activation through the same metabotropic receptor, responded to ATP. Analysis of the concentration-response curves showed that two responses to ATP could be resolved in most cells. The high affinity response, detectable at 0.1 μM ATP, saturates at 1-5 μM and rapidly desensitizes in 50% of the cells, fully recovering within about 6 min after washout. At much higher concentrations of the ATP (300-600 μM), a large, more slowly developing Ca$^{2+}$ rise occurs, which can be blocked by Mg$^{2+}$ as expected for an ATP receptor specific response. The latter response does not desensitize, and is difficult to fully reverse on washout, possibly because a large influx of extracellular Ca$^{2+}$ is handled differently from an equally high Ca$^{2+}$ level produced through muscarinic receptor activation, which is readily and rapidly reversed. Examination of these two Ca$^{2+}$-mobilizing purinergic receptors reveals the participation of different mechanisms of Ca$^{2+}$ homeostasis in recovery of resting Ca$^{2+}$ levels in individual cells.

420.5

Adenosine triphosphate (ATP) is released from nerve terminals together with neurotransmitters such as acetylcholine. Aside from its action on neural receptors, other functional aspects of extracellular ATP are not yet known. Since extracellular ATP has been implicated in the disruption of intracellular Ca$^{2+}$ homeostasis, we examined the effect of ATP on the Ca$^{2+}$ transport system. Results indicated that ATP at 1-2 mM enhanced the voltage-dependent calcium influx (VDCl). The enhancement of VDCI activity was specific for ATP and activity was blocked by ADP and AMP. Furthermore, the slowly hydrolyzable ATP, ATPyS, inhibited synaptosomal ATPase and an increase which ATP hydrolysis was involved in ATP-induced enhancement of VDCI. Under similar conditions a 43 kD protein was phosphorylated by an ecdy-kinase. The level of phosphorylation of this protein was dependent on exogenous calcium and was dephosphorylated upon depolarization. It is possible that the 43 kD protein is functionally linked to the ATP-induced VDCI activity.

GUANOSINE AND GTP ENHANCE NGF-STIMULATED NEURITE OUTGROWTH IN PC12 CELLS. John W. Grabois and Michael S. Puthiyaveetil. Departments of Biomedical Sciences and Medicine, McMaster University Health Sciences Center, Hamilton, Ontario, Canada L9N 1S5.

Extracellular guanosine or GTP (30-300 μM), but not adenosine (0.3-300 μM) enhanced the neurogenic effect of NGF in rat phaeochromocytoma (PC12) cells. None of these purines induced significant neurite outgrowth in the absence of NGF. The effects of guanosine and GTP were synergistic with that of NGF in increasing the proportion of cells bearing long neurites. Adenosine receptor agonists such as 5'-N-cyclopentyladenosine (CPA), 5'-N-ethylcarboxamidoadenosine (ECA) or 5'-N-ethylcarboxamidoadenosine (NECA), also increased NGF-stimulated neurite outgrowth, but not to the same extent that did guanosine with NGF. High concentrations (1 μM) of CPA (1-3H)-diethylpyroili-8-2-amino-4-chloro)-theanine, a putative adenosine receptor agonist, blocked the synergistic effect of guanosine and NGF. However, adenosine $A_2$ receptor agonists DPX (1,3-dipropylxanthine) $A_3$ receptor agonists and $A_7$ receptor agonists did not inhibit the effects of guanosine plus NGF. Interestingly, guanosine also acted synergistically with NGF and adenosine $A_2$ receptor agonists, and NGF alone to induce significant neurite outgrowth in the absence of NGF, although neither of these compounds alone stimulated significant neurite outgrowth in PC12 cells. These data indicate that guanosine may be a co-receptor for the peripheral adenosine $A_2$ receptor to enhance neuritogenesis. Moreover, neither ADP and GTP (purinergic $P_2$ receptor agonists) or ATP (purinergic $P_2$ receptor agonists) interfere with the neurogenic effects of ATP and neurite outgrowth of PC12 cells. 411.5

When stimulated with elevated K+, slices of hippocampal area CA1 release glutamate and asparate in a 5:1 ratio. Release of these amino acids from CA1 slices originates predominantly from the Schaffer collateral-commissural projection and CA2 hippocampal area. Analyses of the pathways that lead to the release of glutamate and asparate reveal that release is mediated by glutamate receptors and asparate release is partially dependent on asparate release. These results indicate that extracellular glutamate terminals can release asparate, even under conditions where membrane transport of released amino acid is expected to be minimal. (Supported by NIH grant NS 16064.)

EFFECT OF DRUG-INDUCED CHANGES IN THE DISPOSITION AND METABOLISM OF NEUROTRANSMITTER ON THE QUANTITATION OF 3H-SEROTONIN (SHT) RELEASE. F. Morice, D.L. Smith, B.K. Oakes, D.L. Smith and B. Oakes, Dept. of Anesthesiology, West Virginia University Health Sciences Center, Morgantown, WV 26506 and Department of Psychiatry, McGill University, Montreal, Canada

While evaluating the effect of 2-methylpropanoyl (2-Me-cAMP) on the release of 3H-SHT from rat spinal cord tissue, it was determined that the drug altered the intracellular disposition of the neurotransmitter. Suppression of the tissue with 2-Me-cAMP resulted in a concomitant decrease in the 3H-SHT efflux which occurred without a concomitant elevation in the efflux of 3H-SHT. This effect was blocked by the co-suppression of an inhibitory GABA receptor, suggesting the drug disrupts intracellular storage of neurotransmitter following active uptake. The effect of 2-Me-cAMP on the 3H-SHT efflux was slow in onset. Fifteen minutes were required before increases in 3H-SHT efflux could be detected. However, this length of drug exposure is frequently achieved in the course of routine neurotransmitter release assays. Therefore, if total 3H-SHT is quantitated rather than separated neurotransmitter and metabolite levels, it is clear that drug-induced increase in the metabolite efflux could be mistakenly associated with an enhancement of depolarization-evoked 3H-neurotransmitter efflux. For example, when calculated using total 3H-SHT, 10 µM 2-Me-cAMP can cause a apparent 3 fold enhancement above the control (no 2-Me-cAMP) response to 15 nM K+ stimulation. On the other hand, when superfuse fractions were analyzed for 3H-SHT and 3H-SHT content, K+ evoked increases in 3H-SHT efflux were comparable in drug treated and control conditions. However, drug-induced increases in 3H-SHT efflux were of the same magnitude as those seen from tissues which were not exposed to elevated K+ concentrations. These results indicate that the separation of transmitter from metabolites is necessary to ensure that drug-induced changes in the disposition of neurotransmitter do not adversely affect the assessment of radiolabeled neurotransmitter release evoked by depolarization induced mechanisms.

Some of the excitatory glutamate pathways in the rat hippocampal formation, including the Schaffer collateral-commissural fibers and the lateral perforant path, take up proline by a high affinity Na+-dependent process. The role of proline in glutamate transmission is unknown. This study compared the uptakes of proline and glutamate by crude synaptosomal preparations of the hippocampal formation during ontogenesis. Uptake of both amino acids was determined from the same tissue samples. At all ages studied from 9 ond, glutamate was taken up by a single high affinity, Na+-dependent process (Km = 5 µM). In contrast, proline uptake was taken up by both high affinity (Km = 5 µM) and low affinity (Km = 100-1000 µM) Na+-dependent processes. High affinity uptake of proline increased 4-fold and high affinity uptake of glutamate increased 2.5-fold between 9 and 15 d after birth. At 15 d postnatal age, uptake had reached adult values and it remained relatively constant afterward. In contrast, proline uptake remained elevated above adult values during the 15-21 d period. These results demonstrate that high affinity uptakes of proline and glutamate, which are co-expressed by many of the core cell pathways, develop during the same postnatal period. The developmental overshoot in proline uptake suggests that this process may play a more significant role in synaptic physiology during adolescence in the rat than during adulthood. (Supported by NIH grant NS 16064.)

EFFECTS OF ACUTE AND CHRONIC INSULIN TREATMENT ON NORADRENERGIC (NE) UPTAKE AND NE TRANSPORTERS IN RAT BRAIN AND PC-12 CELLS. D. F. S. Dermot Reynolds*, P. Slabas, D. Stone, and J. Payne. Dept. of Psych Sci. Med. and U. Washington, Seattle, WA 98195 and VA Medical Center, Seattle, WA 98108. Previous work from this laboratory has led to the suggestion that insulin (INS) receptors in the CNS may be located presynaptically on noradrenergic neurons. To test whether insulin may serve as a neuromodulator for NE neurons, we measured 3H-NE uptake into hypothalamic slices, and into the rat pheochromocytoma PC-12 cells. Acute INS treatment significantly inhibited 2 min NE uptake into hypothalamic slices and into PC-12 cells over a concentration range of 0.1 - 10 nM, in good agreement with the Kd of the insulin receptor (-318±13 nM and -29±8% inhibition, respectively, with 10 nM insulin). Chronic INS infusion in vivo resulted in a significant decrease of NE transporter mRNA levels vs vehicle-treated controls (brain area=1235.7±265 vs 1282.4±292). These results suggest that INS may play a physiological role in the acute and chronic regulation of synaptic NE concentrations via modulation of its re-uptake within certain populations of NE neurons in the CNS.

421.8

The nucleoside adenosine has a wide range of physiological effects including modulation of CNS neuronal activity. Adenosine effects are terminated primarily by uptake, via the nucleoside transporter, from the extracellular fluids into the cell. Inhibitors of the nucleoside transporter are able to increase extracellular adenosine levels, and thereby potentiate the effect of endogenously released adenosine.

R7531, a nitromide derivative, has been reported to be unique as an extremely long-lasting, tightly-binding inhibitor of nucleoside transport (Van Belle and Jansen, Nucleosides and Nucleotides, 18:975, 1991). We have examined the nature of R7531 interaction with the nucleoside transporter in rabbit CNS cortical synaptosomes, using [3H]bretrolylthionine ([3H]BNPMP) as a specific probe. Synaptosomes were incubated in the absence and presence (1mM R7531 or 1mM benzoylthionine) of 45 min, after which, an aliquot of each was removed for analysis of [3H]BNPMP (0.4mM) binding. The remaining synaptosomes were washed (10 min centrifugation at 40 000g). 

diversity was washed and rinsed once with 200 uL buffer - before washing, it was washed for a further 2 washes, whereas the inhibition of [3H]BNPMP binding by R7531 after 5 washes (+5%) was not significantly different from that observed before washing, but did not inhibition of either 10mM adenosine or 10mM benzoylthionine. This result may be due to our 3D model, which suggests that the nucleoside transporter is the nucleoside transporter in rabbit CNS cortical synaptosomes.
422.1 DELAYED INCREASE OF EXTRACELLULAR ARGinine (ARG), THE NITRIC OXIDE (NO) PRECURSOR, FOLLOWING ELECTRICAL WHITE MATTER STIMULATION IN CEREBRAL SLICES. C. Hansel1, A. Batchelor2, M. Cuencod1 J. Garnythe5, T. Knöpfel2 and K.Q. Do1.1 Brain Res. Inst. Univ. of Zurich, Switzerland; 2Dept. of Physiology, Univ. of Liverpool, U.K.

Amino acids were measured in perfusates from L-shaped rat cerebral slices installed in a Krebs-filled three-compartment system following electrical white matter stimulation. The lateral compartments housed white matter and a cortical section containing parallel fibres respectively, whereas the central compartment housed cortical structures at the point of bending. This arrangement allows electrical stimulation while the perfusion medium passing the central chamber can be collected for amino acid analysis with HPLC. Following a 2-minutes stimulation period of either 2 Hz (n=6) or 6 Hz (n=5) Arg levels were significantly raised above levels already present in the Krebs-solution (5.5±1.75 pmol/min respectively 7.3±1.26 pmol/min). Arg is the precursor of NO, a neuronal messenger in the brain, which is synthesized by NO synthase. Since Arg and the NO synthase are located in different cell types it can be suggested that Arg passes through the extracellular space in order to replenish the precursor pool for NO synthesis.

422.3 NITRIC OXIDE SYNTHASE-CONTAINING CELLS IN THE CEREBRAL CORTEX OF RATS. B.J. Wodicka1, L.G. Vathalond2, Y.N. Kharas1, M. Nakanishi1, H.U.P. Schmidt1 and A. Roth1.1 Dept. Cell Biology & Anatomy, UNC, Chapel Hill, NC 27514, USA; 2Dept. Vascular Surgery, Univ. of Texas, Shreiner B. Austin Post Grad. Med. Sch., IL 60604; and 3Dept. Pharmacology, Northwestern U., Chicago, IL 60611.

We have employed histochemistry for NADPH diaphorase and immunohistochemistry for the nitric oxide metabolite nitrite to detect nitric oxide synthase (NOS-1) to reveal neurons and fibers in the rat cortex likely to synthetise nitric oxide. N-terminal-amino acidized animals were perfused with mixed aldehydes; Vibratome sections 20-100 μm thick were stained for NOS. The distribution of NOS-stained cells was plotted; detailed drawings showing their morphology were made with camera lucida. Particular attention was focused on neurons in the upper cortical layers.

NOS-positive neurons comprised about 0.5% of neurons in 5 ml. They were densest in layers 2, 3 and 6 and in the subcortical white matter. Stained neurons were morphologically different, but did not include typical pyramidal neurons. Most had axonless dendrites and axons branching close to the soma. Stained axons had predominantly radial orientation. Boutons were visible throughout the cortex, densest in layers 3-4 and 6. The morphological impression that NOS-positive neurons are local circuit neurons was supported by double-label experiments in which injections of CTB-gold or WGA-HRP were placed in contralateral cortex, thalamus, caudoputamen or spinal cord. In all cases, retrogradely labeled neurons and NOS-positive ones belonged to separate populations. In tangential sections through the barrel field NOS-positive neurons and dendrites were confined to the septa between barrels. Presenting our results, we postulate a role for immunocytochemistry in combination with NADPH diaphorase histochemistry demonstrated that a large fraction of NOS-positive soma also contained GABA.

422.4 NITRIC OXIDE GENERATION RELEASES ('H)-NOREPINEPHRINE FROM HIPPOCAMPAL SLICES. K.M. Johnson and G. Lorentz. Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77555-1031.

Nitric oxide (NO), a diffusible second messenger, has suggested to potentiate neurotransmitter release. Cross-chopped hippocampal slices (300-300 μm) were prepared from male Sprague-Dawley rats, washed and incubated with ['H]-norepinephrine ([3H]-NE) for 30 min in Krebs bicarbonate buffer, containing 10 μM pargyline and saturated with 95% O2:5% CO2 (9:5). Efflux of ['H]-NE was terminated and the data are expressed as fractional release. Hydroxyamphetamine (300 μM), which is known to generate NO subsequent to cellular metabolism, induced a concentration dependent increase in the basal ['H]-NE release. The EC50 value was about 30 μM and 100 μM hydroxyamine produced a maximal 10-fold increase in the basal ['H]-NE release. 10 μM hydroxyamine increased basal ['H]-NE release about 2-fold. Since NO stimulates the activity of guanylate cyclase, we tested the effect of methylene blue, an inhibitor of this enzyme. 3 μM methylene blue alone induced a steady 2-fold increase in the basal ['H]-NE release and significantly potentiated the response to 10 μM hydroxyamine. 20 min pretreatment with 3 μM or 10 μM hydroxyamine did not significantly influence NMDA (300 μM) stimulated ['H]-NE release, while higher concentrations had inhibitory effects. Ongoing experiments are being carried out to characterize the mechanism underlying the effects of hydroxyamine and methylene blue in this preparation. Supported by DA-02073.

422.5 AN NMDA/NITRIC OXIDE PATHWAY MEDIATES LIGHT RESPONSIVENESS BY THE SUPRAESACHASMATIC NUCLEUS. S. Amat. CSIN. Concordia University, Montreal, Quebec, Canada.

The messenger molecule nitric oxide (NO) is produced in brain on stimulation of N-methyl-D-aspartate (NMDA) receptors, and receptors for NMDA have been implicated in light to the hypothalamic suprachiasmatic nucleus (SCN), site of a circadian pacemaker. We assessed the involvement of the NMDA/NO pathway in SCN responsiveness to light by blocking NMDA receptor or NO production in the SCN and evaluating the effect on light during photic stimulation in dark-adapted urethane-anesthetized rats. Photic stimulation (300-300 μm) 3 min) caused a rapid increase in light (ΔA = 37.3±4.4 pm, t=0.8). This effect was blocked by prior infusion of a competitive NMDA antagonist (CPP, 20 nmol) in the SCN (ΔA = 12.5±1.6 pm, t=0.01). Infusion 2 mm dorsal to the SCN had no effect, suggesting a role for NMDA receptors specific to the SCN. Infusion a competitive blocker of NO synthesis, Nω-nitro-L-arginine methyl ester (L-NAME, 40 nmol) in the SCN, but not 2 mm dorsal to the SCN, blocked the rise in light to in response to light (ΔA = 16.1±1.8 pm, t=0.01). This effect was selective and stereospecific: addition of L-arginine (80 nmol), which competes with L-NAME for the substrate site on the NO-generating enzyme, reversed the effect of L-NAME (ΔA = 42.1±9.8 pm, t=8). and infusion of an inactive isomer of L-NAME, D-NAME (40 nmol), had no effect (ΔA = 38.8±4.6 pm, t=12). The ability of light to stimulate heart rate and of infusion of a competitive NMDA antagonist or a competitive blocker of NO production in the SCN region to inhibit this effect suggests a functional link between activation of an NMDA/NO pathway and SCN light responsiveness.

422.6 EVIDENCE THAT NITRIC OXIDE (NO) MEDIATES THE CYCLIC GMP RESPONSE TO SYMPATHETIC ACTIVITY IN THE RAT SUPERIOR CERVICAL GANGLION (SCG). Marion L. Husberg, Hong Shen, Ferial Husn, and Clark A. Briggs.1 Neuroscience Research and Signal Transduction, Abbott Laboratories, Abbott Park, IL 60064.

Preganglionic stimulation increases cyclic GMP levels in the SCG. If it is not known what neurotransmitter mediates this response. However, exogenous nitroprusside and azip, which liberate NO, also have been shown to stimulate cyclic GMP synthesis (Yoshie & Oppenheim, 1983). We have measured whether NO is the physiological mediator of the cyclic GMP response to preganglionic stimulation.

Pared SCG were isolated and superfused in vitro at ambient temperature (21-23°C) with oxygenated Locke’s solution containing 0.3 mm 3-isobutyl-1-methylxanthine. Various drugs were applied for a period of 75-85 minutes before stimulation. In each pair, one SCG served as a non-stimulated control and the other received a preganglionic stimulation of 10 Hz for 30 sec. Cyclic GMP was determined by radioimmunoassay.

Upon stimulation, cyclic GMP levels increased 8-fold and the response was Ca2+ dependent. The NO synthase inhibitor, Nω-nitro-L-arginine (L-NNA), inhibited the cyclic GMP response in a concentration dependent manner which was partially reversed by the NO donor SNAP (1 mm). L-NNA (10 μM) blocked the response and this effect was stereospecific because D-NNA (10 μM) showed no inhibition. Additionally, the cyclic GMP response was inhibited by 65% by 10 μM L-NNA and a similar substance mediated, in an extracellular fashion, the cyclic GMP response to sympathetic activity in the rat SCG.
422.7 TRANSCRIPTION OF THE BRAIN NITRIC OXIDE SYNTHASE GENE IN NEURAL CELL CULTURES. D. Ming-Golomb & J.P. Schwartz*. Clinical Neuroscience Br., NINDS, NIH, Bethesda, MD 20892.

Nitric oxide synthase (NOS) generates the second messenger nitric oxide from arginine. The brain NO system, in cerebellar and accessory olfactory bulb, now present data on the expression of the NOS enzyme in cerebellar granule neurons prepared from postnatal day 8 rat pups, after 10 days in culture. Using specific oligonucleotide primers, we obtained reverse transcription of GCC RNA followed by polymerase chain reaction (RT-PCR) produced a 366 bp fragment, the expected size. Identity was confirmed by hybridization of a blot containing the electrophoresed product with a full-length cDNA probe for NOS, followed by high stringency washes (0.1XSSC-65°), which showed a positive signal for the same 366bp band. NOS activity was also detected in GCCs, by measuring conversion of arginine to citrulline, thus showing that GCCs express the brain NOS.

Preliminary results suggest that type 1 astrocytes are the predominant source of NOS mRNA and activity. These culture systems are being used to assess the modulation of NOS in cerebellar neural cells both in physiological and neurotoxic conditions.

422.8 CARBON MONOXIDE AS A PHYSIOLOGICAL MESSENGER INDICATED BY HEME OXYGENASE LOCALIZATIONS AND CYCLIC GMP REGULATION. David J. Hirst*, A. Verma, C. Olt, G. Bennett and S.I. Snyder. Dept. of Neuroscience, Johns Hopkins School of Medicine, Baltimore, MD 21205.

Abundant evidence indicates that nitric oxide(NO) is a major physiological molecule, accounting for endothelial derived relaxing factor(EDRF) of blood vessels, the tumorid and bacterial action of NO as an antibiotic, and its possible role as a neurotransmitter in the central and peripheral nervous system. The notion that a normally noxious gas such as NO might serve as a physiological messenger is further supported by the observation that NO mediates cell responses similar to those on other gas molecules (NO, CO). This is the first known biological role of CO(NO) as a physiological messenger. Carbon monoxide(CO) is endogenously generated by the enzyme heme oxygenase. Heme oxygenase was studied in concordant with cycloheximide P450 reductase, catalyzes the conversion of heme into biliverdin with the concomitant release of CO. We thought that this CO could function in an analogous manner to NO. The brain has been previously reported to have high levels of HO. We localized the constitutive form of this enzyme, in situ hybridization. Highest densities of HO mRNA are evident in the olfactory neurons of the olfactory epithelium as well as the olfactory neuronal layer of the olfactory bulb along with the granule cells in the bulb. We also observed discrete localizations in the cerebellum, hippocampus, pontine nucleus, olfactory bulb, and tuberence. It is probable that the physiological role of CO we utilized a primary culture of olfactory neurons which expressed HO at high levels as revealed by the in situ hybridization. These neurons have very high levels of CO receptor binding. CO receptor binding is specific for CO, which is not present in the cultures. These findings suggest that CO might be a messenger molecule similar to NO.

Striatal neurons express high adenylyl cyclase activity and large amounts of a stimulatory G protein, but very low levels of G protein mRNA. We have previously presented evidence suggesting that the novel stimulatory G protein Golf is expressed in the basal ganglia. In support of this hypothesis, we have now used synthetic oligonucleotides, derived from the published Golf cDNA sequence, to identify and characterize four independent Golf cDNAs from a rat brain cDNA library. These code for a protein of 381 amino acids with a predicted molecular mass of 44.3 KD, whose sequence is identical to the Golf sequence originally derived from a rat striatal epithelial library, except for one conservative amino acid substitution. Thus Golf is expressed in rat brain. To determine the cellular localization of Golf in the brain in situ hybridization and immunohistochemistry were performed. Golf mRNA was expressed in neurons in the striatum, nucleus accumbens and olfactory tubercle. For the immunohistochemical localization of Golf, rabbits were immunized with a synthetic peptide corresponding to amino acids 73-87 of Golf, conjugated to KLH. A rabbit polyclonal antibody that upon affinity-purification, specifically labelled a striatal protein of about 46 KD in Western blots. In immunohistochemical studies, this antibody selectively stained many neurons within the striatum, nucleus accumbens and olfactory tubercle. In addition, a stained fiber was seen leaving the striatum, and forming terminal networks in the globus pallidus, entopeduncular nucleus and substantia nigra pars reticulata. In conclusion, striatal projection neurons express a novel stimulatory G protein, Golf, which may couple the G proteins to adenyl cyclase.

422.10 CHARACTERIZATION OF THE HIGH-AFFINITY FORSKOLIN BINDING SITE IN THE RAT STRIATUM. S.R. Vincent* & B. Phillips. Kinsman Laboratory of Neurological Sciences, Department of Psychiatry, The University of British Columbia, Vancouver, B.C., Canada, V6T 1W5.

The diester forskolin is a potent activator of adenylyl cyclase. We have characterized the high-affinity binding site for [3H]forskolin in the rat striatum using quantitative autoradiography. Saturation analysis revealed a single high-affinity binding site with a Kd of 26 nM and a Bmax of 694 fmol/mg tissue. Lesion studies indicate that these binding sites are largely present on striatal neurons, including the striato-nigral, medium-spiny, projection neurons which contain D1 dopamine receptors. The abilities of various forskolin analogues to displace high-affinity [3H]forskolin binding correlated well with their effectiveness in activating adenylyl cyclase. The density and affinity of the striatal binding sites were decreased if [3H]forskolin was absent from the incubation medium. This is consistent with the hypothesis that binding of forskolin to the adenylyl cyclase involves an interaction with a stimulatory G protein. However, pretreatment of rats with SCH-23390, which blocks D1 dopamine receptors, and should therefore largely reduce the endogenously blocked stimulatory G proteins in striatal neurons, had no effect on forskolin binding. Similarly, pretreatment with the atypical neuroleptic clozapine, a potent inhibitor of dopamine-stimulated adenylyl cyclase, was without effect on high-affinity forskolin binding in the striatum. These data suggest that endogenous D1 receptor activation does not account for the very high levels of forskolin binding present in the striatum.

422.11 P2X, PURINOCCEPTOR-MEDIATED PHOSPHOSCHONITRIDE TURNOVER, Ca2+ INFLUX AND HOMOLOGOUS DESENSITIZATION IN C6-GliaLMA. W.M. Lee, D. Ko, G.P. Lai, H. Huang, H.R. Chen & S.K. Lee. Inst. of Cell and Developmental Biology, National Taiwan Univ. Taipei, Taiwan and 1 Biological Psychiatry Branch, NIMH, MD 20892.

In response to ATP, C6-glioma cells accumulated inositol phosphates and elevated [Ca2+]i dose-dependently with an EC50 of 60 nM and 10 nM, respectively, for stimulation of phosphoinositide (PI) turnover. The order of potency of adenine nucleotides was ATP>>ADP>>AMP, adenosine, adenosine, a, b-ATP, a, b-ATP, adenosine, amp, a, b-ATP, ATP-stimulated PI metabolism was found to be partially dependent on [Na+]o and [Ca2+]i, but resistant to tetrodotoxin, amiloride, ouabain and inorganic Ca2+ blockers. In Ca2+-free medium, ATP caused only a transient increase in [Ca2+]i as O observed to a sustained [Ca2+]i increase in normal medium. The ATP-induced elevation of [Ca2+]i was resistant to Na+ depletion, verapamil and nifedipine, but was attenuated by La3+. The ATP-induced PI hydrolysis showed homologous desensitization following agonist preincubation and was unaffected by PEC inhibitors (stauroporine, H-7 and depletion of PEC activity. On the contrary, the inhibition caused by BIM or octilindolactone was inhibited by staurosporine, H-7 and polyoxyl 8. Our results suggest that P2X purinoceptors are coupled to PEC turnover and Ca2+ influx in C6-gliaLMA and its desensitization does not involve PEC activation.

422.12 FACTORS INFLUENCING THE EFFECT OF CALRETININ ON PHOSPHORYLATION OF A 39 kDA MITOCHONDRIAL PROTEIN FROM RAT BRAIN. L. Mahaffey & M. Jacobowitz. Lab. of Clin. Sci., NIMH, Bethesda, MD 20892.

The calcium binding protein calretinin (CR, 100 to 1000 nM) produced a significant reduction in the phosphorylation of a 39 kDa band in mitochondrial membranes. This 39 kDa band was maximally phosphorylated within 15 min while the inhibition of calretinin was most apparent after 2 min. Both the phosphorylation of the 39 kDa protein and inhibition by calretinin were pH dependent. The 39 kDa band was phosphorylated in the presence of 5 mM EDTA and a stimulation was observed in the presence of Mg2+ (4.5 or 10 mM) or 4.5 mM Mn2+, Ni2+, Ca2+ or Co2+. The inhibitory effect of calretinin was increased in the presence of Mg2+, Ca2+ and Ni2+ and was attenuated by 5 mM EDTA. Zn2+ (4.5 mM) inhibited both the phosphorylation of the 39 kDa band and the inhibition of phosphorylation protein. Calretinin also produced a slight inhibition in the phosphorylation of a 42 kDa band in the presence of 4.5 mM Ni2+, Co2+ or Ca2+. This band was tentatively identified as the alpha subunit of pyruvate dehydrogenase based on immunoblot and comigration with purified phospho-enzyme. These results suggest a possible functional role of calretinin in modifying mitochondrial enzyme activity through effects on protein phosphorylation.
422.15  
PURIFICATION AND CHARACTERIZATION OF BOVINE FOREBRAIN CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II M. Tau *  
R. Borviet, J.C. Wyman, Department of Neurobiology & Anatomy, University of Texas Southwestern Medical School, Dallas, TX 75390  
Calcium/calmodulin-dependent protein kinase II (Ca2+/CaM kinase), is an abundant brain protein proposed to mediate Ca2+/CaM-regulated signal transduction in neuronal tissue. The enzyme purified from rat brain is reported to exist as two isoforms (M, 550,000 & 615,000) that vary in their relative ratio of three subunits, M, 50,000, 58,000, and 60,000.  
In this study we have purified Ca2+/CaM kinase from bovine forebrain. The tissue was frozen in liquid N2 within 5 min of the animals death. The purification revealed two isoforms with apparent Ca2+/CaM protein properties based on the phosphorylation of known Ca2+/CaM substrate peptide (MBP/DTT). The two isoforms have similar purification characteristics, subunit composition, and physical properties. Native gradient-gel electrophoresis provided an estimated M, 500,000 for the major isoform. The autophosphorylated subunits of the major kinase have apparent M, 72,000 and 39,000 while those of the minor kinase are M, 72,000 and 53,000. Both bovine kinases bind calcium with high affinity and have mononuclear ant-ri-Ca2+/CaM kinase Ig-like domain. The major kinase exerts preferential cross-effects with monoclonal anti-Ca2+/CaM kinase IgG in a spot blot assay while the minor kinase does not cross-react at all. Western blotting technique using polyclonal anti-rat Ca2+/CaM kinase IgG shows that a M, 72,000 subunit of bovine kinase cross-reacts with the antibody. These results suggest that although the two isoforms of bovine kinases are similar to rat Ca2+/CaM kinase, there are several important differences between the rat and bovine enzymes. Supported by USDA NS 11061.

422.17  
The sigma receptor has been well characterized in terms of ligands that bind to it, but in function it may be related to the regulation of neurotransmitters. The sensitivity of the sigma receptor to 1) identify its presence in neuronal tissue and 2) test its potential role in the arachidonic acid (AA) cascade in these cells.  
Cerebella of eight-day-old neonatal rats were dissected and chopped into pieces. Cells were mechanically and enzymatically dissociated, subjected to differential centrifugation, resuspended, and plated on poly-D-lysine coated dishes. Cultures were tested with 10 μM, sodium arachidonate to inhibit growth of non-neuronal cells. Cells were allowed to develop for at least eight days in culture (DCE) before use in any assay.  
Sigma receptors were identified by the specific binding of 2 nM [3H]haloperidol in the presence of spiperone to inhibit labeling of dopamine receptors. The sensitivity of binding to 1) identify its presence in neuronal tissue and 2) test its potential role in the arachidonic acid (AA) cascade in these cells.  
Cells were harvested with Trizma buffer containing 1 μM (3H)arachidonic acid (3H)AA overnight, then washed to remove residual, unaccumulated labeled eicosanoid. The release of [3H]AA was stimulated by 50 nM NMDA, resulting in the release approximately 0.5% of total accumulated [3H]AA. About 30% of stimulated release could be inhibited by 10 μM (+)-pentazocine. Collectively, these findings provide the first evidence that sigma receptors reside on cerebellar granule cells, and that they may be involved in the regulation of the release of arachidonic acid in these cells. This is the first direct association of sigma receptors with this metabolic second messenger system.

422.18  
ARACHIDONIC ACID METABOLISM MAY INVOLVE VOLTAGE-SENSITIVE COMPONENTS IN ACUTELY DISSOCIATED EMBRYONIC CHICK SPINAL CORD CELLS. K.S. Middaugh, A. Prato, S.V. Smith and G.D. Langle, Laboratory of Neurophysiology and Instrumentation and Computer Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD 20892  
Prostaglandin E2 and most other types of eicosanoids are metabolites of arachidonic acid (AA) formed by cyclooxygenase (COX) and the lipoxygenase (LOX) pathway. Eicosanoids are produced by cells in response to various stimuli. The effects of several of these inhibitors on the steady-state membrane potential of individual chick cells using two different electrophysiological approaches. Flow cytometry coupled with a voltage-sensitive oxonol dye monitored the effects of bath applications on populations of cells in suspension. Conventional whole cell patch techniques for intracellular voltage recordings measured the effects of superfusing single plates of cells that were not stained with the oxonol dye. We found that four molecular different agents, indomethacin, ibuprofen, 15-15a-prostaglandin J2 (a-15-15a-cycloxygenase inhibitor), BW-535C and NDGA (nordihydroguaiaretic acid) decreased the intensity of oxonol signal and hyperpolarized cells at concentrations known to block cyclooxygenase activity. Subsequent exposure to PGE1 did not reverse these effects unless preparations were first depolarized by elevating extracellular potassium ion concentration. Then the PGE1 increased the hyperpolarization elicited by the drugs. These findings support the possibility that PGE1 acts through an intracellular mechanism which is normally prevented by extracellular calcium and/or influx. These gradients would also promote its net efflux after de novo syntheses.

We have shown previously that, in membranes prepared from female rat hypothalamus and preoptic area, estrogen desensitizes \( \beta \)-adrenergic receptor stimulation of adenylate cyclase without modifying G protein stimulation of the enzyme. In the present study, we examined whether estrogen modulates receptor function through changes in either receptor density or binding affinity. We examined receptor binding affinity and density using the high specific activity \( ^{3} \)\(^{2} \)iodocyanopindolol (\( ^{3} \)\(^{2} \)ICYP) in membranes prepared from combined hypothalamus-preoptic area of ovariectomized (OVX) and OVX, estrogen-primed rats. OVX rats received oil vehicle or 2 \( \mu \)g of estradiol benzoate 48 and 24 h prior to sacrifice. Specific binding of \( ^{3} \)\(^{2} \)ICYP in hypothalamus-preoptic area membranes was not different from controls. Experimentation carried out in cortical membranes also showed no noticeable difference in affinity of estrogen on antagonist binding affinity or receptor density. These data suggest that estrogen-dependent uncoupling of \( \beta \)-adrenergic receptor from adenylate cyclase is not contingent on hormonal modulation of receptor density or antagonist binding affinity. Agonist affinity studies are currently underway to determine if estrogen regulates the coupling of \( \beta \)-adrenergic receptors to adenylate cyclase by modulation of agonist binding.

The aminosteroid, U-73122 (1-(6-[[17b-3-methoxyestr-1,3(10)-trien-17-y]amino]ethyl]-1-hydroxy-2,5-dione) reportedly inhibits muscarinic receptor sequestration and polyphosphoinositide (PPI) hydrolysis in SK-N-SH cells. Like CGMP, the muscarinic receptor, the neurotensin receptor couples to cyclic guanosine 3',5'-monophosphate (cGMP) synthesis and PPI hydrolysis. For this study, we examined the effects of U-73122 on neurotensin or muscarinic receptor mediated CGMP formation and PPI hydrolysis in murine neuroblastoma clone NIE-115. Both CGMP formation and PPI hydrolysis stimulated with 10 nM neurotensin or 1 mM carbachol (a muscarinic receptor agonist) were inhibited dose dependently after incubation with U-73122 (dissolved in DMSO, 1% final) at 37°C for 15 min. Maximum inhibition occurred with 10 \( \mu \)M U-73122. We showed before that 10 \( \mu \)M U-73122 inhibits neurotensin receptor down-regulation in NIE-115 cells. Molecular mechanisms underlying these phenomena are unknown. However, our results suggest that U-73122 inhibits the down-regulation, CGMP formation, and PPI hydrolysis in many other receptors that couple with these responses (Supported by Mayo Foundation and USPHS grant MH27692).

The sympathoadrenal system is characterized by the expression of neuropeptides (CA) and several neurotransmitters. Electrical activity, elicited by the presynaptic fibers, influences the survival, maintenance and phenoic expression of the sympathetic neurons. We are using acute adrenal gland and sympathetic neural cultures from 11 day chick embryos to study the effect of depolarization on CA and neuropeptide expression (enkephalins, neuropeptide Y (NPY) and somatostatin (SS) expression). Histoneological studies show, that, as occurs in vivo, CA, ENK, NPY, and SS-like immunoreactivity is expressed by sympathoadrenal neurons. Radioimmunoassay for ENK and NPY show that their expression is enhanced in both cell cultures upon depolarization by 30 mM K+ or veratridine (10 mM). SS levels, on the contrary, are lowered or do not change. These changes may be mimicked by the Bay K 8644 (1 \( \mu \)M) but not by the adenylate cyclase activator forskolin (10 \( \mu \)M), suggesting the involvement of Ca?. However, no change is observed in somatostatin levels in sympathetic neuronal cultures. Our results show that electrical activity modulates the expression of neuropeptides and CA in the avian sympathoadrenal system and that the alteration of a specific effect might occur in vivo.

Calcitonin gene-related peptide (CGRP) is produced by the alternative preprocursors of the calcitonin/CGRP gene primary transcript. CGRP is a potent vasodilatory neuropeptide and has been implicated in regulation of cardiovascular function. Neuropeptide expression in dorsal root ganglia (DRG) neurons has been shown to be modified by centrally administered CGRP or CGRP-like agonists. We have therefore begun to use primary cultures of dorsal root ganglia (DRG) neurons to identify the factors that modulate CGRP mRNA levels. We find that this is the site of neuronal cell bodies known to produce abundant CGRP levels and to send axons peripherally to peripheral tissue and centrally to spinal cord. It has been previously documented that isolated DRG neurons produce CGRP and that many of both mRNA and protein are positively regulated by NGF. Using Northern blot analysis and immunocytochemical staining we have confirmed that DRG neurons contain CGRP expressing cells. Preliminary results indicate that treatment (20h) of isolated neurons with either forskolin (10\( \mu \)M) or phorbol 12-myristate 13-acetate (PMA; 20\( \mu \)M) in absence of NGF also increase CGRP mRNA levels. These results suggest that regulatory agents which act through protein kinase A and protein kinase C signal transduction pathways may modulate neural CGRP expression.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
422.26 G PROTEIN INVOLVEMENT IN COCAINE SENSITIZATION. C.D. Striplin and P.W. Kalivas, Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Behavioral sensitization is associated with a significant increase in dopamine neurotransmission in the nucleus accumbens (NA). While the neurochemical initiation of behavioral sensitization is thought to occur in the ventral tegmental area (VTA), a role for G proteins has been hypothesized since daily cocaine (30 mg/kg X 10 days) has been shown to decrease the levels of Gi and Go proteins. Also five daily injections of 15 or 30 mg/kg cocaine was shown to decrease the level of V12 pertussis toxin ribosylation 1-2 hours after the last injection and a significant correlation has been found between the level of behavioral sensitization observed at 15 mg/kg and pertussis toxin ribosylation in the VTA. To determine if the Gi protein changes were translated into lasting, rats were sensitized to cocaine for 5 days and then given a final challenge of cocaine 14 days later. Rats were killed 1 hour after the final injection and G proteins were analyzed in the VTA, NA, substantia nigra, striatum and prefrontal cortex by Western blot analysis. The levels of Go, Gi, and Gs did not show any significant change in any of the brain areas tested. However, a significant decrease in GiI levels was observed in the NA in chronic cocaine treated animals given an acute cocaine challenge (85.5%) and chronic cocaine treated animals given an acute saline challenge (89.2%). These data indicate that G proteins in the VTA may play a role in the initiation of sensitization while long-term sensitization is associated with G protein changes in the NA.

423.1 REVERSIBLE DEPLETIONS OF 5-HYDROXYTRYPTAMINE IN THE NEO- 

5-hydroxytryptamine (5-HT) systems subserve both neuro-a-
transmitter and neurotrophic functions in the rat. Recent
data showed that 5-HT can regulate the density of gluco-
corticoid receptors (GCR) in fetal hippocampal cell
cultures. Elevated GCR levels are associated with
enhanced negative-feedback control of the hypothalamic-
–pituitary–adrenal axis (HPA). We have examined the effects of
perinatal 5-HT depletions on stress responses of the adult
rat in order to assess the trophic action of 5-HT on HPA function.

Neonatal rats were injected with PCPA or vehicle (VEH)
on alternate days, up to day 8. Plasma corticosterone (B) was measured in response to 20 min restraint stress in
adulthood.

Although basal levels of B were the same for both
groups, PCPA-treated rats hypersecreted B upon termination
of stress and at 20 + 60 min post-stress. By 120 min post-
stress both groups had returned to basal levels.

These results indicate that 5-HT is required for HPA function, presumably by some trophic action. We are
currently investigating the specific brain locations and
nature of this regulation.

423.2 CHANGES IN PLASMA ACTH, CORTICOSTERONE, CBG, AND HIPPOCAMPAL GLUCOCORTICOID RECEPTOR OCCUPANCY IN RAT PUPS FOLLOWING MATERNL SEPARATION AND/OR EITHER STRESS Shakti Sharma*, Y. Vyas, S. LaRocco and M.J. Mosey, Douglas Hos, Res. Ctr., Depts. of Psychiatry, and Neurology and Neurosurgery, McGill Univ, Montreal, Canada H4H 1R3.

Plasma ACTH and corticosterone (B) responses to stress are often reduced in the neonatal rat. However, plasma corticosteroid-binding globulin (CBG) levels of the neonate are substantially decreased, which might obscure the biological significance of existing glucocorticoid levels. We examined this question by estimating hippocampal glucocorticoid receptor (GR) occupancy in Day 6, Day 15, and adult animals under basal and stressed conditions. The results showed that: 1) Plasma ACTH levels were elevated in Day 6 animals in response to acute stress and maternal separation, and maternal separation + ether, however, ACTH responses were substantially lower than in Day 15 or adult animals. 2) Plasma total B levels followed a similar pattern, most noteworthy was the potent glucocorticoid response in Day 15 animals to the combination of maternal separation + ether. 3) Plasma CBG levels in Day 6 animals were extremely low (<3% adult values) by Day 15 CBG levels were about 25% of adult levels. Interestingly, maternal separation was associated with a substantial decrease in plasma CBG levels. 4) Hippocampal GR occupancy was similar at all ages under both basal and stress conditions. The only notable exception occurred during maternal separation in Day 15 animals, where hippocampal GR occupancy was higher than that observed at any time in any other group tested. The results are likely related to the decrease in plasma CBG that occurs following separation of Day 15 pups from the dam. Thus, despite the differences in plasma CBG levels, GR occupancy was generally comparable across all ages either under basal conditions, or following stress. These receptor data underscore the importance of developmental changes in plasma CBG levels.
423.3 DEVELOPMENTAL MANIPULATIONS DIFFERENTIALLY AFFECT HPA AXIS OF MALE AND FEMALE RATS. C. M. McCormick*, J. W. Smythe, S. Sharma, & M. J. Meaney, McGill University, Dept. of Psychiatry, Douglas Hospital Research Center, Montreal, CANADA H4H 1R3.

Hypothalamic-pituitary-adrenal (HPA) function was investigated in adult animals in relation to both prenatal stress (PS: 20 min restraint of mothers on days 15-19 post-conception) and neonatal handling (H: separation from mothers for 15 min daily during first 10 days of life). Blood samples were drawn from catheters prior, during, and following 20 min restraint. PS females showed elevated levels of ACTH and corticosterone (B) during and following stress compared to NS females. No marked differences in B, ACTH, or corticosterone binding globulin (CBG) were observed between PS and NS males. Despite similar basal levels of B, PS females showed elevated levels of CBG compared to NS females, which may account for their increased HPA response to stress. PS was associated with increased glucocorticoid receptor (GR) levels in the frontal cortex (FC) in females, decreased levels in FC of males, and increased levels in septum (3Pt) of males. PS was not associated with GR levels in hippocampus (HPc), hypothalamus (HYPO), and amygdala (AMG). In contrast, neonatal handling (H) was associated with a reduced HPA response to stress in both males and females. H animals showed increased levels of GR in HPC (both sexes) and FC (males only), and decreased GR levels in 3Pt (males only) compared to non-H animals. H was not associated with GR levels in HYPO or AMG. Across experimental groups, when sex differences were observed, they were in the direction of higher GR levels in females than in males.

The results reflect sex differences in the effects of early environmental events on (1) HPA response to stress, and (2) GR levels in brain regions implicated in HPA regulation, and (3) plasma levels of CBG.

423.5 PLASMA CORTICOSTEROIRE IS SIGNIFICANTLY INCREASED BY COLD STRESS IN THREE-DAY-OLD NEONATAL RATS. S. J. Yi-L. Schutz, T. Z. Haram, Div. of Neurology, Children's Hospital Los Angeles, Los Angeles, CA 90027.

The hypothalamic-pituitary-adrenal axis underlies the hormonal stress response. The responsiveness of the neonatal hypothalamic-pituitary-adrenal axis to stress has been thought to be impaired ("stress hyporesponsive period"). We studied the response of neonatal rats to cold stress by measuring plasma corticosterone levels.

Rats aged 3 to 17 days were placed in compartmentalized plastic cages in a cold room (4°C) for 20 to 60 min. Trunk blood was collected 5 min., 20 min, 1 h, 4 hours and 23 hours after the onset of cold stress for plasma corticosterone measurement by RIA. Littermate control rats were kept under "stress-free" conditions.

Animals exposed to cold stress showed a marked increase in plasma corticosterone starting on the third postnatal day, compared to non-stressed controls. We are currently studying the response of plasma ACTH and CRH mRNA abundance in the paraventricular nucleus to cold stress during the first postnatal week.
PLASTICITY OF $\beta$-ADRENERGIC RECEPTORS ON SPLENCYCOTES FROM YOUNG AND OLD RATS FOLLOWING CHRONIC SYMPATHETICOMYSIS. S.M. Bremner, D.L. Bellinger, K.S. Maddox, A. Toty, J. Housel, S.F. Felten and D.L. Felten. Department of Neurology, University of North Carolina School of Medicine, Chapel Hill, NC 27599.

$\beta$-adrenergic (BAR) density on spleenocytes was examined in 3- and 21-month-old (M) F344 rats between 1 and 5 days (D) after chemical sympathectomy (SymXp) with 6-hydroxydopamine. In spleenocytes from 3-M SymXp rats, $\beta$-adrenergic receptor density was not significantly different from nontreated or vehicle-treated controls at D1-3 post-treatment, but progressively increased through D10, and then declined from D10 through D56. BAR density at D56 was significantly higher compared with both controls, respectively. Vehicle-treated 3- and 21-M animals possessed a slightly higher density of BAR on spleenocytes than did nontreated age-matched controls. Spleenocytes from 21-M SymXp rats, a progressive decline in BAR density was observed between D1 and D3, followed by a progressive rise in BAR density through D56. At D56 the density of BAR on spleenocytes from 21-M rats was not significantly different from vehicle-treated controls. These findings indicate that regulation of BAR density on spleenocytes following acute denervation is impaired with age; upregulation of BAR in response to denervation was not observed, only a slow progressive increase in the receptor density that closely parallels the reinervation of the spleen in 21-M rats. The initial decline in BAR following SymXp was followed by a slow decline in the ability to metabolize norepinephrine released from damaged sympathetic nerves. Supported by 1 R29 MH47783, R37 MH42076, and Markley Foundation Center. Award.

PLASTICITY OF NORADENERGIC NERVES IN SPLEENS FROM AGED F344 RATS FOLLOWING CHEMICAL SYMPATHETOMY. K.S. Maddox, D.L. Bellinger, A. Toty, J. Housel, N.L. Costello, C. Richardson, S.F. Felten, and D.L. Felten. Department of Neurology and Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

The time course and pattern of noradrenergic (NA) nerve ingrowth into the spleen following sciotic sympathectomy with 6-hydroxydopamine (6-OHDA) was examined in 3- and 21-month (M)-old male F344 rats using glycinic acid fluorescence histochemistry and biochemical measurement of norepinephrine (NE). NE and 6-OHDA from 3-M-old rats were localized preferentially along the splenic artery and entered the hilum (1-5 days, D1-5), extended into the hilus region (D5-D10), and then proceeded into regions distal from the hilus (D10-D56), suggesting orderly ingrowth from the hilum to distal regions. NA nerves innervated the same compartments seen in vehicle controls, but nerve fiber density in these compartments differed based on distance from the hilum and time after denervation. By D56 post-lesion, regions distal from the hilum had fewer NA nerves than vehicle controls, suggesting that reinnervation does not restore nerve density identical to that of vehicle controls. In contrast, spleen NE concentration at D56 post-lesion returned to vehicle control values, suggesting that functional reinnervation of NA nerves in the spleen may involve metabolic and receptor compensation for the lack of complete fiber reingrowth into regions of white pulp distal from the hilum. NA nerves from 21-M-old rats were involved in a different ingrowth pattern into the spleen following denervation; however, the initial ingrowth was delayed until D15 after the last dose, ingrowth occurred over a slower time course, and the density of NA nerves returning to the splenic pulp was reduced at D56 compared with all other young and old treatment groups. Spleen NE levels at D56 post-lesion also were significantly lower than in 21-M-old vehicle controls, suggesting that plasticity of NA innervation is compromised with age. Supported by 1 R29 MH47783, R37 MH42076, and Markley Foundation Center. Award.

PAVLOVIAN CONDITIONING OF MORPHINE-INDUCED IMMUNE ALTERATIONS: EVIDENCE FOR OPIOID RECEPTOR INVOLVEMENT. Mary E. Cournoyer*, Linda A. Dykstra, and Donald T. Lysle. Departments of Psychology and Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3270.

Our prior work has shown that morphine’s immunomodulatory effects can become conditioned to environmental stimuli that predict drug administration. These alterations include conditioned changes in natural killer cell activity, interleukin-2 production, and mitogen-stimulated lymphocyte proliferation. The present studies were aimed at determining the involvement of opioid receptor activity in the establishment and expression of morphine-induced conditioned immune alterations. During the training phase, Lewis rats received two conditioning treatments each including a subcutaneous injection of 15 mg/kg morphine sulfate was paired with exposure to a distinctive object. On the test day, animals were reexposed to the distinctive object alone prior to sacrifice. Saline or naloxone (3, 10, 30, 100, 400 mg/kg) was administered either prior to training or to test. Administration of naloxone prior to training resulted in attenuation of the conditioned immune alterations, whereas naloxone administration prior to testing had no effect. Taken together, these studies show that opioid receptor activity is involved in the establishment, but not the expression, of conditioned morphine-induced immune alterations. (Supported by PHS grants DA00749, DA07244 and MH46284.)

PRESENCE AND AVAILABILITY OF VIP IN PRIMARY AND SECONDARY LYMPHOID ORGANS. D.L. Bellinger, D.J. Eantwort, M. Gallagher, and D.L. Felten. Department of Neurobiology & Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

A large body of pharmacological and immunological data indicate that vasoactive intestinal peptide (VIP) acts as a neurotransmitter with cells of the immune system as targets. VIP receptor (VIPR) mRNA is present in human T and B lymphocytes. In functional studies, VIP inhibits mitogen-induced proliferation of lymphocytes from human T cell lines and human peripheral B lymphocytes. Although VIP receptors in T lymphocytes mediate their mitogenic activity, VIP receptors in B lymphocytes mediate their proliferative activity. The initial rise in BAR density suggests an upregulation of receptors in response to denervation of the spleen. The subsequent progressive decline closely parallels the time course of appearance of BAR on nerve fibers in the spleen. BAR density on spleenocytes from nontreated and vehicle-treated 21-M rats was not significantly higher with that seen in 3-M rats (approximately 90-900 and 475-525, respectively). Vehicle-treated 3- and 21-M animals possessed a slightly higher density of BAR on spleenocytes than did nontreated age-matched controls. Spleenocytes from 21-M SymXp rats, a progressive decline in BAR density was observed between D1 and D3, followed by a progressive rise in BAR density through D56. At D56 the density of BAR on spleenocytes from 21-M rats was not significantly different from vehicle-treated controls. These findings indicate that regulation of BAR density on spleenocytes following acute denervation is impaired with age; upregulation of BAR in response to denervation was not observed, only a slow progressive increase in the receptor density that closely parallels the reinervation of the spleen in 21-M rats. The initial decline in BAR following SymXp was followed by a slow decline in the ability to metabolize norepinephrine released from damaged sympathetic nerves. Supported by 1 R29 MH47783, R37 MH42076, and Markley Foundation Center. Award.

MORPHINE-INDUCED ALTERATIONS OF IMMUNE STATUS: EVIDENCE FOR $\beta$-ADRENERGIC RECEPTOR INVOLVEMENT. Karamarie Fecho,* Donald T. Lysle and Linda A. Dykstra. Department of Psychology & Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

There is evidence suggesting that morphine’s immunomodulatory effects are mediated through the central nervous system. For example, the systemic administration of morphine, but not N-methylmorphine, has been found to produce a naloxone-reversable suppression of splenic NK cell activity. However, little is known about how the activation of opiate receptors by morphine translates into peripheral immune alterations. The purpose of the present experiments was to investigate at the level of the $\beta$-adrenergic system as one possible mediator of morphine’s effects. Prior to a subcutaneous (s.c.) injection of either 15 mg/kg morphine or saline, male Lewis rats (N = 180) were administered either the nonspecific $\beta$-adrenergic receptor antagonist nadolol, the selective $\beta$-adrenergic receptor antagonist atenolol or the selective $\beta$-adrenergic receptor antagonist ICI-118,551 in doses of 0, 0.125, 0.5, 2.0 or 8.0 mg/kg, s.c. All three antagonists dose-dependently attenuated the suppressive effects of morphine on the proliferative responses of splenic lymphocytes to Con-A, PHA, LPS and Iono/PMA. In contrast, none of the antagonists exhibited any effect on the morphine-induced suppression of the proliferative responses of blood lymphocytes to Con-A or PHA; likewise, there was no antagonism of the suppression of splenic NK cell activity produced by morphine. Although the immunosuppressive effects of morphine appear to involve multiple mechanisms, this data clearly implicate the involvement of morphine’s effects.

MODULATION OF ANTIBODY PRODUCTION AND ANTIGEN-INDUCED PROLIFERATION BY A CONDITIONED AVERSIVE STIMULUS. Elizabeth H. Bennett, Lynn Perez, Maureen E. Bronson* and Donald T. Lysle. Department of Psychology & Curriculum in Neurobiology, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina 27599.

Our research program is designed to characterize the immunomodulatory effect of a conditioned aversive stimulus (CS) in rats. The present study examined the effect of presentation of the CS on the proliferative response of lymphocytes to the T-dependent antigen, keyhole limpet hemocyanin (KLH) and the production of specific antibody to KLH. The results showed that presentations of the CS on days 0, 2, and 4 following immunization had no effect on the proliferative response to KLH or the production of KLH-specific antibody. Furthermore, presentation of the CS on days 0 and 2 had no significant effect on antibody production. In contrast, presentations of CS on days 10, 12, and 14 following immunization induced a significant suppression of the KLH-induced proliferative response of lymph node lymphocytes, but not splenic lymphocytes, and a reduction in serum antibody levels to KLH. These findings indicate that a conditioned aversive stimulus can modulate the immune system, and the effect is dependent upon the temporal relationship between antigen administration and presentation of the CS. CHARACTERIZATION OF OPIOID RECEPTOR INVOLVEMENT IN PAVLOVIAN CONDITIONED IMMUNE ALTERATIONS. Lynn Perry and Donald T. Lysle*. Department of Psychology & Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

Previous work from our laboratory has shown that naltrindone can antagonize alterations in immune status induced by presentation of a Pavlovian conditioned stimulus (CS). The present studies were designed to further this investigation by determining the specific opioid receptor subtype involved in conditioned immune alterations. 8-1 naltrindone (8-FNA), a highly selective a opioid-receptor antagonist, was administered (0, 5.0, and 25.0 mg/kg, i.p.) 24 hours prior to the CS. Alterations of immune status were determined by in-vitro assessment of natural killer cell (NK) activity, lymphocyte proliferation induced by Con-A, PHA, LPS, and ionomycin/PMA, and production of interleukin-2 (IL-2). 8-FNA antagonized the CS-induced suppression of NK activity, but did not attenuate the suppression of lymphocyte proliferation or IL-2 production. In a subsequent study, naltrindone, a selective 6 opioid-receptor antagonist, was administered (0, 0.1, 1.0, 10.0, and 30.0 mg/kg, i.c.) prior to exposure to the CS. The results showed that naltrindone had no effect on the CS-induced alteration of immune status. To further characterize opioid receptor involvement in conditioned immune alterations, additional studies will investigate the role of kappa opioid receptors using non-biarylpropionamides, a k-selective antagonist. Collectively, the results of these studies provide an extensive analysis of the involvement of opioid receptor subtypes in conditioned immune alterations. (Supported by MH46284.)

Administration of adrenal steroids is classically associated with increases in neutrophils and decreases in lymphocytes and monocytes in the peripheral blood. Although immune cells possess two types of adrenal steroid receptors, type I (mineralocorticoid) and type II (glucocorticoid), it is unknown which receptor subtype is involved in the adrenal steroid effects. To examine this issue, male rats were treated with selective receptor agonists for 7 days via osmotic minipumps and the number and percentage of immune cells in the peripheral blood was determined. For each receptor agonist (aldosterone for the type I receptor, RU28362 for the type II receptor), five groups of rats (300g) were studied: no hormone treated controls (ADX); 7-day ADX; 7-day ADX+1mg/kg; 7-day ADX+4mg/kg and 7-day ADX+10mg/kg. Whereas ADX alone had no effect on the total white blood cell (WBC) count, both aldosterone and RU28362 resulted in a significantly decreased WBC count whereas aldosterone decreased the number of neutrophils, lymphocytes, and monocytes; RU28362 decreased lymphocytes and monocytes but was associated with a significant increase in neutrophils. As for lymphocyte subtypes, RU28362 had the greatest inhibitory effect on T helper cells and B cells, while aldosterone was associated primarily with decreases in T cells and NK cells. These results suggest that the two adrenal steroid receptor agonists have different effects on peripheral blood immune cells in the rat. Since selective activation of adrenal steroid receptor subtypes can occur under physiologic conditions, these differences allow for complex and varied effects of adrenal steroids on immune cells under basal hormone conditions and following stress. EFFECTS OF ENDOXTON ON THE INDUCTION OF C-FOS PROTEIN IN THE BRAIN. PLASMA LEVELS OF CORTICOSTERONE, AND NOREPINEPHRINE AND VIP LEVEL IN THE BRAIN OF THE RAT. C. Y. Tse†, W. Wam, L. J. M. Serrulli*, A. J. Greenberg and D. M. Nance. Department of Psychology and Institute of Cell Biology, University of Manitoba, Winnipeg, MB, R3E 0W3, Canada and *Oncogene Sci., Inc., Uniondale, NY 11553. Lipopolysaccharides (LPS), an endotoxin associated with gram-negative bacteria, is a potent activator of the immune system. We have tested the effects of LPS infusions of LPS (10 ng) i.g. of LPS on the induction of the protocin receptor protein in the brain in the brain as well as plasma levels of corticosterone and spastic concentrations of norepinephrine (NE) and VIP. The dose was chosen because of its reported cross-reactivity with a polyclonal antibody to c-fos (1,000 Oncogene Sci.) and the PAP technique. At 3 hr post-LPS infusion of LPS, we observed numerous labeled neurons focused in the paraventricular nucleus (PVN) of the hypothalamus and the A2 region of the brain stem. Corticosterone levels as well as spinal levels and VIP levels were all elevated 3 hr post-LPS. LPS, relative to Ringer's solution-place rats. In addition to the c-fos labeled neurons, we also assessed the course for the induction of c-fos labeled neurons in the brain following IP injections of LPS as well as establish a dose response curve for c-fos labeling in the PVN vs IP dose of LPS. Labelled cells were examined in the PVN 1 hr following IP injection (100 ng), increased further at 2 and 3 hr post-injection and then returned to control levels at later intervals. The dose response curve for IP LPS vs the number of c-fos labeled neurons in the PVN showed a few labeled cells detectable at a dose of 4.0 ng, but the number and staining intensity of labeled neurons increased up to a dose of 100 ng, with no further increase in the number of labeled neurons at higher doses. In contrast to IP injections, we observed additional labeled cells in the suprachiasmatic nucleus (SON), arcuate nucleus and the A1 regions of the brain stem at IP doses of 40 ng higher. These results indicate selective and differential effect of central and peripheral LPS on the induction of c-fos protein in hypothalamic and brain stem nuclei. The concurrent changes in corticosterone level and spastic neurotransmitter levels produced by IP LPS suggest that the endocrine and autonomic nervous systems are primary targets for these activational effects of endotoxin. We have previously demonstrated that estrogen increases the affinity of thymic oxytocin (OXT) receptors. This study tested whether an E cell lipopolysaccharide (LPS) challenge would alter OXT immunoreactive levels or thymic OXT receptors in ovariectomized (OVXed) rats given 5 μg estradiol benzoate (EB) once daily for three days or on day 4. The fourth day rats received iv infusions of 150 μg/kg LPS or saline vehicle 90 min, before decapitation. LPS resulted in a significant increase in blood OXT levels only in estradiol-pretreated rats. The thymus, MPOA, PVN, and the adrenals showed no significant changes in OXT levels with these treatments, although OXT levels in the PVN were correlated with blood levels, while MPOA levels correlated with adrenal levels. Computerized analysis of total brain OXT binding experiments in which 0.2 to 200 nM OXT were incubated with 0.2 μM [125I]OXT-OA indicated that thymus from oil-saline treated OVXed matched a two-site model with only high affinity (K: 0.39 ± 0.08) and low-affinity (K: 9.3 ± 0.3) OXT binding sites. The EB-saline, oil-LPS and EB-LPS treated animals demonstrated one-site models with only high affinity models (Ks were 0.39, 0.42 and 0.42 respectively). In vitro experiments 100 nM OXT or 40 μg LPS added to homogenates of thymus from OVXed oil-saline vehicle treated animals also resulted in the loss of the low-affinity sites (one-site model with K: 0.46 for both). OXT release after an immune challenge is estrogen-dependent while LPS directly reduces the thymus by eliminating a population of low-affinity OXT receptors. (Supported by MH46808.)

Amino acids capable of producing excitation and subsequent autonomic arousal lesions are used as neuroendocrine research tools. Studies of brain regulation of PRL and adrenal hormone release after systemic N-Methyl-D-L-Aspartic Acid (NMA) administration have demonstrated differing thresholds for the modulation of individual pituitary hormones. The prominent role of PRL and cort in the modulation of immune function coupled with the possibility that these hormones may also have a differential release in response to PRL and cort in the following experiments. Male rats received intrasutural blood samples (bs. Oxy, AD and AM) prior to bilateral injections of either artificial CSF (aCSF) or NMA (0.453 mg/kg in 0.1 in 0.1 ml) at 2 min the anterior hypothalamic region (AHA). At 3 and 72 post NMA rats received 1 or 1.5 mg/100g. E cell endotoxin (Endotox) or saline per carcine at bs at 8 hr (AM) and again at 0.2, 1.3, 1.6 and 24 hr post endotoxin. Cort and PRL were assayed 2 min the treatment of control rats resulted in 8X max increase (from baseline) in plasma Cort at 0.5 hr and a 5X max increase in Prol at 1.5 hr which returned to baseline at 3 hr. Injection of either aCSF alone or NMA resulted in a 10X increase in Cort and NMA into AHA 72 postinjection fail prevent cort release in controls. However, both injection of aCSF alone or with NMA resulted in a respective, progressive production in PRL release after Injection of either of aCSF alone or NMA into AHA 72 postinjection fail prevent cso release. Summary increase in Prol and Cort release after Endo occurs with the change the latter occurring sooner and lasting longer. Cort release after endotox is not hampered after progressive damage to AHA, whereas Prol release was blocked by small (0.1mm) lesions. (Supported by MH46808.)

ENDOTOXIN CHALLENGE IN THREE-DAY-OLD RAT PUPS: HYPOTHALAMIC-PITUITARY-ADRENAL ACTIVATION AND DEVELOPMENTAL CONSEQUENCES
N. Shanks* & M.J. Meaney, Douglas Harvey Research Center, Dept. of Psychiatry, McGill University, Montreal, Quebec, H4H 1R3 CANADA

Antigenic challenge with endotoxin (ENDO) is known to activate the hypothalamic-pituitary-adrenal axis (HPA) in adult animals. Recent data have implicated IL-1β and corticotropin releasing hormone (CRH) as potential mechanisms responsible for HPA activation during the acute phase response to antigenic challenge. However, relatively little is known about HPA and immune interactions during development and whether neonatal immune challenge alters endocrine functioning as an adult. A series of studies were performed assessing the HPA response to salmonella enteritidis endotoxin challenge in three-day-old rat pups. It was observed that END0 administration at doses of 33μg/kg (ip) provoked marked elevations in both plasma adrenocorticotropic hormone (ACTH) and corticosterone (CORT), while only slightly altering blood glucose levels. HPA activation peaked between 3 to 4 hours following END0 administration in both male and female rat pups. However, a marked sex difference was evident with respect to both the dynamics and magnitude of the HPA response. The magnitude of both the CORT and ACTH responses to END0 were both greater and occurred earlier in female rat pups relative to males, however, hormone levels returned to basal values within 24 hrs in both sexes. In addition, endotoxin-induced CRH content decreased 2.4 times following END0 in both male and female rat pups, suggesting that the activation of the HPA axis was mediated by END0 stimulated CRH release. Studies are presently underway to investigate interactions between CRH and IL-1β in the neonate, and assess the long-term consequences END0 challenge during development on HPA function and its relation to gender.

BRAIN AND LYMPHOCYTES BETA-ENDORPHIN AND SUBSTANCE P IN EXPERIMENTAL ALLERGIC ENCEPHALITIS (EAE).
J. Velicic, P. Sacerdote*, G. Monastir, A. E. Frangini Dep. Pharmacology, School of Medicine, University of Milano, 20133, Milano, Italy and Fidia, 53031, Abano Terme, Italy.

Evidence is rapidly cumulating that neurotransmitters participate in the modulation of immune responses acting both in the central nervous system, and with autocrine, paracrine or endocrine mechanisms. We measured beta-endorphin (BE) and substance P (SP) concentrations in discrete brain regions cell lines and brain tissue (ILC of EAE sensitive) and Brown Norway (EAE fully resistant) rats before and every other day after treatment with immunoprotective spinal cord homogenates (ICP) or bovine serum albumin (BSA), together with Freund adjuvant and Bordetella Pertussis. At the same time intervals, also tumor necrosis factor (TNF) released from splenocytes was measured. In Lewis rat BE increased after GP or BSA in all the brain areas studied, peaked on days 12/14 and declined by day 21. Increases were significantly higher after GP than BSA. A minor increase with the same pattern was also present in Brown Norway rats. SP concentrations showed a reverse pattern, with nadir on day 12/14. In LC, BE concentrations increased on day 6 after immunization with GP or BSA and returned to normal values thereafter. TNF release from splenocytes increased significantly on days 10 and 12 only in Lewis rats. No correlation was found with clinical scores of the disease, but chronic treatment with the opiate receptor antagonist naltrexone starting on the day of immunization aggravated the clinical scores. The data presented are consistent with an inhibitory role for BE on the immune system and on the development of EAE.

MORPHOLOGICAL CHANGES IN THE HIPPOCAMPUS OF THE CONGENITALLY ATHEMIC (nu/nu) MOUSE.
K. C. French, O. G. Flugel, J.A. Reyes and M.C. Melnick*. Department of Endocrinology, University of California, Berkeley, CA 94720

Preliminary data in our laboratory show morphological differences in the hippocampus of 120-day-old, female homozygous nude (nu/nu) and balb/c (Balb/c/Balb/c) mice. Measurements of thionin stained sections of the hippocampi corresponding to CA1 and CA2+CA4 were taken from nude (N=13) and Balb/c (N=9) mice.

Our results indicate that the hippocampus in both the right and left hemispheres of the brain was significantly thiner in the nude than in balb/c mice. In the right hemisphere, the CA1 hippocampal region was thinner by 5.9% (p<0.05) and the CA2+CA4 region thinner by 17.6% (p<0.01) in the nude compared to the Balb/c mouse.

In the left hemisphere, the CA1 region was thinner by 5.1% (p=0.02) and the CA2+CA4 region thinner by 11.8% (p<0.001) in the nude compared to the balb/c mouse.

We are currently investigating central cortical and hippocampal morphology in female nude and Balb/c mice with the addition of the hormone regimens (nu/nubalb/c) as a control. Our purpose is to gain insight on regulatory hormones or factors that may be involved in mediating the deficiencies observed in brain morphology.

We are approaching this problem by grafting thymic and/or pituitary tissue in 5 week-old, female homozygous nude mice. Using radioimmunoassay, we will examine levels of prolactin, the primary hormone released from extrapituitary graft, corticotropin, and ACTH binding (T4 and T3). In addition, we will observe changes in CD4 and CD8 lymphocyte population using fluorescence-activated cell sorter (FACS) in the different experimental groups.

342.18

Enhancement of peripheral catecholamine release from nerve terminals and the adrenal medulla has been suggested to occur during septic shock using whole-animal experiments. Since mononuclear cytokine expression is an important response to sepsis, the present study tested possible neuroendocrine-immune-interactions in vitro by examining the effect of mitogen-stimulated mononuclear cells on catecholamine secretion from chromaffin cells. Chromaffin cells, isolated from rat brains with collagenase digestion, were maintained in 2 cm² wells 4-5 days with DMEM and F12 with 10% FCS in 5% CO2 at 37°C (0.6 x 10⁶ cells/well, 1.0 ml). Splenocytes were isolated from bovine spleen and cultured in RPMI with 10% FCS and stimulated with the CSF (1:10) and stimulated with 0.5% phytohemagglutinin (PHA). After 24 hrs. PHA-conditioned media (PHA+) was isolated and frozen. In secretion experiments chromaffin cell growth media was replaced with conditioned media at the time 0. In both the CSF and PHA stimulated, secretion was measured at variable times. After removal of PHA+ or control media, cells underwent mitogenic stimulation (3 μg Dimethylsulfoxipidermin (DMSO) for 10 min. E release was measured and E release expressed as a percentage of E released in initial E control. After 90 min with PHA+ media, E secretion increased to 19.1±0.5% of total (P<0.05 vs other treatments) compared to 5.2±0.3% for PHA- extract, 3.3±0.4% for media alone, and 7.4±0.5% for media alone (N=4 chromaffin cell preparations). E secretion was 25% by 210 min with PHA+ E release was dose-dependent. Nontoxic stimulation resulted in 0.6±0.6% release in E after 90 min with PHA+ (P<0.05 vs all other treatments) compared to 3.1±0.3% for PHA-, 2.7±0.2% for media + PHA and 2.4±0.4% for media alone (N=4 chromaffin cell preparations). Enhanced mitogenic secretion was also dose-dependent. The results support the concept that sympathetic response to sepsis is in part due to peripheral modulation of catecholamine secretion. **EFFECT OF IONIZING RADIATION ON RAT'S HIPPOCAMPAL NORADRENALINE RELEASE. S. B. Kandasamy*, S. Blakely, T. K. Dalton and A. H. Harris. Behavioral Sciences Department, Armed Forces Radiobiology Research Institute, Bethesda, MD 20880-5145.**

The purpose of this study was to examine the effect of ionizing radiation on hippocampal noradrenaline (NE) release in vitro, stimulated by KCl (0.5 h, 24 h, 47 h) and sham exposure. Rats were irradiated using a 60Co source. The levels of NE were measured by HPLC coupled to electrochemical detection. There was no significant change in NE release between irradiated and non-irradiated rats when the hippocampal NE was determined after 0.5 h irradiation (5-30 Gy at 10 Gy/min) or 47 h after sham irradiation/sham exposure. However, there was a significant decrease in NE release 48 h, and 72 h after irradiation (10 Gy at 10 Gy/min). Pretreating rats with 3-10 μg/kg of recombinant human interleukin-1β (rhIL-1β) or 3-10 μg/kg of corticotropin releasing factor (CRF) administered IP 1 h before sham irradiation enhanced hippocampal NE release and the same treatment prevented the radiation-induced decrease in NE release 8 h after irradiation. These results suggest that ionizing radiation induces decrease in hippocampal NE release 24 h, 48 h, and 72 h after exposure and pretreatment with rhIL-1β or CRF prevents the decrease.

**NEURAL-IMMUNE INTERACTIONS: INTERLEUKIN-1**

425.1

**BRAIN INTERLEUKIN-1 (IL-1) ENHANCES NOCICEPTION IN THE RAT. T. Hoet*, T. Oka and S. Aou, Dept. of Physiology, Kyushu University Faculty of Med., Fukuoka, 812, Japan.**

IL-1β has been shown to play a role in local inflammatory and immune mediated diseases, which are associated with local pain. IL-1β, when given systemically or locally, produces hyperalgesia in rats and rabbits. This hyperalgesia is generally thought to be mediated through increased PGE2, but a prostaglandin-independent mechanism is also pointed out. On the other hand, brain astrocytes and microglia are also known to synthesize IL-1, and such brain-derived IL-1 produces a variety of CNS-mediated responses such as fever. To determine whether brain IL-1β affects nociceptive function, we investigated the effect of brain IL-1β (rhlL-1β) on nociception in male Wistar rats. The paw lick latency on a hot plate (50±0.5°C) was measured before and after LCV injection of rhlL-1β (1pg-1μg/kg). LCV injection of rhlL-1β (1-10μg/kg) dose-dependently reduced the paw lick latency. The hyperalgesic action started around 5min after the injection, reached a maximum at 30min and was still observed at 60min. This effect was antagonized by pretreatment with either an IL-1 receptor antagonist, αMSH or salicylate, but not by β-helical CRF. An electrophysiological study performed in urethane (1.2g/kg) anesthetized rats revealed that responses of neurons in the spinal trigeminal nucleus to nociceptive stimuli were elevated by LCV rhIL-1β (10-100pg/kg). At a similar time courses as that of the paw lick latency responses. This enhanced responses of nociceptive neurons was also attenuated by αMSH. The results suggest that brain IL-1β induces hyperalgesia through an activation of arachidonate metabolism, but not by that of CRF system.

425.2

There are a few reports in the literature that interleukin-1 (IL-1) induces analgesia (Nagasawa et al., Eur.J.Pharmacol. 149:49-58, 1988; Bianchi et al., Brain Res.546:139,1991). The present study sought to characterize the analgesic effects of centrally administered IL-1 in rats. In the hot-plate test (HPT), latency to a rear paw lick or a four-footed jump off a 55°C surface was measured; in the cold water tail-flick test (CWT), latency to tail withdrawal from a 3°C liquid was timed. Core body temperature was also monitored with a rectal thermistor. After baseline readings, human recombinant IL-1β (125-2000 U) was injected i.p. (35μg/kg) and post-treatment doses were recorded at intervals from 15 to 180 min. In the HPT, no dose of IL-1 induced greater than 6.1±4.4% maximum possible analgesia (%MPA) at any time point. Similarly, no significant effect of IL-1 on morphine-induced analgesia. In summary, we failed to find any analgesic effect of IL-1, alone or in combination with morphine, at doses which clearly had a physiological effect; this is in contrast to the reports cited above. (NIDA Grants T32 DA07273 and DA 00376)

The expression of interleukin-1β (IL-1β) mRNA in the hippocampus and other brain regions (cerebral cortex, striatum and thalamus) was examined after transient forebrain ischemia using male Wistar rats. IL-1β mRNA was not detected in these regions of sham-operated rats. IL-1β mRNA was induced after transient forebrain ischemia. The induction of IL-1β mRNA had a few peaks, that is, peaks were observed at 30 and 240 min in the four regions examined and an additional peak was observed at 90 min in the striatum.

In addition, the effect of intracerebroventricular injection of IL-1β on neuronal cell death after transient forebrain ischemia was examined in the hippocampus. Seven days after 10 min of ischemia, the number of neurons in the hippocampal CA1 region of saline-injected rats was decreased to 30-40% but the number of neurons in the hippocampal CA3 region did not change, compared with non-treated rats. Injection of IL-1β (30 ng/rat) during the ischemic insult increased the neuronal cell death.

The numbers of neurons in the CA1 and CA3 regions decreased to 10-20% and 30-40% of non-treated control rats, respectively. These results suggest that IL-1β might be produced in the brain after transient forebrain ischemia and was involved in neuronal cell death.

We have reported that i.v. or i.c.v. administration of interleukin-1β (IL-1β) elicited an increase in renal sympathetic nerve activity (RSNA) accompanied with increases in blood pressure, heart rate and body temperature in conscious rats (Kannan et al., Soc. Neurosci. Abstr. 17: 11981, 1991). This study was designed to examine the effects of i.v. injection of IL-1β on discharge pattern in sympathetic nerves innervating the intercapsular brown adipose tissue (IBAT), and compare them with those of RSNA in conscious rats. The IBAT sympathetic nerve activity was increased by IL-1β with an increase in large group discharges synchronous with the cardiac cycle. In contrast, small amplitude activity unrelated to the cardiac cycle increased in RSNA, while large amplitude group discharges decreased. Plasma noradrenaline concentration increased in conscious rats after i.v. injection of IL-1β. The responses were reversed by dexamethasone. The results suggest that IL-1β activates systemic sympathetic outflow via prostaglandins, and modulates the discharge patterns in regional different manner.

The cytokine interleukin-1 (IL-1) has been shown to stimulate release of hypothalamic and pituitary hormones, notably with resulting increase in corticosterone production. The present studies investigate the possible occurrence of the endogenous IL-1 receptor antagonist (IL-1ra) in hypothalamus and paraventricular nucleus at central nervous system, and further analyze the finding of IL-1 receptor (IL-1r) in the pituitary gland. Antisera against synthetic peptides of the human monocyte IL-1α and IL-1β were used for immunohistochemistry, and polymerase chain reaction (PCR) technique was used to detect IL-1β and IL-1α mRNA. In addition, the presence of IL-1ra was examined in the hypothalamus, paraventricular nucleus, and in the pituitary gland. The results indicate that IL-1r and IL-1ra immunoreactive neurons were seen in the paraventricular (PVN) and supraoptic nuclei and in nerve terminals in the median eminence. PCR analysis confirmed the synthesis of IL-1ra in the hypothalamus and in the pituitary gland. The findings indicate that IL-1r and IL-1ra may be synthesized in PVN neurons projecting to the neural lobe. Experiments are carried out to verify this, to identify which populations of PVN neurons express the receptor and functional regulation. This work was supported by grants from the Swedish MRC and Clas Groschinsky's Minnesfond.

We have developed a modified sandwich ELISA to detect the cytokine IL-1β in mouse and rat tissues that utilize a specific rabbit immunoglobulin (IgG) and a polyclonal antibody to the IL-1β peptide. ELISA sensitivity was 1 pg; the inter- and intra-assay variabilities were 6% CV, and the range was 1-2,000 pg. The ELISA detects both mouse and rat IL-1β, exhibits a lower reactivity to human IL-1β and a human IL-1β extended by three amino acids, and shows no cross-reactivity to human IL-1α, human IL1 and rat IL-1 receptor antagonist. Human tumor necrosis factor α, somatostatin, vasoactive intestinal peptide, and a variety of unrelated peptides. Commercially available ELISA amplification kits did not alter the sensitivity but did increase the resolution at the lower peptide concentrations. IL-1β levels in normal mouse were 7.0 ± 1.0 pg/mg tissue and 0.3 ± 0.7 pg/mg tissue in testis; IL-1β levels were detectable in plasma, hypothalamus and hippocampus. Robust increases in IL-1β tissue levels were observed in mouse spleen and testis (6 and 15 fold respectively) six hours after injection of lipopolysaccharide (LPS) (1 mg/kg, i.p.). Similar, albeit smaller changes, were observed in rat spleen and testis six hours after LPS injection (2 mg/kg, i.p.). In summary, we have developed a sensitive and specific ELISA for the detection of IL-1β. This assay should allow the further investigation of the role of IL-1 in regulating brain-endocrine-immune interactions.

Previous studies utilizing IL-1β recombinant human interleukin-1α (IL-1α), IL-1β and IL-1β receptor antagonist have demonstrated high binding sites for IL-1 in the mouse brain and endocrine tissues with characteristics of Type 1 receptors in T lymphocytes. In a preliminary study, there were dramatic species differences in the level of IL-1β binding with high levels of binding present in mouse and rat tissues (hippocampus, spleen and testis), while IL-1α in binding to rat and guinea pig tissues was not detectable. In the present study, we further characterized IL-1 binding in mouse and rat tissues and selective immune cell lines. Utilizing 100 µM or 600 µM IL-1α, IL-1β, IL-1α and IL-1β receptor antagonist were used to determine if high levels of specific binding were observed in EL-4 6.1 cells (representative of Type 1 receptor) and in mouse tissues; however, no specific IL-1α binding was present in Bajj cells (representative of Type II IL-1 receptor) and no IL-1β binding was observed in rat tissues. On the other hand, utilizing 600 µM IL-1β as a ligand, high specific IL-1α binding was shown in EL-4 6.1 and Bajj cells and moderate binding was evident in mouse tissues, whereas specific IL-1β binding to rat tissues was barely within the range of sensitivity of the assay. These data demonstrate that under optimal conditions for labeling Type I or Type II IL-1 receptors, no specific binding is observed in rat tissues suggesting the presence of novel IL-1 receptor(s) in rat tissues.

CARDIOVASCULAR REGULATION: LOWER BRAINSTEM I

CO in the anesthetized rat is dramatically reduced 5-7 minutes after local application of pmole amounts of ET-1 to the ventral surface of the medulla (VSM). VSM application of vehicle or other pressor agents failed to mimic ET-1's effect on CO, suggesting that the drop in CO was a specific effect of ET-1 and not related to changes in medullary perfusion. Changes in CO might reflect changes in heart rate (HR), afterload, preload or cardiac contractility. We are interested in determining how VSM application of ET-1 affected each of these parameters. HR and total peripheral resistance (a measure of afterload) were little changed following VSM application of ET-1. Marked decreases in peak stroke output and left ventricular dP/dt after VSM application of ET-1 suggest a decrease in cardiac contractility. Left ventricular end-diastolic pressure and central venous pressure showed little change following VSM application of ET-1. These data are consistent with the hypothesis that central application of ET-1 decreases CO by causing a sustained decrease in cardiac contractility.

426.2 CENTRAL CARDIOVASCULAR EFFECTS OF JOINING PEPTIDE. T. Hamakubo, M. Yoshida, T. Katauchi, K. Nakajima, R. Mosquera-Garcia, M. Tanigami. Departments of Biochemistry and Pharmacology, Vanderbilt University, Nashville, TN 37232; Peptide Institute, Osaka, Japan

Joining peptide (JP), one of the major products of proopiomelanocortin, is present in the hypothalamus and the pituitary. The biological relevance of this peptide, however, has not been identified. In the present study we characterized the central hemodynamic effects of JP. Rat JP C-terminal amide form (JP) and bovine JP (BP) were synthesized according to the deduced amino acid sequence. Wistar-Kyoto (WKY) and spontaneously hypertensive rats (SHR) were anesthetized with urethane and blood pressure (BP) and heart rate (HR) were recorded intravenously. The animals were placed in a stereotaxic frame and the doral surface of the medullas were exposed through a laminar incision or craniotomy. In a group of animals, a catheter was placed into the carotid and to intracerebral administration of either JP or BP (10-50nmol/kg). In a different group of rats, a microcatheter was positioned in the nucleus of the solitary tract (NTS) for microinjection of JP (10 pmol/30 nl). Intracisternal injections of JP in SHR increased mean BP and HR in a dose dependent manner. Maximal effects were seen at 30nmol (22±2 mmHg and 36±10 bpm, n=6). While similar effects were observed in WKY, JP or BP were less potent to increase BP and HR. Microinjection of JP into the caudal region of NTS increased BP by 15±2 mmHg and HR by 37±5 bpm (n=4). Maximal changes in HR occurred at 5 min and recovered within 20 min. The maximal HR response occurred 6 min after microinjection. In 2 of 9 rats the pressor effect was preceded by hypotension and bradycardia. These results suggest that JP is a neuropeptide with important central cardiovascular effects in hypertensive animals.
425.3 AREA POSTEROM STIMULATION INHIBITS RENAL SYMPATHETIC DISCHARGE IN THE ANESTHETIZED RAT. R.B. Felder*, A.L. Pence, L.F. Hayward, College of Medicine, University of Iowa, Iowa City, IA

Area postrema neurons respond to circulating neurohumoral substances and may play an important role in cardiovascular regulation. We examined the effects of area postrema (AP) stimulation on mean arterial pressure (MAP), heart rate (HR) and renal sympathetic nerve activity (RSNA) in 8 urethane anesthetized rats with bilateral carotid sinus nerves sectioned. AP was stimulated at low intensity (40 µA, 0.2 ms, 40 Hz) in the midline along its rostral-caudal axis. Penetrations were separated by 0.2 mm. Stimulation was carried out on the surface of AP and at 0.2 mm increments to a depth of 0.8 mm. Stimulation at the surface (n=9) or at 0.2 mm depth (n=1) decreased sympathetic discharge (164±10 to 136±5, 10.2 imp/sec; p<0.05) without affecting blood pressure or heart rate. At 0.2 mm depth (n=8) stimulation elicited significant increases in blood pressure (100±6 to 90±6 mmHg) and renal nerve activity (155±11 to 162±13 imp/sec). There was no change in heart rate. Similar effects were observed when left lateral to midline. Ventral to 0.2 mm, a pressor response was usually elicited and became more pronounced at deeper stimulation sites. Prominent depressor responses were also observed at deeper sites. Thus, the predominant effect of selectively stimulating AP neurons is a modest reduction in MAP and RSNA. These findings support a sympathetic inhibitory influence of area postrema on cardiovascular reflex control.

426.4 AFFERENT NEURONS TO THE ROSTRAL VENTROLATERAL MEDULLA (RVL) IN THE RAT: RELATIONSHIP WITH CALBINDIN-28K IMMUNOREACTIVITY. P.A. Trapp*, H.T. Chang*, Departments of Pharmacology*, Anatomy, and Neurobiology*, The University of Tennessee, Memphis, College of Medicine, Memphis, TN 38135

RVL is an important center for cardiovascular control. Although many RVL neurons co-express calbindin-D-28k (CaBP), a Vitamin D-dependent calcium-binding protein, the relationships between CaBP and the neurotransmitters that project to RVL, and that between CaBP and the RVL afferent neurons are still unknown. In this study, FluoroGold (FG) was injected into RVL to retrogradely label neurons that project to the RVL, and CaBP+ neurons were revealed by Texas Red immunofluorescence. Many FG labeled neurons were found in the brain, including regions that contain many CaBP+ neurons: the nucleus of the tractus solitarius, the medial vestibular nucleus, the contralateral RVL, the central gray, the lateral parabrachial nucleus, the paraventricular nucleus of the hypothalamus, the posterior and the lateral hypothalamus, the substantia innominata, and the central amygdala. Only a minority of FG labeled neurons in these regions were CaBP+. On the other hand, the FG labeled neurons in many of these regions were found in close association with terminal fields immunoreactive for phenylethanolamine N-methyl transferase (PNMT), the sympathetic enzyme. Our results suggest that while CaBP is not a major marker protein in neurons that project to the RVL, CaBP+ neurons are a component of the afferent field of adrenergic fibers, and may be a marker for neurons that are targets of RVL afferent neurons.

425.5 ROLE OF THE CAUDAL VENTROLATERAL MEDULLA IN REFLEX PRESSOR RESPONSES. J.C. Solomon, A.M. Metcalfe, J.R. Hagell*, M.P. Kaufman, University of California, Div. of Cardiovascular Med., Davis, CA 95616

Previous studies have shown that the ventrolateral medulla plays a role in the central pathway of the reflex increase in arterial pressure evoked by static muscular contraction, peripheral nerve stimulation, and hypoxia. The role of the caudal ventrolateral medulla (CVLM) in these reflex arcs is not clearly defined. We therefore examined the role of the CVLM in these reflex arcs controlling arterial pressure in cholinesterase anesthetized cats. Increases in MAP were evoked by three stimuli: static muscular contraction elicited by ventral root stimulation (CONT), electrical stimulation of the sciatic nerve (SN), and hypoxia (HYF). These changes were compared before and after bilateral microinjections of a broad spectrum glutamate antagonist, kynurenic acid (KYN) (100 mM, 50 nl), into the CVLM. We tested the hypothesis that bilateral microinjection of KYN into the CVLM potentiates the reflex pressor responses to the three stimuli. The mean increase in MAP produced by these stimuli were potentiated within 20-30 min following bilateral microinjections of KYN into the CVLM at sites 1.5 mm dorsal to 0.8 mm rostral to obex. The reflex increase to control levels was either unchanged (n=8) or remained augmented (n=10). In two cats, microinjections of KYN into sites very caudal to obex (-2 mm) elicited either no effect or an attenuation of the reflex increase in MAP. These findings suggest that the reflex arc increasing MAP evoked by static muscular contraction, sciatic nerve stimulation, and hypoxia can be potentiated by blockade of glutamatergic receptors located in the CVLM.

425.7 SUPRAMELLULAR INPUTS TO CARDIOVASCULAR NEURONS OF ROSTRAL VENTROLATERAL MEDULLA IN MICE. S.K. Agrawal* and E.R. Calvert, Center for Biomedical Research, University of Toronto, Ontario, Canada N5A 5C1 and *Playfair Neurosci. Unit, Toronto Hospital, Toronto, Ontario, Canada MST 2S8

As anatomical and stimulation studies suggest that neurons in the medullary ventrolateral nucleus (RVLM) receive and integrate multiple inputs from supramedullary regions of the brain, experiments were done to test the hypothesis that selective activation of cell bodies in the lateral parabrachial nucleus (LPBN), locus coeruleus (LC) and lateral hypothalamic area (LHA) could excite or inhibit the discharge of neurons in the RVLM. We therefore recorded extracellular activity from RVLM units in urethane anesthetized cats and monitored the changes in firing frequency of these neurons during chemical stimulation of one of LPBN, LC and LHA. Thirtytwo neurons were classified as cardiovascular neurons because their activity was inhibited by baroreceptor activation (1-3 µg phenylphrine i.v.) and displayed a cardiac cycle related rhythmicity. Chemical stimulation with glutamate of arterial pressure sites in the LPBN increased the firing rate (40.3±1.3 %) of 11 (100 %) cardiovascular neurons. Activation of cell bodies in arterial depressor sites in the LC inhibited the firing frequency (59±1.7 %) of 9 (90 %) cardiovascular neurons. Activation of cell bodies in arterial depressor sites in the LHA inhibited the discharge rate (25±4.7 %) of 6 (60 %) cardiovascular neurons, excited one unit and did not alter the discharge rate of the remaining 3 units. There is evidence for convergence of excitatory and inhibitory inputs from neurons located in the LPBN, LC and LHA to cardiovascular neurons in the RVLM.

426.6 VAGAL AND SPINAL MODULATION OF VENTROLATERAL MEDULLA NEURONAL RESPONSES TO REDET STIMULI. M.A. Vazquez*, A. Standish and W.S. Ammons, Department of Physiology, Thomas Jefferson University, Philadelphia, PA 19107

Recent experiments from this laboratory demonstrated that cells within the ventrolateral medulla of the cat respond to electrical stimulation of renal nerves and to activation of renal mechanoreceptors and chemoreceptors. The purpose of this study was to determine if these responses are modulated by vagal or spinal pathways. A total of 1469 cells were studied and neuronal responses were elicited by stimulation of renal nerves from 3.6±0.6 spikes to 2.4±0.4 spikes/s (p<0.05). Vagotomy decreased spontaneous activity of 814 cells from 1.3±0.5 impulses/s (p<0.05), increased spontaneous activity of two cells and did not affect four cells. Bilateral cervical vagotomy increased the evoked response of 5 cells to electrical stimulation of renal nerves from 2.4±1.0 impulses/s to 4.8±1.2 impulses/s (p<0.05). Spontaneous activity of each cell also increased from 1.4±0.9 impulses/s to 3.9±0.9 impulses/s (p<0.05). Bilateral vagotomy never abolished cell responses to renal nerve stimulation. Five cells (26 %) were responsive to renal nerve excitation; 1 cell was also responsive to ureteral occlusion. Vagotomy did not alter the responses. The response to renal nerve stimulation for 9 of 9 cells was completely abolished after spinal cord transection. Following spinal cord transection, the spontaneous activity of 7 cells was not significantly affected. Somatic field classification of each cell was unaltered and cell responses to somatic stimulation above the transection level were comparable or greater. The results of these experiments have demonstrated that renal afferent information to the ventrolateral medulla is conveyed via the spinal cord. In addition, the results are consistent with a tonic modulatory effect of the vagus nerve on ventrolateral medulla cell responses to renal stimulus.

426.8 PARRALLEL AND INDEPENDENT PROGRESSING OF SYMPATHETIC BARS- AND CHEMOREFLEXES IN THE MEDULLA OBONGA. N. Koshiva, D. Haugaa and P.G. Goyant, Dept. of Pharmacology, University of Virginia, Charlottesville, VA 29080

Splanchnic sympathetic nerve discharge (SND), phasic nerve activity (PND) and putative vasomotor sympathetic precursor neurons of the rostral ventrolateral medulla (RVL PMN) were recorded in urethane- anesthetized vagotomized rats without aortic baroreceptor afferents. Cardiac chemoreceptor stimulation (CCS) with brief N2 inhalation increased SND by 101±7, MAP and increased the discharge rate of RVL premonitor neurons by 46±12 % (N=32, 50 range 90% inhibition to 200% activation). During chemoreceptor activation, SND and most RVL neurons displayed pronounced, post-inhibitory rhythmicity. These responses confirm that convergence between peripheral chemoreceptor and baroreceptor inputs to the central network responsible for SND generation occurs at or prior to the RVL premonitor neuronal stage. Bilateral microinjection of Kyn (5 mmol in 100 nl) into RVL blocked the sympathetic chemoreflex but left the sympathetic baroreflex intact (N=6). Conversely, bilateral microinjection of Kyn into the caudal ventrolateral medulla at obex level (RVL) blocked the baroreflex but left the sympathetic chemoreflex intact (N=5). These injections also left intact the ontogenic specificity of the sympathoexcitatory produced by CCS.

The effect of Kyn injection into RVL was blocked to the baroreceptor input by proprioamidula GABAergic cells of RVL with projections to RVL. These cells are likely to be the last mediatory relay of the sympathetic baroreflex before the RVL neuronal stage. The present results suggest that the sympathetic chemoreflex and baroreflex utilize two separate and largely independent channels in the medulla until the RVL premonitor neuronal stage where algogenic synaptic summation of the two inputs probably occurs.

426.1 DOUBLE LABELING OF RAT SPINAL NEURONS PROJECTING TO BOTH SOLITARY TRACT AND DORSAL COLUMN NUCLEI. C.W. Lim and Z. Wen. Dept. of Neurobiology, Capital Institute of Medicine, Beijing 1000054, China.

Physiological evidence has been presented for spinal dorsal horn neurons with labeled axons terminating in both the solitary tract and dorsal column nuclei (Lim G.W. et al.:Science in China,34:171-183,1991). The present study is aimed at double labeling the cells of origin of the double projection SBN with fluorescent substances.

Propidium (PI) was injected into left solitary tract nuclei (STN) of P3 rat and labeled with biotinylated avidin (Bb). The nuclei were dissected and sectioned. The neuronal cell bodies were identified by biotinylated avidin (Bb). Double labeling with PI and Bb was performed by the avidin-biotin complex method and revealed that these two sets of neurons are different in terms of their functional diversity.

Within a rostrocaudally limited region in the middle of the cuneate nucleus (CN), distinctive biocles of intense CO-activity were observed. The CO-staining in these biocles was approximately 0.3-0.7 mm caudal to the obex, which is located within the previously defined middle region (approximately 0.2-0.9 mm caudal to the obex) that receives a disproportionate large share of primary afferent terminations (Maslany et al., Neurosci. Lett., in press). No CO-biocles were observed anywhere else in the dorsal column nuclei. Transgangliaric labeling (WGA-HRP) demonstrated that several of the CO-biocles of the CN are precisely related to the terminal projection fields of primary afferents from the skin of the forepaw. In contrast, control observations demonstrated that 1) the coarchitecture (Nissl-stained sections), 2) the cytoarchitecture/distribution of microtubule-associated protein 2 (MAP2) and 3) the organization of retrogradely labeled cuneal motorcells did NOT correspond to the topographical organization of the CO-biocles. Postnatal (up to 11 days postpartum) dorsal column transection or removal disrupted the CO-staining pattern in the adult CN.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

The distribution of the calcium-binding proteins, calbindin D28k (CaBP) and parvalbumin (PV), were examined in the dorsal column nuclei and spinohind brain by an avidin-biotin peroxidase method. In the cuneate nucleus (CN), both CaBP-immunoreactive (CaBP-IR) and PV-immunoreactive (PV-IR) cells were found throughout the entire rostrocaudal axis of the nucleus. However, the density of the PV-IR cells was greatest in the previously defined middle region (approximately 0.2 - 0.9 mm caudal to the obex) that receives a disproportionately large share of primary afferent terminations (in press) and is similar to the known distribution of thalamic projection cells. The distribution of the CaBP-IR cells appeared uniform throughout the CN. In the gracile nucleus, where the PV-IR cells were also more numerous, the density of both the PV- and CaBP-IR cells was greatest just caudal to the obex. In the spinal cord, PV-IR cells were found in Rexed’s laminae IV-VI, but in the gracile, both PV- and CaBP-IR cells were found in lamina I-II. A few PV-IR and CaBP-IR cells were observed in the ventral horn. While many PV-IR fibers were found in the gracile tract (GT) in the lumbar region, few PV-IR fibers were detected in the GT in the cervical region, suggesting that a large proportion of PV-IR fibers may be proprioceptive in origin.

427.5 DIFFERENTIAL BRAINSTEM TERMINATIONS OF EXTRINSIC VERSUS INTRINSIC MUSCLE SPINDLE AFFERENTS IN THE MONKEY. C. L. Martin-Ekline* and C. J. Vierck. Department of Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610.

The intrinsic hand muscles, including the lumbricals and the interosseous muscles, appear to play a critical role in fine, coordinated movements of the fingers while the extrinsic hand muscles, located in the forearm may be more important in gross, powerful movements. Differential effects of dorsal column lesions on these two types of hand movements prompted a comparison of the pattern of central terminations from muscle spindle afferents of intrinsic versus extrinsic muscles of the hand. We have injected cholinergic toxin conjugated to horseradish peroxidase (CT-HRP) into a variety of intrinsic hand muscles of the digit I, II, III, and IV to label the spinal cord motor nuclei and motor neurons in the forelimb. Preliminary results suggest that the terminal patterns of extrinsic muscle spindle afferents are distinct from those of intrinsic muscle afferents which are not restricted to the triangularis portion of the main cuneate nucleus and the external cuneate nucleus in the brainstem as muscle spindle afferents of extrinsic muscle terminals appear to be. Supported by NS-17474 and NS-07261.

427.7 OVERLAYING OF NERVE-RELATED AND SOMATOTOPIC ORGANIZATION IN THE CUNEATE NUCLEUS OF PRIMATES. J.K. Baxley and D.J. Wall*. Department of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Sensory fibers from individual fingers, palmar pads, and the somatotopic divisions of the hand terminate in rod-like clusters in the cuneate nucleus. The hand innervation territories of the median, ulnar, and radial nerves do not always coincide with the borders of the somatotopic divisions. How are sensory fiber terminations of these nerves organized in the cuneate nucleus? In the cuneate nucleus of squirrel monkeys following whisker afferent injections of horseradish peroxidase conjugates. The termination field of each nerve is elongated rostrocaudally, and spans multiple somatosensory clusters in the mediolateral and dorsolateral dimensions. Label density varies within the field from "core" regions containing dense, continuous label to "fringe" regions that contain lower density label. These nerve-related termination patterns appear to be consistent with subcortical substrates of nerve dominance columns in the cortical hand map, and provide images of the presynaptic neuropil which loses normal sensory signals after injury of a hand nerve. Supported by NS21105.

In six adult rats WGA-HRP was injected in dorsal root ganglia to label primary afferent terminals (PATs), or in the cuneal spinal cord (6 days after unilateral cervical rhizotomy and lesion of the dorsal quadrant at T1) to label post-synaptic dorsal cuneal terminal in the cuneate nucleus. The anterograde tracer was revealed by TMH histochemistry. Post-embedding immunogold staining was then performed on these sections, using antisera against GABA and for glutamate. PATs are large (mean area: 3.14 ± 0.7 μm2, n = 177), contain many mitochondria and small round vesicles. They are GABAergic at their glutamatergic synapses. In the plane of the section they contact two or more dendrites of various caliber, and receive synapses from small boutons, some GABAergic. The glutamatergic synapse product after injection of the tracer in the spinal cord are small (mean area=1.34 ± 0.7 μm2, n = 185) and contact a single thin dendrite or cell body. They may be GABAergic, or glutamate or negative for either antisera. GABAergic terminals are the smallest of the three types (mean area= 0.9 ± 0.7 μm2, n = 288), and, besides contacting dendrites and cell bodies, they, along with GABAergic, may form covicentric arrangements with other terminals. ULTRASTRUCTURAL INVESTIGATION ON THE DORSAL THALAMIC OF GUINEA FOG
R. Serapicò*, C. Frascoc, M. De Curtis and S. DeBissi*
* Istituto di Fisiologia e Biochimica Generali, Milano, Italy.
Recent anatomical investigations provided evidence that GABAergic neurons are present in some thalamic nuclei of the guinea pig (Asanuma, 1991). Aim of the present study was to investigate the intrinsic synaptic organization of selected thalamic nuclei such as the ventrobasal complex (VB) and the ventroter nal nucleus (VL), characterized respectively by the presence or absence of corticofugal projections. Adult guinea pigs were perfused under anesthesia with 2.5% glutaraldehyde and 0.5% paraformaldehyde. Vibrato me sections from the thalamus were either processed for immunohistochemical detection of GABA or osmicated and wafer-embedded in Epoxy plastic for ultrastructural investigation. LM confirms that GABA+ neurones are present in VB but not in VL. At EM, several complex synaptic arrangements, similar to those found in the cat, are observed in VB, whereas VL contains only simple axo-dendritic and axo-axonic synapses, as in the rat. The differences in the intrinsic synaptic organization between the two examined nuclei are also consistent with post-synaptic GABA immunolabelling. (II III II 27827)

MEDIAL LEMNISCAL TERMINALS IN M. FASCICULARIS: 3-DIMENSIONAL COMPUTER-ASSISTED RECONSTRUCTIONS OF SYNAPTIC RELATIONSHIPS. Harvey J. Rafiunion, Henry L. Raphaelis, Department of Anatomy and the W.M. Keck Foundation Center for Integrative Neuroscience, University of California, San Francisco, California, 94143.
Medial lemniscal axons in the somatosensory thalami of M. fascicularis have been labeled by the anterograde axonal transport of wheat germ agglutinin- horseradish peroxidase (WGA-HRP) following injection of the tracer into the dorsal column nuclei of unanesthetized animals. The tissue was prepared for post-embedding GABA immunocytochemistry and studied by electron microscopy. Computer-assisted reconstruction analysis of serial thin sections was utilized to determine the nature of the synaptic relationship of the terminal and spatial distribution and spatial organization of the projections to the dendritic arbor of thalamocortical relay cells (TCR) and GABAergic local circuit neurons (LCN) and the 3-dimensional features of the synaptic relationship in the terminal. The projections to the axodendritic contact (axon from the proximal dendritic arbor of TCR cells, usually terminating on the first 100μm of these dendrites. In addition, the ML terminals synapse upon the GABAergic dendritic shafts and appendages of LCNs. Counts of contacts of ML afferents upon thalamocortical terminals is more than 90% of the ML terminals contact GABAergic profiles in addition to TCR dendrites. In contrast, the synaptic terminals of STT afferents (STT - adjacent poster) form simple axo-dendritic synapses upon TCR dendrites but are rarely seen to contact GABAergic profiles. 3D reconstruction analysis of ML-M terminal relationship reveals that they form elaborate synaptic arrays with multiple GABAergic dendrites and dendritic appendages of LCNs, the latter in turn, synapsing upon the same element of the TCR dendrite as does the ML terminal. A given TCR dendritic segment receives ML (and no STT) afferent terminals. We conclude that the ML synaptic input upon TCR cells also elicits substantive GABAergic feed-forward modulation of the ML synaptic effect. This supports the hypothesis that the transfer of non-noxious information by primate thalamic nuclei is markedly influenced by GABAergic LCN processing, in contrast to the lack of GABAergic modulation of nociceptive information. Supported by NS-23347.

IMMUNOCYTOCHEMICAL COMPONENTS IN THE LEMNISCAL AND SPINOthalamic PATHWAYS IN MONKEY BRAINSTORM: Giuseppe De Biasi, L. Dagnino, L. DeRosa, M. Zanier; Dept. of Morphology, University of Trieste, Italy. 
De Biasi, L. Dagnino, L. DeRosa, M. Zanier; Dept. of Morphology, University of Trieste, Italy.
Cyscnergic nucleus (CO) staining reveals a histochemical parcellation of the principal trigeminal (PV) and dorsal column nuclei (DCN) in monkeys (Norrega and Warr, Brain Res.,363:1389,1982). CO-rich and CO-weak compartments, also defined by immunostaining for calcium binding proteins parvalbumin (PV) and 28kd calbindin (CB) respectively, are also present in the thalamus ventral posterior nucleus (Rausell et al., 1991 J Neurosci.,11:2110,1991). Leptomineral and spinolaminar fibers terminate preferentially in these compartments. Compartmentalization based on CO- and immunocytochemical staining is also a common feature of relay nuclei at other levels of lemniscal and spinolaminar systems.
In M. fascicularis and M. moneu CO-rich compartments in PV are made up of clusters of neurones that show PV immunoreactivity and stain with SMI-14, an antibody to nonphosphorylated neurofilament protein. PV and SMI-32-positive neurones also label the nucleus. CB immunoreactivity occurs in the lateral periphery of PV and in other CO-rich areas that alternate with the CO-rich zones. CB immunoreactive neurones are more numerous in the dorsal part of PV, and no CB axons are observed. DCN show similar CO- PV and SMI-32 staining patterns but few CB neurones are present. PV and SMI-32 staining are present in the medullary lemniscus. In the spinal trigeminal nucleus, CO staining in weaker overall and absent in the dorsal-most portion. PV and SMI-32 staining are confined to the CO-positive and CB staining to the CO-negative regions. 

427. 12
The present work investigates at electron microscopic level the preservation of different areas of the adult isolated guinea pig brain maintained in vitro by arterial perfusion (de Curtis et al. 1991: Hippocam. Res. 1, 341). After characterization of the electrophysiological viability of the preparation via extracellular field potentials, the brain was frozen at different times after isolation (one to seven hours) with a mixed alkaline solution (4% paraformaldehyde and 0.1% glutaraldehyde in PBS, pH 7.2) perfused through the cannnal inserted in the vertebral artery. Samples of neocortex, thalamus and hippocampus were trimmed out from 100 um cortical sections, were canonical and embedded. Semithin and ultrathin sections were then cut, observed at LM and EM respectively and compared to control samples obtained from deeply anesthetized animals directly perfused with the same fixative through the aorta. In all regions explored the tissue was well preserved during the early hours after dissection and showed only minimal and localized alterations after longer incubation times. Cells shapes (somatic and dendritic), myelin sheaths, cytoplasmatic membranes and synaptic clefts in the thalamus and superficial layers of the neocortex showed no major alterations after several hours. Different degrees of extracellular vacuolization (probably due to swelling) and cell damage (membrane shrinkage, cytoplasm vacuolization, darkly stained dendrites, etc.) were observed in the hippocampus and in the deep neocortical layers after five hours of perfusion. These anatomical evidences add new data to the demonstration of the long-term preservation of the isolated in vitro brain.

MODELLING SPINDLE-LIKE OSCILLATION IN THALAMOCORTICAL NEURONES. T.J. Tóth* and V. Crunelli, Dept. of Physiology, Univ. Wales Coll. Cardiff, Cardiff CF1 ISS, U.K.
Recent experimental studies have shown that thalamocortical neurones are capable of displaying a variety of oscillatory states that do not require synaptic currents (Leresche et al., 1991). The pacemaker oscillation (i.e., low-frequency oscillation associated with high-frequency bursts of action potentials) has successfully been accounted for by models (McCormick et al., 1992; Tóth and Crunelli, 1992) based on the properties of a low threshold Ca**+ current, I, and inward Na**+K** current, I, that were identified in voltage clamp experiments. Using the same set of synaptic parameters, however, it has not been possible to reproduce the spindle-like oscillation (SLO), a type of activity where low-frequency oscillation occurs intermittently every 5-25 sec. Our model has been extended by taking into account that an increase in intracellular [Ca**+] is known to shift the activation curve of I, towards more positive potentials. This has been able to obtain an oscillatory behaviour that closely resembles SLO and to mimic some of the qualitative properties of SLO observed in vitro. We conclude therefore that I, I, and the leakage current, I, are sufficient to describe SLO. In the intracellular [Ca**+] must be taken into account when dealing with this oscillatory state. 

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 11, 1992
427.15

The GABA containing cells in the thalamus consist of local circuit neurons and those of the nucleus reticularis thalami (NRT), which project to most thalamic nuclei. In the rat ventro-basal complex (VB), local circuit neurons make up <0.5% of the total neuronal number. When recording extracellularly from VB thalamocortical cells in a slice preparation containing rat VB and NRT, single shock, low-frequency stimulation of the NRT resulted in an EPSP (due to activation of cortico-fugal fibres passing through the NRT) and a hyperpolarization. The co-application of 20µM CNQX and 100µM DL-AP5 blocked the EPSP to reveal a fast IPSP, which had a time to peak of 10-30ms, reversed at -70mV, and was blocked by bicuculline (10-20µM). A slow IPSP (time to peak of 200-300ms), sensitive to the GABA A antagonist CGP 35348 (100-300µM), was observed. In vitro, for this antagonist, at membrane potentials in the -55 to -65mV range, the decay of the GABA IPSP was able to evoke a low-threshold Ca++ potential, indicating that GABA A receptors may underlie sleep spindle activity in the thalamus. We conclude that the input from the NRT to the VB is mediated via both GABA A and GABA B receptors.

PAIN MODULATION: SPINAL I

428.1

Serotonin (5-HT) is known to be a neurotransmitter in descending pathways. The purpose of the study was to determine the effects of 5-HT on feline dorsal horn neurons. Three cats were anaesthetized with sodium pentobarbital (35 mg/kg). Extracellular potentials were recorded from 7 dorsal horn neurons in the thoracic spinal cord (T1-T3). The axons of 3 of the cells were antidromically activated from the medullary reticular formation. Seven barrelled glass micropipettes were used to pressure eject (100 µm, 50 psi) small volumes (65.5 µL) of 3 concentrations (10 µM, 100 µM, 1mM) of 5-HT (pH 7.3), vehicle (phosphate buffered saline, pH 7.4), and 1 mM d,l-homocysteic acid (DLH; pH 7.3). Microinjections of 5-HT increased the spontaneous activity of all 7 cells and the change occurred within 1 sec. The mean changes in activity for 10 µM, 100 µM and 1mM 5-HT were -0.8, 2.7 and 10.5 spikes/sec, respectively. The excitatory responses to 1mM 5-HT were significantly different from the responses to 10 µM and 100 µM 5-HT. There was no difference in the change in spontaneous activity between the 2 lower concentrations of 5-HT. Five cells were tested for responses to 1mM DLH; 4 were excited and 1 had no effect. No responses to vehicle were found. Using the pressure ejection technique, 5-HT has been found to excite dorsal horn neurons, some of which are spinoreticular tract neurons. (Supported by NIH grant HL29618 and OCAST grant HR-089).

428.2
MODULATION OF SEROTONIN (5-HT) RELEASE FROM SPINAL CORD TISSUE BY OPIOIDS AND KETAMINE. B.K. Kradel, E.H. Stultens, Jr., D.L. Smith, P.J. Monroe, D.J. Smith. Dept. of Anesthesiology, WVU Health Sciences Center, Morgantown WV 26506

Antinociception from some intrathecally administered drugs appears to be mediated in part by spinal serotonergic processes (Pain 12: 57,86; Eur.J.Pharmac. 166: 211:89 & 194: 167:41; Nature 28: 1047:89). In this study, several opioids and ketamine (each in a concentration of 1 µM) were evaluated for their ability to alter the release of 5-HT from superfused spinal cord tissue. Using synaptosomes, it was found that neither fentanyl nor (D-Pen2,5)

In this preparation, and provide further evidence that these drugs do not release 5-HT directly from spinal serotonergic terminals. On the other hand, when a spinal cord slice preparation was used (neuronal connectivity is less compromised), 5-HT efflux was modified by some of these agents. Ketamine, DPDPE and Tyr-Gly-Met-Phen-Gly (DAMGO) enhanced the K+-evoked release of total 5H to 153 ± 13, 190 ± 18 and 178 ± 26% of control, respectively. In contrast, EIC and U50,488 reduced K+-evoked release to 63 ± 14 and 63 ± 13%, respectively. No changes were resolved with either morphine (70 ± 22) or 8-endorphin (105 ± 14%). Thus, these drugs appear to affect neuronal processes that converge on spinal serotonergic terminals. Interestingly, the effect of the various agents on 5-HT release was not always consistent with what would be proposed from the antinociceptive studies that have implicated 5-HT in local spinal actions.

428.3
RELEASE OF ADENOSINE FROM THE SPINAL CORD BY 5-HYDROXYTRYPTAMINE (5-HT) AGONISTS. CHARACTERIZATION OF RECEPTOR SUBTYPES. J. Mason*, D. Leeson, A. Reid, G. Doak and T. White, Dept. Pharmacology, Dalhouse University, Halifax, NS B3H 4H7.

Release of adenosine by 5-HT may mediate a component of the spinal antinociceptive action of 5-HT (Brain Res. 426: 348). In this study, the 5-HT receptor subtypes involved in adenosine release were characterized using behavioral and neurochemical approaches. 8-Phenylthethylphenylacetic acid is a 5-HT agonist but not 5-HT antagonist. Similarly, 5-HT agonists did not release adenosine from dorsal cord spinal cord synaptosomes. In all cases, the adenosine originated from released nucleotide rather than as adenosine per se, as release was reduced by inhibition of 5'-nucleotidase activity. Release of adenosine by 5-HT and CGS 20668 was Ca++-dependent, while that induced by TFMPP and DOX was not. Release of adenosine from the spinal cord appears to be due to activation of a 5-HT receptor subtype; the Ca++-dependent component of release appears to contribute to behavioral effects of 5-HT agonists. (Supported by MRC Canada).

428.4
DESPRAMINE REDUCES NMDA-INDUCED NOCICEPTIVE BEHAVIOUR MEDIATED THROUGH THE SPINAL SHT1A RECEPTOR. N. Meldrum, A. Lund and K. Hole, Department of Physiology, University of Bergen, N-5009 Bergen, Norway.

The mechanism of the antinociceptive effect of despramine (DMI) is unclear. It is generally accepted that excitatory amino acids (EAA's) act as neurotransmitters in primary nociceptive fibers, and in vivo studies have shown that cyclic AMP analogs may influence the NMDA receptor complex.

The modulatory effect of DMI on the nociceptive behavior induced by intrathecal (i.t.) NMDA (0.4 mmol, 7µl) was studied in mice. DMI was administered either i.t. (0.75, 1.5µl) 5 min prior to administration of NMDA. Intraperitoneally (i.p.) (10 mg/kg) 30 min prior to NMDA, or in drinking water during 3 weeks. The nociceptive behavior (biting and scratching) produced by i.t. NMDA was significantly reduced when the animals were pretreated with DMI, either acutely or chronically.

The SHT1A antagonist 8-OH-DPAT inhibits NMDA-induced behavior. A functional upregulation of the SHT1A receptor was found after chronic administration of DMI. We therefore investigated if blocking of the SHT1A receptor would reduce the effects of DMI. A selective SHT1A antagonist, NAN-190 Hydrobromide (10 µg), was injected i.t. 5 min prior to NMDA in animals pretreated with DMI. The SHT1A antagonist reversed the reduction of NMDA-induced behavior produced by DMI.

These findings indicate that both acute and chronic administration of DMI reduce the NMDA-induced nociceptive behavior, and that this may be mediated at least partly through the SHT1A receptor in the spinal cord.
428.5 DIFFERENTIAL EFFECTS OF 5-HT AND NE UPTAKE BLOCKADE ON OPIOD RECEPTOR SUBTYPE SELECTIVE ANALGESIA

D. Paul and A.R. Fowler
Department of Pharmacology, Louisiana State University Medical Center, New Orleans, LA 70112.

Selective antagonism of 5-HT(1A) receptors by pirenzepine, ME-300 or spiroxatrine, or k-opioid receptors produces analgesia through neuroanatomically and neurophysiologically distinct mechanisms. Blockade of 5-HT or NE uptake potentiates morphine analgesia. To determine whether selective 5-HT and NE uptake blockade will potentiate analgesia produced through each of the opioid receptor subtypes, we assessed the analgesic effects of morphine, i.e., DAMGO (mu), i.e., DADLE (delta), U50,488H (kappa), and nalorphine (kappa) in mice treated with zimelidine (10 mg/kg), desipramine (5 mg/kg) or saline using the tail-flick assay. Zimelidine produced a leftward shift in the dose-response curves for morphine, i.e., DAMGO (5-fold), and U50,488H (2-fold). Desipramine produced a leftward shift in the dose-response curves for morphine and i.e., DPDPE (2-fold). These results indicate that a 5-HT may modulate mu, and kappa, analgesia, whereas NE may modulate spinal delta analgesia.

428.8 INTRATHORACIC (I.T.) METOXAMINE POTENTIATES DESMETHYLDOPAMINE SPINAL ANTINOCICEPTION IN THE RAT: EVIDENCE OF A ROLE FOR 5-HT, ADRENERGIC AND ENDOGENOUS OPIOIDS

C. L. M. G. Bolotin, M. D. Madl, E. D. Tarnopol, M. J. Dauvillier, K. D. Proven, K.D. Proven, C. W. van Baal, and P. D. Miller, School of Pharmacy, University of Toronto, Toronto, ON, Canada.

I.t. α-agonists induce selective antinociception (AP) in animals via spinal α-2-agonists, the role of spinal α-2-agonists is less clear. The objectives of this study were to determine: 1) if i.t. methoxamine (MX; α-agonist) potentiates AP induced by i.t. desmethyldopamine (DM), an endogenous antinociceptor in the rat; and 2) if endogenous spinal Met-Enk is involved in this interaction. Male Sprague-Dawley rats (250-450 g) were implanted with i.t. catheters. Rates whose baseline responses and nociceptive function were normal were used in the tail-flick and paw pressure withdrawal tests. All drugs were given i.t. in the following procedure: 10 μg threshold (<10 s) doses of MX to DM yielded an 8-fold leftward shift of the DX dose-response curve (DRC). MX potentiation of DX was not due to a prolonged duration of DX action; and was significantly antagonized by each of the following i.t. pretreatments: prazosin (15 μg), yohimbine (2.5 μg), naloxone (30 μg), or anti-Met Enk (but not by yohimbine preincubated with Met-Enk). Pretreatment with i.t. SCH 32615 (Met-Enk inhibitor) shifted the MX+DX (32615) DRC to the left 6-fold compared to vehicle pretreated rats but had little effect on the DX DRC (no effect on MX). Light microscopy of spinal cord cerebra from rats given MX+DX (twice daily for 3 days) revealed no inflammation, haemorrhage or necrosis, and no changes in substance P- or CGRP-like IR compared to vehicle controls. The data indicate that the MX potentiates DX spinal AP without neurotoxicity. The effect appears to be mediated, at least in part, by spinal Met-Enk, consistent with the known AP interaction between opioid- and α-agonists. (Supported by NRC Canada)

428.9 ALPHA-2-ADRENERGIC AGONIST MEDICATION POTENTIATES ANALGESIC RESPONSES TO OPIOID AND NONOPIOID AGONISTS

The expression of c-Jun, Jun, Jun B, fos B and krox-24 proteins were used to study the antinociceptive effect of ip administered medetomidine (MED), a selective α2-adrenergic agonist, in the rat CNS. Protein levels were detected by immunocytochemistry. MED (100 or 300 μg/kg) was injected 12 min before the injection of formalin (F: 5% 50 μl) in the plantar skin of the hindfoot. The rats were killed and perfused 90 min later, Atipamezole (ATI; 1.5 mg/kg ip) was used to reverse the effects of MED. For induced expression of all studied proteins in the spinal dorsal horn ipsilaterally, and in the medial thalamus. Both MED doses strongly (80-90%) suppressed the expression of all proteins, but not in thalamic neurons. ATI completely reversed the effect of MED. Thus, the expression of immediate-early gene (IEG) encoded proteins is under powerful control of α2-α2-adrenoceptors in spinal but not in thalamic neurons. These IEG data dissociate from recent behavioral and electrophysiological findings (Perrotta, et al. Neurosci.1991.44.705) indicating that in the thalamus also the low but the spinal high MED dose produced antinociception. (Supported by DFG)

428.10 REINFORCEMENT OF SPINAL MORPHOAMNEnergic NEUROTRANSMISSION INDUCES ANTIINOCICEPTION IN THE RAT TAIL FLCK TEST - ONE ADDITIONAL MODE OF ACTION OF THE CENTRAL ANTAGONIST "TRAMADOL".

M. S. Reina, R. H. Schulz, and F. Schneider.

Dept. Pharmacology, Grünenthal GmbH, W-5100 Aachen, FRG.

Tramadol has low affinity for opioid receptors and shows norepinephrine (NE) and serotonin uptake inhibition in standard assays. We tested whether NE blockade occurred at spinal sites and whether it can effect antinociception. Slices of the rat dorsal spinal cord were preincubated with NE, then superfused and stimulated electrically twice. Tramadol enhanced the stimulation-evoked overexpression of trivia, starting at 1 μM, qualitatively similar to the NE uptake blocker desipramine (DMI). The effects were mainly due to the (-)-enantiomer of tramadol. When uptake sites were blocked by DMI, DMI's time-effect was lost, suggesting NE uptake inhibition is responsible for tramadols effects. I.t. injection site of 12 μg tramadol at the lumbar produced a significant effect in the tail flick test; both enantiomers were roughly equally potent. Antinociception was also observed with i.t. DMI, starting with 6 μg. Effects of DMI and tramadol were antagonized by i.p. injection of 1 mg/kg yohimbine. The results from this and in vitro and in vivo experiments provide evidence that tramadol reinforces NE neurotransmission at the spinal site and that this mode of action in addition to opioid-like activity is involved in spinal antinociception.
428.12 MUSCARINIC CHOLINERGIC SPINAL ANTIINOCICEPTION. E.T. Iwamoto*, L. Marion, N.W. Pedigo, and R.D. Guarino, Department of Pharmacology, University of Kentucky College of Medicine, Lexington, KY 40536

Intrathecal (i.t.) administration of the muscarinic cholinergic agonist, (+)-cis-methylycoline (CCL), into the lumbar spinal cord of male Sprague-Dawley rats produced antiinociception as assessed by the P2° C hot-plate and tail-flick (7 sec control latency) assays. i.t. CD induced antiinociception within 5 min for up to 3 hr without altering other motor reflexes or median effective i.t. dose of CD was ~10 nmol in both antiinociceptive assays. Tissue content of CD 30 min after an i.t. injection of 37.5 nmol H-CD was estimated at 1 μM. The antiinociception induced by 37.5 nmol of CD was antagonized by 5 min i.t. pretreatment with pirenzepine or methotrimeprazine at IC50 doses of approximately 1 and 7 nmol, respectively. Five min i.t. pretreatment with 20 nmol LY-53857, 25 nmol 5-(-)zacopride, or 25 nmol idazoxan (doses which were inactive alone) each partially antagonized 37.5 nmol CD antiinociception, whereas buffer, mecamylamine or naloxone had no effect. CD inhibited H-QNB binding in spinal cord homogenates with μmolar affinity. The data suggest that i.t. CD antiinociception may be mediated via M1 and/or M2 muscarinic, 5-HT2 and/or 5-HT3 receptor sites. (Supported in part by NS 28847 and KTRB.)

This study investigated the effects of aging on the antiinociceptive efficacy of the μ opioid agonist DAMPGO. Young, mature and aged Fischer 344 rats (6, 16 and 26 months old, respectively) were injected intrathecally (i.t.) with various doses of DAMPGO. Opiate-induced changes in tail-flick latency (TFL) and nociceptive withdrawal latency (NWL) were recorded 5, 15, 30, 60 and 120 min post-injection. The results demonstrated that DAMPGO dose-dependently elevated TFL and NWL in each of the three age cohorts. When the tail-flick test was used as the nociceptive measure, the potency ratio of DAMPGO was significantly different between the 16 and 26 month old rats. No significant age-related differences were observed in the potency ratio for DAMPGO when the hot plate was used as the nociceptive test. Thus, while higher i.t. doses of DAMPGO are apparently needed to produce antiinociception in older rats, the μ opioid receptor site continues to mediate spinal DAMPGO-induced antiinociception throughout the life span of the rat.

428.15 SELECTIVE INHIBITION OF NON-PEPTIDE SUBSTANCE P ANTAGONIST CP-96,345 ON NOCICEPTION IN RATS. Y.C. Gosed, S.P. Rabby, J.S. Mitchell, R.S. Cohen and J. Sagen, Departments of Anatomy and Cell Biology and Anesthesiology, University of Illinois College of Medicine, Chicago, IL 60612.

Substance P (SP) may mediate nociceptive transmission via the NK1 receptor in the spinal cord. Studies in this field have been limited by the lack of specific antagonists. A recently developed non-peptide SP antagonist, CP-96,345, is specific for the NK1 receptor. The purpose of this study was to assess the effects of this antagonist on nociception. Nociception was determined using tail flick, paw pinch and hot plate tests in rats. The rats received intrathecal injections of various doses of CP-96,345 and pain sensitivity was assessed at several times before and following injection. In addition, the ability of CP-96,345 to inhibit SP-induced biting and scratching was assessed. Results from analgesiometric testing indicated that doses up to 240 μg had no significant effect on either tail flick latency or paw pinch threshold. Hot plate latency was only elevated by high dose of the antagonist. In addition, the SP antagonist failed to inhibit the SP induced biting and scratching. The Intrathecal injection of CP-96,345 produced a dose-related decrease in tail skin temperature, significant only at the NK1 receptor. Preliminary binding studies using [3H]-SP were also performed. Assessment of the ability of CP-96,345 to inhibit the binding of [3H]-SP to the rat spinal cord and rat salivary tissue indicated that CP-96,345 and SP behave similarly at the NK1 receptor. The results of this study suggest that, while CP-96,345 binds the SP site at the NK1 receptor in the spinal cord, this receptor is most likely not involved in mediating some types of acute pain at the spinal cord level. (Supported in part by NS 25054.)

428.14 EFFECTS OF INTRATHECALLY INJECTED NON-PEPTIDE SUBSTANCE P ANTAGONIST CP-96,345 ON NOCICEPTION IN RATS. Y.L. Gosek, S.P. Rabby, R.M. Mitchell, R.S. Cohen and J. Sagen, Dept. of Anatomy and Cell Biology and Anesthesiology, University of Illinois College of Medicine, Chicago, IL 60612.

Substance P (SP) may mediate nociceptive transmission via the NK1 receptor in the spinal cord. Studies in this field have been limited by the lack of specific antagonists. A recently developed non-peptide SP antagonist, CP-96,345, is specific for the NK1 receptor. The purpose of this study was to assess the effects of this antagonist on nociception. Nociception was determined using tail flick, paw pinch and hot plate tests in rats. The rats received intrathecal injections of various doses of CP-96,345 and pain sensitivity was assessed at several times before and following injection. In addition, the ability of CP-96,345 to inhibit SP-induced biting and scratching was assessed. Results from analgesiometric testing indicated that doses up to 240 μg had no significant effect on either tail flick latency or paw pinch threshold. Hot plate latency was only elevated by high dose of the antagonist. In addition, the SP antagonist failed to inhibit the SP induced biting and scratching. The Intrathecal injection of CP-96,345 produced a dose-related decrease in tail skin temperature, significant only at the NK1 receptor. Preliminary binding studies using [3H]-SP were also performed. Assessment of the ability of CP-96,345 to inhibit the binding of [3H]-SP to the rat spinal cord and rat salivary tissue indicated that CP-96,345 and SP behave similarly at the NK1 receptor. The results of this study suggest that, while CP-96,345 binds the SP site at the NK1 receptor in the spinal cord, this receptor is most likely not involved in mediating some types of acute pain at the spinal cord level. EVALUATION OF THE EFFECT OF NITRIC OXIDE ON THE RELEASE OF ICRP FROM THE DORSAL HORN OF THE SPINAL CORD IN RATS.
M.G. Gary*, H.E. Geier, and K.M. Hargens. Univ. of Minnesota, Dept. of Restorative Sciences, and Dept. of Pharmacology, Minneapolis, MN.

Nitric oxide (NO) is a gaseous, biologically active molecule that plays a role in numerous physiological processes. In this study, we evaluated the effect of NO on the release of ICRP (i.e., substance P) from the dorsal horn of the spinal cord in rats.

NO was administered to rats via intrathecal injection, and the release of ICRP was measured using an in vitro radioassay. The results showed a significant increase in the release of ICRP following NO administration, indicating that NO plays a role in the release of ICRP from the dorsal horn of the spinal cord in rats.

REGULATION OF TACHYKININ RECEPTOR mRNA EXPRESSION IN RAT DORSAL HORN DURING NOCICEPTION. K. E. McCarron and J. E. Krause. Depnt of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

The tachykinin peptide family includes substance P (SP) and neurokinin B (NKB). These peptides are both contained in the dorsal horn of the spinal cord and are involved in the modulation of nociception. In this study, we investigated the regulation of tachykinin receptor mRNA expression in the dorsal horn during nociception.

The dorsal horn was isolated from rats, and the expression of tachykinin receptor mRNAs was measured using reverse transcription-PCR. The results showed that the expression of tachykinin receptor mRNAs increased during nociception, indicating a role for these receptors in the modulation of nociceptive responses.

PAIN MODULATION: SPINAL I

Monday PM

429. 1

Activation of nociceptors, peripheral inflammation, or noxious pressure elicits excitability of spinal cord neurons. We investigated the activity of dorsal horn cells during hyperalgesia induced by UV radiation in rats.

The rats were divided into two groups: a control group and a UV-induced hyperalgesia group. The UV-induced hyperalgesia group was exposed to UV radiation, while the control group was not. The activity of dorsal horn cells was recorded using a microelectrode technique.

The results showed a significant increase in the excitability of dorsal horn cells following UV radiation, indicating that UV-induced hyperalgesia increases the excitability of spinal cord neurons.

USE OF FOS-LIKE IMMUNOREACTIVITY TO STUDY THE EFFECTS OF ANALGESIC COMPOUNDS IN SPINAL CORD NEURONS OF POLYARTHRITIC RATS. C. Abadie and J. M. Boussert. INSERM U161 and EPHE, 2 rue d’Alkma, 75014 Paris, France.

We have recently shown that during the development of adjuvant-induced arthritis (AIA) in the rat, the number of SP-immunoreactive (SP-IR) neurons in the lumbar spinal cord was maximal 3 weeks after induction of the disease, which is the acute phase of hyperalgesia. The number of SP-IR neurons increased by a factor of 4 in the AIA group compared to the control group.

In this study, we investigated the effects of analgesic compounds on the number of SP-IR neurons in the lumbar spinal cord of polyarticular rats. The rats were divided into four groups: a control group and three experimental groups treated with different analgesic compounds. The results showed that the number of SP-IR neurons was significantly reduced in the experimental groups compared to the control group, indicating a role for analgesic compounds in the modulation of nociception.

THE ROLE OF ACTIVATION OF SPINAL NEURONS IN TONIC PAIN AND EDEMA DEVELOPMENT AFTER FORMALIN-INDUCED TISSUE INJURY. A. C. Durrant and T. Wheeler. Anesth. Dept. of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140, USA.

Behavioral and electrophysiological studies of the response to formalin (FL) in rats suggest that neuronal changes associated with the early phase may be required for full expression of the tonic nociceptive responses. Here, saline (2%) or formalin (0.25%, 1%, 5%) was injected into 70-90 g male rats at either -10 min or 10 min after FL (0.25%, 5%) into the right hind paw (n=8).

Formalin-induced hyperalgesia (FL, 0.25%) was recorded in the right hind paw at 1 min, dose dependent function and increases 50% no-water foot lick latency only transiently (~15 min), but when it is given in 2% formalin is significant and prolonged spontaneous hyperalgesia. Moreover, 0.25% formalin produces a biphasic response in rat paw, whereas 2% formalin induces only slight hyperalgesia.

In contrast, post-FL latencies have a more significant effect than FL exposure, which results in more foot lick latencies, after which formalin gradually recovers to control levels. Although FL, it intrinsically reduces development of edema (3-5 h). However, formalin exposures cause significant reductions in hyperalgesia. Our data suggest that, immediately after the barrage of primary afferent firing impinging on spinal neuronal sparsus supraspinal reorganization of spinal response is initiated. These changes may also be associated with the development of inflammation as well as pain-related behaviors. Since brief protection of spinal neurons significantly reduces the tonic response, our findings suggest the use of local anaesthetics to prevent the development of functional neuronal changes in response to tissue injury (DA90365 & DA97237).
429.5 DORSAL HORN NEURONS SERVING THE LOW BACK ACTIVATION BY SYMPATHETIC STIMULATION. R.G. Gillette, R.C. Kramis, and W.J. Roberts*. Dept. of Neurosurg, & R.S. Dow Neurologic. Sciences Inst., Good Samaritan Hospital & Medical Center, Portland, OR.

Most somatosensory afferents in the extreme lateral dorsal horn of L4-S in cats have receptive fields in the lumbar region and/or hip and proximal hindlimb. They are hyperconvergent WDRs which receive input from all or most of the following tissues: paraspinal muscles, fast joint capsules, vertebral periost, spinal dura, disc, hip and proximal leg muscles, and skin. Such neurons are likely to subserve low back pain.

Clinical reports indicate that sympathetic blocks reduce low back pain in some patients, suggesting a segmental sympathetic role. We therefore tested somatosensory neurons in the lateral lumbar spinal cord for responding to electrical stimulation of the lumbar sympathetic trunk. Single unit recordings were made from L4-S in adult pentobarbital anesthetized cats. Of 82 neurons with conus and/or deep receptive fields in the lumbar region, 70% were responsive to sympathetic stimulation (SS). Excitatory responses to SS were differentiate into: a) short-latency, enhanced responses; and b) longer-latency, non-enhanced responses. The former were resistant to systemic alpha-adrenergic antagonists and are thought to result from activation of afferent fibers in the sympathetic trunk, some of which innervate paraspinal tissues. The non-enhanced responses were attenuated by alpha antagonists and are thought to result from direct or indirect sympathetic activation of afferents. The results indicate that both somatosensory afferent and sympathetic efferent activity in the lumbar sympathetic trunk can contribute to low back pain.

429.8 NEUROKININ RECEPTOR ANTAGONISTS MODIFY THE RESPONSES OF PRIMATE STT NEURONS TO CUTANEOUS STIMULI. W.D. Willis*, J. Palecek, V. Paleckova, J. Ragland, and W.D. Willis. Department of Neuroscience and Anatomy, 200 University Blvd., University of Texas Medical Branch, Galveston, Texas 77550-2702.

We explored the effects of two second messenger systems, the inositol phosphatase cascade (activated by trans-ACPD) and the protein kinase C pathway (activated by phorbol ester, PMA) on the responses of STT cells to cutaneous and chemical stimuli. The experiments were conducted in 5 young adult monkeys (Macaca fascicularis). STT neurons were identified by antidromic activation and recorded using a carbon dioxide electrode in the center of a multibarrel array, the outer barrel of which contained extracellular amino acids (EAAs). The responses of the STT cells to cutaneous stimulation (BRUSH, PRESS and PINCH) and to noxious chemical stimuli (HCl) and acrolein were studied. The responses of the STT cells to cutaneous stimuli were enhanced, i.e., CAP and PMA produced a decrease in response latency. In contrast, the responses to noxious chemical stimuli were suppressed. The enhancement of cutaneous responses by trans-ACPD was suppressed by TTX, indicating that the enhancement was due to the activation of the transmembrane calcium channel. The enhancement of noxious chemical responses by trans-ACPD was enhanced by TTX, indicating that the enhancement was due to the activation of the transmembrane calcium channel. The enhancement of noxious chemical responses by trans-ACPD was suppressed by TTX, indicating that the enhancement was due to the activation of the transmembrane calcium channel. The enhancement of noxious chemical responses by trans-ACPD was suppressed by TTX, indicating that the enhancement was due to the activation of the transmembrane calcium channel.

429.9 EFFECTS OF SYSTEMIC MORPHINE ON LAMINA I NEURONS IN THE CAT. L.P. Serrano* and A.D. Craig. Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

The action of morphine on lamina I spinothalamic tract (SCT) cells, which form half of the STT, has not been determined. Previous work demonstrated that morphine enhances the activity of "cold"-sensitive lamina I STT cells. This study further tests the hypothesis that morphine's actions are organized in the belief by examining its effects on nociceptive lamina I units. Units recorded with tungsten microelectrodes in L7 in barbiturate-anesthetized cats were characterized with natural stimuli and with antidromic activation from the thalamus. L7 lamina I neurons that identified with PHA-L. Quantitative heat and pressure stimuli were used to measure the effects of increasing doses of systemic morphine (0.1-2 mg/kg iv) on the responses of 10 nociceptive lamina I cells (6 STT, 3 non-STT, 1 unclassified) that had receptive fields in the ventral hindpaw. All cells had graded sensitivity to noxious heat. Morphine inhibited the responses of 9 cells (mean=54% of control), including all 6 STT cells. Seven of 10 STT lamina I cells was inhibited and 25 non-STT cells were enhanced by low doses (154%). Morphine in higher doses suppressed the responses of 2 non-STT WDR neurons to heat but not to pinch. Naloxone reversed the effects in 7/8 cells. These observations are consistent with the claim that lamina I STT cells form an integral component of the central representation of pain, since all such cells were inhibited by morphine. However, these results also suggest that some STT lamina I neurons are not morphine sensitive, which supports the hypothesis that opioidergic modulation of lamina I neurons is facioally organized. (Supported by DA 07402)

Discipline in mice (MK-801), a non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist, has been shown to reduce thermal hyperalgesia in rats with hindpaw inflammation. Other excitatory amino acid (EAA) receptor antagonists were examined to further elucidate the involvement of NMDA receptors in the hyperalgesia associated with inflammation. Hyperalgesia, assessed by paw withdrawal latency (PWL) to a heat stimulus, was induced by a single injection of carrageenan (CARRA) (6.0 mg) into the hindpaw of rats. The effects of NMDA receptors were examined by intrathecal (I.T.) injection of the EAA receptor antagonists: (2)-aminoo-5-phosphono-pentoic acid (AP-5), (2)-3-(2-carboxyphosphatase)-propyl-1-phosphonic acid (CPP), MK-801, ketamine hydrochloride (KET), 7-chlorokynuric acid (7-CK), and 6-cyano-7-nitroquinolxaline-2,3-dione (CNQX). Whereas PWLs of non-injected paws and those of naive rats were not significantly affected, PWLs of injected paws were dose-dependently elevated. The rank order of potency of these agents to reduce hyperalgesia was: MK-801 > AP-5 > CPP > 7-CK = KETA >> CNQX > 0. In contrast, I.T. injection of the opioid receptor agonist, [D-Ala2,MePhe4,Gly-ol5]-enkephalin (DAMGO, μ-selective) produced antinociception in both injected and non-injected paws. DAMGO was about 66 times more potent than MK-801. The dose-dependent effects of various NMDA receptor agonists provide additional evidence that NMDA receptors are involved in CARRA-induced thermal hyperalgesia.

429.12 DIFFERENTIAL ROLES OF NMDA AND NON-NMDA RECEPTOR ACTIVATION IN INDUCTION AND MAINTENANCE OF THERMAL HYPERALGESIA IN RATS WITH PAINFUL PERIPHERAL MONONEUROPATHY. D.J. Mayer*, A. Macl, J.L. Hazl, J. Lat*, and D. Price*. 60892.

Dept. of Anesthesiology, Medical College of Virginia, Richmond, Virginia 23298. "Division of Neurosurgery, University of Texas, Houston, Texas 77025. Exciatory amino acid (EAA) receptor activation within the spinal cord has been implicated in neuropathic pain following nerve injury. Using a rat model of peripheral mononeuropathy (Bennett and Xie, Pain, 1988, 33:87), we compared the effects of intrathecal treatment with NMDA receptor antagonists (MK801) and H/A/66) and a non-NMDA receptor antagonist (CNQX) on induction and maintenance of thermal hyperalgesia induced by chronic constrictive injury (CCI) of the ligated sciatic nerve. Four daily saline treatments with 20 nmol H/A/66 or CNQX beginning 15 min prior to nerve ligation (pre-injury treatment) reliably reduced thermal hyperalgesia in CCI rats on days 3, 5, 7, and 10 after nerve ligation. Thermal hyperalgesia also was reduced in CCI rats receiving a single gastroinjury with H/A/66 (20 or 80 nmol) or MK801 (5 or 20 nmol) on Day 3 after nerve ligation when thermal hyperalgesia was well developed. In contrast, a single post-injury CNQX (20 or 80 nmol) treatment failed to reduce thermal hyperalgesia or to potentiate effects of H/A/66 or MK801 on thermal hyperalgesia. Moreover, multiple post-injury CNQX treatments utilizing the same dose regimen as employed for the pre-injury treatment attenuated thermal hyperalgesia only when the treatment began 1 or 24 hrs (but not 72 hrs) after nerve ligation. The results suggest that NMDA and non-NMDA receptor activation may have differential roles in induction and maintenance of thermal hyperalgesia following constriction nerve injury and that mechanisms underlying post-injury neuropathic pain may be associated with EAA-mediated central alterations. Supported by NIH grants NS 24009.

Dept. of Pharmacology, The University of Iowa, Iowa City, IA, 52242.

NMDA (1 nmol-1 pmol) was administered through an 8.5 cm intrathecal (I.T.) catheter to the lumbar spinal cord of awake Sprague-Dawley rats. Changes in tail-flick (TF) latency in response to noxious heat were monitored 0.5, 1, 2, 5, and 10 min post-drug. Lower doses of NMDA (100 fmol-1 pmol) produced a dose-dependent facilitation of the TF reflex (maximal at 0.5-1 min) while greater doses (0.25 nmol-1 pmol) produced a dose-dependent decrease in the TF reflex (maximal at 2-5 min), and also produced a caudally-directed scratching and biting behavior and vocalizations (CBSV). Maximal facilitation was produced by 10 pmol NMDA while maximal inhibition and CBSV were produced by 1 nmol NMDA. Pre-treatment with D-APV (1 fmol-1 pmol, I.T.), which produced no change in baseline TF latency, blocked all NMDA-produced effects in a dose-dependent manner (100 fmol D-APV produced maximal blockade for about 40 min). D-serine (10 nmol-1 pmol, I.T.) and glycine (10 pmol-1 pmol, I.T.) produced a dose-dependent facilitation of the TF reflex which was comparable to the facilitation produced by NMDA (10 pmol); the facilitatory effects of NMDA and D-serine were blocked by 7-chlorokynurenic acid (10 pmol-10 pmol, I.T.). The NMDA-produced biphasic effects on TF latency, but not the CBSV were similar in lightly pentobarbital-anesthetized rats and produced a similar facilitation at 10 mg/kg. In non-anaesthetized rats completely abolished the inhibition of the TF reflex produced by 1 nmol NMDA while the facilitation produced by 10 pmol NMDA remained unchanged.

In summary, these data suggest that while NMDA-produced facilitation of the TF reflex may be a local phenomenon, inhibition of the TF reflex and CBSV may be produced by activation of descending pathways that in turn engage a descending inhibitory pathway to produce inhibition of the TF reflex.

429.14 HYPERESTHESIA INDUCED BY SPINAL GLUTAMATE AND NK-1 TACHYKININ RECEPTORS IS REDUCED BY INTRATECHAL NON-NTRITERAL ANTI-INFLAMMATORY DRUGS (NSAIDs). A.B. Malhotra and T.L. Yaksh*. Dept. of Anesthesiology, UCSD. La Jolla, CA 92035-0818.

Spinal administration of NSAIDs can significantly diminish the second phase, behavior induced by subcutaneous injection of formalin in the paw. Based on the growing appreciation of the involvement of excitatory amino acids (EAA) and substance P directly into the spinal cord. Intrathecal injection of NMDA (7 nmol), AMPA (1 nmol) and substance P (7 nmol) each resulted in a dose dependent decrease in the latency of the response evoked by a thermal stimulus applied to the hind paw. The selective antagonists MK-801 (29 nmol), CNQX (77 nmol) and PSN,1,345 (330 nmol), respectively, given 10 min before the agonists, blocked the observed thermal hyperesthesia for the respective agonists. Importantly, injection of the antagonists 10 min after the agonists failed to block the decreased paw withdrawal. To assess the potential role of prostaglandins released by the spinal activation of the respective receptors, we examined the effects of several NSAIDs on the evoked thermal hyperesthesia. We found that acetazolamide (100 nmol), ketorolac (75 nmol) and indomethacin (25 nmol) resulted in a complete reversal of the induced thermal hyperesthesia. Importantly, the intrathecal NSAIDs were equally effective in reducing the thermal hyperesthesia whether administered before or after the agonists. Additionally, the inactive stereoisomer R-73480 failed to show any effect at doses 10 times higher than the active isomer S-73480. This emphasizes that the NSAIDs action were mediated by an effect upon cyclooxygenase. These data provide evidence that activation of spinal glutamate and NK-1 receptors results, at least in part, in local generation and release of prostaglandins, which mediate a spinal facilitation of the animal's response to noxious stimuli. (Supported by NIH DA 02110, T.LY)

Prostaglandins(PGs) influence the development of hyperalgesia in the periphery. However, centrally their role is not yet well defined. This experiment was designed to investigate the influences of intrathecally administered PGE2 and PGF2α on behavioral responses to non-noxious, and noxious somatic and visceral stimuli in rats. Intrathecal catheter was implanted at the level of L2-L3 in rat. The tail flick (TF) test and colorectal distension (CD) test were employed to measure the responses to noxious somatic and visceral stimuli, respectively. Alpha adrenergic (A2) to mechanical pressure produced by three kinds of Semmes-Weinstein monofilaments (SWMs) ranging 0.08 g to 2.33 g was further significantly increased following administration of both PGF2α and PGE2 and the effects lasted for at least 2 days, while in the saline group there was no significant difference. This result suggests that PGs may act on hyperalgesic processing in the spinal cord.
430.2 RESPONSES IN THE RAT TO NOXIOUS COLORECTAL DISTENSION IN THE PRESENCE OF ACETIC ACID. M. Burton* and G.P. Gehart
Department of Pharmacology, University of Iowa, Iowa City, IA 52242.

The mechanisms of visceral pain have recently been a major focus of investigation. Distension of hollow organs has been shown to be noxious to the body. Clinically, there is usually some pathology associated with pain from visceral organs; however, this has not been extensively studied in animals. Therefore, the aim of this study was to determine the effects of acetic acid irritation on the responses to noxious colorectal distension (CRD).

Pre- and post motor (EMG) responses to CRD (80 mmHg, 20 sec, 3 min apart) were examined in unanesthetized, chronically instrumented, male Sprague-Dawley rats before and 6 and 24 hours after 1 ml intracolonic 5% acetic acid (or vehicle). The results of a separate group of rats were examined 4, 6, 8, or 24 hours after 1 ml intracolonic acetic acid for evidence of leukocyte infiltration. Acetic acid did not produce any change in resting mean arterial pressure (MAP), or in the MAP in response to CRD at any time tested. In contrast, the magnitude of both baseline EMG and ΔEMG produced by CRD were significantly increased at 6 and 24 hours after acetic acid, as noted in the table. Acetic acid had no effect on the number of leukocytes in colonic tissue at any time tested. These results suggest that irritation, but not inflammation, of the colon produced by acetic acid results in an increase in the magnitude of nociceptive responses to CRD.

control 6 hr 24 hr

ΔEMG (%) 100 182 ± 47 216 ± 34

430.4 EFFECTS OF MANIPULATING INTRACELLULAR CALCIUM ION CONCENTRATION USING VOLTAGE SENSITIVE CALCIUM CHANNEL BLOCKERS AND DANTROLEN ON PERSISTENT HINDLIMB FLEXION IN SPINALIZED RATS. M.S. Anderson and J.T. Baradelli
Department of Psychiatry, St. Elizabeth's Hospital of Boston, Boston, MA 02135 & Department of Pharmacology, University of New England, Biddeford, ME 04005.

Stimulation (2mA, 7ms, 100Hz, 60min) across the musculature of the upper hindlimb in the spinalized rat produces a persistent hindlimb flexion. Previously, we have shown that NMDA receptor antagonists interfere with the induction of this flexion. Given NMDA receptor stimulation indirectly may activate voltage sensitive calcium L-channels, the dose response of pretreatment with nimodipine, nifedipine and diltiazem on induction of a persistent hindlimb flexion was examined.

Following spinalization of adult Long Evans rats under halothane anesthesia, animals were pretreated with one dose of a particular test agent (nimodipine: 0.03, 0.1, 0.3, and 1.0mg/kg ip, nifedipine: 0.1, 0.3, 1.0, and 3.0mg/kg, ip, diltiazem: 0.03, 0.1, 0.3, and 1.0mg/kg, ip) and wound clips were applied to the musculature of the right upper hindlimb. After a 30min waiting period, current (2mA, 7ms, 100 Hz, 1 hr) was delivered across the clips. In all groups, flexion was reduced in a dose dependent manner. Since 1) the systemic administration of calcium L-channel blockers may promote skeletal muscle relaxation and 2) NMDA receptor activation may effect release of intraneuronal calcium ion stores, the dose response of pretreatment with dantrolene sodium which theoretically inhibits the release of both skeletal muscle and neuronal calcium ion stores was studied. Following the above protocol, dantrolene sodium (0.1, 0.3, 1.0, and 3.0mg/kg, ip) pretreatment reduced poststimulation flexion in a dose dependent manner. These data suggest that induction of a persistent hindlimb flexion in the spinalized rat depends on both adequate intraneural and skeletal muscle intracellular calcium ion levels and 2) activation of skeletal muscle afferents. (Support: Mead Johnson & St. Elizabeth's)

430.6 ENDOGENOUS ANTI-ALGALERGIA: EFFECTS OF ANYGILADA, DORSAL RHAPHE & SPINAL LENSES L.B. Watkins*, E.P. Wier telak, K. Mooney-Herber ger, R. Grun & S.F. Maier,
Dep. Psychology, University of Colorado at Boulder, Boulder, CO 80309.

We have shown that rats can learn to activate neural circuitry that blocks opiate analgesia (Wiertelak et al., Science, 1992). Using classical conditioning procedures, "danger" signals (cues predicting shock) come to elicit conditioned analgesia & "safety" signals (a light cue predicting that shock will NOT occur for some period) come to elicit conditioned anti-analgesia. To begin defining anti analgesia, we tested the anti analgesic effects of central nucleus of the amygdala (CeA; bilateral), dorsal raphe nucleus (DRN) & spinal dorsal funiculus & bilateral DRN & sham controls. Each of these areas has been previously implicated in fear &/or analgesia.

After surgery, rats received training to contextual "danger" signals & the discrete light "safety" signal (see Wiertelak et al., Science, 1992). Tail flick (TF) latencies were recorded during each of the 4 days of conditioning to assess the effect of the various lesions on acquisition of conditions of analgesia & anti-analgesia. Conditioned analgesia was then extinguished across 4 days. All rats were injected with morphine the next day to test whether any lesion would prevent reversal of morphine analgesia.

The results were as follows. CeA lesions (a) blocked development of conditioned analgesia, yet (b) did NOT block shock safety signal reversal of intra-thalamic morphine analgesia. DLP lesions (a) blocked development of conditioned analgesia yet (b) prevented reversal by the safety signal of both conditioned analgesia & 5 mg/kg s.c. morphine analgesia. Taken together, these data provide strong evidence that anti-analgesia is mediated by neural circuitry different from that previously defined for analgesia systems. 430.7 INTERNAL AVERSIVE STIMULI ELICIT ACUTE & CONDITIONED HYPERALGESIA. E.D. Wierstel*, R. Mooney-Heiberg*, W. Van Wyhe, G.J. Piatellie II, S.P. Makar & L.F. Watkins. Department of Psychology, University of Colorado, Boulder, CO 80302. Hypoalgesia aversive to external stimuli promotes effective defense/escape behaviors. Perhaps, then, the adaptive response to aversive internal stimuli is hypoalgesia, to promote recuperative behaviors. An emotive agent (0.15 M inhum chloride [LiCl]) was used to produce an aversive internal stimulus. Indeed, LiCl produced pronounced hyperalgesia (tail flick), compared to controls. This appeared specific for nociceptivity, as sensitivity to non-palpable stimuli (vony) hairs was unchanged. LiCl-induced hyperalgesia involves activation of a centrifugal pathway since it is blocked by spinal transection. Further, this effect appears to be mediated by cholecystokinin (CCK) since it is abolished by prolylamic (0.4 mg/kg s.c.), a CCK antagonist. Paradoxically, 7 mg/kg naloxone produced profound hypalgesia, but not in vehicle control rats.

Since illness clearly could produce hyperalgesia, could hypealgesia be conditioned to cues associated with illness? To address this question, 2 groups were tested using a taste aversion paradigm. The first received saline paired with LiCl. The second (control) received equal numbers of LiCl & saccharine exposures, but in an unpaired fashion. On test day, all rats received saccharine. The rats that previously had saccharine paired with LiCl showed profound hypalgesia, compared to controls. Conditioned hyperalgesia was again abolished by prolylamic, indicating a role of CCK. Again, paradoxically, naloxone produced profound hypalgesia in the rats that previously had saccharine paired with LiCl.

These results suggest that conditioned effects on pain sensitivity are bidirectional. External danger cues can produce analgesia. The present data demonstrate that aversive internal stimuli can produce analgesia as can learned cues that signal such events. Supported by NIH MH33241H14617-15, K.M.H & W.V.W. supported by the Hughes Fund.

430.9 MILD SHOCK PRODUCES AN UNCONDITIONED, NALTREXONE-INSENSITIVE INCREASE IN REACTIVITY ON THE VOCALIZATION MAGNITUDE AND THRESHOLD TESTS. P.A. C. Parada & J.W. Grau. Dept. of Psychology, Texas A&M Univ. College Station, TX 77843.

This work suggests that an aversive event can produce either an increase (hyperalgesia) or decrease (hypolgesia) in pain reactivity. Although stress-induced hyperalgesia has been extensively explored both at the behavioral and neural levels, relatively little is known about stress-induced hyperalgesia.

Here, we first establish a paradigm that produces a robust increase in reactivity to pain. Subjects were trained to receive either mild shock (0.5 - 1.0 mA), never anything, or nothing. Subjects were trained to receive either mild shock (0.5 - 1.0 mA), never anything, or nothing. The paradigm resulted in a substantial increase in vocalization threshold (hyperalgesia) that decayed over time (Experiment 1) and a decrease in vocalization threshold (hypolgesia) when vocalization was blocked (Experiment 2).

This experiment was performed to compare the effects of capsaicin and its new derivatives on the tail-flick and jaw opening reflex evoked by noxious stimuli and content of Substance P in spinal dorsal horn and trigeminal sensory nucleus. Tail-flick reflex was tested by hot water immersion method in rat after subcutaneous injection of capsaicin, parado, shogao and demethoxy-NE (DM-NE). Neural conduction of peripheral sensory nerve was determined in saphenous nerve. Saphenous nerve was exposed and action potential was evoked by noxious electrical stimulation. Capsaicin and its derivatives were dissolved in vehicle and applied to saphenous nerve between stimulating and recording sites for 30 minutes. Amplitude and conduction velocity of action potential was compared before and after application of drugs. Substance P of spinal cord and trigeminal sensory nucleus was determined by radioimmunosassay. Capsaicin inhibited neural conduction of mainly C-fiber but parado and shogao had inhibitory effect on both Aβ- and C-fiber. Capsaicin and DM-NE significantly increased latent period of tail-flick reflex at first day after injection. Capsaicin decreased the substance P in spinal dorsal horn and central part of trigeminal sensory nucleus.

430.11 A COMPARISON OF NOCICEPTIVE RESPONSES USING TWO TEMPERATURE THRESHOLD VERSUS REFLEX LATENCY. Premyslaw Mark1, Anpolary L. Vavassorop 1, Bogdan Sadowski1 and John C. Liebeskind1. 1Dept. of Psychology, UCLA, CA 90024, 2Dept. of Psychology, U. of Orleans, LA 70148, and 3Institute of Genetics and Animal Breeding, Jastrzebie, Poland.

Mice bred for high (HA) and low (LA) stress-induced analgesia displayed differences in baseline hot-plate latencies. Interpretation of baseline sensitivity in the hot-plate test, however, is confounded by the stressful nature of this test and it is unclear whether such differences are due to stress-induced analgesia (produced by the test itself) or due to differences in tonic pain inhibition. We have recently developed a method of measuring hot-plate pain sensitivity which reduces the stress component. HA and LA mice were habituated for 20 minutes to a hot-plate maintained at 37±1°C. The temperature of the hot-plate was then gradually increased and the temperature values at which pain reflexes occurred were found in baseline temperature thresholds for HA and LA mice. In contrast, HA mice showed higher baseline responses than LA mice when the cold-plate was used (i.e. plate maintained at 56±1°C). Morphine produced a dose-dependent analgesia in both tests. These results suggest that this method of measuring absolute temperature thresholds would be a simple, effective method of assessing pain sensitivity, which greatly reduces the confounding effects of stress. Supported by NIH Grant NS07628 and an Unrestricted Research Grant from the Bristol-Myers Squibb Company.

430.12 EXPOSURE TO A HEAT STRESSOR INDUCES AN OPIOID CONDITIONED HYPOALGESIA IN RATS TESTED FOR NOCICEPTION TO FORMALIN. P. Fosse and R.F. Westbrook. School of Psychology, University of W.S.W. Sydney, Australia.

Rats exposed to a heated floor in a distinctive environment (EI) and subsequently tested there on that floor are hypoalgesic. This conditioned hypalgesia is naloxone irreversible and not cross-tolerated with morphine. However, morphine-tolerant rats come to acquire the conditioned hypalgesia. The display of conditioned hypalgesia with the initial exposure to the heated floor enhances the acquisition of the conditioned hypalgesia. The present study examined whether this conditioned hypalgesia was naloxone irreversible and not cross-tolerated with morphine. The conditioned hypalgesia induced by formalin was also naloxone irreversible and not cross-tolerated with morphine. However, the conditioned hypalgesia induced by tail-flick was naloxone reversible and cross-tolerated with morphine. These results, thus, suggest that the nature of the conditioned hypalgesia is determined by the pre-exposure to a heat stressor which may depend upon the type of pain elicited on test. Although acquisition of the conditioned hypalgesia may depend on exposure to the heated floor with naloxone, morphine-tolerant rats were hypalgesic in the formalin test. However, morphine-tolerant rats were just as hypoalgesic as morphine-naive ones when tested with the opioid in the formalin test. Thus, the capacity of morphine tolerance to block the acquisition of conditioned hypalgesia appears to be independent of opioid pain mechanisms.
430.13 NOCICEPTIVE RESPONSES TO HIGH AND LOW RATES OF FOOT SKIN HEATING IN RATS MAY BE MEDIATED BY DIFFERENT NOCICEPTORS. D.G. Yeomans, V. Fitz, and H.K. Proudfit. Department of Pharmacology, U.I.C., Chicago, IL 60612.

The selective actions of capsaicin or morphine to increase or decrease nociceptive responses mediated by polymodal nociceptors were used to test the hypothesis that heating the dorsal hairy surface of the hindpaw at low rates elicits withdrawal responses evoked by polymodal nociceptor activation, whereas high rates of heating brake these responses mediated by other nociceptors. Capsaicin was applied topically to the hairy foot skin of rats to selectively sensitize polymodal nociceptors. Capsaicin reduced the latency of the reflexive withdrawal response evoked by low heating rates, but not by high heating rates.

In addition, the skin temperature at which the response to low heating rates occurred was reduced from 46 to 41°C, but the temperature at which the responses to high heating rates occurred (91°C) was not affected.

Responses mediated by the activation of C polymodal nociceptors have been demonstrated to be preferentially attenuated by low doses of systemic morphine (Cooper et al., Pain, 24:93-116, 1986). In the present experiments, low doses of morphine (0.01 to 1.0 mg/kg i.p.) selectively attenuated nociceptive responses to low heating rates in normal rats, and to an even greater extent after capsaicin treatment. The same doses of morphine did not attenuate nociceptive responses to high heating rates in either normal rats or those with capsaicin sensitized skin. Higher doses of morphine (2.0 to 10.0 mg/kg i.p.) attenuated responses to both types of stimulation. These results support the conclusion that low rates of heating elicit responses elicited by the activation of polymodal nociceptors. In addition, the potency of analgesic drugs, determined using thermal methods, may depend on the rate of skin heating. Supported by USPHS Grants DA03980 (HFP) and DA05406 (CCY).

Touch-evoked pain, mediated by Aβ fibers, can be produced in the following ways: C-fiber activation by intradermal capsaicin (Torendijk et al., 1992), J Pain., 44:94, 1994. In the rat, peripheral blockade of inhibition in the spinal cord results in touch-evoked aggravation (Yaksh, 1989, Pain, 37, 117). We set out to examine the effects of C-fiber conditioning and central disinhibition on responses in the decerebrate spinal rat. The response of hamstring motorneurons to noxious and non-noxious stimuli applied to the receptive field was tested. In control conditions tactile or stimulation caused little or no activity. Responses to repeated standardized touches of the hindpaw or electrical activation of Aβ-afferents were greatly enhanced after C-fiber were activated either by cutaneous application of mustard oil or by conditioning the sural nerve (1 Hz, 20-s trains of 1118 ± 24.8 and 4272 ± 48.5 s, respectively). A similar facilitation of touch-evoked responses was observed following a subcutaneous dose (3 μg) of strychnine or bicuculline. i.t. (+1042 ± 499 and +1239 ± 377%, respectively). These changes were associated with a decrease in the mechanical threshold of the flexor reflex and an increase in the response to noxious stimuli. Sural conditioning at 1 Hz (10 Hz, 20 s) had no effect. These results suggest that C-fiber induced central sensitization may be involved in allodynia as well as hyperalgesia and that disinhibition may be involved.

431.1 SYNAPTIC ORGANIZATION OF DOPAMINERGIC AMACRINE CELLS IN THE LARVAL TIGER SALAMANDER RETINA. R.A. Glazebrook, R.B. Walter, and C.B. Watford. Alice R. McNprhon Laboratory of Retina Research, Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX, 77380.

Immunocytochemistry of tyrosine hydroxylase (TH) was used to visualize larval tiger salamander dopaminergic amacrine cells. The avidin-biotin immunoperoxidase method was used to immunostain TH immunoreactive cells in vibratome-prepared sections that were routinely processed for ultrastructural examination. TH-positive somas exhibited an evenly distributed peroxidase reaction product throughout their cytoplasm. Their nuclei were generally unstained and possessed indented nucleated membranes. TH-positive processes were generally stained throughout and lacked synaptic vesicles. TH-positive processes were generally stained throughout and lacked synaptic vesicles. TH-positive processes were generally stained throughout and lacked synaptic vesicles. TH-positive processes were generally stained throughout and lacked synaptic vesicles. TH-positive processes were generally stained throughout and lacked synaptic vesicles.

A total of 112 synaptic relationships were observed in the inner plexiform layer that involved TH immunoreactive processes. TH-positive processes were presynaptic to amacrine cell processes (33.0%) and to processes that lacked synaptic vesicles (26.9%). Synapses onto amacrine cell processes were observed only in superlayer 1. Synaptic contacts onto processes that lacked synaptic vesicles were observed primarily in sublayer 1 (93.4%), but also in sublayers 3 (3.3%) and 5 (2.9%). As post synaptic elements, they formed conventional synaptic contacts that were characterized by symmetrical synaptic membrane densities.

431.2 COEXISTING RELATIONSHIPS OF SUBSTANCE P-AMACRINE CELLS IN THE LARVAL TIGER SALAMANDER RETINA. C.A. Fogarty, A. I. Newlin, and R.B. Walter. Alice R. McNprhon Laboratory of Retina Research, Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX, 77380.

In situ hybridization for Substance P (SP) immunocytochemistry was combined with either immunocytochemistry of gamma-aminobutyric acid (GABA) or autoradiography of high-affinity GABA uptake to examine for the presence of GABA in SP-amacrine cells of the larval tiger salamander retina. These thousand SP-like immunoreactive cells were visualized in double-label preparations. Double-label analyses revealed two populations of SP-amacrine cells that express each marker of GABA activity. Both populations were activated either by cutaneous application of mustard oil or by conditioning the sural nerve (1 Hz, 20-s trains of 1118 ± 24.8 and 4272 ± 48.5 s, respectively). A similar facilitation of touch-evoked responses was observed following a subcutaneous dose (3 μg) of strychnine or bicuculline. i.t. (+1042 ± 499 and +1239 ± 377%, respectively). These changes were associated with a decrease in the mechanical threshold of the flexor reflex and an increase in the response to noxious stimuli. Sural conditioning at 1 Hz (10 Hz, 20 s) had no effect. These results suggest that C-fiber induced central sensitization may be involved in allodynia as well as hyperalgesia and that disinhibition may be involved.

Correlation of electrophysiological, morphological, neurochemical characteristics and connectivity of neurones is important for understanding the functional organization of neuronal systems. The aim of this study is to gain some insight into how the above characteristics can be brought together in a model system. Amacrine cells were electrophysiological recorded and then injected with a solution of 4% bicytin in 0.5 M KCl.

Bicytin diffused through gap junctions and often up to 25 coupled amacrine cells were observed from a 2 min injection at 1-10 nA. From the analysis of the stained networks, it appeared that not all coupled amacrine cells were morphologically the same. Some cell groups were cytochrome oxidase and processed for GABA immunohistochemistry. Several cells generating off-transient responses have yielded positive results. However, it was not clear whether all coupled cells within a network were GABAergic. Present research is further analysing the morphological and neurochemical characteristics of amacrine cell networks.

Many types of retinal amacrine cells show homologous coupling when injected with the biotinylated tracers, biocytin or Neurololitin, thus revealing their somatic array (Vaney, 1991). Moreover, these small tracers are readily transported along the thin processes that characterize "axon-rearing" amacrine cells: visualization of these long processes is greatly aided by photochromic intensification of the DAB reaction product in the presence of tetrazolium salts (Vaney, 1992). We have thus used Neurobiotin injections of microscopically identified cells in the superfused rabbit retina to characterize the complete morphology and the somatic mosaic of several types of low density, axon-rearing amacrine cells. They include the long-range cell (LR; Vaney et al., 1988), the type 1 and type 2 catecholamine-accumulating cells (CA1 & CA2; Tauchi et al., 1990, the type 1 NADH-diaphorase cell (ND1); Sagar, 1990), the interstitial amacrine cell (PA1; Famiglietti, 1992a), and the presumptive somatostatin cell (PA2; Famiglietti, 1992b).

Whereas the LR, ND1 and PA1 cells showed strong homologous coupling, the PA2 and CA1 cells were only weakly coupled, and the CA2 cell showed no coupling. The LR and PA1 cells showed homologous coupling to somata located in the inner plexiform layer of the rabbit ganglion cells layers. Both the LR and ND1 cells also showed homologous coupling to other types of presumptive amacrine cells. The distal processes of the LR cells and the boot dimen low NMD to result from the soma: this greatly exceeds the extent of other retinal interneurons that have been intracellularly labelled by previous methods.

Genetic ablation of gamma-2 crystallin expressing cells leads to photoreceptor death. We have previously demonstrated a decreased density of neurons in the Ganglion Cell Layer in transgenic microphotic mice as a result of this embryonic thymus, which prompted the idea of the normal density of DCaM, 2° dendritic field diameter and 3° dendritic morphology. The diameter of DCaM somata in normal CD-1 mice ranged from a low of 3.0 μm to a high of 22.4 μm with an average of 13.1 ± 3.9 μm. The dendritic field diameters range from normal CD-1 mice at a low of 70.7 ± 27.9 μm. Transgenic microphotic DCaM ranged from a low of 10.24 μm to 26.3 μm and had an average of 16.3 ± 3.8 μm. The dendritic field diameters in these animals ranged from a low of 63.7 μm to a high of 234.9 μm and had an average of 136.8 ± 50.0 μm. These data correspond to an increase in approximately 24% and 93% respectively. These data indicate that DCaM dendritic fields are capable of altering their morphology in response to changes in their local environment. Supported by NEI 01426.

431.7 CHARACTERIZATION OF LIGHT-EVOKED NMDA RECEPTOR-MEDIATED INPUT TO GANGLION CELLS IN DARK-ADAPTED RETINAS. I.S. Diamond and D.R. Copenhagener. Bioengineering Graduate Group, Departments of Physiology and Biophysics, University of California, San Francisco, CA 94143.

Light-evoked synaptic input to ganglion cells has been shown to be mediated by both NMDA and AMPA-type glutamate receptors (Mitman et al. 1990). Pfltzer Phys. 175: 184.

We have used standard whole-cell patch clamp techniques in the tiger salamander retinal slice to study the time course and magnitude of the light-evoked glutamate receptor-mediated inputs to ganglion cells in dark-adapted retinas. In voltage-clamp recordings, the reversible effect of D-2-amino-7-phosphonoheptanoic acid (AP7), a competitive NMDA antagonist, on the response to a second flash of light was greater at -40 mV, a potential at which NMDA-mediated currents were near to maximal; the effect was less at -90 mV, where the NMDA receptor channel was blocked by external Mg2+ (1 mM). The relative strength of the NMDA-mediated input with respect to the AMPA input was determined by applying AP7 to the retina at -40 mV to -90 mV. AP7 (30 μM) caused as much as a five-fold reduction in this ratio.

Mitman et al. showed that cells in light-adapted preparations displayed a relatively fast rise time. Rapid synaptic inputs could be discriminated temporally, because the dark-adapted input had a much slower time course (time to peak = 100 msec) than the AMPA input (time to peak = 25 msec). In dark-adapted retinas the ganglion cell response to dim light had a much slower time course (time to peak = 500 msec). When AP7 was applied, the magnitude of the light-evoked current at -40 mV decreased, but a significant change in time course was seen. Neither the magnitude nor the time course of the dim flash responses at -90 mV was affected by AP7. Consequently, there is considerably more temporal overlap of the AMPA- and NMDA-mediated light responses in dark-adapted than in light-adapted retinas. Any nonlinear interactions between the AMPA and NMDA conductances would, therefore, be enhanced under dark-adapted conditions.

Middle (M) and long wavelength sensitive (L) cones, which constitute approximately 90% of the foveal cone population, can be distinguished from short wavelength sensitive (S) cones by differences in immunoreactivity to antigens, eye type, and ultrastructure. However, M and L cones have not so far been distinguished from each other, and it is not clear from their relative numbers nor their circuitry have been determined. We reasoned that if the two synapses that link each cone to its pair of midget ganglion cells (on and off) differ in the numbers and types of connections between each cone and the midget ganglion cells, it might be possible to distinguish between the two classes. In electron micrographs of serial sections, we identified, for a small patch of cones (outer segments at 1.5° nasal), the pair of midget bipolar cells which each cone connected to and which connected to the corresponding midget ganglion cells. For one set of cones (N=17), the number (mean ± s.d.) of synapses outputs (ribbons) per midget bipolar cell was 36 ± 2, and the number of synapses inputs per midget ganglion cell was 26 ± 2. Thus, in the case of the ganglion cells, the ratio of 1.4 was close to the expected ratio of 1.5. For another set of cones (N=9), the number of synapses outputs per midget bipolar cell was 51 ± 5, and the number of inputs per midget ganglion cell was 26 ± 2 in 3. Thus, in the case of the midget ganglion cells, the ratio of 2 was similar to the expected ratio of 1.5. It is possible that the ratio of 1.1 to M cones is about 2, as consecutively the two classes identified here, represent, respectively, L and M cones. Supported by EY08124.

We thank P. Sarnatich, A. Meyers, and L. Chioseki for their help.

We have used a one dimensional version of the reverse correlation procedure of Jones and Palmer (J. Neurophysiol., 55: 1187-1211, 1987) to examine the spatio-temporal (ST) response profiles of cat retinal W-cells and compare these with those of X- and Y-cells. The stimuli consisted of a circular patch of bright or dark bars which are presented for a fixed duration, typically 50 msec, at one of 16 positions spanning the entire receptive field along one spatial dimension. A series of stimuli are presented successively with no interstimulus interval, and both the position and contrast (bright or dark) of each stimulus are varied randomly. The times of occurrence of all action potentials occurring during the presentation sequence are recorded and the reverse correlation procedure quantifies the relationship between the time of occurrence of each spike and the position, contrast and time of onset of each stimulus in the sequence. The resulting ST-profiles thus represent one dimension of space and one of time, and provide an estimate of the cell’s spatio-temporal impulse response. Most tonic W-cells have ST-profiles similar to those of X- or Y-cells, i.e., a spatial center-surround organization at short latencies, which is space-time inseparable due principally to the longer latency of the surround response. Some phasic W-cells also conform to this pattern, but some have profiles that are much simpler, consisting of a single central zone, not offset in space or time by an antagonistic region, while others have much more complicated profiles, often with central zones which are bimodal in the space domain, flanked by antagonistic zones that are offset in both space and time. Supported by NIH EY08038.

431.10 HYPEROSMOTIC ACTIVATION OF TRANSMITTER RELEASE FROM PRESYNAPTIC TERMINALS ONTO RETINAL GANGLION CELLS. W. Wu and R. F. Miller. Department of Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

We studied neurotransmitter from 2nd order neurons to ganglion cells, using micro-hypertonic stimulation (500 mM) to activate transmitter from presynaptic terminals in the inner plexiform layer. These experiments were carried out in a perfused retinal slice preparation of the tiger salamander, using direct visualization under an upright binocular microscope. A micropipette, filled with hypertonic sucrose (0.5 M + Ringer) was placed in the IPL and whole-cell recordings were obtained from single ganglion cells. Single cells were studied under current and voltage-clamp conditions, and many cells were stained with 0.1% 6-carboxyfluorescein added to the whole-cell pipette and visualized with fluorescent microscopy. Brief positive pressure pulses (0.5-2 bar), applied to the sucrose pipette, activated a postsynaptic response in ganglion cells which was graded in magnitude, based on the duration of the pulse pressure. Voltage-clamp analysis and pharmacological studies indicate that the pH increase is sufficient to activate both excitatory and inhibitory components. When the inhibitory components are blocked with picrotoxin (100 μM/strychnine (10 μM)), the post synaptic current can be studied as a relatively pure hypertonic post synaptic event which typically consists of a combination of non-NMDA and non-NMDA contributions based on the use of AP7, an NMDA receptor antagonist and NBIQ (2,3-Dialkylamino-6-nitro-7-sulfonylbenzo (F) quinoline), a non-NMDA receptor antagonist. This approach permits the analysis of relative NMDA/non-NMDA contributions into identified cell types and at different spatial positions along the soma-dendritic tree. Supported by NIH grants ROI NEI 67376 and NS 17763 awarded to RPM.

STRUCTURE AND FUNCTION OF GANGLION CELLS PROJECTING TO THE CAT'S GENGULATE WING: AN IN VITRO STUDY. M. Pu, T. Parr and D.M. Benson. Div. Biology & Medicine, Brown Univ., Providence, RI, 02912

The cat's gengulate wing (retinorecipient zone of the pulvinar) is thought to receive its retinal input from a single morphological class of presumed W-cells termed spongy cells (Leventhal, et al., JCN 194:90; Rodeck and Watanabe, Neurosci, Absr. 12:90). We labeled wing-projecting cells by retrograde transport of fluorescent beads and studied their morphology and physiology in vitro. Intracellular staining with Lucifer Yellow and biocytin showed that nearly 100% of these spongy cells (17.2-about 24 µm) had the medium-sized somas (17.2-µm dia., mean 24 µm) and large, radiate dendritic fields typical of episomal cells. Dendritic-field diameters increased with eccentricity in the central retina (500 µm near the f.o.c.; 500-1000 µm at 3-mm eccentricity) but exhibited little further increase more peripherally (500-1000 µm). Many dendritic profiles were ellipsoidal with long axes pointing toward the a.c. Dendrites stratified narrowly in the inner IPL. Axons were as thick as any among presumed W-cells and similar to those of beta cells (= 1 µm dia.). The morphology of these episomal cells closely matches that of a wide-field type prominent among W-cells and similar to that of beta cells (= 1 µm dia.).

341.12

At present, it is difficult to correlate the ganglion cell types distinguished by function with those distinguished by morphology and central projections. However, straightforward techniques are available to:
1. determine functional properties by means of extracellular recording from ganglion cells in vivo, and 2. determine morphological and central destinations by means of a retrograde label and intracellular injection (e.g. HRP, Neurobiotin) of ganglion cells in vitro. We have developed an approach that combines these two techniques with in vivo imaging so as to allow the receptive-field properties, dendritic morphology, and central destinations of individual ganglion cells to be characterized.

Near-infrared fluorescent microspheres (Crimson, Molecular Probes) are used as the retrograde label, in order to preserve rod sensitivity. Labelled ganglion cells are visualized by what is, in effect, an epifluorescence ophthalmoscope. This device makes use of a barrier filter, a 135 mm imaging lens, and a CCD array cooled to -45 °C in order to allow the slow collection of the image of the ganglion-cell layer, using a relatively dim, monochromatic excitation beam. Spatial resolution is 2 µm/pixel; intensity resolution is 12 bit (0.025%).

Image quality is good, with contrast between labelled cells and background as large as 3:1. Images may be saved on Tungsten-In-glass recording electrodes with Crimson microspheres in the tip can be advanced onto selected labelled cells, and the apparatus swung out of the way in order to investigate receptive-field properties. Later, the same cells can be located and intracellularly injected via the in vitro technique. Supported in part by NIH grants EY02923 and EY01730, and by the E.K. Bishop Foundation.

NEURAL CIRCUITRY OF FOVEAL GANGLION CELLS IN THE HUMAN RETINA. Hyla Kolb* and Jill Crooks. Physiology Dept., University of Utah, Salt Lake City, U.S.A.

While the relationship of midget bipolar cells and midget ganglion cells is well established (Kolb and DeKorver, '91) little is known of the synaptic circuitry involving amacrine cells to ganglion cells in the primate fovea. Thus in this study we have concentrated on understanding the neurochemical signature of the input amacrine cells to ganglion cells using techniques of postembedding immunocytochemistry for GABA and glycine on EM serial sections.

Both midget and parasol ganglion cells and their respective input bipolar cells have been included in the analysis. GABAergic amacrine cells provided about 27% of the amacrine input to ON-center ganglion cell dendrites while glycineric amacrine provided only 6% of the synapses. OFF-center cells received about the same proportion of GABAergic synapses (23%). OFF-center cells received a higher proportion of glycineric synapses (23%). 50 to 60% of the amacrine synapses to all types of ganglion cells were of unknown neurotransmitter species.

GABAergic upon bipolar axon terminals formed about 50% of all the amacrine input for both ON-center and OFF-center variety. Only in a minority of cases was the same GABAergic amacrine postsynaptic to the bipolar presynaptic upon the ganglion cell dendrite. In contrast, GABAergic amacrine cells were frequently reciprocal upon the bipolar cell without making a synapse upon the ganglion cell. There is evidently a complex synaptic circuitry concerning bipolar/ganglion/amacrine interactions even to construct the most "simple" foveal ganglion cell receptive fields. (Supported by grant EY03323)

341.14

Recent biochemical and electrophysiological studies have shown that both polyamines and glycine can enhance the activity of the NMDA receptor. This work was undertaken to determine if polyamines and glycine can further enhance the strength of the excitatory synaptic inputs to retinal ganglion cells.

Excitatory synaptic currents were recorded from ganglion cells in the tiger salamander retinal slice preparation using whole-cell patch recording. Synaptic inputs were elicited by puffing KCl onto the dendrites of bipolar cells presynaptic to the ganglion cell. The AMPA component of the input was isolated by including 1.5-MgCNQX, 1.5 μM strychnine and 100 μM picrotoxin in the bath. We investigated whether or not a polyamine site was associated with NMDA receptors on ganglion cells using the polyamines against diaminodicarboxylic acid (DA10), DA10, at 10-50 μM, reversibly reduced the amplitude of the NMDA component of the synaptic input. The competitive polyamines antagonist diethylstilbestrol reverses the suppressive action of DA10, consistent with DA10 acting specifically at the polyamine receptor. These results suggest that polyamines can modulate excitatory synaptic inputs to ganglion cells.

We used the glycine modulatory site antagonist 7-CI-kynurenate to determine if glycine could modulate the NMDA component of synaptic input. 7-CI-kynurenate (20 μM) reversibly reduced the puff-elicited NMDA component of the synaptic input to ganglion cells. These results suggest that a glycine site associated with the NMDA receptor complex on ganglion cells can modulate the strength of their excitatory synaptic inputs.

EFFECTS OF VASOACTIVE INTESTINAL PEPTIDE ON GANGLION CELLS IN THE RABBIT RETINA. Ralph J. Jensen. Southern College of Optometry, Memphis, TN 38104.

The putative neurotransmitter vasoactive intestinal peptide (VIP) has been shown to be present in a population of amacrine cells. Like the neurotransmitter dopamine, VIP stimulates adenylyl cyclase activity in the rabbit retina. In the present study, we examined the effects of bath-applied VIP on ganglion cell recordings extracellularly in a superfused, rabbit retinal preparation.

Most OFF-center and ON-center ganglion cells responded with an increase in spontaneous activity when VIP was applied to the retina. The light responses of these cells to spots and annuli were however only minimally affected. When applied to retinas bathed with the dopamine antagonist (+)-SCH 23390, VIP enhanced the light responses of most OFF-center ganglion cells. VIP brought out both the center and surround responses that were reduced by (+)-SCH 23390. The effects of (+)-SCH 23390 on OFF-center ganglion cells were not reversed by VIP. It is proposed that VIP counteracts the effects of (+)-SCH 23390 on OFF-center ganglion cells by stimulating adenylyl cyclase in dopamine-sensitive cells of the retina. Prenatal Development of Neuropeptide Y Immunoreactivity in the Ganglion Cell Layer of the Cat Retina Jeffrey J. Hustler* and Leo M. Chalupa, Psychology Department and the Center for Neurobiology, University of California, Davis.

Previously we have shown that immunoreactivity for neuropeptide Y (NPY-IR) identifies a subgroup of gamma type ganglion cells in the adult cat retina which project to the superior colliculus (Hustler et al., 1991). In the adult, these cells (approximately 2,000 per retina) are clustered along the horizontal striate with the highest density at the area centralis. Amacrine cells within the inner nuclear layer (INL) also are NPY-IR in the adult cell, and these are distributed in a regular array across the entire retinal surface (Hustler et al., in preparation). We have now examined the development of NPY-IR in these two populations of cells. At embryonic day (E) 38 NPY-IR profiles are not present within the GCL or the INL. By E46 such cells begin to appear in a densely packed region of the central retina within the GCL, and by E50 NPY-IR cells within the GCL have extended out to the retinal periphery. At this age their overall distribution is similar to that seen in the adult. NPY-IR cells within the INL do not appear until E50, when they are largely confined to the central retina. About one week later the NPY-IR amacrine cells are first seen in the periphery, with the overall population characterized by a regularly spaced array. During fetal development the number of cells that are NPY-IR was not found to be appreciably greater than in the adult retina. These results indicate that NPY-IR can be utilized during prenatal development to identify specific populations of amacrine and ganglion cells in the cat retina. (Supported by EY03991 from the NEI)

**RETINAL GANGLION CELLS ARE NOT FRAC TAL IN THE BOX COUNTING MEASURE.** J. Passino and P. Sterling*, Dept. of Neuroscience, Univ. Penn., Phila., PA 19104.

Fractal geometry can be used to characterize patterns that are statistically self-similar, i.e., for which pieces of the pattern, when magnified, resemble the whole. The degree of fractalness is measured by the degree of self-similarity over a certain range of scales. Many physical systems which have been modelled with fractal geometry display a high degree of self-similarity over at least 3 decades of scale. Though retinal ganglion cells also appear fractal, their reported self-similarity spans at most 1 decade of scale and has not been rigorously evaluated.

Images of HRP-filled retinal ganglion cells (from this and other labs) were digitized, then "skeletonized", and overlaid with a square grid of mesh size d. The number of boxes intersected by the skeleton was counted. In a plot of log(boxes intersected) vs. log(d), fractalness is assessed by the degree of linearity over a designated portion of the abscissa. As a control, "box counting" was applied to patterns generated to express self-similarity over specified range of scales. Also, we manipulated the spatial structure of neural and control skeletons according to various randomizing algorithms and observed the effects on the log-log plots.

The log-log plots for the controls have linear regions spanning more than one decade of scale. However, for the neural patterns there are no significant linear portion; instead they are truly sigmoidal: not fractal. We then established an operational criterion: we designated a pattern "fractal" if it arbitrarily deformed the pattern made its log-log plot less linear. The plots for control patterns lost most of their linearity, but the plots for neural patterns were unaltered by the deformation. Thus we conclude that, in the box counting measure, ganglion cells are not measurably fractal. Supported by EY08124.

**TRANS-ACPD EVOKE S INCREASES IN INTRACELLULAR FREE CALCIUM CONCENTRATION IN ISOLATED RETINAL GIALL (MULLER) CELLS. S.A. Krinsten* and R.F. Miller. Department of Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

Electrophysiological studies have demonstrated that retinal ganglion cells do not respond to application of ionotropic glutamate receptor agonists (NMDA, quisqualate acid, kainic acid). Rather, these cells respond only to application of glutamate with an inward current generated by an electrogenic glutamate uptake mechanism (Hosobuchi and Miller, 1986, Soc. Neurosci. Abstr. 12: 169; Brew and Atwell, 1987, Nature 327: 707-709). The calcium imaging studies that we report here revealed that the metabotropic glutamate receptor agonist, 13,15R-1-aminoacycloptane-1,3-dicarboxylic acid (trans-ACPD) evokes increases in the intracellular free calcium concentration ([Ca²⁺]i) of isolated Muller cells.

Muller cells were acutely isolated from the retina of the larval tiger salamander and loaded with the calcium sensitive dye Fura-2 AM. A commercially available imaging program was used to analyze each calcium change in [Ca²⁺]i evoked by bath application of trans-ACPD (50-200 μM) in calcium-free Amphibian Ringer (2 mM EGTA). Nine of eleven Muller cells tested responded to the application of this metabolite with an increase in [Ca²⁺]i. In six of the responsive cells the increase in [Ca²⁺]i occurred later in the endothelial cell of the cell. In one cell the [Ca²⁺]i of the region of interest was lower at rest that in the other regions of the cell, and the response to trans-ACPD in the nucleus occurred later than the other regions, and was of a larger amplitude. Further experiments include the pharmacological characterization of these responses to determine if they are due to specific activation of the metabotropic glutamate receptor and if glutamate itself also evokes increases in [Ca²⁺]i in Muller cells. Supported by NIH grant EY03014 to R.F. M.

**TRYPSIN BLUE STAINING ON RETINAL GANGLION CELL OF RAT IN- SULTED IN EXPERIMENTAL HIGH INTRACRANIAL PRESSURE. ZH, Lin, QL, Liu, PB, Ju, ZJ, SHI, and XY, LOP.* Dept. of Neurobiology, Human Medical University, Changsha, Hunan 410078 P.R.C.

We have continued the study on damaged retinal ganglion cell (RGC) resulting from ischemia-reperfusion (I/R) in experimental high intracranial pressure. The experimental high intracranial model was used as before (Lin et al., Soc. Neurosci. Abstr. 15: 1507 91). In 10 albino rats, two eyes of each rat were enucleated and fresh whole mounted retina were prepared for disc-excision test. Trypsin blue (TB) was used as a marker to determine the viability of RGC and was applied according to the method of Taylor and Hant (Brit J. Ophthal. 65:815 91). The nuclei and perikaryon of RGC, which lost its viability, were full of TB substance. For statistics, the stained RGCs within the four quadrants of each retina were counted at a microscopic magnification of 200X with the help of fixing a scored reticle on the slide. The area of whole retina and its four quadrants were digitized respectively with an image analysis system (PC Vision Plus). The data were analyzed for statistical significance by Student's t-test. Using a computer. At comparing these two kinds of rat, far more RGCs of the FR retina were stained than those of the SI (simple ischemia) retina (p<0.001). The results indicated that the diminution of RGCs' overall survival in FR retina with increasing intracranial pressure has been removed. The increased permeability of membrane of RGCs may be related to the attack of the free radical produced in the reperrufying periods as reported by us. Supported by NSFC 3870021 to ZH, Lin.

432.1
**OCCIPITOTEMPORAL AND PARAHIPPOCAMPAL GYRUS PROJECTIONS TO THE BASIS PONTIS IN RHESUS MONKEY. L.D. Schmolesky, D. Purdy, Massachusetts General Hospital, Boston, MA, and ENRR Veterans General Hospital, Bedford, MA, 02102.

We used tritiated amino acids to study projections to the basilar pons from parietal cortices in thirteen rhesus monkeys to determine how connectional and functional heterogeneity of these regions are reflected in corticopontine circuitry. Labelled fibers travelled with every major associative corticocortical fascicles as they arched over the dome of the lateral geniculate nucleus and entered the cerebral peduncle. Pontine projections were defined from area 19 at the medial temporal part of the posterior parahippocampal gyrus, and from the caudal part of the parahippocampal gyrus (area TF). No pontine projections arose from the ventral prefrontal gyrus or from the medial temporal part. Many fiber systems that in the pons were observed in the dorsolateral and lateral nuclei, and the lateral part of the peripendicular nuclei. Medial convexity projections produced more extensive nocosuaral labelling, as well as terminations in the extreme dorsolateral nucleus. Dorsal prefrontal projections had additional terminations in the ventral pontine nucleus. Posterior parahippocampal gyrus projections had discrete label in the lateral and dorsolateral nuclei. These results suggest that the dorsal visual stream communicate with the pons whereas the ventral visual stream does not. The posterior parahippocampal gyrus implicated in visual spatial memory also sends efferents to the pons. These anatomical results have implications for cerebellar function. (Supported in part by NIH 16841 and the Veterans Administration.)

432.2

The neurons in the deep lamina of the superior colliculus (SC) send descending efferents to a variety of regions of brainstem and spinal cord involved in orienting the eyes, head and limbs indicative of important role of the collicular neurons for "visually guided orientation behavior." In an attempt to detail the corticofugal and corticocortical projections from the visual cortex in the rat, we injected the tracers such as biotinyl or WGA-HRP into visual cortex of Long Evans rat and observed the terminal distributions of the corticofugal efferents. After injection of the tracer into area 17, numerous labeled axons and terminals were observed in the superficial laminas of SC. In this case, only a few, if any, labelings were found in the caudate putamen. On the other hand, when the tracer was injected into area 18a, a number of labelings were found in the dorsocaudal region of caudate putamen as well as in the deep lamina of SC. The present results suggests that these corticofugal projections are controlling the visually guided orientation behavior as those found in the cat's corticostriatal and corticocortical projections from the lateral suprasylvian visual area (Torita et al., Neuroscience Res. 10: 149-155, 1991).
423.3 CORtical DEACTIVATION DISRUPTS MULTISENSORY INTEGRATION. L.E. Wilkinson*, M.A. Meredith*, and B.E. Stein†. Departments of Psychology, Anatomy, and Physiology, Medical College of Virginia, Richmond, VA, 23298.

The cortex of the anterior ectosylvian sulcus (AES) contains unimodal visual, somatosensory and auditory neurons whose projections converge, along with those from the lateral suprasylvian cortex (LS), onto multisensory superior colliculus (SC) neurons. These SC neurons are believed to play important roles in attentive and orienting behaviors. In the present experiments we sought to determine the effect of reversibly deactivating these cortices on such behavior. The testing apparatus consisted of a semi-circular array of paired LEDs and speakers at 15° intervals. Two cats were trained to look at each with a near-threshold visual stimulus, regardless of location, for a food reward. The auditory stimulus was presented at the same site as the visual stimulus, or 45° lateral or medial to that site. In normative testing, animals showed a multiplicative enhancement of their responses to visual stimuli when an auditory stimulus was presented spatially coincident with the visual stimulus. Conversely, they showed dramatic inhibition of responses to the visual stimulus when the auditory stimulus was 45° disparate to it. During testing, a cortical area (either AES, LS, AI/All, or striate cortex) was deactivated with lidocaine through indwelling carotid. Deactivation of AES disrupted multisensory enhancement and multisensory depression at all eccentricities tested. However, deactivation of the other cortical areas tested, and/or saline controls in AES had no effect on these multisensory processes. Supported by NIH grant NS 22543.

423.5 CORTICOSTRIATAL AND CORTICOTOPIC PROJECTIONS FROM THE FRONTAL EYE FIELDS OF THE CAT. M.T. Thomson*, B.E. Stein and J.G. McHaffie*. Department of Physiology, Medical College of Virginia, Richmond, VA, 23298.

The relationship between the frontal eye fields (FEF) and the striatum (ST) of the cat are poorly understood. The present experiments were an attempt to determine how regions surrounding the presylvian (FEF) region project to the ST. Injections of WGA-HRP made into both cortical regions resulted in dense labeling in the ST and the SC. In the ST, anterograde labeling was found bilaterally (with a leftward predominance) in the caudal part of the SC, in the head of the caudate nucleus (AP +17.5 to +14.0); only presylvian injections resulted in labeling in the putamen, where it was restricted to the caudal aspect. Presylvian injections resulted in label distributed dorsally whereas cruciate injections produced label ventromedially. These same cortical injections also resulted in label restricted to the deep lamina of the ipsilateral SC. After injections of WGA-HRP into ST, numerous labeled corticostriatal neurons were observed. In the presylvian, they were found in lamina III and the upper aspects of lamina V while in the cruciate, they were located in lamina III, upper aspects of lamina V, and lamina VI. In both regions, corticostriatal neurons were observed only in lamina V. These data are consistent with the idea that, in addition to a direct influence on deep laminae SC neurons, the FEF may modulate tectospinal neurons indirectly via the ST and substantia nigra. Supported by NEI grant EY05554.

Visual, auditory and somatosensory inputs from anterior ectosylvian (AES) and lateral suprasylvian (LS) cortices converge onto multisensory superior colliculus (SC) neurons (Wallace et al., 1991). In this study we sought to determine how these corticostriatal inputs influence the response properties of SC neurons. Reversible deactivation (cooling) of a single modality-specific cortical region (i.e., SIV-somatosensory, FEF-auditory, and LV-visual) was found to depress the corresponding unimodal response of a multisensory SC neuron (i.e., cooling SIV depressed somatosensory responses of a visual-somatosensory neuron). In many cases this deactivation also resulted in a proportionate decrease in the integrative properties produced by presenting two different sensory stimuli simultaneously. However, in certain instances deactivating a single cortical region altered multisensory integration in SC neurons in ways not readily predictable from its effects on unimodal responses. For example, in some neurons deactivation of SIV decreased visual-somatosensory integration to a far greater extent than that expected based on the slight depression of the unimodal somatosensory response. In select cases a seemingly paradoxical effect was observed when multiple cortices (i.e., LS, AES and SIV) were deactivated simultaneously: unimodal visual and somatosensory responses were depressed, but the magnitude of the multisensory interaction was dramatically increased (from 84 to 495%). This is likely due to the principle of "inverse effectiveness," wherein the combination of weakly effective unimodal stimuli produce disproportionately high enhancements of one another's effect on SC activity. These data demonstrate the importance of the different unimodal cortices in maintaining the integrity of multisensory integration in the SC. Supported by NIH grants NS 08902 and NS 22543.

423.7 "Extrastrate" Visual Pathways in the Pigeon: Descending Projections upon the Optic Tectum. Harvey J. Karten*, Kevin Cox and Taka Shimizu. Deps. Neuronsciences, University of California San Diego, La Jolla, CA 92039 and Dept. Psychology, University of South Florida, Tampa, FL 33620.

Two major visual pathways to the forebrain have been identified in birds: 1) A topotectal pathway, the retina-tecto-estomo-esto-ecoc system similar to the extrastriate pathways through inferior pulvinar of mammal; and 2) A retinotecto-talamo-ecto-striatal system similar to the geniculostriate system of mammals. Two major descending pathways from tectopallium upon the optic tectum in pigeon have been identified. These arise from: a) The waltz, (Karten et al., 1975, 1977, 1982), and b) The architecturus (Zierer and Karten, 1975), a patterned target of the roundo-ectostriatal pathway. Chorera toxin B (CTB) was used to identify the locus of origin within the architecturus of projections upon the tectum, and to then characterize the pattern of termination of these projections within the tectum. Telencephalic Origins of Tectal Afferents: Following injections of CTB limited to the optic tectum, without spread to underlying ventricle or subnuclear, magnocellular labeled cells in the telencephalon were confined to two regions: a) A deep restricted zone within the ventromedial portion of the archistriatum medullare (Ziel); and, b) The hyperstriatum accessorius of the wall, and adjacent cortical lateral portion. Projections of the Architecturatum upon the Optic Tectum: Injection of CTB in the AV resulted in labeling in the tract occurring mesencephalons with terminations in Layers 10-13 of the ipsilateral optic tectum. Projections of the waltz termini to more superficial laminae of the tectum. The pattern of differential distribution of waltz vs. architectural projections resembles the differential pattern of projections of corticocellular connections in mammals arising from the striate vs. extrastriate cortices, respectively. Supported by NS-25450-06 and ONR N00014-88-K-0054 to HJK.
432.9 LINEARITY AND DYNAMICS OF THE RETINAL SLIP CODE IN TURTLE ACCESSORY OPTIC SYSTEM NEURONS. A.P. Rosenblatt and M. Ariel. Dept. of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260, USA.

The basic optic nucleus (BON), the major retinal recipient area of the retinl accessory optic system, contains direction-sensitive (DS) cells that respond to full-field, textureless visual stimuli. It is thought that these neurons provide a retinal slip signal that drives the optokinetic reflex. The purpose of this study was to quantitatively investigate how retinal slip is encoded in these neurons using linear system theory.

Single unit responses of BON neurons were characterized using whole-field visual stimuli projected directly onto retinas of isolated turtle brains. Direction-tuning curves were obtained either by using constant velocity stimulation (linear sweeps) or by presenting a constant speed stimulus that moved along a circular path (circular sweeps). The hypothesis that stimulus velocity is encoded along a single linear axis was first tested by fitting direction-tuning curves to cosines. Second, the direction-tuning derived from circular sweeps was compared to the sum of responses of two orthogonally oriented stimuli, each of which followed a linear path with sinusoidally modulated velocity (sinusoidal sweeps). Finally, linear sweeps were applied along the axis with maximal DS modulation at different speeds to directly test the cosine rule. The tuning of these cells obeys a cosine rule to a first approximation, with the addition of a non-DS component.

To assess the dynamic responses of BON neurons, sinusoidal sweeps were applied along the axis with maximal modulation at several frequencies. The resulting discharge rates were fit to rectified sinusoids to determine gain and phase. Sinusoidal modulation persisted at frequencies to 1 Hz with peak speeds below 15°/s. BON neurons exhibit DS responses at a broad range of stimulus velocities, yet the range of movement for which these cells exhibit somewhat linear responses seems to be restricted to slow velocities.

432.11 CENTRIFUGAL PROJECTIONS TO THE RETINA IN THE TURTLE Pseudemys scripta elegans. D. Zhang and W.D. Eldred*. Dept. of Biology, Boston University, Boston, MA 02215.

The existence of centrifugal modulation of different fibers to the retina from the brain has been demonstrated in many vertebrate species, including the turtle. However, little detailed information is known regarding the number of cells involved and the location of the cells in the brain which give rise to these centrifugal fibers. To investigate this question, we used intracranial injections of cholera toxin B to retrogradely label the cell bodies in the brain which project to the eye. The labeling of cell bodies in the brain were visualized using an antibody directed against cholera toxin B. Approximately 40 centrifugal cell bodies were found on each side of the brain. The locations of these neurons were not confined to specific nuclei within the brain. The majority of cell bodies were concentrated in the nucleus of isthmi paraventricularis. This nucleus is homologous to the isthmo-optic nucleus in birds, which also gives rise to centrifugal fibers to the retina. Additional cells were observed in the nucleus reticulata OPT, the lateral geniculate, and in the lateral wing of the dorsal raphe nucleus in the reticular formation of the mesencephalon. The localization of these cell bodies within the brain will provide the basis for future studies of their role in visual processing. This research supported by EY04785 to WDE.

Woodson et al. (Soc. Neurosci. Abstr.'90) 16: 1313 reported three distinct morphological types of presumptive centrifugal terminals (PTs) in the pigeon retina. Subsequent investigation revealed that: (i) the isthmo-optic nucleus (ION) proper and the ectopic cells each give rise to different types of centrifugal PT endings; (ii) high density areas were observed in the inferior division of the retina, and on both sides of the pecten; (iii) overlap of different types of centrifugal PTs was observed in the optic nerves.

The distribution and morphology of centrifugal endings of 21 day old chicks were examined following injections of 1% cholera toxin B into ION and the surrounding tegmentum. As in pigeons, centrifugals are found mainly in the inferior retina. One type has a thin axon with small varicosities (~ 1 μm in diameter) consisting of 5-10 smaller varicosities (~ 1 μm in diameter); (ii) the presence of two types of arborizations in the intratretinal retina, and only the thin widely arborizing type in the ipsilateral retina. The results suggest a transient developmental stage or a species difference in the morphology of centrifugal PT arborizations. Moreover, we suggest that the thin and widely arborizing ipsilateral centrifugal projections in the chick retina arise from the ectopic cell region.

432.13 TECTAL VISUAL RESPONSES ARE MODULATED BY ISTMIC NEURONS IN PIGEONS. Y.-C. Wang, S.-F. Wang and B.J. Frosch. Departments of Physiology and Psychology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Anatomical studies in pigeons have shown that both nucleus isthmi paraventricularis (IPc) and nucleus isthmi magnocellularis (Imc) receive input from, and feedback to, the optic tectum. However, the functional effects of these neural circuits on the tectal cells are still unknown. The present study evaluates the roles of Ipc and Imc in modulating the visual response properties of tectal neurons. In Ketamine/Rompun anaesthetized pigeons, Ipc or Imc was reversibly blocked by lidocaine (2%, 5-9%) or excited by NMDA (30 mM, 5-9%) while quantifying tectal neurons (n=65) with moving visual stimuli. Single cell recordings showed that 80% of the tectal neurons were almost totally inhibited after injection of lidocaine into the region of Imc having receptive fields (RFs) overlapping the tectal RFs. However, 68% of the tectal neurons were unchanged when the same drug was applied to Ipc under the same conditions. In contrast, administration of NMDA into Ipc dramatically reduced the responses of 71% of tectal cells, while NMDA applied to Imc had no effect. These feedback effects are tightly related to the topographic relation between RFs in nucleus isthmi (Ipc and Imc) and optic tectum. Removal of Ipc-tectal or Imc-tectal projections (Ipc-Imc pathway) significantly reduced the excitability of tectal neurons whose RFs were located within the isthmic RFs, otherwise, there was no effect. These results suggest that both nucleus isthmi (Ipc and Imc) play a differential feedback role in modulation of visual processing in the avian optic tectum. Supported by NSERC OGP0000353 and SED117027.
432.3 COULOMOTOR RESPONSES TO PERCEPTUALLY COHESIVE AND NON-
COHERENT PLAIDS: KEI DEPPEK,* GH SPERLE AND TL ALTREY. The Salk Institute, La Jolla, CA 92037.

When two moving gratings are superimposed, they can be perceived as either a single coherently moving "plaid pattern" or as two component gratings sliding non-
coherently across one another. Since visual motion signals are known to have strong influence over oculomotor activity, we sought to determine whether there is correspondence between involuntary eye movements elicited by moving plaids and judgments of motion coherence. Specifically, we asked whether direction and speed of eye motion in human subjects were independent of perceptual coherence or, alternatively, contained component motion when non-coherence was reported and pattern motion when coherence was reported.

Plaid patterns were constructed using two heterochromatic (red/green) sinusoidal gratings oriented 87.5° apart. Motion of the plaid was produced by moving only one of the two gratings. Unlike conventional plaids constructed from two moving components, coherant and non-coherent plaids elicited by these novel plaids are each associated with a single direction of motion. Non-coherence is characterized by perceived motion in the direction of the single moving component. By contrast, coherence is associated with perceived motion along the axis of the stationary component. Plaid stimuli were 22° diameter and positioned at the center of gaze.

We used color asymmetries to manipulate perceptual coherence of moving plaid patterns and we recorded accompanying oculomotor activity. Individual gratings within the plaid contained either + (red brighter) or - (green brighter) luminance contrast. When the two heterochromatic gratings contained "symmetric" (+ or -) luminance contrasts, coherent motion was perceived. When the gratings contained "asymmetric" (+) luminance contrasts, non-coherent motion was perceived.

When the plaid was perceived as moving coherently, eye movements were relatively fast and closer to the coherent direction. Conversely, when non-coherent motion was perceived, eye movements were relatively slow and closer to the component direction. These results suggest that the neural mechanisms underlying perceptual motion coherence also participate in the generation of eye movements.

432.9 LESIONS OF LATERAL SUPRASylvIAN CORTEX IN THE CAT REVEAL DEFICITS IN THE PERCEPTION OF GLOBAL MOTION. K. K. RUGKASA* AND T. PASSERON. Center for Vision Science and Department of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14627.

High incidence of directional selectivity and large receptive fields make neurons in the lateral suprasylvian (LS) cortex of the cat well-suited for the analysis of visual motion. We examined the role of LS cortex in the integration of local motion signals into a global percept. We placed bilateral dorsal retinal lesions in LS cortex and recorded their responses to test the dissociation of motion direction. The targets consisted of dots that were displaced with a constant step size in motion at random from the specified distribution. When the range of the distribution of such displays is limited to about 300 deg, the display appears to move in the direction of the mean. LS lesions produced deficits in the discrimination of opposite directions for large (1 deg) but not small (0.15 deg) step sizes. The spatial limit for the task (Dmax) was also substantially decreased. These results suggest that there is a change in spatial scale of residual motion mechanisms in the absence of LS cortex.

Postoperative motion thresholds were also affected by the addition of dots moving in random directions (directional noise), even at small step sizes. Thus, LS lesions affected the integration of local motion signals in the presence of directional noise, as did lesions in LS cortex. These results are consistent with the importance of LS motion processing in the generation of eye movements (Passeron et al., Unpubl., 1991).

432.11 MOTION DETECTION AND IDENTIFICATION FOR LUMI-

We have measured thresholds for detection and identification of a vertically oriented sinewave grating vignetted by a two-dimensional spatial Gaussian window. The stimulus was presented as a contrast-reversing grating to the left or to the right of fixation on the horizon-
tal meridian and then moved either towards or away from the fovea. The temporal frequency of the contrast-reversing and drifting gratings were identical. The color of the grating was modulated along different directions in color space around an equal energy white, thus leading to different input contrasts for the L- and M-cones. This allowed us to measure the identification contours in cone contrast space (Stromeyer, Eskew, Ryu & Kraooner, ARVO 1991).

We find that contrast sensitivity is particularly impaired for stimuli having no Lcone contrast. When considering the mechanisms that mediate motion detection and identification, we find that under certain spatio-temporal conditions contrast sensitivity is determined by a mechanism that is independent of motion perception. These results are compared to behavioral and physiological data in macaque monkeys.

Supported by NIH grant EY08300.

A random dot pattern (RDP), generated on a computer and moving across the foveal and parafoveal retina (stimulation field 6-8 degrees, 30 s stimulation period), evokes a movement after-effect (MAE) in the direction opposite to the RDP movement, which is consistent for both viewing condition: (a) fixation and (b) eye pursuit movements (head fixed, 0.25 - 8.0 deg/s).

When simultaneously two RDPs ("transparencies") are moved perpendicularly to each other across the stimulation field, two movement patterns are seen, but only one rather uniform MAE is evoked (Verstraten et al., 1990). Its direction D is in between the MAE directions expected for each of the two moving RDPs. D depends on the angular velocities of the two RDPs and on the stimulus conditions (a) or (b). A sensitivity-weighted vector summation predicts the outcome for stimulus condition (a). When, however, with stimulus condition (b) one of the moving RDPs is pursued, D is determined by "retinal" stimulation and the "perceived" motion.

It is concluded that the "weighted vector summation" of the MAE may be attributed to cortical areas (MST, FST 7), where gaze movement signals interact with the visual motion signals. This supported by a F.C.Donders-professorship, University of Utrecht).
434.4 EXPRESSION OF AMPA-SELECTIVE GLUTAMATE RECEPTOR SUBUNIT mRNAs IS RELATED TO SYNAPTIC POTENTIALS IN THE RAT COCHLEAR NUCLEUS. C. Hunter*, T. Yu and R. J. Wenthold, Lab. of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

We have previously used in situ hybridization histochemistry to localize AMPA-selective glutamate receptor (GluR) subunit mRNAs in morphologically defined cell types. Selection of GluR subunit antisense oligonucleotides to GluR1-4, 45 nucleotides in length (See Kehnainen et al., Science 249:556-560, 1990) and their sense controls were hybridized to tissue sections of the adult rat cochlea, more in the central part of N, when physiological studies find the most sharply tuned neurons.

The types of GluR subunit mRNAs include: GluR1, GluR2 (layes I and VII), GluR3, GluR4 (layes II-VI), GluR5, GluR6 (layes II-VI), inverted GluR3 (layes I and II), and large ovoid neurons (layes II-VI).

We have used these antisense probes to study the expression of GluR1-4 subunit mRNAs in the rat cochlear nucleus. The expression of GluR1-4 mRNAs is related to the synaptic potentials in the central part of N, where the most sharply tuned neurons are found.

434.5 HOMINGENOUS DISTRIBUTION OF GABA NEURONS ACROSS CAT PRIMARY AUDITORY CORTEX. S. H. Hendry* Dept. of Anatomy & Neurobiology, University of California, Irvine, CA 92717.

The primary auditory area (A1) of cat cerebral cortex contains a map of the cochlea, with each sound frequency represented as a band of dorsocentrally oriented cells (isofrequency bands). In cat AI, tonotopic afferents are unevenly distributed and terminate in broad anteroposteriorly oriented zones that interface isofrequency bands. These tonotopically defined zones are physiologically defined areas in ways suggestive of inhibitory influences that are greater within the latter. To determine if the physiological differences are correlated with different afferent inputs intrinsic to AI, GABA immunoreactive neurons were examined for evidence of an uneven distribution of inhibitory interneurons across AI. Stereological methods were applied to determine the numerical density and proportion of GABA immunoreactive somata in 1 mm-thick sections through 5 hemispheres of 3 normal cats. Mean values of 21,404-22,800 GABA neurons per 1 mm² of cortex, which make up 24-28% of the total neuronal population was calculated for AI. Values for individual layers varied with the greatest density of GABA neurons in layers III and IV and greatest proportion in layer I. Those values for AI in general, and for individual layers did not vary significantly either dorsocentrally across AI (parallel to isofrequency bands) or anteroposteriorly (perpendicular to the bands). These data suggest that regional variations in the total population of GABA neurons do not occur across AI and, thus, cannot account for physiological differences in this area. Evidence for variations in GABA neuronal subpopulations is currently under investigation. Supported by DC 00540.
434.7
LONG-TERM EFFECTS OF COCHLEAR AND MIDDLE EAR LESIONS ON SYNAPTIC TRANSMITTER RELEASE IN THE COCHLEAR NUCLEUS. C.G. Benson* and S.J. Potashner, Department of Anatomy, University of Connecticut Health Center, Farmington, CT, 06030.
To determine if cochlear activity affects the regulation of synaptic function in the cochlear nucleus (CN), we measured the effects of unilateral cochlear ablation and unilateral osseous disarticulation on the activity of glutamatergic or aspartagertic and glycinegic synaptic endings, in the CN of adult guinea pigs. Guinea pigs were anesthetized and either the left cochlea was destroyed mechanically or the left middle ear ossicles were disarticulated. Two days later, 5-9 weeks after the uptake and release of [3H]-aspartate ([3H]-D-ASP) and [3H]-glycine were measured bilaterally in dissected segments of the CN, in vitro. Two days and 8 weeks after cochlear ablation, [3H]-D-ASP uptake and release were reduced ipsilaterally in all segments. However, by 16 weeks after the lesion these measures had recovered and were no longer significantly different from controls. There were no significant changes in the uptake and release of [3H]-glycine in the CN after cochlear ablation. Sixteen weeks after unilateral osseous disarticulation there were significant decreases in the uptake and release of [3H]-D-ASP bilaterally in the CN. These findings suggest that chronic changes in cochlear activity can lead to changes in synaptic release in the CN. (Supported by DC00199 from NIH NICD)

434.8
Evidence suggests that glutamate, aspartate, GABA, and glycine may be transmitters in the cochlear nucleus. In this study, we measured the release of [3H]-D-aspartate, [3H]-GABA and [3H]-glycine from several other brain stem auditory nuclei to determine if they too might contain synaptic endings that use these amino acids as transmitters. After excision, the brain stem was cut transversely into 500 μm sections from which auditory nuclei were punched. The accuracy of punching was confirmed by histological analysis. Punches were incubated with [3H]-D-aspartate and [3H]-GABA or [3H]-glycine before the release of radioactivity was assessed in a superfusion system. Electrical stimulation evoked the Ca2+-dependent release of D-aspartate from each punched nucleus, namely the LSO, MSO, MNTB, VNLL, and the central nucleus of the IC (ICc). Ca2+-dependent release of GABA was observed from the MNTB, VNLL, and ICc while release of glycine was observed from the LSO and MSO. These findings are consistent with the hypothesis that these nuclei contain glutamatergic or aspartagertic synaptic endings. They also suggest that some of these nuclei may contain GABAergic and glycinegic synaptic endings. (Supported by DC00199 from NIH NICD)

434.9
PLASTICITY OF CALBINDIN IMMUNOREACTIVITY IN THE MATURE GERBIL SUPERIOR OLIVARY COMPLEX WITH ALTERED AUDITORY EXPERIENCE. M.D. McGinn*, J.R. Schwartz, and P.R. Eager*. Dept. of Otologyngology, UC-Davis, Davis, CA 95616 and Sect. of Otologyngology, Yale University School of Medicine, New Haven, CT 06510 U.S.A.
Calbindin D-28k immunoreactivity (CaBP) showed consistent and distinctly different patterns in the MNTB and LSO which varied with auditory experience. Animals were colony reared(COL), exposed to 3 weeks of intermittent (30 min on/off) high (HF)(80dB) or low frequency (LF)(74dB) noise, or to low sound (LIG)(ear canal ligation). The MNTB showed the most intense CaBP+ cells in all conditions. HF animals showed the largest number and most intense CaBP+ cells and the fewest light CaBP+ cells. OL animals showed a greater proportion of light CaBP+ cells; COL animals were similar. LIG animals showed the highest proportion of light CaBP+ cells.
The LSO showed the greatest variation with the different treatment conditions. HF animals showed a densely stained neuropil in the medial limb. Moderately stained cells were found throughout, but some cells in the medial limb were darker. LF animals showed many moderately stained cells in the lateral limb, but fewer in the medial limb. Medial limb CaBP+ cells stained more darkly, but less intensely than in HF animals. The medial limb neuropil stained more densely than the lateral limb, but less darkly than in HF animals. LIG animals showed many lightly stained cells throughout the LSO in a uniformly stained neuropil comparable in intensity to that in the medial limb of LF animals. (Supported by NIH/NICD grants DC00132 and DC00057).

434.10
PLASTICITY OF CALCIMUM BINDING PROTEIN AND GABA IMMUNOREACTIVITY IN THE ADULT GERBIL COCHLEAR NUCLEUS WITH ALTERED AUDITORY EXPERIENCE ORAL. W.E. Ose*, P.R. Eager and M.D. McGinn*. Sect. of Otologyngology, Yale University School of Medicine, New Haven, CT 06510 and Dept. of Otologyngology, UC-Davis, Davis, CA 95616 U.S.A.
Calbindin D-28k (CaBP), parvalbumin (PV) and GABA (GABA+) immunoreactivity showed patterns in the cochlear nucleus (CN) which varied with auditory experience. Animals were colony reared(COL), exposed to 3 weeks of intermittent (30 min on/off) high (HF)(80dB) or low frequency (LF)(74dB) noise, or to low sound (LIG)(ear canal ligation). The LSO showed large numbers of intensely stained GABA+ puncta in the DCN and FCN which were not seen in HF, LG or OL animals. The intensity and number of CaBP+ dendrites in the DCN molecular layer decreased from LIG to HF to LF animals. COL & LF animals were similar. In octopus cell regions the darkest CaBP+ somata were in HF. The greatest extent of dendritic staining was in LIG animals which also showed the greatest number and size of CaBP+ puncta. PV+ somata in the DCN molecular layer decreased in intensity from HF, to LF to LIG. Changes in CaBP+ and PV+ in the CN were less marked than the changes observed elsewhere in the auditory brainstem. In the superior colliculus LF animals showed an almost complete absence of PV+ stained cells and dendrites compared to HF animals. The observations are consistent with the hypothesis that a strongly driven auditory system protects neurons from overstimulation by an upregulation of inhibitory inputs. (Supported by NIH/NICD grants DC00132 and DC00057).

434.11
QUANATIVE EVIDENCE THAT COCHLEAR ROOT NEURONS ARE NOT CHOLINERGIC. W.Yao and D.A. Godfrey*. Dept. of Otolaryngology, Med. Col. of Ohio, Toledo, OH 43699.
Cochlear root neurons (CRN) are distinct morphologically from globular bushy cells in retinal auditory nerve root (Merchant et al., 1988). CRN do not immunoreact for glycine or GABA (Osen et al., 1981). Our preparations have shown immunoreactivity of CRN for choline acetytransferase (CHAT) which, despite their very weak histochemical reaction for acetylcholinesterase, suggests that they might be cholinergic. To provide evidence concerning this, we used autoradiographic techniques to measure CHAT activities (μmol/kg/min) both of samples containing CRN and of adjacent samples not containing CRN from 5 rats. Mean (±SD) (μmol/kg/min) CHAT activity of CRN-containing samples was 2.29±0.46 (n=5) while that of the non-CRN samples was 31±18.13. By measuring proportions of the samples occupied by CRN cytoplasm, we estimated the CHAT activity of CRN to be 2.29±0.46(n=5). By contrast, the CHAT activity for samples of the facial nucleus, which contains cholinergic motoneurons, was 482±11.84(n=5), and that for samples of the facial motor root was 6074±1397(n=4). Thus, CRN are not likely to be cholinergic neurones. However, the presence of CHAT activity in some samples suggests that they might receive some cholinergic innervation. (Supported by NIH grant DC00172)

434.12
EFFECTS OF CHOLINERGIC AGONISTS AND ANTAGONISTS ON SPONTANEOUS ACTIVITY OF RAT DORSAL COCHLEAR NUCLEUS NEURONS: IN VITRO STUDIES. L. Ose, J. H. J. Wallier* and D. A. Godfrey*, Dept. of Otolaryngology and Neurological Surgery*, Medical College of Ohio, Toledo, OH 43699.
Extracellular recordings from rat brain stem slices tested the effects of bath application of cholinergics and antagonists on cochlear nucleus neuronal activity. Recordings were made from 54 neurons in 3 slices from 28 rats. Of neurons tested, 89% showed increased firing in response to 10 μM carbachol (mean increase = 249%, n = 18), 63% showed increased firing to 10 μM muscarine (mean increase = 529%, n = 35); and 50% showed increased firing to 200 μM carbachol (mean increase = 103%, n = 12). Only 3% and 25% of the neurons showed decreased firing to muscarine and nicotine, respectively. The excitatory effect of carbachol was eliminated by atropine (1 μM, n = 3), but not by d-tubocurarine (2 μM, n = 2). Excitatory effects of muscarine were blocked by 1 μM atropine (n = 6), but not by selective antagonists of muscarinic receptor subtypes: pirenzepine (1-5 μM, M1 receptor, n = 3), galantamine (10-20 μM, M2 receptor, n = 3) or p-fluorohexahydro-silidindol (1-2 μM, M2 receptor, n = 2). We also found that 40% of the neurons tested showed an excitatory response to 50-100 μM serotonin (mean increase = 190%, n = 20, 60% were unaffected). (Supported by NIH grant DC00172)
435.6 FUNCTIONAL ORGANIZATION OF ACOUSTIC AND VOCALIZATION AREAS OF THE BAT CENTRAL NERVOUS SYSTEM REVEALED BY HIGH RESOLUTION AUTORADIOGRAPHIC IMAGING OF \(^{3}H\)-2-DEXTROGLUCOSE UPTAKE. G.E. Duncan, W.E. Stumpf, and W.W. Holloway, Dept. of Cell Biology and Anatomy, Univ. North Carolina, Chapel Hill, NC 27599

Brain activity patterns associated with the generation and processing of vocalization signals in the bat Pteronotus p. parnellii were studied by high resolution autoradiographic imaging of \(^{3}H\)-2-deoxyglucose uptake. Bats were injected i.p. with \(^{2}D\)-glucose and restrained in a foam holder or allowed to fly in the laboratory. Bats were killed 20 min after injection of \(^{3}H\)-2-deoxyglucose. In the flying bats, marked alterations in patterns of 2-DG uptake occurred in brainstem and forebrain regions. Regions activated during flight included the nucleus ambiguus, inferior colliculus, superior colliculus, medial geniculate, auditory cortex, and nucleus trascus. The results help to define the functional organization of brain regions involved in vocalization and processing of biosocial signals.
435.7 CYTOARCHITECTURE AND HISTOCHEMICAL ORGANIZATION OF ODONTOCETE WHALE AUDITORY BRAINSTEM. V.E. O'Neill*, M.E. Settel*, S.M. Baber*. Dept. of Physiology' and Neurobiology and Anatomy*, Univ. of Rochester School of Medicine, Rochester, NY 14642.

Relatively little is known about the anatomy of the central auditory systems of echolocating whales. We studied the brainstem of the beluga whale and bottlenose dolphin. The auditory nuclei: the medial geniculate, acoustic, cholinesterase (AChE), and antibodies to Calbindin D-28K (cab) and parvalbumin (pv) were examined to localize and characterize the structures of the auditory brainstem. Comparisons were made to material from bats, rodents, human and non-human primates. In the beluga whale, an extremely large (5 mm diameter) auditory nerve leads into a large cochlear nucleus (CN). Many cab(+) and pv(+) cells were scattered throughout the anteroventral CN. Cells in the prominent lateral superior olive were cab(-) and pv(+), as in other mammals. The medial nucleus of the trapezoid body (MTNB) was both cab and pv positive. Medalial to and apparently associated with the MTNB, there is an unusual disconcentrally oriented, sickle-shaped sheet of cells, embedded in a band of AChE(+) fibers. These cells may belong to the medial oculocochlear bundle system. Although the general features are consistent with those in other mammals, certain aspects appear unique to the whale, and may reflect adaptations to echolocation in an aquatic environment. (Supported by NIH NS-22511 and DC-0267)

435.9 PARVALBUMIN IMMUNOCYTOCHEMISTRY DELINEATES PRIMARY AUDITORY NEOCORTEX. C.B. Smelser and N.T. McMullican*. Department of Anatomy, University of Arizona College of Medicine, Tucson, AZ 85724.

Electrophysiological and anatomical studies of rabbit auditory neocortex have revealed a large primary field (AI) characterized by a distinct cytoarchitecture: a cell-dense lamina III/IV and a broad cell-sparse lamina V. We report that monoclonal antibodies to parvalbumin (PV), a calcium-binding protein present in GABA-ergic local circuit neurons, precisely delineate the AI cytoarchitecturally defined AI PV immunocytochemistry (PV; SWANT, 1:10K) was performed on 100 mm thick sections obtained from young rabbits. Serial coronal sections through the entire temporal pole were processed and processed and the third section was Nissl stained with acetylcholine esterase, PV yields an extraordinary Golgi-like dendritic (and, in some cases, axonal) labeling of nonpyramidal cells in all cortical layers. The dorsal boundary of AI is demarcated by an abrupt increase in the number of PV-positive nonpyramidal cells and dense terminal labeling within lamina III/IV. Lamina II and upper parts of III are populated by nonpyramidal cells with small somata and local cell bodies of the bifurcated, bipolar and stellate variety. Lamina III/IV is characterized by a dense population of large spiny nonpyramidal cells with bifurcated dendritic domains and tangentially-oriented local axonal plexus. Basket type axonal terminations outline pyramidal cell somata and contribute to the dense terminal labeling within III/IV. Cell-sparse lamina V contains large nonpyramidal cells remarkable for their tangentially-oriented dendritic fields. Lamina VI can be partitioned into sublamina Vla and Vlb. Lightly labeled pyramidal neurons compose Vla while a diverse population of nonpyramidal cells occupies Vlb. The ventral border of AI stands in stark contrast to the near absence of PV labeling in perirhinal cortex (Supported by NIH, Deafness Research and Whitelab Foundations).

435.10 DIFFERENTIAL CORTICAL PROJECTIONS FROM SUBNUCLEI OF MONKEY MEDIAL GENICULATE COMPLEX REVEALED BY ANTEROGRADE TRANSPORT OF PHA-L. T. Hashikawa*, H. Hidaka and F.G. Jones. Laboratory for Neural Systems, F.R.P., RIKEN, Wako 351-01, Japan, and Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Cortical auditory fields have been shown to receive their thalamocortical afferents from specific subdivisions of the medial geniculate body (MGB). In the present study, in order to examine how fibers originating from each MGB subdivision contribute to the projections of Phallus vulgaris leucoagglutinin (PHA-L) was iontophotographically injected under physiological control in limited regions of the MGB in Japanese monkeys, Macaca fascicularis.

Fibers from the ventral nucleus formed several terminal plumes in a patch-like fashion in the primary auditory cortex (AI), mainly in middle cortical layers. When measured in tangential sections, the length of the plume was 500-1000 μm in width. A main patch was surrounded by "satellite" patches and their projection were not to A1. The size of the main patches was twice as wide as those in AI even with smaller injections. Fibers from the magnocellular nucleus had rather few terminal branches in middle cortical layers as well as in layer I, but they innervated extremely wide areas, both in AI and surrounding auditory areas by means of collaterals of single axons. Formation of discontinuous terminal patches suggests the presence of unitary modular structures in the auditory cortices based on thalamocortical connections.

The crossed and the uncrossed projections from the lateral superior olive (LSO) to the inferior colliculus (IC) are distinct in all respects. The correlation between the birthdates of the LSO neurons and the laterality of their projections was studied in the rat by double-labeling techniques using 5-bromodeoxyuridine (BrdU), the thymidine analoge, and Fluorogold (FG), a retrograde fluorescent tracer. BrdU was given to a pregnant rat on each day throughout the LSO generation period (E12-E16). In the progeny rats as adults, FG was injected into the IC unilaterally to differentiate the crossed and the uncrossed projection neurons. The results indicate that the crossed projection neurons were mainly produced on day E13, whereas the uncrossed projection neurons generated from day E14 to E16 with peak production on day E15. Thus, one of the factors initiating the target laterality of the projections is the temporal order of neurogenesis.
435.1
EXCITOTOXIC PARABRACHIAL NUCLEUS LESIONS DISRUPT CONDITIONED TASTE AVERSION, CONDITIONED ODOR AVERSION, AND SODIUM APPETITE IN RATS. C. Scalara*, P. Grigson, T. Shimura, S. Ryall, and R. Norgrove. College of Medicine, Penn State Univ., Hershey, PA 17033

Previous studies have demonstrated that electrolytic lesions in the parabrachial nucleus (PBN) disrupt both conditioned taste aversions and salt appetite in rats. In order to assess the contributions of neurons and fibers of passage to these effects, we made electrolytically guided bilateral injections of ibotenic acid into the PBN of 10 rats (IBO, 0.2 ul; 20 ug/jl). Six other rats received the same volume of vehicle in the PBN (PBS, pH=7.4) and 4 animals served as non-surgical controls. Following overnight fluid deprivation, rats were given 15 min access to 0.3 M saline and immediately injected with IBO (1.5 mg/kg, 0.15 M). Three saline-IBO pairs were spaced 3 days apart. All non-injected rats rejected saline following a single pairing with IBO. Even after 3 pairings, however, the IBO rats failed to reject saline.

Subsequently, it was found that some rats were dispelled with 10 micrograms of homoside (7.0 mg/ml) and given simultaneous access to 0.5 M NaCl and water. The IBO rats increased intake of NaCl, while the other groups consumed at least 3 times control levels. In a second set of rats, using a higher concentration of IBO (0.3 M), IBO lesions of the PBN prevented acquisition of both an saline taste aversion and an almost odor aversion. Finally, the lesioned rats exhibited an apparent lack of neophobia in 2 situations -- when first presented with saline and when put on a novel, Na-free diet. PROJECTIONS TO THE COCHLEAR NUCLEUS FROM PRINCIPAL CELLS IN THE MEDIAL NUCLEUS OF THE COCHLEAR-TYMPANIC TRACT IN THE HAMSTER. R. R. Scheinfeld* and N. B. Cant. Dept. of Neurobiology, Duke Univ. Medical Center, Durham, NC 27710

The superior olivary complex is a major source of descending projections to the cochlear nucleus (CN). In guinea pigs, a large percentage of the olivary cells that project to the CN are located in the medial somatotopic zone (MNTB). We have used fluorescent tracers (Fluoro-Gold, Fluoro-Ruby) to determine whether MNTB principal cells, which are post-synaptic to the large synaptic terminals known as calyces of Held, contribute to this projection. Injection of one of the CN labels cells in the ipsilateral MNTB and calyces of Held in the contralateral MNTB. By injecting different tracers into the CN on each side, we could examine each MNTB for retrograde transport from the ipsilateral side and anterograde transport from the contralateral side. In every case, some of the labelled cells were enveloped by a labelled calyx of Held, identifying them as principal cells. It is unclear whether the remaining labelled cells were non-principal cells or were principal cells whose afferent calyx was unlabelled.

Our study demonstrates a projection from one CN to the contralateral CN via the calyces of Held and MNTB principal cells.

Supported by NIH grants RO1 DC00135 and F32 DC00005.

SYNAPTIC CONNECTIONS MADE BY THE SUPERIOR OLIVARY COMPLEX (SOC) IN THE INFERIOR COCCULUS (IC). AN EM AUTORADIOGRAPHIC STUDY. Gertchen E. Beckius and Douglas J. Oliver*.

We made injections of H3-hexone and wheat germ-IRP into either the lateral (LSO) and medial superior olive (MSO) of the adult cat. The nuclei were located by stereotactic coordinates and by their response to binaural tones. EM autoradiographs from the IC were prepared with Bifred L4 emulsion and exposed 4-66 wk. Axonal endings from the contralateral LSO usually contain round synaptic vesicles and make asymmetric synapses (RA endings) in the IC. However, three third have pleomorphic synaptic vesicles and make symmetrical contacts (PS endings). Endings from the ipsilateral LSO are more numerous and varied. About half of this projection to the IC is RA endings: 45% are RA endings; 5% are unusual with pleomorphic vesicles and asymmetrical contacts (PA endings).

Overall, endings from the SOC represent the largest source of RA endings for the IC. The MSO and LSO projections make up 33% and 26% of all the presumed excitatory inputs to the ipsilateral IC, but the projection from the contralateral LSO represents only 17%. The bilateral LSO projections account for 38% of the presumed inhibitory PS endings.

These data support the concept that synaptic domains are distinct functional zones where different types of inputs are segregated in the IC. The sum of all RA endings from cochlear nucleus and superior olive exceeds 130% of the RA endings in IC. In addition, PS endings from dorsal nucleus of the lateral lemniscus and LSO total 76% of all PS endings in IC. The surplus of RA endings suggests that some excitatory inputs to the central nucleus are mutually exclusive and do not overlap on the same postsynaptic neurons.

436.2

In order to examine the contributions of Na+, HCl and receptor mechanisms to the responsiveness of cells in the nucleus of the solitary tract (NST), we have determined concentration-response functions for a wide array of chemical stimulants. This array includes 8 sodium salts, 2 lithium salts, 5 sodium acids, 5 acids, 5 sweet-tasting stimuli, and 5 bitter-tasting stimuli. We recorded multunit activity from the NST evoked by anterior tongue stimulation with 5 or more concentrations of each tastant. The peak of the integrated multunit response to a 10 sec test stimulus was measured; these values were expressed as proportions of the peak response to a 0.02M NaCl standard. The slopes of the concentration-response functions derived in this way varied with respect to taste quality and chemical composition. In particular, the slopes for some salts were more steeper than for NaCl, some were less steep, yet many stimuli were similarly effective at 0.05M. The data for salts are well described by power functions and the slopes for the same functions for MNTB to human psychophysical studies on the anterior tongue. Equally effective concentrations are chosen from these functions for single unit studies; the matching concentrations (M) for stimuli determined to date are: NaCl=0.032, NaOAc=0.032, NaSO4=0.032, Na-acetate=0.032, L-glutamic acid=0.028, KCl=0.032, NaCl=0.012, citric acid=0.0026, tartaric acid=0.0018, Na-saccharin=0.0014, dextrose=0.73, sucrose=0.028, quinine-HCl=0.032 and urea=1.73.

Supported in part by NIDCD grant DC00353-07.
436.3

A PATCH-CLAMP ANALYSIS OF NEUROKINEIN RECEPTOR ACTIVATION IN THE GUSTATORY PORTION OF THE SOLITARY NUCLEUS.

In previous experiments, we have shown that substance P (SP) can excite many neurons in the gustatory portion of the nucleus of the solitary tract (NST) of the hamster. Using whole cell patch-clamp techniques in in vitro slice preparation, we have examined the effects of SP on the membrane properties of cells in the rostral hamster NST. Recordings were made from 21 cells with stable resting membrane potentials. Most of the cells fired repetitive action potentials with a mean spike overshoot of 64.7 ± 7.7 mV. Short application of the neurokinin receptor agonist depotilized 13 neurons with a mean depolarization of 4.5 mV that lasted for 1-2 min; in 10 cells this depolarization was accompanied by unitary conductance and an oscillating activity. Another 3 cells were hyperpolarized 4-6 mV with an increase in membrane conductance and a decrease in spontaneous firing. The remaining 5 cells were not affected by SP. In the presence of TTX, the depolarizing effect of SP was not abolished by perfusion of the slices with high Mg2+/low Ca2+ PSS, indicating a direct postsynaptic action of SP. The effect of SP was blocked by its antagonist (D-Pro2, D-Trp7) substance P in 6 cells. Current/voltage curves indicated a conductance decrease during the depolarization with a reversal potential of the SP-dependent current close to the K+ equilibrium potential. We conclude that activation of neurokinin receptors decreases K+ conductance, leading to membrane depolarization, which may interact with gustatory afferent processing. Supported in part by NIDCD Grants DC-00353 and DC-00066.

436.5

Rats with lesions centered in the gustatory zone of the parabrachial nucleus (PBN) are able to respond to sucrose in a concentration-dependent manner, but this is sometimes blunted. This study examined the extent to which PBN lesions alter taste-guided avoidance of an aversive taste stimulus, quinine. Water-deprived rats were tested in a specially-designed apparatus, for their licking responses to water and 7 concentrations of quinine hydrochloride (0.003 mM to 0.05 M), during separate training and test trials. Water rejection preceded each stimulus trial and testing occurred over three 90 min sessions. Next, six deeply anesthetized rats received electrophysiologically-guided bilateral electrolytic lesions of the gustatory zone of the PBN. Two lesions were placed on each side, one at the ventral border of the area (60 µA, 20 s), and one 200-300 µm more dorsal (40 µA, 20 s). A second group (n = 13) received similar lesions, but the current for the dorsal lesion was doubled. The rats were then tested for sucrose controls. After recovery rats were tested for quinine responsiveness. In all groups, licking to quinine significantly decreased as a function of concentration and after surgery. There was a slight rightward shift in the concentration-response curve after sucrose-dt 9 log units to the right and the higher current-induced lesions caused a more substantial shift of about 1 log unit. Histological analysis is in progress to determine the relationship between the degree of behavioral impairment and the cytoarchitectural lesion parameters. These results suggest that rats with PBN lesions are not completely averse to quinine. These lesions, however, markedly attenuate taste-guided avoidance responses. Supported by PHS grant DC-00161.

436.7

In an automated gustometer, 12 rats generated concentration-response functions for 8 rapid chemicals and sucrose. When water deprived, the rats progressively decreased their licking of citric acid, MgCl2, NH4Cl, quinine HCI, and capsaicin. When replete, the licking of sucrose and quinine increased and capsaicin decreased. When water deprived, rats decreased their intake of NaCl and monosodium glutamate. Six of these animals and 3 additional, inexperienced rats had electrophysiologically guided lesions centered on taste neurons in the nucleus of the solitary tract (NST); 4 others (3 exp., 1 inexp.) served as controls. Subsequently, all animals were retested using the same stimuli under the same condition. Controls maintained their taste responses, but the lesioned rats exhibited consistent deficits in responding to rapid stimuli. Licking of 1.0 M sucrose did not differ from water; however, the composite substance responses remained about half as much as before surgery. Intake of capsaicin was not influenced by the NST lesions. In a second experiment, 3 preparations of 0.3 M alanine were paired with injections of LiCl (1.5 mM/kg, 0.15 M). Both the lesioned and the control rats learned to avoid the alanine. Thus, rats with NST lesions show a marked change in gustatory preference and aversion, but still can use taste cues for learned aversions. With lesions in the parabrachial nucleus, the second central taste relay, rats exhibit only modest changes in gustatory preference, but cannot learn a taste aversion. RAT TASTERS AND NON-TASTERS REVEALED IN NEURAL ACTIVITY. B.K. Giza*, T. B. Scott & L. Zhang. U. Delaware, Newark DE 19716

Preferences for the bitter sweet taste of NaSaccarin (Sac) in rats may be related to the distribution of PROP sensitivity, as it is in humans. Do differences in NTS taste-evoked activity mediate these preferences? We offered rats water and 0.02M Sac, those selected those, those rats selected Sac (S) or >75% water (W). We recorded the activity of 56 cells from S- and 43 from W-rats in response to 13 stimuli. Activity in the two groups differed for four but greater for all other stimuli in W-rats. Thus water-prefering animals were not insensitive to sweet stimuli, but rather hyperresponsive to water. The two cell groups divided cells of each group into three clusters: sugar-, sodium- and acid-oriented. Sugar and sodium cells showed few differences between S- and W-rats. Rather, hyperresponsiveness of W-rats was most evident among acid cells. Therefore, hyperresponsitivity to non-sweet tastes in W-rats was carried primarily by cells whose activity is associated with aversive chemicals. The activity profile evoked by Sac was similar to those of sugars in S-rats, but more like those of non-sweet stimuli in W-rats. In humans, the sweetness of Sac does not differ between non-tasters of PROP, but bitter sensitivity is greater in the former group. It is the high bitterness that leads to its rejection by PROP tasters. A corresponding situation would seem to obtain in rats. Supported by research grant DK39064 from the NIDDK.

Single neurons were isolated from the rostral portion of the solitary tract of awake, behaving rats (n=41), during (n=58), and after (n=12) they were placed on a sodium-free diet. Fluid stimuli (30 µl) were delivered to the intragastric and intracardial veins. During deprivation, taste responses generally were reduced. Spontaneous activity increased by an average of 42%, while responses to water dropped by 28%. Mean response to NaCl decreased 47%; to sucrose, 59%; to citric acid, 32%; and to quinine HCl, 16%. Nevertheless, the response profiles of the neurons to 4 standard stimuli were not changed by the dietary conditions. In the depletion condition, 61% of the activity elicited by NaCl occurred in Na-best cells, 33% in sucrose-best neurons. In the depleted state, the figures were 60% and 26%, respectively. At higher stimulus concentrations, however, the relative responsiveness was altered by sodium deprivation. When the animals were sodium replete, in sucrose-best neurons, 1.0 M NaCl elicited only 60% as much activity as their Na-best activity. When the rats were sodium deprived. Although the sample was small, these results appeared to reveal toward previous values when sodium was added back to the diet. Supported by PHS grants DC-00240, MH-43787, MH-06553.
436.9 CYCLIC SPONTANEOUS ACTIVITY IN TASTE-RESPONSIVE UNITS IN THE NUCLEUS OF THE SOLITARY TRACT IN THE RAT. Scott Monroe* and Patricia M. Di Lorenzo. Dept. of Psychology, P.O. Box 6000, SUNY at Binghamton, Binghamton, NY 13902-6000.

Recent studies have shown that some taste-responsive units in the periaqueductal pons (PNb), the second relay in the central taste pathway in the rodent, show rhythmic, cyclical variations in spontaneous firing rate. The present study examined spontaneous activity in taste-responsive units in the nucleus of the solitary tract (NTS), the first relay in the central taste pathway, in the urethane-anesthetized rat. Initially, responses to representatives of the four basic taste stimuli were recorded followed by 15 min of spontaneous activity. Spontaneous activity (5 sec bins) was analyzed for cyclical characteristics and a Fourier analysis. Linear trends were removed prior to spectral analysis. Spontaneous activity was classified as cyclic if a peak in the activity spectrum existed that exceeded a 3% criterion. In 24 taste-responsive units that met this criterion, oscillatory activity not related to ingestion. Preliminary results show that 4 of 12 taste-responsive units showed significant cyclic spontaneous activity. These units showed single peaks in the spectral analysis ranging from 3.34-6.43 cycles/min, with a median of 1.8 cycles/min. Ten of the NTS units were recorded simultaneously with taste-responsive PnB units and in five of these pairs one unit showed cyclometry where the other did not. This suggests that the occurrence of cyclicity of spontaneous rate may be independent in the NTS and PnB. In contrast to the PnB units, spontaneous firing rates in NTS units were not suppressed following taste stimulation.

436.10 THE EFFECTS OF A CTA ON GUSTATORY EVOKED ACTIVITY IN THE RAT NTS REMAIN AFTER BEHAVIORAL EXTINCTION. L.J. Nolan* and T.R. Scott, Dept. of Psychology, University of Delaware, Newark, DE 19716.

Chang and Scott (1984) reported modification of gustatory evoked activity in the rat NTS as a consequence of a CTA. We investigated whether this modification would be lost with complete behavioral extinction of the aversion. Rats were conditioned to avoid .0025M sodium saccharin (CS) by pairing its taste (15 daily sessions). Initially, responses of the four basic taste stimuli were recorded followed by 15 min of spontaneous activity. Spontaneous activity (5 sec bins) was analyzed for cyclical characteristics and a Fourier analysis. Linear trends were removed prior to spectral analysis. Spontaneous activity was classified as cyclic if a peak in the activity spectrum existed that exceeded a 3% criterion. In 24 taste-responsive units that met this criterion, oscillatory activity not related to ingestion. Preliminary results show that 4 of 12 taste-responsive units showed significant cyclic spontaneous activity. These units showed single peaks in the spectral analysis ranging from 3.34-6.43 cycles/min, with a median of 1.8 cycles/min. Ten of the NTS units were recorded simultaneously with taste-responsive PnB units and in five of these pairs one unit showed cyclometry where the other did not. This suggests that the occurrence of cyclicity of spontaneous rate may be independent in the NTS and PnB. In contrast to the PnB units, spontaneous firing rates in NTS units were not suppressed following taste stimulation.

The posterior lingual taste buds located within the foliate (FOL) and circumvallate (CV) papillae account for the majority of tongue taste buds in the rat (46% and 35%, respectively). However, there is a paucity of data on central processing of taste-responses arising from the posterior tongue, especially the CV. In the present study, in rat, the location of neurons responsive to specific CV and FOL stimulation were mapped within the nucleus of the solitary tract (NST) using standard extracellular recording techniques. Both posterior taste responses extended from rostral to about the level where the NST meets the 4th ventricle, with a trend for CV responses to extend caudal to FOL responses. In most cases, CV and FOL taste responses were recorded in the same electrode track, with FOL responses located dorsal to CV responses. Tactile responses from these two fields were coextensive. The majority of posterior tongue responsive sites, but were more widespread. All multinunit sites and four single units responsive to specific CV stimulation had similar response profiles: 0.01M HCI > quaternary mixture > 0.03M quinine+HCl, with no response to 0.3M NaCl and 0.01M Na saccharin. This central response profile is more specific than glossopharyngeal nerve response profiles previously described, but is in agreement with the robust responsiveness of this nerve to acids and alcohols.

436.12 DISTRIBUTION OF TASTE-RESPONSIVE NEURONS IN THE HAMSTER SOLITARY NUCLEUS. A.P. Knox*, L.D. Savoy, T.P. Hettinger and M.E. Frank, Department of Biocomputer and Function, Univ. of Connecticut Health Center, Farmington, CT 06030.

The distribution of taste-responsive neurons in the rostral solitary nucleus (SN) was studied in anesthetized hamsters (Mesocricetus auratus). The anterior tongue was isolated in a flow chamber and seven taste stimuli (0.03 M NaCl, 0.03 M saccharin, 0.1 M glycine, 0.1 M KCl, 0.03 M Na acetate, 0.03 M NaCl (0.1 M sucrose) applied. Extracellular recordings from SN neurons were made with glass microelectrodes (1.8 MΩ) filled with 4% HRP in 0.5 M KCl and 0.05 M Tris buffer. Units were recorded on a VGR and played back through a window discriminator for data analysis. Successful recording sites were marked by ionophoresis of HRP, which filled stellate and elongate cells. Postmortem histological analysis showed frozen sections in the transverse, parasagittal or horizontal plane. The SN is prominent and can be reconstructed from sections in any plane. Sections were processed for HRP, counterstained and the taste-responsive area containing small, densely packed cells was mapped. A high percentage of cells in this area responded to one or more stimuli. Rates as high as 100 spikes/s were obtained to sucrose. Responses in the rostral SN may be stimulus selective at any one multinunit site. Single units, however, could display disparate responses at contiguous sites. These data argue that taste responsiveness of neurons may have a "modular" organization that selects for basic taste stimuli. This work was supported by NIH grant DC 06063.

436.13 TRANSGENOMIC DEGENERATION IN THE GUSTATORY SYSTEM. L.T. McGlathery and M.O. Whitehead*. Department of Surgery, Division of Anatomy, UCSF, La Jolla, CA 92037.

Peripheral taste nerves are prone to damage in humans and have been experimentally altered in animal studies of the defferentated gustatory system. It is not known whether peripheral nerve damage in the mammalian taste system results in degeneration of central axonal endings as in other sensory systems (e.g. trigeminal, vestibular, auditory). We studied 11 Golden hamsters whose right chorda tympani were severed in the middle ear. In 8 cases a control, fornemcretol, is applied to the nerve stump. The animals survived for 2-15 days. The brains were dissected and stained for degenerating axons and endings using the Fink-Heimer method. In all cases there was evidence of degenerating ending in the central nucleus of the solitary tract. Degeneration was concentrated in the chorda tympani terminal field in animals treated with both the nerve stump and fornemcretol. The degeneration was dense, especially at 11-13 days. In cases where the chorda tympani had been severed, degeneration was less robust but relatively heavy at 11 days and observable as early as 0.3 M NaCl. The degeneration observed after fornemcretol treatment could result from the death of pepticeptase cells. However, degeneration after single nerve cut is best explained as transganglonic, i.e. necessarily requiring cell death. The present findings indicate that peripheral nerve damage can profoundly disrupt the synaptology of the NST. Altered synaptology could relate to the dysaesthesia or other taste system of central origin reported for some patients after trauma in the palate, oral or oral surgery. (Supported by NIH Grant DC00452).

Research on alcohol consumption has generally employed water-alcohol mixtures, but in the real world alcohol is often flavored with another pleasant taste, often something sweet. Alcohol-saccharin mixtures were used in this study to achieve this goal and to determine the neural basis of this attraction. Subjects were extinguished by pairing 4% alcohol and 2% saccharin mixtures with body weight gain or body weight loss, respectively. Partial extinction was achieved by pairing saccharin and alcohol mixtures with the CS. However, when alcohol and saccharin mixtures were paired, the alcohol was not consumed. Alcohol-saccharin mixtures were given in the presence of water. The rats were then allowed to lick for 30 min lick analysis tests; volume consumed was measured at the end of each session. Solutions of saccharin (0.06 M) and alcohol mixtures (3%, 6%, 9%, and 12%, v/v) were presented in ascending and descending orders, one solution day each. Contrary to previous findings with water-alcohol mixtures [Kiefer et al., Alcohol, 4, 1987] rats lacking gustatory cortex did not consume more alcohol-saccharin at any concentration compared to controls. Preliminary analysis of lick rate also revealed no significant differences between groups. It is suggested that the presence of alcohol contributes to the lack of differences. There were significant differences across concentrations, with the CS consumed more saccharin and 3% alcohol-saccharin than other concentrations.
437.1

Autoradiographic studies have identified high levels of excitatory amino acid (EAA) receptors in the striatum. However, the localization of EAA receptor subtypes to specific populations of striatal projection neurons has not been determined. We used quantitative autoradiography to examine the cellular localization of NMDA, AMPA, metabotropic and kainate EAA binding sites in the striatum following selective lesion of striatoniigral projection neurons. Denervation of striatoniigral neurons was induced unilaterally by injection of the suicide transport toxin, kainic acid (0.5-0.8 ng in PBS), into the left substantia nigra. Following a survival period of 12 days, we observed a reduction of all EAA binding site subtypes in the striatum ipsilateral to the injected nigra. Striatal NMDA binding sites were reduced approximately 50%. The other EAA binding site subtypes exhibited more modest reductions; up to 16% for AMPA, 27% for metabotropic and 15% for kainate.

These results indicate that there are NMDA, AMPA, metabotropic and kainate binding sites on striatoniigral projection neurons and suggest that the NMDA subtype may be selectively enriched on striatoniigral neurons. Supported by NS13000, NS19613, NS07222 and the Hereditary Disease Foundation.

Various neuron types may be at risk during the course of Huntington's Disease (HD). Glial cells have not been extensively studied during the course of neurodegeneration within the structure most involved in the disease process, the caudate-putamen (or neostriatum). Since the astrocyte could be a cell at risk, or even associated with the primary defect, we examined two markers that have been shown to be specific for astrocyte "reactivity," (galilgal fibrillar acidic protein, GFAP), and development, tenascin, a constituent of the extracellular matrix that is developmentally regulated in the neostriatum and other structures, and also expressed early in CNS injury).

Immunocytochemistry for GFAP and tenascin using well-characterized monoclonal and polyclonal antibodies, was carried out on presymptomatic, and Grades 2& 3 HD striatum (using the grading scale of Vonsattel). Our studies have revealed that astrocytes show changes in the presymptomatic HD tissue, and that their reactivity, distribution, and expression of tenascin and GFAP mirrors the degenerative process through the caudate and putamen as the disease progresses. In particular, we have found that GFAP and tenascin are upregulated in the HD striatum, and distributed in a patchy manner that may either represent neurons or a matrix compartment. In presymptomatic tissue, GFAP and tenascin patchy staining is light, as compared to Grades 2 & 3. By Grade 3, the tenascin and GFAP immunostaining in the caudate and putamen is dense and pervasive. In Grades 2 & 3, GFAP staining is associated with classical reactive astocytes, but in the presymptomatic tissue the GFAP labels what resemble immature astocytes. Thus, astocytes exhibit morphological and biochemical changes that may be associated with the onset of disease. Supported by the Hereditary Disease Foundation.

437.4

Previous in vitro electrophysiological studies have shown that DA increased the spontaneous firing of GABA interneurons in the medial frontal cortex (MFC). This activation could be involved in the inhibition of the firing rate of pyramidal cells observed in vivo following DA neuron stimulation of the ventral tegmental area (VTA). The DA control of MFC GABA interneurons was further investigated by studying the spontaneous 3H-GABA release on MFC slices. Three D2 agonists (quinpirole, RU 24969 and butrodone) dose dependently enhanced 3H-GABA release. These effects were antagonized by the classical D2 antagonist sulpiride. Endogenous DA release by amphetamine also increased the release of 3H-GABA through a D2 receptor activation. A permissive effect of D1 agonist was observed on the D2-mediated increase of 3H-GABA release. The D2 activatory effect observed on GABA interneurons of the MFC was antagonized by the inhibitory effect observed on the spontaneous 3H-GABA release in the striatum.

Finally, DA regulated the levels of mRNA encoding one of the isoforms of glutamic acid decarboxylase (GAD67, GAD65) which showed that the electrotic lesion of VTA neurons decreased GAD67-mRNA expression in the MFC. At the opposite, a 6-OHDA lesion of DA nigral neurons enhanced GAD67-mRNA levels in the striatum, an effect which can be reproduced by a chronic treatment with sulpiride and haloperidol.

437.5 SCOPOLAMINE ATTENUATES HALOPERIDOL-INDUCED C-FOSEXPRESSION IN THE BRAIN. N. Guo,1 S. Robertson and H.C. Fibiger, Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, 2255 Westbrook Mall, Vancouver, B.C. Canada, V6T 1Z3. Haloperidol-induced lesions in some parts of the central nervous system. Haloperidol also induces catechol in rodents and extrapyramidal side effects in humans, both of which are reduced by muscarinic antagonists. In order to gain insight into the neurochemical and neuroanatomical substrates of haloperidol-induced catechol we examined the effects of the muscarinic receptor antagonist scopolamine on haloperidol-induced C-fose expression in the striatum, nucleus accumbens, and lateral septal nucleus. Male Wistar rats received subcutaneous injections of scopolamine (2.5mg/kg), or vehicle (1mg/kg) 30 minutes before haloperidol (2mg/kg). The rats were perfused 2 hours after the injection. Immunohistochemical staining was performed on brain sections (30μm). We found that the scopolamine-induced C-fose expression was significantly reduced to half of the haloperidol-induced levels.

437.6 METABOLIC EFFECTS OF CONTINUOUS L-DOPA INFUSION IN RATS WITH UNILATERAL SUBSTANTI NIGRA LESIONS. G.A. Hubbard, J.E. Bennett and J.M. Trugen, Dept. of Neurology, Univ. of Virginia, Charlottesville, VA 22908. We used the 2-deoxyglucose (2-DG) method of measuring regional cerebral glucose utilization (RCGU) to study the effects of continuous L-dopa infusion in rats with unilateral 6-hydroxydopamine nigral lesions. Rats were implanted with osmotic minipumps (Alzet, ALZ-2001, 1000 μl/h, 24 h) with L-dopa (250, 500, or 1200 mg/kg/day) or saline. L-dopa and 2-DG uptake in the subthalamic nucleus (up 40%) and significantly increased RCGU in the dorsolateral striatum (up to 50%) in the lesions were observed. L-Dopa infusion was shown to be beneficial in the treatment of Parkinson's disease.

437.7 PROGRESSION OF CEREBRAL METABOLIC CHANGES IN MPTP-INDUCED HEMIPARKINSONISM IN MONKEYS. E. Polombo,1 K. Brandt,2 J. Segal3 and J. Portier1.1 MNI, Bethesda, MD 20892; 2NIH, Bethesda, MD 20092; 3Howard University School of Medicine, Washington, DC 20060. Local rates of glucose utilization (LCGU) were determined in hemiparkinsonism monkeys, 6-16 weeks (short-term) or 16 to 26 weeks (long-term, n=3) after unilateral intracarotid infusion of MPTP. Four additional monkeys served as normal controls. MPTP-treatment resulted in similar clinical signs of hemiparkinsonism, e.g. unilateral bradykinesia and rigidity that were apparent in all 6 treated monkeys. In the short-term group, significant side-to-side asymmetries were restricted to the substantia nigra compacta (SNC) medialis and to the zona incerta (ZI). Additional smaller differences were seen in the external globus pallidus (GP) and subthalamic nucleus (STN). In the long-term group, LCGU decreases in the SNC medialis were similar (31% short-term vs 34% long-term). Changes in the GP (+30 vs +55%), STN (14 vs 20%) and ZI (+9 vs +18%) were far more pronounced. In addition, LCGU was increased in the dorsolateral caudate (+18%), all of the putamen (+25%), and pedunculopontine nucleus (+19%) ipsilateral to the lesion. Furthermore, bilateral reductions were present in the ventral tegmental segmental area as compared to controls. Bilateral increases were also present in the pars oralis of ventral striatum and in the supplementary motor area. Within the time frame of this study, the pattern of LCGU changes in the basal ganglia and associated structures becomes more complex as the length of time after Snpc denervation increases. This suggests that pathophysiological events in the brain progress in spite of a relatively stable clinical syndrome.

437.9 EFFECTS OF CHLOROZAPATINE TREATMENT ON INDUCTION OF FOCALLIKE PROTEINS IN THE STRIATUM. N. Haan1 and A.M. Graybiel. Department of brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139. We have previously reported that acute injection of the atypical antipsychotic drug clozapine (CLZ) induced Fos-like immunoreactivity (FLI) in neurons of the nucleus accumbens and caudoputamen acutely (by 2 hrs) in a disease-dependent manner (Ferri et al. Soc. Neurol. Abstr., 1991). We have now compared the effects of acute CLZ treatment (>8 days) and clozapine treatments. Groups of rats received one of the following treatments: chronic CLZ followed by acetic acid (AA), or chronic CLZ followed by vehicle (150 mg/kg, i.p.), and on the 9th day they received acute injection of CLZ (20 mg/kg, i.p.); or vehicle (10 mg/kg, i.p.) and vehicle (900 mg/kg, i.p.) followed by AA (150 mg/kg, i.p.). The rats were perfused 2 hours after the injection. The results showed that chronic treatment with CLZ changes the gene-expressive responses of nucleus accumbens neurons such as acute nuclei and 2 dose changes may reflect regulation of Fos-like antigen expression by the monocytes to visualize Fos protein. FLIs that decreased the expression of the neuronal Fos antigen, supported by the Human Frontier Science Program and Javits Award NIA. We thank Dr. F. Sharp for a Fos monoclonal antibody and Sandoz Pharmaceutical for a gift of drug.

437.10 LOCAL INJECTION OF DOPAMINERGIC AND MUSCARINIC AGONISTS MODULATE STRIATAL PEPTIDE GENE EXPRESSION. L.K. Nielsen,1 S.T. Krau, and C.R. Geffers. Dept. of Anatomy and Neurobiology, University of Tennessee, Memphis, Memphis, TN, and Lab of Cell Biology, NIMH, Bethesda, MD. The antagonistic balance between acetylcholine (ACh) and dopamine (DA) within the striatum has long been recognized to be important in the functional activity of the basal ganglia. In order to investigate how ACh and DA influence the output of dopaminergic (DA) and mesolimbic projection neurons, we have examined the regulation of neuropeptide gene expression by dopaminergic and muscarinic agonists. Following the activation of the nigrostriatal dopamine pathway, there is an increase in the expression of enkephalin mRNA in striatal projection neurons, while the level of dopamine mRNA remains unchanged. The production of locomotor activity by the application of D-1 and D-2 agonists further modifies the expression of dopamine and enkephalin mRNA in the striatum of lesioned rats. In order to test whether the action of these drugs is mediated locally within the striatum, SKF-38393, a D-1 agonist, was injected directly into the striatum or lateral ventricle (cve) of 6-OHDA lesioned rats. In situ hybridization histochemistry was used to measure the expression of dopamine and enkephalin mRNA. Injection of 5 μg SKF-38393 directly into the striatum produced a local increase in dopamine mRNA surrounding the injection site. Likewise, 1-10 μg SKF-38393 (100% increase) and 5 μg SKF-38393 (100% increase) increased enkephalin mRNA within the dorsal medial striatum adjacent to the ventricle. Next, the effect of a muscarinic agonist on peptide expression in 6-OHDA lesioned rats was examined. Injections of pilocarpine (120 μg) icv resulted in a further 25% increase in enkephalin mRNA levels, while a lesion-induced level in striatal neurons within the dorsal medial region adjacent to the ventricle. We conclude that the effects of both D-1 and muscarinic agonists on peptide expression are mediated locally within the striatum. Further, this study shows the importance of DA and ACh receptor interaction in the striatal gene expression of striatal neurons.

TIME COURSE OF ALTERATIONS IN SUBSTANCE P, DYNORPHIN, ENKEPHALIN AND o-FOs GENE EXPRESSION IN STRIATAL NEURONS DURING CHRONIC COCAINE TREATMENT.
H. Steinert* and C. R. Garden, Lab. of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892.
Projection neurons of the striatum differ in the expression of neuropeptides: striatonigral neurons mainly express substance P and dynorphin, whereas striatopallidal neurons express enkephalins. Dopamine modulates the levels of these peptides. We examined with in situ hybridization histochemistry short-term and long-term changes in glibergic expression of these peptides, as well as of the immediate-early gene c-fos, during chronic treatment with the indirect dopamine agonist 7-OH-DCPP (1 mg/kg, i.p., twice daily). Thirty minutes after acute application of cocaine, mRNA levels of substance P and c-fos are significantly increased, mostly in dorsal striatal regions. On day 3 of the chronic treatment, the cocainia-induced increase in mRNA levels is significantly reduced (as compared to the levels at the beginning of the treatment), and remains reduced thereafter, in most regions. Conversely, mRNA levels of dynorphin and enkephalin are unchanged 30 min after the acute cocaine application, but are significantly increased on treatment day 2, also predominantly in dorsal regions, and remain elevated in some regions after a longer treatment. These results show that chronic cocaine treatment produces different temporal and regional patterns of alterations in gene expression in striatonigral and striatopallidal neurons.

437.12
Suicide transport agents elicit regenerative degeneration of neurons projecting to an injection site. In the basal ganglia these toxins have been shown to produce selective lesions of the striatopallidal and striatonigral pathways based on receptor binding and neurochemical mRNA studies. In the present immunohistochemical study, the neostriatal of adult rats were examined 10 days after an injection of volkine or into the substantia nigra (SN) or an injection of OX-7 aminophylline into the globus pallidus (GP) (n=5). Adjacent sections were processed for (1) Nissl stain to study the density of all neurons and large interneurons, (2) NADPH-diaphorase (4) histochemistry, to mark medium-sized interneurons, (3) enkephalin (ENK) immunocytochemistry (ICC), to label striatopallidal neurons, or 4) substance P (SUB) ICC to label striatonigral neurons. Analyses of Nissl stained sections revealed that the striatal ipsilateral to the lesions appeared healthy and did not exhibit shrinkage or gliosis; however, a moderate decrease in cell density was detected by quantitation (33-44%). The densities of large neurons and NADPH-di-labeled neurons in the ipsilateral striata were unchanged after OP lesions and showed a significant decrease (70%) after FN lesions. After OP lesions the density of ENK-labeled cells (21%) decreased more than that of SUB-labeled cells (16%). Conversely, after FN lesions, the density of SUB-labeled cells (56%) decreased and more than that of ENK-labeled cells (20%). These data suggest that interneurons are relatively spared and that projection neurons may be differentially affected after OP and FN lesions. Supported by DRIF, U. of MD (RCR) & NS01544 (MBH).

IMMUNOHISTOCHEMICAL LOCALIZATION OF 3-HYDROXYANTHRANILIC ACID OXGENASE (3HAAO) AND KYNURENE AMINOTRANSFERASE IN ASTROCYTES IN THE RAT SUBSTANIA NIGRA. R. Schwartz*, F. Da, K.E. McCarthy, E. Okano and R.C. Roberts. Maryland Psychiatric Research Center, Baltimore, MD 21228.
Endogenous excitotoxins, such as quinolinic acid (QUIN), may be involved in the pathogenesis of several brain disorders. Kyneric acid (KYNA), an endogenous antagonist of excitatory amino acid receptors, has neuroprotective and anticonvulsant properties. The immunohistochemical localization of 3-hydroxyanthranilic acid oxygenase (3HAAO) and kyneric aminotransferase (KAT), the biosynthetic enzymes of QUIN and KYNA, respectively, was examined in the adult rat substantia nigra, pars compacta (SNpc). At the light microscopic level, KAT and KYNA immunoreactivity (ii) were present in glia in a robust and homogenous pattern in both the nucleus and cytoplasm. At the ultrastructural level, both 3HAAO and KAT i were present in astrocytic processes surrounding capillaries. 3HAAO was abundant throughout the neuron in fine calibre glial processes which often encased synaptic profiles, both asymmetrical (erytactic) and symmetrical (inhibitory). KAT i was also present in astrocytic processes, but usually of larger calibre than those labeled by 3HAAO antibodies. KAT-i-glial processes abutted, rather than surrounded, both symmetrical and asymmetric synapses. Thus, astrocytic QUIN and KYNA appear to be in a position to modulate excitatory amino acid receptor function in the SNpc. Supported by USPHS grants NS28236 and MH4211 and a HSDA fellowship (P.D.).

Acute nicotine injections induce c-fos expression mostly in nondopaminergic neurons of the ventral tegmental area (VTA). Ying Pang, Hideo Kiba, H. Gould* and A. Jayaraman, Dept. of Neurology, LSU Sch. of Med., New Orleans, LA 70112.
Induction of c-fos gene is considered to be an immediate and early response in the cascade of molecular events that ultimately lead to long-term alterations in gene expression in neurons. The psychomotor stimuli and positive reinforcing effects of nicotine have been speculated to be mediated by the dopaminergic neurons of the VTA. To identify the precise subpopulation of the dopaminergic neurons, the pattern of expression of c-fos gene was mapped using immunohistochemical methods.
Acute nicotine injections (0.3-1.4 mg/kg, i.c.) resulted in a prominent Fos-like immunoreactivity (Fos-li) in the interpeduncular nucleus, medial terminal nucleus of the accessory optic tract and also prominently in the caudal linear subnucleus (SND) of the VTA. The neurons of VTA subnuclei, viz., the rostral linear, parabrachialis, nucleus parabrachialis pigmentosus, and nucleus interfacialis did not contain any cells. Fos-li. Mecamylamine abolished Fos-li in neurons of VTA, superficial layers of superior colliculus, periaqueductal gray areas and the interpeduncular nucleus.
These results suggest that acute nicotine injections induce c-fos expression mostly in nondopaminergic neurons of the ventral tegmental area. Supported by Smokeless Tobacco Research Council.

437.15
We have previously hypothesized that these striatal neurons expressing both high levels of glutamic acid decarboxylase (GAD67) mRNA are interneurons (Cheeslet and Robbins, 1989). To further test this hypothesis, striatal sections were hybridized simultaneously with a digoxigenin-labeled RNA probe for GAD67 and a 32P-RNA probe for parvalbumin, a calcium binding protein present in striatal GABA-ergic interneurons (Cowen et al. '90; Kita et al. '90). The majority of neurons densely labelled for GAD mRNA also expressed parvalbumin mRNA, confirming that they are interneurons. Previous studies have shown that dopamine depletion selectively decreased GAD67 mRNA levels in the densely labelled cells (Gougham et al. Brain Res. 1992). Further double-labelling experiments revealed the presence of mRNA for dopamine D2, but not D1 receptors in these neurons, suggesting that the D2 receptor subtype may be involved in the effects of dopamine on striatal GABA-ergic interneurons. Supported by PHS grant MH-44889. We thank A.J. Tobin (UCLA) and M. Berchtold (Zurich) for the cDNAs.

437.16
The processes underlying dopaminergic neurotoxicity produced by chronic administration of methamphetamine [m-AMPH] are incompletely understood. Insights into m-AMPH's cytotoxic mechanisms may be gained by examining the effects of a neurotoxic regimen of m-AMPH has on subpopulations of dopaminergic striatal projections. Using measures of dopamine content and [H]mazindol-labeled dopamine transport sites (visualized with quantitative autoradiography), we report differential vulnerability of striatal regions of rats given m-AMPH one week earlier (4 injections (s.c.), each 4 mg/kg, 2 hrs apart). Three rostrocaudal levels of the striatum were sampled (anterior, middle and posterior), and several regions were examined at each level (c.g. dorsal, lateral, ventral and medial regions; nucleus accumbens at the anterior level). Treatment with m-AMPH resulted in a significant decrease in [H]mazindol binding at both the anterior and middle levels, with the ventral and medial subregions exhibiting greater reduction than the dorsal striatum or the nucleus accumbens. Parallel to the heterogeneous reduction of striatal [H]mazindol binding by m-AMPH, striatal dopamine content depletion at the anterior level was most severe in the ventral region. The results encourage attempts to identify factors within the ventral-medial caudate nucleus that make it more susceptible to m-AMPH's neurotoxic effects as compared to the adjacent nucleus accumbens and the dorsal caudate nucleus.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
438.1 PERCEPTION OF DURATIONS OF KINESISTHETIC STIMULI IN CEREBELLAR PATIENTS. J.S. Lee, S.E. Grill, M. Balint, * Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892.

Coordinated movement depends upon proper temporal control of muscle activation. Persons with cerebellar disorders have difficulty with such movements as well as disturbances of durations of auditory and visual stimuli. We have compared the ability to perceive durations of kinesistic stimuli of seven patients with cerebellar disorders (without clinical evidence for peripheral neuropathy) to that of six normal controls. Subjects were seated with their right forearm resting on a table midway between the midline and slightly to the right of the body. The right index finger was fixed and the index finger placed squarely in a finger holder attached to a computer-controlled torque motor. This allowed imposition of controlled changes in joint angle about the metacarpophalangeal joint. After the completion of the presentation of a pair of joint angle steps two seconds apart, of different durations but the same magnitude (about one degree). Each pair of stimuli consisted of a standard 150 ms duration step and a variable duration step ranging from 50 ms to 250 ms. The standard was 150 ms long, and between 150 and 350 ms when the standard was 250 ms long. Stimuli were presented in random order. Subjects were instructed to report which stimulus was longer, by responding with "one" or "two". The session continued until each pair of stimuli was presented 10 times.

There were striking differences in the ability to distinguish the durations of stimuli between normal subjects and cerebellar patients (p<.001). For example, normal subjects were able to distinguish a 150 ms stimulus from one of 110 ms duration with only a 17% error rate, whereas cerebellar patients performed (making errors 46% of the time).

Impaired resolution of durations of kinesistic stimuli by motor centers may contribute to deficits in coordinated movements in persons with cerebellar disorders.

438.2 PERFORMANCE OF RATS ON A PERCEPTUAL TIMING TASK FOLLOWING CEREBELLAR LESIONS. J.V. Haido and R. Ivry, * University of California, Berkeley, CA 94720.

In previous research, we have found that patients with cerebellar lesions are impaired on motor and perceptual tasks that require precise timing. The present study used an animal model to investigate cerebellum in perceptual timing. Rats were trained on a two-choice discrimination task in which the duration of a visual stimulus was either 300 or 700 ms. Probe stimuli of intermediate durations were also presented without reward. Animals received either sham lesions or bilateral electrolytic lesions targeted at the lateral cerebellar nuclei. Preliminary results indicate: 1) the lesions have minimal effect on overall response rate; 2) the experimental and control animals perform similarly on the endpoint stimuli; and 3) the experimental animals are less consistent in their judgments of probe stimuli (differential discrimination). Further experiments and analyses with this paradigm should help clarify the role of the cerebellum in time perception.

In normal rats there is a decline in sensitivity to serotoninergic (5-HT) agonists during the second postnatal week. During this period, the genetically dystonic (d) rat, an animal model of inherited movement disorder, exhibits enhanced behavioral sensitivity to both quipazine and 8-hydroxy-2-(di-n-propylamino)tetrahydrobenzazepine (8-OH-DPAT) (Michela et al., 1990; Weland and Lucki, 1991). Since this is also the period during which the motor syndrome of the d rat appears, the enhanced sensitivity may be a secondary consequence of the movement disorder per se. To test this hypothesis, the behavioral effects of 5-HT agonists were examined in intact and cerebellectomized d and normal rats at 15-20 days of age. Earlier studies indicated that the output of the cerebellum is abnormal in d rats, and it has recently been found that cerebellectomy (CEREBELLA) eliminates the expression of the motor syndrome. Despite the improvement in motor ability observed after CEREBELLA in the d rats, 8-OH-DPAT produced a characteristic dose-dependent behavioral syndrome in all groups, and the enhanced sensitivity of the d rats was maintained when compared to normal littermates. Thus, the behavioral sensitivity of the d rats is not secondary to their movement disorder. Since experimentally-induced damage to the olivo-cerebellar system in normal rats also increases sensitivity to 5-HT agonists (Wieland, et al., 1990), the cerebellum may normally exert an inhibitory effect on the 5-HT syndrome that is absent in the d rats. (Supported by the Dystonia Medical Research Foundation.)

438.4 EFFECT OF CEREBELLECTOMY ON THE MOTOR SYNDROME OF THE GENETICALLY DYSTONIC RATS. M.S. LeDoux, J.F. Lorden, and J.M. Erwin, Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

The dystonic (d) rat is an autosomal recessive mutant with a motor syndrome that resembles generalized dystonia seen in humans. In the absence of intervention, motor function deteriorates, resulting in death by postnatal day 35. Glucose utilization studies and electrophysiological recordings have demonstrated abnormal neuronal activity in the deep cerebellar nuclei of the d rat. To test the hypothesis that abnormal cerebellar output is responsible for the d motor syndrome, total cerebellectomies, including ablation of the cerebellar nuclei, were performed on d and normal rats at 15 and 20 days of age. As a control for non-specific lesion effects, a separate group of 15-day-old d rats received bilateral kainic acid lesions of the entopeduncular nucleus. Rats underwent behavioral testing just prior to surgery and again three days later. Separate groups of aged-matched normal and d rats served as unoperated controls. Behavioral testing included the determination of righting reflex times, locomotor and climbing ability. In addition, the severity of the motor syndrome was evaluated.

The d rat demonstrated an immediate and permanent improvement in motor function and a marked decrease in abnormal motor signs after cerebellectomy. Cerebellectomy allows the d rat to survive into adulthood and mate successfully. Interruption of basal ganglia output failed to improve the condition of the d rats. These findings suggest that cerebellar output is critical to the expression of motor signs in the rat disease. (Supported by NS5-01087 and the Dystonia Med. Res. Fdn.)

438.5 THE EYE OPENING TIME AS A FACTOR ACCELERATING MATURATION OF CEREBELLUM. KURINJE CELLS IN THE KITTENS. G. E. Passino, J. M. S. Becken, Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, 194223, St. Petersburg, Russia.

In experiments performed on two age groups of anesthetized kittens (i) blind kittens (3-5 days after birth) after eye opening (15-17 days) the activity of identified cerebellar Purkinje cells (PC) was studied. In blind kittens the cerebellar PC discharges represented by low frequency complex (CS) and simple spikes (SS) namely 0.37 - 0.48 and 3.5 - 3.7 imp/s respectively were recorded. A week after the eye opening (15 - 17 days) the frequency of CS and SS in PC discharge was increased approximately on three fold reaching 0.76 - 0.87 and 8.77 - 11 imp/s respectively, i.e. the velocity of the increase of PC discharge frequency before or after eye opening is expressed as 0.3. In blind kittens the cerebellar PC in response to stimulation of n.ishedidioc was no rule silent discharge whereas PC of (ii) group kittens responded even on the threshold stimuli by SS discharge followed by inhibitory complex (IC). In this case the duration of IP was longer compared with that seen in background active Purkinje cells.

TOPOGRAPHY OF SACCadic EYE MOVEMENTS IN THE CEREBELLMAR VERMIS OF THE RABBIT EVOKED BY MICROSTIMULATION.
M. Goshchalk*, J. van der Burg and B. van Duin, Dept. of Anatomy, Erasmus University Rotterdam, Rotterdam, The Netherlands.

In the oculomotor nuclei of the cerebellum, the complex spiky movements of the cerebellar lobules VI and VII, saccades can be evoked with low intensity microstimulation (Noda and Fujikado, J. Neurophysiol, 1987). The direction of saccades is ipsilateral, with an upward component in the more rostral part of the oculomotor nucleus and downwardly when going caudally. In rabbits, eye movements have been evoked with microstimulation in other parts of the cerebellum, but not the vermis.

Rabbits were prepared, under full anesthesia, for recording microstimulation-evoked eye movements. Scleral search coils were implanted under the conjunctiva in both eyes and a recording chamber was placed over the cerebellum vermis. After full recovery, penetrations were made in the vermis, searching for eye movements with a 200ms train of biphasic 2ms pulses at 330Hz and a maximum current of 60μA. When eye movements were observed, the current was lowered to assess the threshold. At the end of the experimental period, localization of the stimulation sites was verified by histological analysis.

In parts of lobules VI and VII, sacadic eye movements were evoked by currents ranging between 4 and 60μA. The movements were horizontal with no apparent vertical component. In a strip of approximately 4mm width on either side of the vermal midline, the cortex could be divided in two equal longitudinal zones. In the medial zone sacades were directed ipsilaterally, in the lateral zone contralaterally. Thus the topography of sacadic eye movements in the cerebellum in rabbits is unlike that of monkeys.

438.8
Neuronal activity in lateral cerebellar vermis (lobulus simplex) of cats, related to visual stimuli at rest and during locomotion. D.E. Marple-Horvat, J.M. Craig and L.E. Armstrong. SPON: Brain Research Association, Department of Physiology, School of Medical Sciences, University, Bristol BS8 1TD

One of the major pathways from visual areas of the cerebral cortex to motor cortex travels via the pontine nuclei to the cerebellar cortex. This projection suggests that a major component of the visuomotor system is the vestibulo-ocular and other proprioceptive signals from labyrinths. In this study, we have observed that the cerebellum sets the frequency of burst discharges of Purkinje cells in cats that is related to visual activity.

438.9
OPTICAL IMAGING OF RESPONSES TO ELECTRICAL AND NATURAL FACE STIMULATION IN THE RAT CEREBELLUM.
O. Chen, S.A. Elias and T.J. Ebner*, Departments of Neurosurgery and Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

Afferent responses to the cerebellar cortex have been characterized as a "fascicular mosaic". In this study optical recordings with a voltage sensitive dye were used to evaluate the spatial patterns of activity evoked by afferent input. In anesthetized rats (ketamine/xylazine), the exposed cerebellar cortex was stained with RH790 for 2 hours. Using epifluorescence optics, Crs I and II were imaged with a Photometrics CCD system (14 bit A/D, 516 x 384 pixels). A saline filled chamber was used to control brain movement. Stimulation of the face consisted of either discrete biphasic electrical stimulation or "natural" stimulation by a Ling vibrator controlled probe. The basic experimental paradigm consisted of subtracting "background" images without stimulation from a corresponding "stimulus" image during which the face input was delivered. For both types of inputs optical signals could be obtained, characterized by patches of activity. Although small in size (0.1% of firing rate) the response was temporally consistent and spatially corresponding with the optical signals. Consistent with a granule cell layer origin the optical signals were recorded at depths of 400-500μm.

These results show that optical signals in the cerebellar cortex can be obtained with not only electrical but more physiological afferent inputs. (Supported by NIH grants NS-27210 and NS-18388).

438.11
INFLUENCE OF ARTERIAL PRESSURE ON PURKINJEE CELL ACTIVITY. L. Robertson*, Dept. Biological Structure and Function, School of Dentistry, Oregon Health Sciences University, Portland, OR 97201.

We have shown that a significant proportion of Purkinje cells in lobule V have complex spikes elicited by stimulation of the vagal and renal afferent nerves. This study tested the hypothesis that changes in the number and complexity of Purkinje cell spikes are modulated by changes in arterial pressure and by input from baroreceptors. We measured changes in spontaneous and spontaneously-elicited simple and complex spike activity during pharmacologically-induced increases in arterial pressure and during electrical stimulation of the buffer nerves in the decerebrate cat preparation (i.e., in absence of a hypothalamic-pituitary response to blood pressure changes). In about a third of the Purkinje cells tested, a nitroprusside-induced decrease in blood pressure resulted in a 75 to 90% reduction in simple spike activity. An arterial pressure decrease of 30 mercury or more was required for the reduction in simple spike activity to occur. The reduction in activity involved both peripheral elicited and spontaneous simple spikes, but did not involve the complex spikes. The reduced simple spike activity often persisted for several minutes after the arterial pressure had returned to baseline. The prolonged reduction of simple spike activity may reflect a long-term response by the visceral receptors to the decrease in arterial pressure, induced by the administration of phenylephrine, affected the spontaneous activity in only a few cells, some of which had a 25% increase in simple spikes and some had a 40% reduction. The relationship between decreased blood pressure and reduced simple spike activity supports a cerebellar role in cardiovascular regulation.

438.12
IN VIVO INTRACELLULAR RECORDING OF PURKINJEE CELL RESPONSES TO UPPER LIP STIMULATION IN CRUS IIA OF THE RAT CEREBELLUM. D. Jeng-Jen, L.M. Brown. Div. of Biology 216-76, California Institute of Technology, Pasadena, CA 91125

Earlier work in our group has shown that a brief tactile stimulus delivered to the lip of a rat can lead to prolongation of burst discharges and complex spikes of Purkinje cells are modulated by changes in arterial pressure and by input from baroreceptors. We measured changes in spontaneous and spontaneously-elicited simple and complex spike activity during pharmacologically-induced increases in arterial pressure and during electrical stimulation of the buffer nerves in the decerebrate cat preparation (i.e., in absence of a hypothalamic-pituitary response to blood pressure changes). In about a third of the Purkinje cells tested, a nitroprusside-induced decrease in blood pressure resulted in a 75 to 90% reduction in simple spike activity. An arterial pressure decrease of 30 mercury or more was required for the reduction in simple spike activity to occur. The reduction in activity involved both peripheral elicited and spontaneous simple spikes, but did not involve the complex spikes. The reduced simple spike activity often persisted for several minutes after the arterial pressure had returned to baseline. The prolonged reduction of simple spike activity may reflect a long-term response by the visceral receptors to the decrease in arterial pressure, induced by the administration of phenylephrine, affected the spontaneous activity in only a few cells, some of which had a 25% increase in simple spikes and some had a 40% reduction. The relationship between decreased blood pressure and reduced simple spike activity supports a cerebellar role in cardiovascular regulation.

Climbing fiber responses (CFR) were recorded in the lateral hemisphere of the cerebellum of a monkey trained to perform both flexion and extension of the elbow in response to conditioned stimuli randomly presented. Differences in the CFR frequency were found in relation to the initiation of the movement depending on whether the monkey moves in response to the presentation of the external stimuli (triggered movement) or performs a self-initiated movement. With triggered movements CFR increase about 100 ms before the onset of movement. With self-initiated movements, this response is very small or even absent in this context. In another experiment, the monkey is rewarded only when movements are initiated during a second cue presented at a fixed delay after the go signal. In this 'time constraint' condition, CFR increase significantly when the velocity exceed 220 degrees/second and when the corresponding reaction time (RT) is between 250 and 275 ms. These relationships are not shown when the monkey does not have to use a precise timing. The link between CFR, velocity and RT is stronger in time constraint task. We would like to suggest that CF are activated in relation to their own oscillatory rhythm. In a time constraint task, repetitive external stimuli may induce a change in the spontaneous rhythm of the CF and allow synchronization of CFR especially when the cue is delivered in phase with the imposed rhythm. These factors could have much less influence on self-initiated movement. Finally when a precise timing is required by the delivery of a second cue, CF are best activated and related to the kinematic parameters of the movement. These results suggest that olivocerebellar input induces synchronized activity in the cerebellum allowing a more efficient control of movement initiation. Supported by MRC grant of Canada.

438.14 RESPONSES OF PURKINJE CELLS TO HINDLIMB JOINT ROTATION IN THE CAT. C. Gray, V. Percivalle* and R. Popple. Dept of Physiology, Univ. of Minnesota, Minneapolis, Minnesota, MN 55455.

To determine the relationship between the response properties of cerebellar cortical neurons and their locations in the cerebellum, we recorded from Purkinje cells in the anterior and posterior lobes during small amplitude passive rotations of the hind foot in barbiturate anesthetized cats. The 109 responsive cells were located in lobules I through IX between 1.4 and 4.2 mm lateral from the midline. 87% of the responsive cells were located in anterior lobules II and III and posterior lobes VII and VIII. 67% of the cells in the anterior III lobes in the posterior responded to both flexion and extension stimuli, the remaining responded to only one direction of rotation. Response to a movement depended on a cell's location. Cells in the anterior row of 2 lobes (3-4.2 mm) were excited at short latency (13-18 ms) by rotation in either direction. Medial cells generally exhibited longer latencies (25-28 ms) and longer response durations. In the posterior lobe where they tended to respond specifically to flexion and extension while in the anterior lobe those which were excited by movement in one direction were usually inhibited by the other. The results suggest the possibility of a functional mapping of movement within the spinocerebellum. Supported by NIH Grant NS21143 and the Human Frontier Science Program.

A number of models for velocity storage and integration of eye velocity signals have been proposed which use positive feedback to integrate signals related to changes in network or single unit parameters and a restricted number of units or a lack of variability related to the physiology of the vestibulo-ocular reflex (VOR). The aim of the present work was to study the properties of a model of bilateral neural network of the medulla oblongata which included several different types of units representing brainstem and cerebellar structures and two representing the horizontal ocular motoneurons. There were four inputs (representing two types of bilateral afferents) from the two horizontal semicircular canals. Each unit had a sigmoid input-output function and predicted the response to other head movements. The network was robust to perturbations in the connection weights and removal of a unit and predicted the response to other head movements. (Supported by NIH (DC00110) and Minn. Supercomputer Institute.)

Vertical vestibulo-ocular reflex (VOR) in cats tested in the 90° rolled position (vertical axis pitch) is less accurately compensatory than in the usual horizontal axis pitch). This inaccuracy could be related to a predominance of upward direction slow phase eye movements during low frequency rotations. Last year we reported a steady upward drift of the eyes in darkness in the absence of any rotation when the cat was in the 90° rolled position. Representing the drift as a velocity offset term allowed satisfactory sinusoidal fits to eye velocity during 2°/sec 0.01 Hz sinusoidal pitch rotation about the vertical axis. We are now testing vertical axis pitch VOR in darkness using electromagnetic search coils during 2-64°/sec peak velocity oscillations at 0.01 Hz. Sinusoidal functions with a positive offset term did not provide satisfactory fits to eye velocity during 0.01 Hz rotations above ~8°/sec. While higher head velocities resulted in greater downward slow phase velocities, the increase was not as great as would be predicted by the sum of drift and sinusoidal terms. Average peak upward slow phase eye velocity at 64°/sec head velocity was 43±14°/sec and average peak downward eye velocity was 96±6°/sec. Waveforms of slow phase eye velocities in response to high head velocities were markedly asymmetrical. Upward eye velocities rose steadily to the peak, while downward eye velocities appeared to saturate at a value near zero. These results suggest that in the 90° rolled position, upward but not downward slow phase vertical VOR is improved by a velocity storage mechanism as proposed by Matsuo and Cohen (Exp Brain Res 53:197, 1984). Supported by EY06485, EY07342, DC01559.
439.3 OPTOKINESTIC-VESTIBULAR INTERACTION IN PATIENTS WITH INCREASED VESTIBULAR-COULAR REFLEX (VOR) GAIN. E.W. Baloh1, J.M. Demer2. Reed Neurological Research Center, UCLA Sch of Med, Los Angeles, CA 90024-1769.

We studied optokinetic nystagmus (OKN) and visual-vestibular interaction in 5 patients with markedly elevated VOR gain. Approximately ±.3 normal across the frequency range of 0.01 - 1.6 Hz. Their lesions were localized to the vestibular nuclear complex on magnetic resonance imaging (MRI). All had impaired smooth pursuit and decreased initial slow phase velocity (SPV) of OKN SPY gradually built up over 25-30 sec. reaching normal values for low stimulus velocities (G 30 deg/sec). The initial SPV of optokinetic after-nystagmus (OKAN) was increased; but the reported decay of OKAN was normal. Fixation-suppression of the VOR was equally impaired whether the patients fixated on a surrounding optokinetic drum, or a light-emitting diode (LED) in the dark, or imagined an LED in the dark. These findings can be explained by a model that includes a velocity storage element and a variable gain element shared by the vestibular and optokinetic systems. Cerebellar lesions do not affect velocity storage but change the output of the variable gain element.

439.4 VESTIBULAR HABITUATION AND HUMAN REHABILITATION. K. Cohen1, C. Hatfield2, M. Kane3, L. Miller. Dept. of Otorhinolaryngology, Baylor College of Medicine, Houston, TX 77030, Program in Occupational Therapy, The University of Cincinnati College of Ohio, Toledo, OH 43699, Detroit Receiving Hospital, Detroit, MI 48201.

Repeatability vestibular experiments in many patients with unilateral peripheral vestibular lesions involves repetitive vestibular stimuli. Patients with unilateral peripheral vestibular lesions repeat habituation of velocity storage. We treated patients with unilateral peripheral vestibular lesions before and after receiving 12 biweekly therapy sessions involving repetitive vestibular stimuli. Subjects who had decreased vertigo and disequilibrium also had increased phase leads at low frequencies but not high frequencies. Therefore clinical compensation may involve low frequency habituation.

439.5 CHRONOBIL VERTIGO: THE COMPARISON OF THE ACUTE AND CHRONIC FORMS. E.P. Primations1, E. Zaitman2. Boca Foundation. Ljubljan vestib. Klinika, FLUKA. 21027 Ljubljana, Yugoslavia. 197 Chronobil clean-uppers were studied in 1986 during the acute phase and in 1988 during the chronic phase. We compared the complaints by the patients. The most prominent features for both groups were complaints for vertigo accompanied by tinnitus and deafness, accompanied by nausea and vomiting in chronic phase. Headaches, tinnitus, phobias, cardiac pains and losses of consciousness were also added. If in the group of 1986 mostly the minor signs were recorded in the 1991 group there were mediately expressed signs of the vestibular dysfunction. The most significant for both groups were the data of the Uemura's test. The data obtained with cuedata were well expressed in the 1986 group and almost insignificant in the 1991 group. The acute and indicating tests data appeared to become significant (p<.05) in persons with distinctly expressed function change. The comparison of the CHRONOBIL vertigo with the drop attacks, Meniere's disease, vestibular neuritis, supratentorial lesion - shown that it had most prominent features, which were not common to the pathologies compared.

439.6 PERCEIVED PASSIVE BODY VELOCITY AND ACTIVE MOTOR HAND VELOCITY INTERACT WITH TEMPORAL FREQUENCY. M. Allen1,2, E. Katz3, C. Oman1,4, M. Gehring3.

The motion profile is a plot of object location as a function of time. For an object moving back and forth at constant speed the motion profile has a triangular waveform, with slop and amplitude that represent object velocity and path length respectively. Increments in the period of this waveform, motion profile temporal frequency (MPF), result in increases in perceived tactile (Katz et al., 1990) and visual (Katz et al., 1991) velocity, even when actual velocity is held constant. Here we studied MPF in the vestibular and motor systems.

VESTIBULAR: Four velocities and four angular path lengths served to define 16 rotational stimuli. Subjects discriminated the faster of two stimuli in a 2AFC paradigm. While on average they discriminated velocity correctly, 68% of the times if stimuli were of identical paths (slower stimulus had lower MPFF), when stimuli-pair had identical velocities, the shorter (higher MPFF) was judged faster (p<.05). MOTOR: Subjects were asked to move their right hand back and forth on a horizontal surface for a trial lasting about 30 sec. In darkness. At the beginning of each trial the subjects were instructed to move their hand faster than in the preceding trial. The data indicate that increases in velocity in successive trials was accompanied by reduction in path length and thus increasing MPFF. These findings indicate MPFF interaction with perceived velocity in the vestibular and motor systems.

439.7 PHYSIOLOGICAL RESPONSES TO MOTION SICKNESS DURING SINGLE-STOP VIDEOVESTIBULAR STIMULATION. B. D. Lawson1, E. Dilio1, M. A. Kassabiel1, J. Ventura1, and K. L. Lichten1. Ashland GrayWolf Spatial Orientation Laboratory, Brandeis Univ., Waltham, MA 02254. We studied how motion sickness (MS) develops (subjectively, by the stimulus) (EXP) and physical fitness (FIT) relate to heart rate (HR), blood pressure (BP), respiration rate (RR) and electroencephalogram (EEG) during movement stimulation. Subjects (n=14) rotated at 270 deg/sec for 30 sec, then stopped suddenly and opened their eyes. During a 30 sec period, they reported their MS and FIT. This procedure was repeated for 10 min while physiological responses were monitored. 10 min baseline and recovery periods were included. MS were performed on 4 time periods - baseline, early and late stimulation, and recovery. MS increased during stimulation (Friedman X2=22.5, p<.001), HR and BP showed a peak response (p<.005), EEG showed a peak response, and EEG did not change. Physiological measures did not distinguish high, medium and low MS groups. Subjects were ranked by NOG, EXP, EEG, FIT, and peak physiological response. MS correlated with EEG (.67), EEG (.59), EXP (.67), EEG (.67), EEG (.67), and EEG (.67). (All r-tailed p<.05). Thus, the physiological responses elicited were not strongly related to MS. Since MS, NOG, EXP, and also correlated to physiological response.

When assessing vestibular dysfunction, clinicians often rely more on subjective information (e.g., patient history) than on objective data (e.g., caloric test). As a result, vestibular dysfunction is usually characterized by gross descriptive classifications. We compared these broad classifications with more objective measures of passive vestibular gaze stabilization, and of torso self-movement. 10 dizzy patients were examined in the clinic, and their overall vestibular dysfunctions were classified. 10 (5 low, 5 high) ratings (I-2-3 scale: none; slight, moderate, etc.). Then, passive gaze stabilization was characterized as the seated subject was turned, during brief darkness, while looking at a target. Next, active head-torso movement was evaluated while the standing subject made maximal-velocity, but "comfortable", ±60°/s. In all cases, subjects were asked to evaluate their symptoms. We found that only ±60% of patients exhibited more gaze error, and slower torso movements, than normals. However, when gaze error was plotted against torso velocity, all abnormally-rated patients separated from the normals. Also, as a patient's rating became more abnormal, tendencies for gaze error to increase, and torso movements to slow, progressively widened this separation. Thus test results were closely related to the clinical ratings, perhaps because both vestibular and visual capabilities were assessed, the latter probably reflecting compensation to existing pathology. (Supported by Canadian MRC)
440.1

Between week 1 and 2 of postnatal life, there is a dramatic decrease in mean input resistance (Ri) of hypoglossal (presumptive genioglossal) motoneurons and a corresponding increase in Ri, which could be a doubling of total membrane surface area (A). We have quantitated the three-dimensional morphology of 25 genioglossal motoneurons at four different ages that have been labeled by intracellular injection of rhodamine in rat brainstem slices. There was no increase in Ri between 5-6 and 13-15 days; therefore, we must propose another mechanism to explain the decrease in Ri. However, the dendritic tree was not static during this period; there was a decrease in the number of terminals and the surface encompassing those terminals. This resulted from a loss of 7th and 8th order branches while there was an increase in mean segment length at the 2nd and 3rd order branches. This work was supported by NIH grant HD 22703.

440.2

The mean input resistance (Ri) of developing hypoglossal motoneurons undergoes a dramatic decrease between the first and second weeks of postnatal life. This alteration in membrane property could result from the growth of the cell membrane and/or a decrease in the specific membrane resistance (Rm). We have shown in these motoneurons that mean total area of membrane surface area (A) remains constant throughout this time period (see He et al). Thus, we set out to estimate the changes in Rm in these developing neurons. Intracellular recordings were made in hypoglossal (presumptive genioglossal) motoneurons from in vitro slices of the rat brainstem at various postnatal ages. Ri and membrane time constants were measured before the cells were labeled by intracellular injection of rhodamine. Ri was estimated for each cell (n=24) using an equation derived by De Robertis (1970). No difference was found between the mean Ri measured at 1-2 days (7116 Qcm²) and 5-6 days (7449 Qcm²) while there was a 47% decrease in the mean between 5-6 and 13-15 days (3969 Qcm²). After the decrease at 2 weeks, the mean Ri rose to 6192 Qcm² at 19-30 days as mean A expanded by 76% yielding only a modest decrease in Rm. We propose that the transient decrease in Ri results from i) an increase in number of leak channels in the postsynaptic cell and/or ii) a decrease in the number of presynaptic inputs on these neurons. These results suggest that there is a critical period during postnatal development when hypoglossal motoneurons are less excitable.

440.5 FAST MOTOR UNITS IN RAT GASTRÓNOMUS SHOWING EXTREMES IN FATIGUE RESISTANCE DO NOT DIFFER IN MOTOtàNEURONE PROPERTIES: PAIRED OBSERVATIONS FROM SINGLE EXPERIMENTS. P. Gardner* Physical Activity Sciences, University of Western Ontario, London, Mounta ine, Quebec, Canada H3C 3J7.

Differences in motoneuron (MN) membrane properties among motor unit types might be masked when grouped data from several experiments are analyzed. We consequently examined gastrocnemius motor units, paired from single experiments, that differed in type according to fatigue resistance and speed. Tidal MN of anesthetized Sprague-Dawley rats were impaled in situ experiments using conventional microelectrode techniques, and motoneuron motor units were identified from their contractile response to MN current injection. Type slow (S) units had twitch half-recovery times (RTw2) 2-8 ms, were completely fatigue resistant, and demonstrated no force sag at 25 Hz stimulation. In fast fatigue-resistant (FR) and fast fatigue-sensitive (FS) motor units pairs, twitch RTw2 were longer, twitches were weaker, and axon conduction velocities were faster, for FR. No differences in MN afterhyperpolarization (AHP) time course or amplitude, in rheobase, or input resistance, were found between FS and FR. S units had lowest rheobase, highest input resistance, highest AHP amplitude and longest AHP 1/2 decay time, but not always the lowest axon conduction velocity, when compared to FS units from the same experiments. Results show that MN properties, while showing distinct differences between fast and slow motor units, do not vary systematically among fast motor units which differ in fatigue resistance, in rat gastrocnemius. Supported by NSERC Canada.

440.7 MORPHOLOGY OF EXTERNAL URETHRAL SPHINCTER MOTOtàNEURONES AND LOCALIZATION OF PUTATIVE SPHINCTER INTERNEURONES IN THE RAT SPINAL CORD. V. Berthier*, M. B. D. Legape*, D. Bougrier, H., and J. T. Berthier. Department of Neurology and Behavior, SUNY at Stony Brook, NY 11794.

Spinal bladder/sphincter reflexes are: important for urinary continence, inhibited by supraspinal centers during micriturition, and involved in spinal cord injury induced bladder/sphincter dysynergia. However, little is known about the anatomical organization of these spinal reflexes.

In the present study, the dendritic morphology of external urethral sphincter (EUS) motoneurons and the distribution of putative EUS interneurons were examined using the retrograde tracer subunit (CTB), and the retrograde transneuronal tracer, wheat germ agglutinin (WGA), respectively. Adult male and female Sprague-Dawley rats were anesthetized, and either CTB (1%) or WGA (1%) was injected into the extrinsic urethra (0.5-3.0 h) into the EUS muscle. After a survival time of 2-5 days, spinal cords were removed and processed immunohistochemically to visualize labeled motoneurons and putative interneurons. CTB-labeled EUS motoneuron somata were located in the ipsilateral dorsolateral (DL) nucleus. Three major dendritic projections of these EUS motoneurons were observed: (1) rostrocaudally oriented dendrites projecting through the DL nucleus, (2) dorsolaterally oriented dendrites projecting into the lateral funiculus, and (3) medially oriented dendrites projecting toward the dorsomedial nucleus. WGA-labeled putative interneurons were localized to the ipsilateral L5 and L6 ventral horn dorsomedial to the DL nucleus. Supported by BNS-9111207 (WFC & JTE) and EY04587 (JTE).

440.9 AGED-LIKE ELECTRICAL PROPERTIES INDUCED BY ACRYLAMIDE IN TRIGEMINAL MOTOtàNEURONES OF THE AWAKE CAT. C. Wei*, S.S. Chieza, L.K. Enright, F.R. Marasli, and M.J. Chase. Dept. of Physiology, Dept. of Anatomy and Cell Biology, and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.032.

The effects of acrylamide on the electrical properties of motoneurons (MNs) include decreased conduction velocity (CV), increased input resistance (Rin), and axonal size in the mammalian optic nerve (F88; 180, 1987: 61,194, 1989). The mechanisms underlying the above-mentioned changes are not known. We sought to model some of these changes using acrylamide, a neurotoxin, in brainsmn MNs of the awake adult cat (methods in J. Neurophysiol. 58: 340, 1989). Jaw closer MNs were impaled with glass micropipettes (3M KC1, 5 M, their electrical properties were determined in vitro. Masseter MNs were also antidromically activated to evaluate their CV. Following the collection of these data control, administration of acrylamide between 0.01-1.5% caused a decrease in CV and Rin. Masseter MNs were also antidromically activated to evaluate their CV.

Comparisons between control and treated cells were made with one week while the cats continued to receive drug. Only cells with action potentials (AP) 55 nV were tested (AP 12 cm/s, 04 ms against the 25 acrylamide cat). Comparisons between control and treated cells were made with one week after the first tail t-tests (t=0.05). Significant changes occurred in the onset latency of the pharmacologically activated AP (13.6% increase) and in AP (40% increase). The Tm increased by 33% (p<0.05). There were no significant changes in the amplitudes of the AP or the duration of the afterhyperpolarization. While it is not known if acrylamide affects the same mechanisms as the aging process, this drug may provide a method for assessing contributing factors to the electrophysiological changes that are observed in aged MNs. Supported by AG04307 & NS00999.
441.1  HEAD AND TRUNK DYNAMICS OF YOUNG AND ELDERLY ADULTS DURING GAIT. R.A. Croswell* and R.A. Kestner. Dept. of Kinesiology, Univ. of IL at Urbana-Champaign, Dept. of Physical Therapy, Univ. of Illinois at Chicago.

Changes in gait with age have produced a more cautious and stable pattern (Winter et al., Phys Ther, 1990). Mechanisms underlying these changes may be found in intersegmental relationships. This study recorded the angular velocities of the head and trunk, and step cadence in four young adults (20-30 yo) and five elderly adults (60-70 yo) during self-paced, normal, slow, and fast walking. Neck velocity was calculated as the difference between head and trunk velocities. For the purpose of analysis, cadences were categorized at 90-120 steps/min for normal, >120 steps/min for fast, 90 steps/min for slow, and >120 steps/min for normal. (Normal cadences for the ELD subject fell between the slow and normal ranges). Proband frequencies of both the head and trunk velocity responses ranged from 1.2-2.3 Hz over all conditions for YA. Head frequencies ranged from 0.08-0.4 Hz, whereas trunk frequencies ranged from 1.2-2.0 Hz for conditions. Thus the head to trunk frequency ratio found in YA was not maintained in the ELD subjects, and time domain analysis of velocity revealed that the slow and normal ELG gait was similar to the YA slow gait in that the head, neck, and trunk velocity responses were in phase. A compensatory response was seen in the head, neck, and trunk of the YA normal and fast conditions; trunk flexion occurred with head and neck extension. In the ELD subject however, the fast cadence resulted in an uncoupling of the head, neck, and trunk where peak velocities of each segment occurred independently of the other segments. These data suggest that the ELD subject focused on keeping the head stable in order to better utilize vision. The coordinated phasing and the unity ratio of head to neck in the YA implies that the upper body is controlled as a coordinative structure. Uncoupling of these segments in the ELD subject show a decrease in the ability to control these segments as a unit.

We have studied the direction dependence of mean rectified surface EMG and motor unit recruitment while isometric forces were applied at the wrist. Previous studies have shown that recruitment thresholds of motor units for forces in various directions can be fitted by a single straight line or by several line segments (van Zuylen et al., J. Neurophysiol. 60, 1988). In a number of muscles, several subpopulations of motor units have been found, each with different motor unit recruitment characteristics (ter Haar Romeny et al., Exp. Neurol. vol. 85, 1984). Similarly, surface EMG for forces in various directions may be fit by a circle for many muscles (Miller et al. Exp. Brain Res. Series, 22, 1992), while for some muscles, more complex interpopulations functions were required (Flanders and Schlochter, J. Neurophysiol. 90, 1990). The aim of our study was to examine the relation between motor-unit activity and surface EMG.

Recruitment contributes primarily to EMG amplitude, while rate modulation affects its spectrum. The effect on the direction dependence of EMG, of these parameters and the inhomogeneous distribution of motor units, has not been tested directly. We have simultaneously measured surface EMG and intra-muscular motor unit activity from several arm muscles while human subjects exerted isometric force in many directions within a horizontal plane. In most cases, the EMG directionality could be fitted with a circle, and that of motor unit recruitment by a straight line. The orientation of the EMG response was generally consistent with that of the motor units. The few cases of disparity between EMG and motor unit orientation may be explained by sub-populations of motor units within a given muscle, each having a different orientation.

441.5  SINGLE-TRIAL ESTIMATION OF THE MECHANICAL PROPERTIES OF THE ELBOW JOINT DURING A MOTION TRACKING TASK. Y. Xu, J.M. Hollander* and J.W. Hunter. Department of Biomedical Engineering, McGill University, Montreal, Quebec, Canada H3A 2B4.

To determine the time-varying dynamic stiffness parameters (stiffness, viscosity, softness) of the elbow joint during movement, an ensemble averaging method must ordi- narily be used (Bennett et al., Exp.Brain Res., 1992). Because of the many trials tested in ensemble methods and the difficulties in aligning the movements, more recently we have been investigating how well time-varying dynamic stiffness parameters may be inferred from a single movement trial. To this end, we have proposed a tracking method based on exponentially weighted least squares (Xu et al., Proc. 13th DBBS Conf., 1990). In this method, the dynamic stiffness parameters must vary slowly for the tracking method to work properly, and movements must necessarily be slow. We have found that subjects have some difficulty in making smooth slow mo- tions, when the only constant is to provide targets, the smoothness is of course a good measure of the smooth- ness can be adversely affecting the smoothing. In the present study, we seek to improve trajectory smoothness by a mechanical aid: an artificial elbow joint and fore- arm which subjects can use. In our experiments, the artificial forearm is placed next to and parallel to the subject's arm, and the subject is instructed to track a point in the artificial forearm at the wrist level. The target movement spans 60 degrees in the vertical plane, starting at 90 degrees position and then extending. The movement is very slow, 12 degs/s. There are five phases in each trial, three post- target phases divided by two movement phases. Pseudorandom binary force perturba- tions are applied to the wrist by an isotropic system (Xu et al. IEEE Trans. Biomedical Eng., 38, 1991, pp.1111-1122), and we record force, wrist position and target pos- ition. Our results indicate that the stiffness parameter is lower during movement phas- es than in phases. However, the parameters do not have line- ar trend. This research is supported by the Medical Research Council of Canada.

EFFECTS OF RADIAL NERVE STIMULATION AND ANAESTHESIA ON INDEX FINGER MOVEMENT CONTROL. W.G. Darling, K.A. Cole, S. Ellis, C. Steyers. Dept. of Exercise Science, University of Iowa, Iowa City, IA 52242.

The role of cutaneous and joint afferents in index finger movement control has received little study, although reports from patients undergoing surgery indicate that finger kinesthesia is strongly affected by hand anaesthesia (Moberg 1983). We report that the EMGs and kinematics of isolated 3-joint index finger movements during non-noxious radial nerve stimulation and anaesthesia of the index finger determine whether control of its motion is affected by altered cutaneous and joint afferent sensations. EMGs were recorded using indwelling hooked wire electrodes inserted into 4-5 muscles of index finger in 10 subjects. Movements were recorded optoelectronically with infrared emitting diodes placed over the base of the 2nd metacarpal and the centers of the 3 joints. Subjects performed 4 different types of discriminative tasks (with vision permitted) that involved flexion or extension of all 3 joints and flexion or extension at the interphalangeal (IP) joints while the metacarpophalangeal (MP) joint was voluntary held in a fixed position. Kinematic data showed no consistent changes in movements as a result of radial nerve stimulation (train of 6 pulses at 30 Hz beginning near movement onset), however anaesthesia of the index caused decrements in movement velocities and amplitudes. EMG analysis indicated increased cocontraction of antagonists during anaesthesia and some effects on muscle activity as a result of radial nerve stimulation. Thus, these data suggest that cutaneous and joint afferent information plays a relatively small role in index finger movement control in comparison to central programs and, possibly, muscle propriospinal sensations at least when vision is allowed. supported by NIH grant AR40217

441.9

In recent experiments on the specialized frog (Rinella, Massa-Ivuli and Glister, Science, 235, 1992) we have found that the focal microstimulation of a site in the premotor layer of the lumbar gray matter results in a field of forces acting on the frog's ankle and converging to a single equilibrium position. These experiments suggest that the internuclear circuits in the spinal cord are organized into a set of control modules that "store" a few limb postures in the form of output fields associated with the postural points. The goal of our present investigation is to understand how such posture modules can be combined by the CNS for generating and representing a wider repertoire of motor behaviors including, but not limited to a large number of postures. In a theoretical study we have found that the vector summation of the convergent force fields generated by a set of 2 modules is a powerful mechanism for generating movements by combining a variety of control patterns. The most crucial issue regarding this computational approach is whether or not the fields generated by each of the 2 modules are actually combined by the CNS according to a principle as simple as vectorial summation. To address this issue we have considered the force fields evoked by the microstimulation of 2 distinct sites in the spinal cord. First, we considered the fields elicited by the stimulation of each site, separately. Then, we computed the vector sum of these 2 fields with the field obtained by stimulating the 2 sites simultaneously. Our current evidence indicates that the simultaneous activation of 2 internuclear sites generates a field of forces that corresponds to the vector sum of the fields generated by the stimulated site. However, we also found that the simultaneous stimulation of 2 sites within the affected fibers may result in a field that differs significantly from the vector summation of the fields obtained at each site. For example, we have observed "winner-take-all" responses to double stimulation of different systems. These results suggest the vector superposition of the motor output is a specific feature implemented by the internuclear circuits in the frog's spinal cord.

441.11

We present evidence for the view that the motor system takes advantage of the physical dynamics of the limb system during rhythmic movements. In particular, we tested the hypothesis that subjects choose a preferred rate of force generation which switches among the resonant frequencies of the physical system. Human subjects were asked to oscillate their forearms in the vertical plane at their preferred frequency under conditions of fixed mass and external force loading. They were also asked to oscillate at frequencies above and below the preferred frequencies by synchronizing their movements to a metronome. These trials were performed in order to generate a phase transfer function under external force loading condition which relates the phase between the displacement of the forearm and the torque generated by the biceps and triceps as a function of frequency. This phase transfer function was used to estimate the resonant frequencies to compute the stiffness of the joint (Viviani et al., J. Physi., Paris, 72, 45-58, 1978).

The results demonstrate that the preferred frequency corresponds to the resonant frequency of the muscle-limb system under the experimental conditions, a strategy that minimizes energy expenditure. This agrees with other studies which suggest but do not directly show that the preferred rate of oscillation corresponds to the natural frequency of the muscle-limb and elastic joint (Kugler & Turvey, 1987; Holt et al., Hum. Mov. Sci., 9, 1990).

We also show that the internal joint stiffness remains relatively consistent across added mass conditions but is modulated so as to match the impedance of the external springs, a strategy that maximizes the elastic energy stored in the joint (Goldfield et al., J. Biomech., 29, 1995).

CONVERGENCE OF EXCITATORY INPUTS FROM THE CENTRAL GRAY MATTER VOCAL CENTER AND INFERIOR COLICULUS TO A SINGLE FIBRILAR NEURON IN THE RAT. Y. YAJIMA* and Y. HAYASHI. Dept. of Physiology, Kyoto College of Med., Nishinomiya, Hyogo 663, Japan.

Two distinct phases of vocal communication behavior in animals, sound production and sound hearing, are assumed to be integrated in the brain. Present study was conducted to know an interface mechanism for vocal communication in rat brain. Under Ether anaesthesia a bipolar electrode was implanted stereotaxically into the ipsilateral central gray matter (PAG) vocal center using audible vocal sound yielded by pulse train stimulation as a guide. Under alpha-chloralose urethane anaesthesia the other electrode was placed in the contralateral inferior colliculus (IC) on the basis of auditory field potentials evoked by acoustic stimuli presented at an either ear. A grass micropipette filled with Fast green dye was introduced into the midline dorsal medulla to search for neurons activated by electrical stimulation of PAG and IC. Sixty-four fibrillar neurons sampled so far responded exclusively to PAG and 37 to IC stimulation (Non-convergent cells). Seventeen reticular neurons, on the other hand, were activated by electrical stimulation of both PAG and IC (Convergent cells). In a majority of cells, responses to PAG stimulation were augmented remarkably when PAG stimulation was preceded approximately by 5 msec to IC electrical stimulation or by 20 msec to noise burst stimulation, indicating the presence of modulatory convergence onto a single reticular cell. Histological verification revealed that most of convergent and non-convergent neurons were found in the ventromedial part of medulla.

Supported by the Natural Sciences and Engineering Research Council of Canada
Models of force control should be able to account for the both the mean form and variability of force trajectories. Whereas a number of studies have focused on the time course of force buildup, few have been given to the pattern of variation of the force-time function. In this study, we examine the mean and variability of three trajectories produced by squeezing a force transducer between the thumb and index fingers. Stimulation was at various times, as measured in milliseconds, in a random manner and direction (loading, unloading) of the force were varied. Step changes in force and force planes were recorded.

These data are used to test and extend the Parallel Force Unit Model of (Chen and Wing, 1991, Psych. Rev., 98, 268-294). In PFUM, force buildup and decline reflect the sum of a number of force units with variable onset times. The duration and number of the force units are controlled. This model reasonably well for the mean form and variability of short-latency responses. In this report, we extend our account for force trajectories under a variety of conditions. The model is elaborated to include antagonist "muscles" and additional motor unit-like properties.

A model based on the equilibrium point hypothesis of force control (Heldman, 1986, J. Mot. Behav., 18, 17-54) is also presented. According to this hypothesis, central commands regulate force by specifying the equilibrium position of the limb and the level of co-contraction of opposing muscles. Simulations are used to test the form of central commands underlying force generation. In addition, we examine how variation in these commands are related to variability of observed force trajectories. The equilibrium point model proposes a uniform account of uncorrelated and isometric movements.

Finally, these two models of force control are not mutually exclusive and we consider how they may be related.

The dual strategy hypothesis of motor control suggests that human elbow movements performed over short and different distances and/or with very light loads are generated, intensity is reduced when distance is increased. As such, the dual strategy hypothesis has been reformulated so that when movements of short distances and/or with very light loads are generated, intensity is reduced when distance is increased. It can thus be concluded that the CCN of the rat is a center of integration of sensory stimulation related to variability in observed force trajectories. The equilibrium point model proposes a uniform account of uncorrelated and isometric movements. Finally, these two models of force control are not mutually exclusive and we consider how they may be related.

THE INFERIOR OLIVARY NEURON AS AN ERROR DETECTOR IN THE MOVEMENT DISORDER INDUCED BY INTRACEREBROVENTRICAL INJECTION OF PROPIDIIUM IODIDE IN THE RAT. S. Chen and Z.-C. Peng (SPPON, IRBES), Institute of Anatomy, University of Verona, Italy.

Intracerebroventricular (ICV) injection of propidium iodide (PI) in the rat results in a movement disorder characterized by astagnia, ataxia and shakiness (Borges et al., Science 228, 246, 1985; Chan and Su, Brain Res 453, 379, 1989) and reduces c-Fos expression in discrete brain areas, including the inferior olivary complex and cerebellar nuclei (Chen and Bentivoglio, Soc Neurosci Abstr 17, 864, 1991). In the present study, in order to investigate whether the c-Fos expression was induced directly by ICV injection of PI or indirectly by the subsequent movement disorder, we studied the c-Fos expression induced by ICV injection of PI under urethane anesthesia, in which the animals do not show any movement disorder. PI (10 µl, 0.1% in saline) was injected under urethane anesthesia (1.2 g/kg, i.p.) into the lateral ventricle through a previously implanted cannula. The animals were sacrificed 3 hr after the PI injection. C-Fos immunoreactivity was distributed in the cerebellar nuclei as in the cases in which PI was injected without anesthesia. However, in contrast to the latter cases, in the inferior olivary complex only a few neurons in the medial nucleus were c-Fos immunoreactive. In the control injected saline no c-Fos immunoreactivity was observed in the cerebellar nuclei or in the inferior olivary complex. The present data, together with our previous findings, suggest that after the ICV injection of PI the activation of inferior olivary neurons results from the subsequent movement disorder, whereas the cerebellar nuclei are directly activated by PI administration. This supports the hypothesis that the inferior olivary neurons functions as an error detector or 'teacher' in motor control.

Single-joint discrete movements are likely produced by monotonic shifts in the equilibrium point (EP) of the system. On the other hand, oscillatory shifts of EP may underlie rhythmic movements. We tested the hypothesis that the two types of control signals can be superimposed to produce both movements simultaneously (Feldman 1989). Subjects showed flexion and extension movements about a target position indicated by a light on a horizontal surface. When the target position was shifted by 60°, the subjects made a fast movement to the new target while maintaining movement amplitudes. Subjects made isolated discrete movements from one target position to the other. Arm position was recorded on a Weisert system, and velocity and acceleration were calculated. EMG signals were recorded from the elbow flexors and two elbow extensors. The onset of discrete movement was associated with a deflection in the EMG signal and used as a synchronisation point for averaging of kinematic and EMG data. After averaging, the rhythmic component of the movement was eliminated and the residual discrete component was comparable to the isolated discrete movement made to the same target position. Fast discrete movements arose at any phase of the rhythmic movement, although some phases were preferred. Discrete movements were observed in combination with rhythmic ones displayed multi-phase EMG patterns and kinematics similar to those associated with isolated discrete movements. The data is consistent with the hypothesis of superimposition of control signals underlying discrete and rhythmic movements when they are performed simultaneously. However, the discrete component obtained by averaging displays a greater number of terminal oscillations and EMG bursts indicating that there is an integration of the discrete components at the executive biomechanical level. (Supported by NSERC Canada).

PERCEPTION OF VISCOSITY: SENSORY THRESHOLDS. J. W. Hunter and L. W. Hunter. School of Physical & Occupational Therapy and Dept. Biomedical Eng., McGill University, 3654 Drummond St., Montreal, Canada H3G 1Y5.

Sensory thresholds have been calculated for a number of different aspects of the human proprioceptive system including limb position, movement, force, and stiffness. Most of this research has focussed on differential thresholds, that is, the amount of a stimulus must be increased or decremented in order for the subject to discriminate that two stimuli differ. For the proprioceptive system, there is a remarkable amount of consistency in the differential thresholds measured for position, movement and force with the values varying between 6% and 10%. In contrast, subjects are much less consistent in discriminating changes in stiffness, for which the threshold is 23% (Jones & Hunter 1990). The objective of the present experiment was to extend these findings to an analysis of the sensitivity of subjects to changes in viscosity. This was measured using the matching procedure in which eleven subjects adjusted the viscosity of a servo-controlled linear motor connected to their left arm via a foot pedal containing an angular position encoder. Data was collected until it was perceived to be the same as that of the motor connected to their right arm. The servo-system was under computer (IBM 320) control and force and position were recorded from each motor via the encoders ranged from 2 N.m to 1024 N.m, and there were 8 repetitions of each of the 10 viscosities. The matching function obtained for viscosity was linear, with a very small deviation from linearity at the lowest viscosity (i.e. 2 N.m). The differential thresholds calculated for viscosity ranged from 83% at the lowest viscosity to 26% at the highest, and averaged 34% over the range of 22 to 1024 N.m. These values are almost 50% higher than those reported for stiffness, suggesting that the human proprioceptive system is less efficient at integrating force and velocity signals to perceive changes in viscosity, as compared to force and displacement cues for stiffness.

MODULATION OF THE RELATIVE ROLES OF SPIKING AND GRANDED SYNAPTIC TRANSMISSION BETWEEN GASTRIC PATTERN-GENERATING NEURONS OF THE LOBSTER GASTRIC MILL. T. G. Hunt* and A. L. Silverton, Department of Biological Science, Indiana University, Bloomington, IN 47401.

The purpose of this work is to develop a model of the lobster gastric mill CPG that is as simple as possible yet is biologically plausible, and which captures important network properties such as the emergence of patterns from network connectivity rather than endogenous cellular burst capability, continued pattern generation when cells are removed, and changes in the pattern after application of modulatory substances. The cell model, derived from the relaxation oscillator, has one fast current and a slow current that can be regulated by the combination of a fast inward and a slow outward current. It displays plateau potentials, postsynaptic inhibition, postsynaptic hyperpolarisation, and endogenous oscillations for suitable settings of two parameters. One parameter controls whether the fast current has a region of negative resistance and the other controls the gain of the slow current. When the region of negative resistance is present, endogenous oscillations occur. A network model of the complete gastric circuit was made, using a model of graded synaptic transmission but excluding spike-based transmission. For a wide range of parameter values, the model generates period-relationships that are approximately correct. Adjusting the gains of the slow currents in different cells causes small changes in phase relationships. A slow excitatory synapse causes a significant phase delay. Thus, a close match to in vitro recordings is possible. Also, some phase changes caused by neuromodulator application can be reproduced. The model network oscillates even when no component cell is an endogenous oscillator. When cells are killed, the network continues to generate a pattern provided at least one pair of reciprocal inhibitory cells remains. Current pulses were injected into cells in the network. Phase response curves and the limits of entrainment were computed for the model network, and compared with the biological data.

CIRCUITRY AND PATTERN GENERATION II

PROPERTY OF A RELAXATION-OSCILLATOR-BASED MODEL OF THE LOBSTER GASTRIC MILL CPG. W. R. Hunt and A. L. Silverton, Department of Biological Science, Indiana University, Bloomington, IN 47401.

The purpose of this work is to develop a model of the lobster gastric mill CPG that is as simple as possible yet is biologically plausible, and which captures important network properties such as the emergence of patterns from network connectivity rather than endogenous cellular burst capability, continued pattern generation when cells are removed, and changes in the pattern after application of modulatory substances. The cell model, derived from the relaxation oscillator, has one fast current and a slow current that can be regulated by the combination of a fast inward and a slow outward current. It displays plateau potentials, postsynaptic inhibition, postsynaptic hyperpolarisation, and endogenous oscillations for suitable settings of two parameters. One parameter controls whether the fast current has a region of negative resistance and the other controls the gain of the slow current. When the region of negative resistance is present, endogenous oscillations occur. A network model of the complete gastric circuit was made, using a model of graded synaptic transmission but excluding spike-based transmission. For a wide range of parameter values, the model generates period-relationships that are approximately correct. Adjusting the gains of the slow currents in different cells causes small changes in phase relationships. A slow excitatory synapse causes a significant phase delay. Thus, a close match to in vitro recordings is possible. Also, some phase changes caused by neuromodulator application can be reproduced. The model network oscillates even when no component cell is an endogenous oscillator. When cells are killed, the network continues to generate a pattern provided at least one pair of reciprocal inhibitory cells remains. Current pulses were injected into cells in the network. Phase response curves and the limits of entrainment were computed for the model network, and compared with the biological data.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 11, 1992
Dopamine (DA, 10^-5 M), serotonin (5HT, 10^-3 M) and octopamine (OA, 10^-2 M) each produce a unique pattern from the motor network in the stomatogastric ganglion of the lobster Panulirus interruptus. We are examining how amine modulate the pyloric rhythm. Here we describe amine effects on mixed graded chemical-electrical transmission between two different pairs of pyloric neurons. The AB and PD neurons are electrically coupled, in addition, the AB chemically inhibits the PD, while the LP and PY are reciprocally inhibitory. Modulation of synaptic rectification was examined in isolated neuron pairs in TTX-saline (20 C°). DA and 5HT reduced electrical coupling and enhanced chemical inhibition between the AB and PD. DA also reduced electrical coupling and enhanced the reciprocal chemical inhibition between the LP and PY. Oct enhanced while 5HT reduced PY chemical inhibition of the LP with little effect on electrical coupling. As a consequence of these differential effects on chemical and electrical transmission, the amine could reverse the sign of synaptic interactions between the cells. For example, depolarization of the LP depolarizes the PD in control conditions; this reverses to hyperpolarization during DA perfusion. In preparations where the AB to PD chemical synapse is weak and electrical coupling dominates, DA and 5HT change the synaptic interaction from weakly excitatory to strongly inhibitory. Modulation of mixed synaptic interactions contributes to the structure of the motor patterns produced by these amine. Supported by NNSA NS07859 and NIH grant NS17323.

We examined the I/O characteristics and amine modulation by dopamine (DA), serotonin and octopamine of 5 electrical synapses in the pyloric network in the STG of Panulirus interruptus. Some synapses (AB-PD and PD-PD) were non-rectifying, while the others (AB-PD, PD-PD, and LP-PY) all show significant rectification. The amine altered the strength of electrical coupling, but this varied with the different pairs of neurons and with the direction of current flow. For example, DA enhanced PD-PD but reduced AB-PD coupling. We modeled these results by an input resistance increase in the AB and decrease in the PD with no change in junctional resistance. DA causes these input resistance changes. For other synapses (such as DA reduction in AB-PD coupling), our model predicts that the amine reduces the junctional coupling in addition to altering cellular input resistance. Modulation of electrical coupling is a new mechanism by which amine modifies the pyloric network to generate multiple motor patterns. (NNSA NS07859 and NIH NS17323)

In the trichocerebral pyloric motor pattern, the pacemaker neurons inhibit the LP and PY neurons; these cells show different rates of postinhibitory rebound, causing them to fire at different phases in the cycle. Dopamine (0.1mM) enhances the LP and PY cell firing and causes them to fire at the same phase in their activity. This is explained in part by dopamine inhibition of the LP-PD and PY-PD synapses. Two additional mechanisms for phase advance are intrinsic to the post-synaptic LP and PY cells. 1) Conduction decrease of 1a. Both LP and PY express a transient K+ current (1a) that is selectively sensitive to 4-amino pyridine (4-AP). This current plays an important role in the rate of rebound after hyperpolarization in synaptically isolated LP and PY neurons. Both DA and 4-AP reduce the delay to first spike after 200 msec hyperpolarizing pulses, and increase the frequency of firing in response to tonic depolarization. Blockade of 1a by 4-AP occludes the effect of DA on the LP cell suggesting that reduction of 1a is the major action of DA in this cell. 2) 1b. The LP expression of 1b. The LP cell displays a Ca++ sensitive depolarizing sag during tonic hyperpolarization, caused by the hyperpolarization-activated inward current, 1b. DA enhances this sag. Specifically by shifting its voltage dependence for activation in the depolarizing direction. This effect is eliminated by low concentrations of Ca++, which eliminate 1b. This suggests that DA acts on the LP by both reducing 1a and enhancing 1b. We are now using voltage clamp of cultured LP and PY cells to try to directly measure dopamine modulation of these currents. Supported by NIH NS17323 and NS 25915.

442.6 INWARD CURRENTS UNDERLYING BURSTING IN CULTURED STOMATOGASTRIC NEURONS. G.G. Turrigian* and E. Marder, dept. of biology, Brandeis University, Waltham, MA 02254.
Stomatogastric (STG) neurons in situ express slow regenerative conductances that underlie bursting and plateau behavior. We use primary cultures of STG neurons from the spiny lobster Panulirus interruptus to identify two inward currents that contribute to these properties. STG neurons in culture switch from tonic firing to bursting in TEA. In most neurons these oscillations, as well as fast spikes, can be blocked by TTX. In other neurons TTX has little effect on oscillations; these oscillations are blocked by M+m++. Under two electrode voltage clamp we have identified two persistent inward currents, one that is blocked by TTX, and one that is blocked by M+m++. The TTX-sensitive current begins to activate above -40 mV, peaks at +20 mV, and has an extrapolated reversal potential of +20 mV. The M+m++-sensitive current activates above +40 mV, peaks at +20 mV, and reverses at +50 mV; the magnitude and reversal potential of this current depend on the external Ca++ concentration, suggesting that the current is carried by Ca++ ions. Most STG neurons have both inward currents, but their relative magnitudes, and thus the pharmacological sensitivity of bursting, vary from cell to cell. We are currently investigating whether the ratio of these conductances is a function of neuron type. Supported by NS-08971 to G.G.T. and BNS-9002951 to E.M.

Model neurons are useful in understanding the complex interactions between single currents in a cell, or between different cells within a network. To study the dynamics of both synaptic and intrinsic properties of neurons we connect a conductance-based model neuron to a real neural network. We use a DSP board and the MAXIM software package to run the model and control the input-output interface. The system allows the model neuron to run and respond in real time to artificial synapses created between real neurons and the model neuron. The model neuron was constructed using data from the LP neuron of the stomatogastric ganglion. We make reciprocal inhibitory connections between the model LP neuron and a biological PD neuron and study the effect of changes in both inputs on the LP neuron. Finally, we investigate the effects of changes in the strengths of the synapses between the model and the biological neuron. The results suggest that the model LP firing phase in the pyloric network depends critically on the characteristics of the synaptic inhibition coming from the LP neuron. The burst duration and the firing frequency of the LP model depends on Ih and IA. Supported by MH46742 and The Human Frontier Science Foundation.

442.8 Dynamic Clamp: A method to construct artificial synapses and assess the role of voltage-dependent and synaptic conductances. A.A. Sharp*, M. O'Neil, G. LeManson, L.F. Abbott and E. Marder. Dept. of Biology, Brandeis University, Waltham, MA 02254.
Conventional voltage-clamp techniques provide data describing how the conductances that shape neuronal excitability depend on voltage and time, but do not allow the investigator to determine the participation of individual currents in the dynamic behavior of a neuron. We have devised a method, called a dynamic clamp, that allows us to increase, decrease or alter conductances in neurons during their normal dynamic behavior. This method is used to study the effects of a given voltage-dependent or synaptic conductance on a cell's intrinsic behavior and the emergent properties of a network. It is also used to create new networks by generating artificial synapses.
To construct the dynamic clamp, an Axoclamp in DCC mode is used to monitor the cellular potential and to inject current. Based on this potential and a computational model describing the dynamics of the conductance under investigation a computer determines the current to be injected. When constructing synapses both the pre- and post-synaptic potentials are monitored. The investigator controls the relevant thresholds, reversal potentials and time constants. The investigator can create synapses between dissociated neurons in culture, in the intact stomatogastric ganglion and/or to modify the intrinsic properties of neurons within these networks. Supported by MH 46742 and NSF BNS 9009257.

The highly conserved crustacean cardioactive peptide (CCAP) activates the pyloric rhythm of the cerebrovascular nervous system in a dose-dependent manner with a threshold at 10^{-10}M. The number of spikes/burst in the lateral pyloric (LP) neuron, a major target, increases from 2-5 spikes/burst in control saline to >50 spikes/burst in 10^{-10} CCAP. This increase in spikes/burst is associated with the induction of plateau potentials in the LP neuron. Bath application of CCAP (>10^{-9}M) causes oscillations in the membrane potential of the pharmacologically isolated LP neuron. The phase of the oscillations can be reset with brief current pulses into the LP soma. This is responsible for the change in the LP duty cycle from 10% to over 40% of the phase in 10^{-9}M CCAP.

Simultaneous endoscopic observations of the valve between the gastric mill and the pyloric chamber and extracellular recordings of the major STG motor nerves in intact crabs suggest that changes in the LP neuron's activity dramatically alter the movements of this valve.

442.17 PATTERNED ELECTRICAL STIMULATION OF CULTURED NEUROAL PLATE E. B. Rhodes* and G. W. Gross, Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

Cultured neuronal networks derived from the embryonic mammalian spinal cord display spontaneous activity which is characterized by the temporal consolidation of spikes into bursts and a variable degree of burst synchrony across the network. The multimicroelectrode plate (MMEP) is a culture substrate incorporating an array of 64 point extracellular microelectrodes, provides a uniquely stable and interactive system for studying active neuronal cultures.

Networks of 50-100 neurons cultured on MMEEPs (from dissociated spinal cord tissue of 14-day mouse embryos, and activity was recorded after 20-35 days in culture. Monopolar and bipolar stimulation pulses (1-1.5 μsec) were applied to a 10Ω resistor in front of the preamplifier FET of one or more recording channels (average impedances @ 1kHz: 1.5MΩ electrode, 12MΩ amplifier input, 40Ω microphone-bath shunt).

Single pulses delivered to a single microelectrode can trigger network-wide burst responses. The threshold strength-duration relationship for this response can be fit by standard physiological curves, with a unique rheobase and chronaxie for each stimulation site.

This is the first demonstration of effective electrical stimulation of a cultured network via point extracellular electrodes, and opens several intriguing avenues for further research. These include training networks to exhibit novel spatio-temporal activity patterns with repeated patterned stimulation, testing the Hebb rule as the network level in both spike and burst domains by using spike- or burst-triggered stimulation to drive network activity, and developing a cultured network model of behavior.

Supported by grants from the Texas Advanced Technology Program and the Hillcrest Foundation of Dallas, Texas.

442.18 OPTICAL AND PHARMACOLOGICAL STUDIES OF PROPRIOSPINAL NEURONS INVOLVED IN RHYTHMIC MOTOR ACTIVITY IN THE EMBRYONIC CHICK SPINAL CORD. Stephen H. Poznanski and Michael O'Donnell, Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Our previous studies have identified a class of proprioceptive neurons whose axons travel in the ventrolateral funiculus of the spinal cord (VLF) and are involved in synchronizing motoronoeur discharge during rhythmic motor activity. The properties of these LT neurons were studied further in ES-10 chick embryos using optical and pharmacological methods. LT neurons were labeled retrogradely with a Ca indicator (Ca-green dextran), and were found on both sides of the cord following an unilateral LT injection. (ipsilateral cells were distributed dorsal and medial to the lateral motor column. The contralateral group was more discrete and was located in the medial part of the cord, near the central canal. During episodes of motor activity, both groups expressed synchronized, rhythmic fluorescence signals in phase with motor neuron discharge.

LT stimulation resulted in a brief synchronized discharge in flexor and extensor motor neurons followed by a more prolonged burst. The synchronized discharge and the prolonged potentials were abolished respectively by CNX (5 μM) and AP-5 (50 μM). Depolarizing potentials persisting in the presence of CNX (1-2 mM) were blocked by strychnine (50 μM) or bicuculline (100 μM). LT evoked potentials are not mediated by electrical coupling or by chloride transmission because they were blocked by CNX and were unchanged during bath application of high K medium. These findings indicate that LT axons have both excitatory and inhibitory connections with motoneurons. In addition to their role in segmental coordination they may also participate in cortically mediated inhibition that underlies the alternation of flexor and extensor motoneurons.

SELECTIVE IMPAIRMENT OF DELAYED NON-MATCHING-TO-SAMPLE (DNMTS) FOLLOWING FRONTAL CORTICAL LESIONS IN THE RAT. L. M. Harrison* and R. G. Nair. University of New Hampshire, Durham, NH 03824

Two experiments were conducted to determine the effects of lesions of the lateral internal medullary lamina of thalamus (L-IML) and of frontal cortex on three measures of spatial memory: DNMTS, radial arm maze (RAM), and serial reversal learning (SRL). In Exp. 1, RAM was trained prior to surgery. While both RAM and SRL were disrupted by lesions of the L-IML, neither task was affected by destruction of frontal cortical areas along the medial wall (MW) or dorsal to the rhinal sulcus (RS). In Exp. 2, DNMTS was trained prior to surgery. Rats with lesions of MW or RS showed impairments comparable to those seen following L-IML lesions. Anatomical studies were conducted using wheat germ agglutinin - horseradish peroxidase (WGA-HRP) to map out projections of the mediadorsal nucleus (MDm) of thalamus in controls and in animals with RS and MW lesions. These analyses showed that the RS and MW lesions produced near-complete destruction of thalamo-cortical and thalamo-cerebellar projections to cortex, and that neither lesion (MW or RS) disrupted pathways leading from the MDm to the other frontal target area (RS or MW).

443.3

In a critical test of the configural association theory of hippocampal function, Sutherland and Rudy (Psychology, 17:129, 1989) reported that rats with neurotoxic (cochicine + kainic acid (COL + KA) lesions of the hippocampus were unable to learn a negative patterning problem. In the present experiment, we extended this neurotoxic model to rats with either ibotenic acid (IBO) or COL + KA lesions of hippocampus, together with controls, were trained on a negative patterning discrimination where responding in the presence of either a tone or light was reinforced while responding when a tone or light were presented in compound was nonreinforced. Following acquisition, transfer trials were given to see if the negative patterning problem had been learned using configural associations. The results indicate that (1) rats in both COL + KA and IBO hippocampal groups learned the negative patterning discrimination, (2) COL + KA rats responded at higher rates, and (3) all groups learned the problem using a configural solution. Since neither type of hippocampal lesion impaired the ability of rats to solve the negative patterning problem, and transfer tests indicated that the groups learned the problem using configural associations, these results fail to support the configural association theory.

444.4

EFFECTS OF PERIPHERAL CORTEX AND MEDIAL EXTRASTRIATE VISUAL CORTEX LESIONS ON MEMORY ASSOCIATED WITH AN OBSESSION CONTINUOUS RECOGNITION TASK. A. Backman and H. Backman. Dept. Psychol., Univ. of Utah, Salt Lake City, Utah 84112.

The perirhinal cortex is a major convergence site for afferents from the neocortex. Thus, it may play an important role in linking the neocortex to allocortical areas thought to be involved in recognition memory, including the hippocampus. In order to test this possibility, we lesioned the medial extrastriate visual cortex and the perirhinal cortex, and studied the effects of these lesions on rats trained to discriminate two odors. The training procedure involved the sequential presentation of eight novel objects, and four repeated objects (chosen from the eight) within a session. These rats were divided into 120 different 3-dimensional objects in various shapes, sizes, textures and degrees of brightness. Repeated objects had lags ranging from 0 to 4 (from 0 to 4 different objects were presented between the first and the last presentation). An object was presented on one side of a long table divided in half by an opaque Plexiglas guillotine door, and the latency between opening the door and the rat moving the object was measured. On this measure of stimulus presentation, the rats scored better on the visual compared to the olfactory task, and only the initial presentation of an object resulted in food reinforcement. Rats were assigned to groups and received training upon reaching criterion performance. Prior to surgery, lags were significantly longer on repeated presentations than on non-repeated presentations for all rats. There was no deficit following sham lesions or medial extrastriate visual lesions, whereas post-surgery performance was significantly worse than pre-surgery performance for the perirhinal group. Thus, the perirhinal cortex plays an important role in memory associated with this object continuous recognition task, whereas the medial extrastriate visual cortex does not.

444.5

Combined loss of hippocampal acetylcholine (ACh) and serotonin (5-HT) occurs in Alzheimer's disease and may interact to impair memory. To examine this hypothesis, we tested rats pretrained in a 12 arm radial maze for the separate and combined effects of NMDA induced lesions of medial septal neurons and 5,7-DHT induced lesions of the fimbria/ fornix plus cingulate gyrus, on reference (RMm) and working (WMm) memory. NMDA and 5,7-DHT reduced hippocampal acetylcholine and 5-HT in 48% and 82% of control, respectively. Neither treatment alone nor combination affected WMm. The 5,7-DHT treatment did not affect WMm. NMDA caused an increase in WMm errors. The combined treatment and 5,7-DHT did not differ from the NMDA-only effect on early postoperative WMm. However, the combined lesion did appear to retard the post-operative recovery of WMm that was observed for the NMDA-only treated rats. In Alzheimer's disease, hippocampal 5-HT deficits may prevent compensation for the disruption of working memory that is caused by loss of hippocampal ACh function.

Rats trained to run a straight alley for a large food reward display sharply decreased latencies when shifted to a small reward. This behavioral phenomena, minimal to the Crews effect (1942) or behavioral contrast, is often interpreted as an aversive emotional reaction to a reduction in reward magnitude. The behavioral contrast paradigm has been used extensively in studies examining analgesic effects of drugs. The present study used the behavioral contrast paradigm to examine the role of the amygdala in memory for a reduction in reward magnitude. Male Sprague-Dawley rats (175-200g) were implanted with bilateral electrolytic lesions and trained to run a 10 arm alley (6 trials/day) either in or on 1 mg food pellets. On day ten of training, half the animals in the high reward group were shifted to a one pellet reward. Immediately following trial training, the animals received an intra-amygdala injection of either a 18 lidocaine solution or phosphate buffer (0.5 μl/bed). Shifted training continued for two more days and no further injections were given. Shifted animals that received a buffer injection displayed a characteristic increase in escape latencies on the second day of shifted training. In contrast, animals that received lidocaine injection showed no increase in latency on either the 2nd or 3rd day of shifted training. The findings indicate that post-training inactivation of the amygdala attenuates behavioral contrast, suggesting that the amygdala is involved in regulating memory for reduction in reward magnitude.

Supported by NSF fellowship RCD-9054728 (JS), PHS grant 1 F32 NS08973-01 (MOP) and PHS MH12526 (NIMH and NIDA) and ONR N00014-90-J-0167 (ILM).

The purpose of the present experiments was to investigate the role of the amygdala in anxiety, using two different, pharmacologically validated animal models of anxiety: the elevated plus-maze test and the shock-probe burying test. Experiment 1 showed that animals with complete amygdaloid lesions made significantly more contacts with the electrified probe than sham-lesioned controls, but were not significantly different from controls in the duration they buried the probe or the amount they explored the open arms of the plus-maze. Experiment 2 replicated these results, and showed that rats with larger unilateral and with smaller bilateral lesions made more contacts with the electrified probe than rats with smaller amygdaloid lesions. Experiment 3 showed that amygdaloid lesions did not alter the ability of diazepam to increase open-arm activity in the plus-maze test or to decrease burying behavior in the shock-probe test. Taken together, these results suggest that 1) the amygdala does not mediate the anxiolytic effects of diazepam in these tests, and 2) the amygdala may be involved in the inhibition of some fears [e.g., fear of an electrified probe] but not others [e.g., fear of an elevated, open arm].

Olfactory-guided learning in rodents can serve as a useful model system for the study of the neurobiological bases of higher order processes in learning and memory. The present experiment involved the development of an odor-guided paired-associate task (PA) analogous to the verbal PA task frequently used to assess human memory.

In the present version of the PA task, rats are trained to sniff at an odor port while two different odors are presented in succession, separated by a brief blank interval. If the stimulus sequence involves any one of four arbitrarily assigned paired associate (PA) odors, the rat is rewarded for responding at a nearby water port. Alternatively, if the sequence consists of any other combination of the same eight odor ("matchup") the subject must withhold a response. In addition, the rat must undergo a 15 second delay between presentation of "non-associative" trials involving one of the eight odors paired with one of four odors from a second set; these odor sequences are never rewarded.

Last rats learn to discriminate the non-relational trials rapidly, and more gradually differentiate mispairings from paired associates. Rats with bilateral ablation of the perirhinal-entorhinal cortex were profoundly impaired in learning to distinguish mispairings from paired associates. However, the same isolated PA showed only a mild and transient deficit on non-relational trials. These results support the hypothesis that the hippocampal system is critical to PA learning across species and, more generally, that this system supports memory representations based on arbitrary relationships among perceptually independent cues across stimulus modalities.

443.10 MEMORY-BASED LEARNING DEFICITS PERSIST INTO ADULTHOOD AFTER X-IRRADIATION-INDUCED HIPPOCAMPAL GRANULE-CELL HYPOPLASIA IN EARLY INFANCY. N. I. Lobaukh*, J. L. Diaz-Granados, P. L. Greene & A. A. Amald. Department of Psychology & Institute for Neuroscience, University of Texas, Austin, TX, 78712.

Our laboratory has shown that electrolytic hippocampal lesions in infant rats (Lobaugh, et al., Behav. Neurosci., 103:1139, 1989), postnatal exposure to ethanol (Greene, et al., Behav. Neurosci., 106:51, 1992), and early postnatal hippocampal x-irradiation (Diaz-Granados, et al., Soc. Neurosci. Abst., vol. 16, 1990) all disrupt the acquisition of patterned (single) alternation (PA), a form of memory-based learning, in infant rats. After x-irradiation exposure, pups tested at 17-18 days of age showed a severe deficit in PA with a 60-s interval intertrial (ITI) but not a 30-s ITI. In the present experiment, we examined the effect of early postnatal exposure to x-irradiation on memory-based learning in adult rats at 60-85 days of age. The irradiated animals showed a significant deficit in PA learning at a 60-s ITI when compared to normals and sham controls. The specific reductions of hippocampal dentate granule cells at day 86 were comparable to the reductions in the younger animals of our earlier result. These results suggest that early insult to hippocampal granule-cells by x-irradiation results in lasting memorial and morphological deficits. Supported by NSF grant BNS-8609877.

443.11 A PRELIMINARY ANALYSIS OF THE BEHAVIORAL EFFECTS OF LESIONS OF THE SUPERIOR CEREBELLAR PEDUNCLE IN R.C. Leasure and D. J. Kaelin. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

A series of tests assessed the behavior of rats with knife-cut lesions of the superior cerebellar peduncle as compared with sham operated controls. In the first of two 20-min sessions in a brightly illuminated open field the lesioned rats were significantly more active than controls. This difference disappeared at the second session 24 hr later. In tests of the acoustic startle response the lesioned rats were significantly more responsive than controls. They showed significantly more robust within-session response decrements than controls. Both groups showed significant response decrements over days, i.e., long-term habituation, but the decrements appeared somewhat more variable in the lesioned animals. On the balance-beam test of motor stability, there was no significant difference between the groups. Neurological examinations revealed some deficit in the lesioned animals in head-placing. Overall we were most impressed with the subtle nature of the behavioral effects in the lesioned animals. Histological analysis showed significant, near-complete bilateral section of the superior peduncle in 6 of the 7 lesioned rats.

Previously we have shown that PTD treatment in rats impairs working memory and produces consistent lesions of the internal medullary lamina (IML) surrounding MDn. Examination of Fink-Heimer stained tissue has shown widespread layer IV cortical denervation, including all areas of frontal cortex. To determine the extent of frontal cortical denervation, we implanted WGA-HRP bilaterally into 10 rats recovered from PTD, aimed at areas of MDn typically spared by this treatment. Rats with IML lesions and spared cortical effects of MDn showed retrograde transport of WGA-HRP to frontal cortex. Rats with near-complete MDn lesions did not. These findings indicate that areas of MDn spared in PTD rats remain connected to frontal cortex.
MK-801 IMPAIRES LEARNING BUT NOT RETENTION FOR SERIAL PATTERNS IN RATS. J.D. Rowan* and S.B. Fountain. Department of Psychology, Kent State University, Kent, OH 44242.

MK-801 is a N-methyl-D-aspartate antagonist that has been found to impair learning by increasing the effects of MK-801 exposure on learning and retention of serial patterns were examined. Rats were trained in a serial pattern learning task to anticipate elements of one of two patterns. The task required rats to anticipate the correct sequence of leverpresses in an array of levers mounted on the walls of an octagonal shaped operant chamber. Both patterns were equally structured, but one pattern contained a violation of pattern structure. In the first phase of the experiment, male hooded rats were exposed to i.p. injection 30 minutes prior to testing each day during acquisition. Rats exposed to MK-801 during acquisition were significantly impaired in learning the patterns compared to saline injected controls. The rats showed impairments primarily in learning the pattern containing the violation of pattern structure. In the second phase of the experiment, saline control rats from the first phase that had already learned their patterns were injected with 0.0625 mg/kg MK-801 to assess its effects on retention of the serial patterns. Compared to saline controls, rats exposed to MK-801 were not significantly impaired in retention. These results support the view that MK-801 impairs the acquisition of new serial patterns but does not affect retention of previously learned serial pattern information. (Supported by NIH BRSG 5078R7208 and NIMH MH48402.)

DIFFERENTIAL BEHAVIORAL EFFECTS OF SINGLE OR COMBINED LESIONS TO THE INFRA- AND SUPRACALLOSAL, SEPTO-HIPPOCAMPAL PATHWAYS IN THE RAT: WORKING MEMORY DEFICITS ARE NOT AMELIORATED BY OCETROMINI H PILOCARPINE. P.L. Green, J.C. Cassel, C. Kelche, H. Jeltch & B.E. Wib*, N.B.C. UPR 419 du CNRS, Université Louis Pasteur, 67000 Strasbourg (France).

Female Long-Evans rats sustained single electrolytic infrastrucal (group IN, n=13) or aspirative supracallosal (group SU, n=12), or combined lesions (group INSU, n=12) of the septo-hippocampal pathways at 90 days of age. Sham-operated animals (group SH, n=13) served as controls. Infra- and supracallosal pathways were chosen because of their differential content of cholinergic fibers. There was an infrastructural lesion-induced groups IN and INSU) increase in open-field and home-cage activity, and decrease in spontaneous alternation and habituation to novel stimuli 15 days post-lesion. Of these effects, only increased open-field activity and decreased spontaneous alternation were again observed at 75 days post-lesion. Performance in an 8-arm radial-maze task was impaired as well, again only in groups IN and INSU. These differences in radial-maze performance between groups became more robust with a one-minute delay imposed between the 4th and 5th choices. Ocetromine (0.1 & 0.03 mg/kg) and Pilocarpine (1.0 & 0.32 mg/kg) were ineffective at improving the performance of impaired animals either with or without a delay between the 4th and 5th choices in the radial-maze task. There were no differences between groups SH and SU among the behaviors observed in the present study. The results are discussed in relation to the importance of septo-hippocampal cholinergic pathways in working memory and in terms of the possible relevance of interactions between acetylcholine and other neurotransmitters in memory function.

RF LESIONS OF THE LATERAL INTERNAL MEDULLARY LAMINA (L-IML) OF THALAMUS IN THE RAT INCREASE THE RATE OF TEMPORAL DECAY OF A DELAYED NON-MATCHING TO SAMPLE TASK. E.E. Kylvahan* and R.G. Mair. Dept. of Psychology, University of New Hampshire, Durham, NH 03824.

36 rats were matched for performance on a DNMTS task and then randomly assigned to control or to 1 of 3 lesion groups: L-IML, mediiodorsal nucleus of thalamus (MDN), or fornix (Fmx). After recovery, rats were trained for laterality on DNMTS at 6 delays from 1.8 to 8.8 s. L-IML animals performed significantly worse than all other groups, exhibiting significantly faster rates of decay up to 6.3 s (when their performances reached chance level). MDN and Fmx rats were not significantly impaired on DNMTS. All 3 lesion groups were significantly impaired compared to controls when subsequently trained on an 8 arm radial maze task.

PUTATION OF ODOR AVERSION BY TASTE IS DIFFERENTIALLY AFFECTED BY 6-OHDA OR QuISUlate INJECTIONS. J. Fernández-Ruiz, R. Guzman, M.I. Mirgoja, E. Berndez-Battan, and P. Druet-Ronc, Departamento de Fisiología, Facultad de Medicina y Instituto de Fisiología Celular, UNAM, 04510 México DF.

It has been demonstrated that Parkinson's disease patients have an olfactory deficit. One possible cause may be that dopamine depletion of the olfactory structures leads to an olfactory dysfunction. To test this hypothesis we submitted two control groups, three quisqualate and three bilateral 6-OHDA lesioned rat's groups to a modified potentiation of odor aversion by taste paradigm. The regions tested were the insular cortex, the amygdala and the hippocampus dorsalis. At the end of the experiment the 6-OHDA brains were prepared for HPLC. The behavioral results showed that both the Injection of 6-OHDA or quisquulate in the insular cortex produce the disruption of taste, but not odor aversions. On the other hand, the lesion of the amygdala with 6-OHDA or quisquulate, caused the disruption of the potentiated odor, but not the taste aversions. Finally, the quisqualate, but not the 6-OHDA lesions in the hippocampus dorsalis produced a disruption of both taste and potentiated odor aversions. The HPLC showed a decrease in catecholaminergic contents of the lesioned sites. These results indicate that the Injection of 6-OHDA in the amygdal region, but not in dorsal hippocampus nor in the insular cortex, produced a severe olfactory deficits. Supported by FIRESIN and DGAPA-IN-204689.
CORTICAL CYTOARCHITECTURAL ABNORMALITIES CORRELATE WITH COGNITIVE DEFICITS IN MICE. J.C. Holzmann*, J.L. Sweitzer, E. Backman, G. Older; Kennedy Krieger Institute, Baltimore, MD; Wellesley College, Wellesley, MA; Harvard-MGH, Boston, MA
In neonatal mice, lesions of the basal forebrain (Bf) projecions to cortex in rats elicit profound cholinergic denervation which lead to persistent changes in cortical connectivity and cytoarchitecture. Because these cytoarchitectural abnormalities manifest morphological changes observed in human mental retardation, this is a model for developmental disabilities. We have shown previously that Bf lesions in neonatal rats increased motor activity, decreased anxiety and increased swim maze latencies in adult mice. The purpose of this study is to determine whether there are correlations between histological abnormalities and behavioral impairments in these mice. 25 Balb/C by C57Bl/6 mice received lesions to the Bf (24±4 hours after birth. Behavioral testing began at 8 weeks and included assessment of motor activity, retention of passive avoidance task) and swimming task. Following behavioral testing, 9 mice were killed for Nissl and AChE histochemistry. Morphological abnormalities were evaluated and scored. Lesions varied in size, anterior/posterior and medial/lateral extent of damage and severity of altering cortical abnormalities. Independent of lesion location and size, cortical AChE intensity and distribution were comparable to controls. Motor activity did not correlate with passive avoidance or swim maze latencies. Additionally, lesion location, size and cortical cytoarchitectural abnormalities did not correlate with motor activity or passive avoidance retention latencies. Cortical histology did, however, correlate with swim maze latency at 60; p = 0.0003), i.e., severely abnormal cortical morphology predicted high swim maze latencies. These data indicate that cortical cytoarchitectural abnormalities resulting from Bf lesions in neonates correlate with impaired learning, but not stress-related measures in adult mice. Thus in this lesion model and, by extrapolation, in neonatal retardation, mutant changes in the cortex which result from ontogenic abnormalities could lead to behavioral changes later in life.

INTERACTIONS BETWEEN EMOTION AND MEMORY FORMATION: A PROPOSED HYPOTHESIS. D. Galey*, Laboratoire de Neurosciences comportementales et cognitives, CNRS URA 339, Université Bordeaux I, avenue des Facultés, Talence Cedex, France.
Using two inbred strains of mice (BALB/c and C57Bl/6), we have attempted to elucidate the relationships between memory processes and the modulation of activity of the septo-hippocampal cholinergic pathway.

At first, we have shown in BALB/c mice that medial septal stimulation (30 nA, 300 Hz) applied 30 sec after the partial acquisition of an operant lever press condition increased subsequent retention performance 24 hours later with a temporal gradient of the stimulation effect less than 30 sec before. This result suggested that the stimulation improved consolidation processes. In these conditions, C57Bl/6 mice which display the greater increase in septo-hippocampal cholinergic activation evidenced poor consolidation abilities (Galey et al., submitted for publication).

Additional analysis revealed in fact that these two parameters are negatively correlated. Thus it is suggested that the consolidation of informations would be possible only after a decrease of the level of cholinergic activation.

Finally, our data suggest the systems by which emotional states could act on informations processing and storage through the modulation of the septo-hippocampal cholinergic pathway.

The ECGs of CF and CA3 are rapidly and transiently expressed in response to intense smells in several species of experimental manipulation. Protein encoded by these rapid response genes may act as transcription factors that regulate the expression of downstream target genes, and so thereby function as mediators of long-term responses such as those necessary for the consolidation of memory. In support of this idea, Campeau et al. (1993) showed that conditioned fear significantly elevates a dorsal loci of amgual. We used c-fos and adf-26 per mRNA probes and in situ hybridization to investigate the effect of odor discrimination learning on the expression of ECGs in the rat brain. Initially we found that the learning rate for the first time and/or placing them in a novel environment (the training apparatus) eluates cis and trans-34 mRNA levels significantly above control levels in regions such as hippocampus and neocortical cortex. This expression was more pronounced in cis-34, and was greater in the CA1 than in the CA3 subfield of the hippocampal for both CEs. These differences were decreased significantly by repeated handling and intense in the training environment. To determine if specific brain regions are affected in experienced animals performing a novel odor discrimination, we compared cis and adf-26 expression levels in two groups of rats. Rats in both groups had been previously trained to solve seven odor discrimination between two simultaneously presented odors. Odor presentation was (5) 5'-19' performed on an eighth odor discrimination (for 30 min) and the remainder (e = 12) were simply placed in the training apparatus (for 10 and 30 min) as "control contexts." Animals were perfused 30 mins after their last experimental treatment. Animals performing the task had significantly higher c-fos levels in CA3 when compared to control contexts (p = 5%, barred runs). Such a change in expression was not found in the CA1 or any other region measured, nor was it found for adf-26 expression levels in the same region in adjacent tissue sections. These results suggest that selective areas of the brain elicit enhanced ECG induction/activation during odor discrimination behavior.

GENENDER DIFFERENCES IN BEHAVIORAL STRATEGIES AND RESPONSES TO CHOLINERGIC DRUGS. J.L. Sweitzer, B.L. Richardson and C.F. Holzmann, Wellesley College, Wellesley, MA; Johns Hopkins University, Baltimore, MD; Kennedy Krieger Institute, Baltimore, MD.
We have previously shown that basal forebrain lesions in neonatal mice lead to persistent behavioral impairments in adult mice. We now test whether cholinergic reconstitution therapy with physostigmine (PHY) can ameliorate the lesion-induced deficits. Our behavioral studies show both female and male mice become more impaired in performance in the swim maze task. Female gender is not readily detectable. Gender differences have been reported in other behavioral paradigms, the effect of lesion on performance in the control female and male population on a passive avoidance and spatial navigation task before and after administration of PHY. In passive avoidance, mice were injected with either saline or PHY (0.1 mg/kg, i.p.) after acquisition, then retention latencies were measured 24 hours later. In the spatial navigation task, mice were trained to swim to a hidden platform and then were injected with either saline or PHY (0.1 mg/kg, i.p.) 15-20 mins before testing. Small sex-related differences in performance existed in the absence of drug treatments, most notably, in acquisition of spatial navigation. Analyses of swim paths and patterns suggest that females and males use different strategies. The most drastic differences in performance, however, occurred in response to PHY. The same dose of PHY significantly increased passive avoidance latencies (7.6 ± 2.6 to 168 ± 12 s) and decreased swim latencies (19.9 ± 2 to 11.1 ± 3 s) in males but did not significantly alter performance in females. Full dose response curves are currently being generated. We characterize gender differences in response strategies and sensitivity to PHY and other cholinergic drugs.

LEARNING-ASSOCIATED CHANGES IN MONOAMINE RELEASE IN THE RAT BASAL FOREBRAIN. K. Tanaka., K. Horii., M. Oda., M. Iwaki and M. Nomura., Dept. of Pharmacol. Res. Lab., Toa & Co. Ltd., Chiba, Japan. We have previously shown that extracellular levels of monoamines and their metabolites were correlated with learning performance (Gallagher et al., 1987). To correlate extracellular levels of monoamines and their metabolites with learning performance, we have measured the monoamine and monamine metabolite content in the midbrain of rats (n = 12) which have acquired the operant brightness discrimination learning paradigm (Yamashita et al., 1987) during the first session. DA, dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA), and 5-hydroxyindole acetic acid (5-HIAA) levels during the learning test showed a trendancy to increase as compared to the pre-learning period. The percent increases in the monoamine and metabolite concentrations were then compared with various parameters of learning. We found a significant positive correlations between the percent increases in DOPAC, HVA and 5-HIAA concentrations and the correct response rate. The percent increases in the concentrations of metabolites, on the other hand, were significantly correlated with neither the total responses nor the reinforcements. These results imply that the monoaminergic inputs to the basal forebrain may play an important role in the learning process.

Recent work from this lab has shown substantial variation in the spatial learning abilities of aged rats, such that some aged rats are impaired in the Morris water maze performance, while other aged rats, as well as young rats. In the present study we assessed the effects of aging on nonspatial cognitive performance in odor-guided continuous delayed nonmatch to sample (cDNM). Rats were initially trained to perform the cDNM task under minimal delay and interference conditions, then challenged with longer delays and assessed for the effect of delay on performance. The same rats were then tested in the Morris water maze to compare performance across the two tasks. As in the maze task, we found a substantial variation in aged rats' ability to acquire the cDNM task. Aged rats were significantly retarded in acquisition of the cDNM task, however they were only slightly, if at all, impaired in later testing under increased delay-of-match methods. The cDNM tasks. These results reveal a relationship between the effects of aging on spatial and non-spatial tasks that may reflect a more broadly based deterioration in cognitive function than that commonly ascribed to a spatial memory impairment.
444.7 VIGILANCE AND SELECTIVE ATTENTION IN RATS USING AUDITORY STIMULUS DETECTION. P. J. Bushnell1 and K.L. Kelly2.
Vigilance involves maintaining attention to repeated stimuli over time, and selective attention may be inferred from changes in behavior due to manipulation of the likelihood (expectancy) of discriminative stimuli. To study vigilance, rats worked in operant chambers in which an auditory signal (a 20-msec increase of 1 to 7 dB in the intensity of continuous white noise) was presented on half of the trials. A food pellet was delivered if the rat pressed one of two retractable response levers on a signal trial, or if it pressed the other lever on a blank (no signal) trial. Signal detection analysis showed monotonic increases in signal sensitivity (sensitivity index, 5) and bias (response index, RI) with increasing signal intensity, showing that the accuracy of signal detection improved and the criterion for response to a signal became more stringent as signal intensity increased. Acute exposure to toluene vapor (2000 ppm) reduced SI at all signal levels greater than +1 dB without changing RI. Selective attention was studied with a similar procedure which required rats to detect either a 50 msec increase (+7 dB) or a 50 msec decrease (-6 dB) in continuous white noise. The probability of signal type (increase or decrease) did not affect SI when both signal types required the same response (e.g., press the left lever) and blank trials required the other response (e.g., press the right lever). However, the probability of signal type greatly affected response accuracy when each signal required a different response. These results suggest the importance of the response in demonstrating effects of expectancy on selective attention in rats.

444.9 MATCHING BEHAVIOR IN RATS SELF-STIMULATING IN THE MEDIAL FOREBRAIN BUNDLE. T. A. Mark1, J. C. Sim and C. R. Gallistel.
1Dept. of Psychol., UCLA, Los Angeles, CA 90024-1563.
Rats pressing two levers for brain stimulation reward on concurrent variable-interval schedules allocate their time between the levers in accord with relative reward abundance (subjective reward magnitude multiplied by rate of reward) - the matching law. This preparation may therefore provide a model system in which to study the neuropsychology of elementary computational processes. We studied the kinetics of matching after step changes in the relative reward magnitudes, the relative rates of reward, or both. Rats very rapidly altered their relative allocation (time on one lever/time on the other lever) in response to a change in either component of relative reward abundance. Transitions were commonly complete after one interreward interval on the leaner schedule. Relative time allocation tracked the random short term fluctuations in relative interreward intervals inherently present in two concurrent Poisson processes; hence, the extended to which run cannot be matched law depended on the method used to estimate overall reward rates and overall time allocations. [Supported by NSF Grant BNS 89-96266.]

444.10 REWARD SATURATION IN ELECTRICAL SELF-STIMULATION OF THE MFB. Janine M. Simmons2 and C.R. Gallistel.
2Interdepartmental Neuroscience Program, UCLA, Los Angeles, CA 90024-1563.
Rats press a lever to deliver a train of brief electrical pulses to the medial forebrain bundle (MFB). The time the animal spends on the lever depends on the remembered effect of the stimulus (the subjective magnitude of the reward). Increases in either current or pulse frequency increase the subjective reward magnitude, but only up to a frequency called the saturation frequency, above which reward magnitude no longer increases. We used a two-lever choice paradigm with variable interval schedules on both levers to determine the subjective reward magnitude as a function of pulse frequency at currents ranging from 1000 mA down to the 'current wall'. We find that the saturation frequency depends strongly on current, varying from 251-631 pps at the lowest currents (100-251 mA) to 63-200 pps at a 1000 mA. Increasing current shifts the function for reward-magnitude-versus-pulse-frequency to the left and sometimes increases its asymptote. These results make it unlikely that the saturation is due to a failure of frequency following in the first-stage axons.

444.11 EVIDENCE THAT HIPPOCAMPAL PLACE CELL REPRESENTATIONS OF MULTIPLE ENVIRONMENTS ARE NOT STRICTLY TOPOGRAPHIC. J.L. Kubie1, R.U. Muller1, B.M. Nawsey and C.P. Jia.
1Dept. of Anatomy and Physiology, S.U.N.Y. Brooklyn, Brooklyn, NY 11201.
The discovery of hippocampal place cells led to the hypothesis that the rat hippocampus is involved in spatial representations of the environment (O'Keefe and Nadel, 1976). Two questions that arise are: 1) How are multiple environments represented? and 2) Are the environments topographically mapped within the hippocampus? Previous work implied that there are independent representations of different environments (Muller and Kubie, 1987), but left open the question of topographic organization (Eichenbaum et al., 1990). In this study, we trained rats to chose food pellets in a square chamber and a cylinder. To date, we have recorded 7 sets of at least two cells in each environment. When two cells have firing fields in one environment, the relationship between the fields is called either overlapping or disjoint. We often see that a pair of cells with overlapping fields in one environment has disjoint fields in the second. These observations corroborate the idea of independent representations of different environments. They also strongly imply that the hippocampal representation of space is not topographic. In addition, we find that temporally correlated pairs of cells are less often recorded in the same environment. This result has consequences for theories of how the representation of a particular environment is established and maintained. [Supported by NIH NS20686.]

*Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563. Electrolytic lesions in the medial forebrain bundle at the junction between the posterior hypothalamus and ventral tegmental area were found to attenuate the rewarding efficacy of stimulation at the level of the lateral hypothalamus, as measured by the shift in the rate-frequency functions at several different current amplitudes. These results are consistent with findings by Waraczynski and her collaborators, that MFB lesions attenuate the rewarding efficacy of stimulation at sites rostral to the cut, but often have no effect on the rewarding efficacy of stimulation at sites caudal to the cut. A surprising finding was that our lesions had to be reasonably large (300 μA cathodal current for 200 s) before any decrease in rewarding efficacy of stimulation became evident.

444.13 SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
444.13 LESIONS OF THE NUCLEUS ACCUMBENS IN ADULT Rhesus Monkeys RESULT IN A DEFICIT OF MOTOR LEARNING BUT NOT IN S-R ASSOCIATIVE LEARNING OR MEMORY. R. Killiany* and H. Matul. Department of Psychology, Northeastern University, Boston, MA 02115

The results of the study demonstrated that lesions of the nucleus accumbens in adult rhesus monkeys resulted in a deficit of motor learning but did not affect associative learning or memory. This suggests that the nucleus accumbens plays a specific role in motor learning.

444.14 A METHOD FOR THE SEPARATION OF ATTENTION AND MEMORY IMPAIRMENTS FROM MOTIVATIONAL AND NON-SPECIFIC DEFICITS DUE TO WORK SCHEDULE SHIFTS. W.N. Tan†, B.L. Servatius, A.A. Petral, S.D. Drotar, M.T. Begic, V.A. Medical Center, E. Orange, NJ 07059 & New Jersey Med. Sch., Newark, NJ

This study presents a method for separating attention and memory impairments from motivational and non-specific deficits due to work schedule shifts. The method involves analyzing performance data to identify specific impairments.

444.15 BASAL FOREBRAIN (BF) LESIONS IN MONKEYS PRODUCE IMPAIRMENTS IN ATTENTION. M. Volytko*, M.S. Otten, R.P. Richardson and D.L. Price. Neuropsychology Laboratory, Johns Hopkins University Sch. of Medicine, Baltimore, MD 21205.

This study examined the effects of basal forebrain lesions in monkeys on attentional performance. The results indicated that basal forebrain lesions impair attentional processes.

444.16 TEMPORAL ORDER MEMORY IN MONKEYS IS IMPAIRED BY MEDIAL THALAMIC LESIONS. E.C. Gower* Boston VAAMC and Boston University School of Medicine, Boston, MA 02130.

This study investigated the effects of medial thalamic lesions on temporal order memory in monkeys. The results showed that medial thalamic lesions impair temporal order memory.

444.17 LOCUS COERULEUS UNIT ACTIVITY IN RESPONSE TO NOVELTY AND CHANGE ENCOUNTERED DURING ENVIRONMENTAL EXPLORATION. S.J. Sear, A. Vykroy and A. Beent. Inst. A. Beent, CNRS, GUYVETTE, FRANCE

This study examined the activity of the locus coeruleus in response to novelty and change encountered during environmental exploration. The results showed that locus coeruleus activity increased in response to new stimuli.

This study investigated the cognitive deficits in early-treated PKU (ET-PKU) due to dopamine depletion. The results showed that cognitive deficits were present in ET-PKU.

444.19 A NARROW BAND OF COGNITIVE FUNCTION IS POSSIBLY RESPONSIBLE FOR THE DECREASED PERFORMANCE ON SELECTIVE ATTENTION TASKS IN ADULTS WITH MODERATELY INTELLIGENT. B. Killiany, J. Komiyama, C. Lovett, M. Killiany. Department of Psychology, Northeastern University, Boston, MA 02115

This study examined the cognitive function responsible for decreased performance on selective attention tasks in adults with moderate intelligence. The results indicated that a narrow band of cognitive function is responsible.

444.20 IS THERE A HINT OF THE INHERITANCE OF COGNITIVE DEFICITS IN ADULTS WITH MODERATELY INTELLIGENT? B. Killiany, J. Komiyama, C. Lovett, M. Killiany. Department of Psychology, Northeastern University, Boston, MA 02115

This study investigated the inheritance of cognitive deficits in adults with moderate intelligence. The results suggested that cognitive deficits may have an inherited component.
445.1 LEARNING-INDUCED INCREASE OF TONE-EVOKED RESPONSE IN THE AUDITORY THALAMUS DURING PARADOXICAL SLEEP.
E. Havener*, C. Mabo and B. Hara. Laboratoire de Neurophysiologie de l’Apprentissage et de la Memoire, URA 1491, Université Paris XI, 91405 Orsay Cedex, FRANCE.
We have previously provided behavioral (Behavioral Brain Res., 18:241, 1985) and electrophysiological (Psychobiology, 19:193, 1991) evidences that a relevant stimulus can be detected during paradoxical sleep (PS). We report here that when an acoustic stimulus has acquired significance by conditioning during waking, its processing in the auditory system is enhanced during PS. After 1 session of habituation to a tone, waking rats underwent 3 conditioning sessions with the tone as CS preceding a footshock. After each session, the same tone was presented during PS periods, without any preceding of the animal. Multunit activity in the medial division of the medial geniculate body was recorded at each tone presentation during waking and during PS. After conditioning, tone-evoked response was increased both in the waking and PS states. No such changes were observed in pseudoconditioned animals receiving unpaired tone-shock presentations. Increased responses to meaningful stimuli, occurring in the sensory pathways on a background of limited responsiveness, could explain how an organism in PS is able to discriminate a relevant stimulus from all the other inputs.

445.3 INHIBITION OF DAY-TIME MEMORIES DURING NON-REM SLEEP AND SUPPRESSION OF MEMORIES OF DREAMS IN THE HIPPOCAMPUS.
Yoshinori Kuroda* and Satoshi Fujii*. Dept. of Molecular and Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience, Fuchu, Tokyo 183 and *Dept. of Biochemistry and Molecular Biology, Kyorin University, School of Medicine, Mitaka, Tokyo 181, Japan.
A "tracing circuit association" model has been proposed in which multimodal memory traces in cortical cell assemblies (tracing circuits) are consolidated by prolonged tracing through cortico-hippocampal projections and associated by LTP in intra-hippocampal connections (Kuroda, Y. Concepts in Neurosci.2:221, 1991). However, such multimodal associative memory connections in hippocampus could be easily saturated. Here, we propose a hypothesis that erasing of weaker connections occurs during non-REM sleep. Receptive low-frequency stimulation (reża=1 Hz) of excitatory input (depotentiation brought about by LTD) (310±50 mV in CA1 neurons in the slice, as well as long-term suppression of LTD (LTS; LTD cannot be formed for approx.60 min.). LTD is not induced by the activation (Pujol, S et al.: Brain Res.556:112, 1991). Such low frequency (1-2 Hz) activity of hippocampal neurons is observed as the slow wave during non-REM sleep in rat (Suzuki, S et al.: Electroenceph. Clin. Neurophysiol., 67:348,1987). Therefore, LTP of intrahippocampal connections can be reversed by DP with only strong LTD persisting after sleep. During sleep, especially REM-sleep, random associations of cortical activities (dreams) should be memorized by the association model, however, LTS caused by previous non-REM sleep may have inhibited formation of associative memory by LTP in REM-sleep. Some dreams may occasionally be scored by PTP and by strong LTD in the hippocampus which LTS fail to inhibit.

445.4 SUPPRESSION OF LTP INDUCTION IN THE DENTATE GYRUS DURING ALERT WAKEFULNESS BUT NOT DURING "ENHANCED" REM SLEEP AFTER AVOIDANCE LEARNING.
Rapid eye movement (REM) sleep is thought to play a critical part in memory formation. Learning events, such as active avoidance conditioning, are followed by a transient increase in the amount of REM sleep which is necessary for normal memory retention.

Rats were chronically implanted for unilateral stimulation of the perforant path and recording of evoked potentials in the dentate hilus. Test potentials were collected during REM sleep and a still-REM (SAL) behavioral state. After baseline recording rats were trained on a 40 trial shuttle-box avoidance task. Conditioned rats exhibited a significant increase in the duration of REM episodes relative to pseudoconditioned, yoked controls. High-frequency trains were applied during the second, third and fourth post-REM episodes. Another group was tetanized at the same time points during SAL. LTP was reliably induced during both SAL and REM following tetanization. In SAL, however, tetanization in SAL failed to elicit LTP of the EPSF slope (8% increase) while normal LTP developed after tetanization in "enhanced" REM (32% increase). There was no difference in the magnitude of population spike LTP.

We conclude that avoidance learning affects subsequent LTP induction in a state-dependent manner, allowing normal induction during post-REM REM but suppressing it during alert wakefulness.

445.5 SACCADES MODULATE UNIT ACTIVITY IN MEDIAL TEMPORAL LOBE IN THE DARK.
J. Ringo* and S. Sobota. Physiology, U. of Rochester
In primates, saccadic eye movements frame the visual input. They may then be triggered by an association of visual and mnemonic processing. Thus, we thought to look in the hippocampus and nearby temporal cortical areas for unit activity coupled to eye movements. Such responses turn out to be common, strong, and widespread, in both light and dark. It was found through 12 of 16 implanted guide tubes aimed at hippocampus, inferotemporal and medial ventral cortex.
In our sample analyzed to date (n>300, 3 monkeys), over 25% of the single units showed clear responses coupled to eye movements in the dark. For some cells, the altered activity begins 100ms before the saccade. Both increased and decreased activity were seen. Responses were usually dependent upon the eye movement's direction.
Post-saccadic time histogram analysis in the dark, triggered on each saccade (0 on abscissa). The ordinate is in spikes/sec.

445.6 A HEAD-FIXED PREPARATION FOR ELECTROPHYSIOLOGICAL STUDIES OF LEARNING AND MEMORY IN THE BEHAVING RAT.
A number of electrophysiological investigations of learning and memory could be more directly controlled and more easily accomplished in behaving rats if one could fix the animal's head in space and utilize recording techniques conventional in acutely anesthetized preparations. The successful development of a head-fixed behavior rat preparation depends on a long-lasting rigid head mounting system, techniques for adapting the rat to the fixed-head training environment, and selection of learning tasks in which such rats can perform well but experience brief rest periods. We have been developing such a preparation, adapting head-fixing and training techniques from recent successes with similar preparations by C.D. Woody and T. Ono, and exploiting rats' superb learning abilities when guided by olfactory cues.
Male Long-Evans rats were pre-trained on an odor discrimination task then, under ketamine-xylazine-anesthesia, implanted with multiple miniature self-tapping skull screws, a bipolar MFB electrode, and two horizontally-oriented cannulae on the skull surface. After recovery, they were habituated under successively smaller doses of acetaminophen to stereotactic fixation of the head using pins inserted into the calvaria. Then they were shaped to lick a water spout in order to receive sugar-water plus 400μA MFB stimulation. Later they were re-trained on the odor discrimination. Following these procedures rats could then be trained within a single session on novel odor discriminations. Furthermore, large single hippocampal complex spike and other cell types were readily isolated with brief pulses and could be recorded with stable, large signal-to-noise ratio during behavioral performance.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

The present study examined roles of hippocampal neurons by recording their single units while the rat performed auditory working and reference memory tasks. The working memory task was continuous nonmatching-to-sample (Sakurai, Behav. Neurosci., 104: 253, 1990). The reference memory task was continuous discrimination. The apparatus, stimuli, and sequence of the stimuli were identical for both the memory tasks. Around 10% of the units from CA1, CA3, and dentate gyrus showed behavioral correlates only in the working memory task. Behavioral correlates mean differences in unit's activity to the types of stimuli and/or responses in the tone presented and/or delay periods. Between 20% and 30% of the units showed behavioral correlates only in the reference memory task. About half of the units showed behavioral correlates both in the working and reference memory tasks. Types of these correlates were different between the tasks. These results suggest that there are different types of mnemonic neurons in the hippocampus and more of the neurons are related to both spatial and working and reference memory processes. (Supported by Grants-in-Aid Nos. 02552008, 02610040 and 03251213).

445.9 FUNCTIONAL SIGNIFICANCE OF ANATOMIC CONNECTIONS BETWEEN CAI AND CA3 HIPPOCAMPAL CELLS DURING DELAYED MATCH TO SAMPLE BEHAVIOR IN THE RAT

R.E. Hampson*, M.T. Kirby, K.E. Alexander, V.C. King and S.A. Deadpool. Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157.

Recent studies of the intrinsic anatomic connections between the principal cells of the hippocampus (CA1 and CA3 pyramidal cells) have proposed an intimate gradient of connectivity which traverses the longitudinal axis of the hippocampus (Amaral & Winans, Neuroscience 31:771-991, 1989; Itohnsaka et al. J. Comp. Neurol. 295:580-623, 1990). The functional significance of these connections was investigated using many neuron recording and classification strategy to identify cells which appear to be functionally 'coupled' by these gradients in an in vitro monkey delayed match a delayed match to sample task (Heyser et al. Soc. Neurosci. Abstr. 15:170, 1989). Custom fabricated arrays consisting of 2 rows of 8 microelectrodes implanted to sample the longitudinal axis of the hippocampus, with the electrodes in each row positioned in either the CA3 or CA1 cells. Spike triggered histograms were constructed from spikes on each of the 8 microelectrodes for the entire set of spikes on the CA1 set 180 in 180 spikes in each of 5 10 s epochs. Extracellular spikes from individual cells were isolated by a multichannel online spike sorter (Spectrum Scientific) and cell firing correlated with various phases of the DMTS task. Several of the CA3 cells exhibiting task specific firing correlated also showed long latency 'coupled' discharges associated with CA1 cell spikes. Both the position and the degree of coupling between pairs of CA1 and CA3 cells across these electrode arrays as well as their relation to hippocampal activity will be described.

445.11 BLOCKADE OF MITRAL/TCUTTED CELL HABITUATION TO ODORS BY ASSOCIATION WITH REWARD. D.A. Wilson* and R.M. Sullivan*, Psychol. Lab., Dept. Psychology, University of Oklahoma, Norman, OK 73019

Association of odor and reward during the early postnatal period modifies rat pup behavioral responses and olfactory bulb neural responses to subsequent presentations of that odor. Recent evidence from our lab has shown that olfactory bulb output neurons, including neurons in the mitral cell layer, receive convergent odor and reward inputs. Here, we examined the effect of reward input on M/T cell response to odors during associative training.

Single-unit recordings of M/T cells were made in PN11-12, urethane anesthetized Wistar rat pups. Responses of cells were examined during training, with odors presented and stimulation of the medial forebrain bundle/lateral hypothalamus. Odor responsive cells were then randomly assigned to either a PAIRED training group, receiving 4 sec odor pulses with MBFI/LH stimulation at odor offset or ODOR-only training. For both groups odors were delivered every 30 sec. Response magnitudes were measured in a control session (control LH stimulation) was compared across 15-30 conditioning trials.

The results suggest that contiguous odor-reward pairings prevent M/T cell habitation to the odor that normally occurs to repeated odor-only stimulation. Supported by NBS8819189 from NSF to DAW and DC05489 from NIH and BNS9110506 from NSF to RMS.

445.12 MODULATION OF THE EARLY AND LATE COMPONENTS OF EMG STARTLE ACTIVITY IN THE RAT

Laura L. Price and Valerie R. Nickerson, Psychology, St. Mary’s College of Maryland, St. Mary’s City, MD 20686

The reflex pathway of the acoustic startle response is a simple, fast-latency system within the brainstem of the rat. Short-term habituation of startle occurs within the reflex pathway, but long-term habituation relies upon the inhibition of the reflex response by neural mechanisms outside of the reflex circuit. The startle response also is modulated by other processes such as prepulse inhibition and potentiated startle. The short latency of the reflex places serious timing constraints upon these modulators of startle amplitude. The modulating effects of long-term habituation, prepulse inhibition, and potentiated startle on the startle reflex were studied using EMG recordings in the spinotrapezius muscle of 24 rats.

Acoustic startle stimuli provoked a bimodal EMG response with response latencies of about 8 and 18 ms. Preliminary evidence suggests that the late component may undergo stronger long-term habituation than does the early component. Both components, however, respond to changes within a test session, including manipulations of stimulus intensity and interstimulus interval. Furthermore, the amplitude of both components decreased during prepulse inhibition testing. Preliminary evidence suggests that the responses of the two EMG components are not altered within a potentiated startle paradigm when the startle stimulus serves as the conditioned stimulus paired with aversive footshock.

EFFECTS OF DORSAL CORTEX LESIONS ON HABITUATION TO A LOOMING STIMULUS IN TURTLES. A. S. Footner* and L. Mylick.
St. John's University, Jamaica, NY 11439.

Previous investigations in our laboratory have shown that dorsal cortex lesions impairing habituation. The present study was undertaken to determine whether habituation to a looming stimulus (LS) would be affected by such lesions. Painted turtles (Chelydra serpentina) were given dorsal cortex (n=4) or sham lesions (n=5). The apparatus consisted of a platform on which the turtle was restrained in front of a rear-projection screen on which the LS was presented. Head withdrawals were detected by a photocell beam that was shadowed when the subject's head was extruded. Turtles with sham lesions showed rapid habituation to the restraint and showed both within- and between-day habituation to the LS. Turtles with dorsal cortex lesions took significantly longer to habituate to the restraint, and 2 animals failed to show such habituation. There was a nonsignificant suggestion of an impairment in between-day habituation in the 2 turtles that were able to be tested on habituation to a LS. The results suggest that dorsal cortex lesions may produce a deficit in habituation in turtles.

445.14

A FREQUENCY ANALYSIS OF HABITUATION IN STATIONARY RESPONSE-VISUAL CELLS IN THE AMPHIBIAN TECTUM. M. M. Nikoletses.* Dept. of Anatomy, U. of Puerto Rico, Sch. of Med. San Juan, PR 00936.

Tectal cells of various sensory modalities were reported to be habituated. Habituation is traditionally defined as a decrement in the number of responses as a function of repeated stimulus presentation. In this study, a quantitative analysis of habituation was undertaken with emphasis on the changes in interspike intervals. Frogs (Rana catesbeiana) were anesthetized and paralyzed. A light stimulus (duration 0.50 ms, ISI: 100 ms) was presented in the center of the receptive field of stationary response-cells (SR-cells) (movement-sensitive and directionally-selective cells were excluded) for 1.5 min, and spikes were preamplified and fed into a computer for off-line acquisition and analysis. Use of various filters excluded stimulus artifacts and noise from the analysis. The main findings are: 1. These cells had very low spontaneous activity. 2. The increment in response rate as a result of stimulus presentation gradually declined with repetition but never reached spontaneous levels. 3. As habituation progressed interspike interval lengthened (coding by frequency). 4. In spontaneous recovery there was generally a return to high response rates and short interspike intervals. 5. The frequency coding mechanism is independent of that of spike count. In conclusion, during habituation SR tectal visual cells employ the same coding mechanisms as do somatosensory and auditory tectal cells previously reported.

446.1

Physiol. & Pharm. and Dept. of Foods and Nutrition, Univ. of Georgia, Athens, GA 30602.

In a recent selection study we have reported that rats fed dietary tallow consume increased amounts of high protein/low carbohydrate diet compared to control, corn oil fed rats (J. Nutr. 120: 1418, 1990). These studies suggest that some factor or condition associated with ingestion rates influenced rats diet in a shift in diet selection. In this study we examined the effect of AP/mNTS-lesions on selection of a high protein/low carbohydrate diet versus a low protein/high carbohydrate diet. We found that rats that received an AP/mNTS-lesion at least 12 weeks earlier selected a greater percentage of their daily diet from the high protein/low carbohydrate diet than unlesioned control rats (AP/mNTS-lesion, 41.5 ± 10.4% vs. CON, 15.1 ± 3.7%). Weight loss by the lesioned group does not appear to explain altered diet selection as weight matched control rats consumed only 2.24% of daily intake from the high protein diet. These data provide support for a role of the AP in diet selection. (Funded by NIH DK42533)

446.2

LESIONS OF AREA POSTREMA (AP) ABOLISH CONDITIONED TASTE AVERSIONS BUT NOT AOREXIA INDUCED BY LICI IN RATS. K. S. Curtis, A.P. Ryed, J.G. Verbalis, E.M. Stickert., Dept. of Behavioral Neurosciences, University of Pittsburgh, Pittsburgh, PA 15260.

AP lesions were produced by vacuum aspiration in adult male Sprague-Dawley rats. When given with previous findings, when water-deprived rats were allowed to drink flavored fluids just before treatment with LICI (3 mg/kg, ip), sham-operated (n=8) and non-operated control rats (n=7) demonstrated a pronounced aversion to the fluids whereas rats with AP lesions (n=12) did not decrease fluid consumption significantly. However, in a 30-min test period after overnight food deprivation, rats with AP lesions and control animals reduced food intake significantly and to an equivalent degree after pretreatment with either LICI (3 mg/kg, ip) or hypertonic saline solution (2-3 ml of 2 M NaCl, ip). These results are consistent with the traditional view that AP mediates the sensation of nausea produced by LICI treatment (hence the loss of conditioned taste aversions after AP lesioning) but suggest that neither nausea nor AP is critical for the marked disinclination to eat that is induced in rats by systemic treatment with LICI or with hypertonic NaCl solution.

446.3

Neuroscience Program, Univ. of Western Ontario, London, Ontario, CANADA N6A 5C2.

The present study examined the role of the area postrema (AP) in mediating the effects of lithium on taste reactivity (TR) responses. Rats received lesions of the AP (APX, N=12), or sham lesions (APS, N=14), followed by implantation of an introral cannula. On the first test day, half of the rats in each group were injected with either LiCl or equimolar NaCl (0.6 M, 5 ml/kg, i.p.). Ingestive TR responses (rhythmic mouth movements, tongue protrusions, and lateral tongue protrusions) and aversive TR responses (vomiting and chin rubs) were videotaped during 30 sec intraoral infusion of 0.3 M sucrose. Infusions began immediately post-infusion and at 5 min intervals for 30 mins. Three days later this procedure was repeated. Rats were tested 72 hours later for the expression of a conditioned taste aversion. APS rats given NaCl showed higher levels of ingestive responses during all trials. APS rats given LiCl showed a decline in ingestive responses and an increase in aversive responses (p<.001). In comparison, APS rats treated with either LiCl or NaCl displayed high levels of ingestive responses similar to the APS/NaCl group (p>.10). It was concluded that lithium-induced activation of the AP is required to produce palatability shifts and the formation of CTAs. (Supported by a NSERC operating grant to KPO).

446.4

Increased extracellular ACh in the nucleus accumbens (NAC) is associated with precipitated morphine withdrawal (Rada et al. 1991) and suppression of feeding (Mark et al., 1991). If these findings indicate an aversive action of the transmitter, then ACh increase in the NAC may be sufficient to induce a conditioned taste aversion.

Male Sprague Dawley rats were water deprived and trained to drink during 30 min. daily access to water. After training, animals were presented 2.5 mM sodium saccharin in water, and the taste was paired with either 4 µg/µl neostigmine (n=7) or vehicle (n=7) injected bilaterally in the NAC (0.5 µl per side). A pseudoconditioning control group received NAC in the NAC paired with water presentation (n=7). In a two bottle preference test, the saccharin-neostigmine group showed a significant aversion to saccharin (P<2.18) x15.57, p<.0001) compared to the two control groups. There were no differences in overall fluid consumption. These results suggest that an increase in extracellular ACh in the NAC may be sufficient to produce an internally aversive state.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

Male rats were chemically laryngectomized by intratracheal injections of sodium carboxylate (Gyn VNS). Control rats were given intratracheal injections of isotonic saline (Group VNS). All rats were exposed to a 23 hr/day water deprivation schedule and then exposed either to a conditioned taste aversion (CTA) procedure or a control procedure. The CTA technique involved the pairing of a novel saccharin taste (0.15% solution) with subsequent i.p. injection of ethanol (1.5 g/kg, 15% solution). The control procedure involved the pairing of the saccharin taste with an injection of isotonic saline (10 ml/kg). Following 2 conditioning trials and 3 days of water only, saccharin preference ratios were obtained (2-bottle choice test) on 4 consecutive days. VNS rats exposed to saccharin plus ethanol exhibited a strong CTA (p<0.01) relative to VNS controls. VNX rats given saccharin plus ethanol showed a strong CTA (p<0.01) if conditioning occurred 29-30 days post laryngectomy. However, CTAs were abolished in VNX rats conditioned 19 days post laryngectomy. Thus, ethanol-induced CTA formation varied across the post laryngectomy time period. (Supported by a NSERC operating grant to KPO).

466.7 EVIDENCE OF LEARNING IN THE ETIOLOGY OF POISON-ELICITED PICA. D. Mitchell* and J. B. Nast. Department of Psychology and Psychobiology Program, University of Southern California, Los Angeles, CA 90089-1061.

Both humans and other animals frequently engage in pica (the consumption of non-nutritive substances) when suffering from gastrointestinal malaise. We have previously shown that a specific form of pica, geophagia (clay consumption), can be used to quantify the severity of gastrointestinal malaise induced by a variety of toxins and emetics, including lithium chloride. Though a small dose of lithium chloride reliably elicits robust conditioned taste aversions, the same dose elicits only a modest pica response compared to other toxins and emetics. This apparent inconsistency between the robust effectiveness of lithium chloride as a UCS in conditioned taste aversions and its modest effectiveness in eliciting pica led us to examine the putative role of learning in the etiology of poison-elicited pica.

Rats maintained with food, water, and kaolin always available were administered repeated intraperitoneal injections of 1.5 M lithium chloride (127.2 mg/kg) every fifth day for a total of ten trials. Results showed that the animals learned to engage in pica; clay consumption gradually increased across the first five trials from 1.5 g on the first trial to 15.3 g on the fifth trial. Thereafter, it remained stable across the remaining trials. These results are consistent with clinical literature which suggests that learning plays an important role in the etiology of pica.

Following adrenalecetomy, rats consume less food than sham-operated controls. If adrenalecetomy produces illness or nausea, it is possible that adrenalecetomy (ADX) rats show reduced food intake because they have developed a conditioned aversion to the diet consumed following surgery. To test this hypothesis, rats were introduced to a novel diet (either C-21 or AIN) for a period of seven days immediately following adrenalecetomy or sham-adrenalecetomy. ADX rats consumed significantly less food than sham-ADX rats during this period. On the eighth day following surgery, a preference test was administered. Rats were 8 hr. food-deprived, and then provided 4 hr. access to both C-21 and AIN. Mean 4 hr. food intakes for each of the groups, expressed as grams of C-21 consumed divided by total consumption during the preference test, were: sham C-21-maintained, 86; ADX C-21-maintained, 95; sham AIN-maintained, 34; ADX AIN-maintained, 35. Statistical analysis by ANOVA revealed that ADX groups did not show significantly lower preference than sham ADX groups for the diet to which they were exposed during the week following adrenalecetomy. ADX rats tended to consume a higher percentage of their food as C-21 than sham-ADX controls during the preference test, but this trend was not significant. These data do not support the hypothesis that decreased food intake following adrenalecetomy is due to illness or malaise.

466.9 WHERE IS AVERSION: LATERAL HYPOTHALAMUS OR VENTRAL PALLIDUM/SUBSTANTIA INNOMINATA? H.C. Cromwell*, D. Baraban and C. Unger. The University of Michigan, Department of Psychology, Ann Arbor, MI 48109

Many previous studies have reported that LH damage induces aversion (Tolka et al., 1976; Bliss et al., 1978). However, a study of neuron loss restricted to the LH found aphagia without aversion (Berridge, 1989). The purpose of this study was to resolve where the crucial site for aversion inducing lesions was located. Small bilateral excitotoxic lesions (QUIN, 60nm in 0.5ml of PBS) or bilateral sham injections of the lateral hypothalamus (LH), nucleus accumbens (NAcc), or the ventral pallidum (substantia innominata, VP; SI) were completed to determine the exact locus related to aversion enhancement. The taste reactivity test (Gill and Norgren, 1978) using oral taste infusions of sucrose (1M) was completed and the number of aversive responses (gasps, chin-rubbing, head shaking and forelimb flail) to the palatable sucrose were tallied. To identify the lesions, two lesion mapping techniques were used: 1) a conventional neuron counting procedure, in which an attempt is made to count all neurons within a brain region, and 2) a new modified 'fractionator' procedure consisting of accurate 40X magnification counts at many point locations within a brain region. Results indicated that food aversion is produced following bilateral neuron loss exceeding 70% in a 500ym diameter area of the caudal ventromedial VP/SI alone, and not from NAcc or anterior LH damage. The crucial adrenergic targets are medial to the globus pallidus, and dorsal and lateral to the lateral hypothalamus.

466.10 2,5-Anhydro-D-mannitol (2,5-AM) INCREASES FOS-LIKE IMMUNOREACTIVITY (Fos-Li) IN THE AP InVERSE REGION BY STIMULATING VAGAL SENSORY NEURONS. T.T. Drescher, B. Ritz and M.L. Friedman, Washington State University, Pullman, WA 99164-6520 and Monell Chemical Senses Center, Philadelphia, PA, 19104.

The antinociceptive effects of 2,5-AM, 2,5-hydroxybenzylamine, and 2,5-dimethyl-2,5-dihydroxybenzylamine (2,5-DA) were examined in rats to determine whether the effects were centrally mediated or not. Rats were intraperitoneally injected with 1.0, 2.5, or 3.0 mg of 2,5-AM. At each dose level, 2,5-DA was also administered. The results showed that both compounds produced significant decreases in pain-related behaviors, but not all effects were centrally mediated. The effects of both compounds were blocked by a centrally acting opioid antagonist, naloxone, but not by a peripheral antagonist, 2,5-DAM. These data suggest that 2,5-AM may act on both central and peripheral sites to produce its effects on pain behavior.
446.11 CHARACTERIZATION OF GASTRIC VAGAL AFFERENT MECHANOSENSOR RECEPTORS TO CLOSE ARTERIAL INFUSIONS OF CCK IN RATS: G.J. Schwartz, P.P. McHugh, & T.H. Moran. Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

We have shown that gastric vagal mechanoreceptors also respond to close arterial infusions of the brain-gut peptide CCK. To examine the pharmacological specificity of these CCK-elicited responses, we compared the chemosensory activity of single rat cervical vagal afferent fibers sensitive to both gastric loads and CCK (N=14) before and after administration of the selective A and type B CCK receptor antagonists, L-364,718 and L-365,260. Some of these fibers (N=9) were also monitored for their responses to the above stimuli after acute pylorotomy. In addition, we investigated the ability of JMV-180, a selective CCK-1 receptor antagonist, to attenuate the responses to CCK, both before and after acute pylorotomy, without altering the response to gastric loads. L-365,260 (10 pmol/ml) failed to attenuate the gastric vagal afferent response to either gastric saline loads or 100 pmol infusions of CCK. In intact rats, celiac artery administration of 100 nmol of JMV-180 completely blocked the ability of 100 pmol CCK to stimulate gastric afferent fibers, again without attenuating the response to gastric saline loads. These results demonstrate that CCK-elicited responses in a population of gastric vagal mechanoreceptive fibers are mediated by non-pyliotic, type A CCK binding sites similar to pancreatic low affinity CCK receptors. Supported by DK19302.

Following bilateral removal of the superior cervical ganglion, pseudobacteria (vir 15 ul, 8x10^5 pfu/ml) was injected into the anterior digastric muscle, or temporal muscles of rats. The animals were allowed to survive from 72 to 120 hours. Primary injections were restricted to trigeminal motor neurons (Mo 5) in a predictable myotopic pattern. Secondary injections appeared in neurons in areas known to project to Mo 5, including the Kollik-Fuse, parabralachial, and principal trigeminal nuclei, as well as the supratrigeminal and subcoeruleus zones. Within these areas, however, infections of different muscles produced different distributions of labeled cells. Similarly, differential labeling was observed in regions thought to be involved in the central pattern modulation of Mo 5 activity, such as the gigantocellular and paragigantocellular areas. In the brainstem, increasing survival times revealed polysynaptic connections to the subpedunculopontine and pedunculopontine nuclei in the midbrain, the lateral tegmental and the oral, ventral, and caudal pontine nuclei in the pons, and the parapontalgial, solitary, and rostroventromedial nucleus in the medulla. With longer survival times the infection also spread to the forebrain, particularly in the hypothalamus, amygdala, and olfactory lobes. Nevertheless, the neocortex, thalamus, and most of the striatum remained remarkably free of labeled neurons. Supported by PHS grants DC 00240 and MH 00653.

Lesions of the area postrema/nucleus of the solitary tract (API/NTS) abolish lipoprotein and glucoprotein feeding induced by metoclopramide (3 mg/kg and 2-DOG) respectively. Since the IPBN is a major relay site for ascending visceral sensory input from the AP/NTS region, electrolytic and ibotenate lesions of IPBN subnuclei were made to investigate their involvement in the central pathways of metabolic control of food intake. Lesions were confirmed either by cresyl violet staining or by glial fibrillary acidic protein immunohistochemistry. Lesioned rats were tested for feeding in response to 0.2% NaCl (s.c. or i.p.), MA (400, 800, and 800mg/kg, i.p.) and 2DG (100 and 200 mg/kg, s.c.). Electrolytic lesions of the dorsal, central, superior and external IPBN abolished lipoprotein but not glucoprotein feeding. Ibotenate lesions of the external and superior subnucleus did not impair lipoprotein or glucoprotein feeding, but ibotenate lesions of the dorsal and central subnuclei did abolish lipoprotein feeding. These results suggest that the cells bodies in the dorsal or central IPBN control lipoprotein and glucoprotein feeding. Electrolytic lesions of the inferior and superficial subnuclei appear to have damaged fibers of passage important for this control, possibly those in transit to or from the dorsal and central subnuclei.

446.16 REFEEDING AFTER 48 HOUR FAST INDUCES C-FOS mRNA AND PROTEIN IN RAT BRAINSTEM AND HYPOTHALAMUS: T.A. Hoerr, T.C. Wessel, T.H. Ishi, and A.C. Towle. The Bourne Lab. and the Burke Medical Research Institute, Cornell University Medical College, New York, NY 10032.

In order to identify specific brain regions stimulated at the transcriptional level by food ingestion, we examined the expression of the proto-oncogene c-fos in brainstems and hypothalami by immunochemistry and in situ hybridization in three groups of rats: ad lib. fed controls, rats fasted for 48 hrs, and rats fasted for 48 hrs and allowed to eat Purina Lab Chow ad lib. (50 animals per group). For in situ analysis, 4um tissue sections were hybridized overnight with a [35S]-labeled c-fos oligonucleotide. Sections were dipped in emulsion and developed 4-6 days later. Adjacent sections were immunohistochemically stained for c-Fos-related proteins.

One hour of feeding following a 48 hr fast caused intense c-fos mRNA expression and immunoreactivity to be localized in several regions of the brainstem. The expression was very strong in the nuclei of the solitary tract; in the rostral hypothalamus, strong c-fos expression was seen in the paraventricular and supraoptic nuclei, and more diffuse expression was seen in the anterior hypothalamic nuclei and bed nuclei of the stria terminals; at the level of the caudal hypothalamus, the dorsal medial nuclei and the thalamic habenular and paraventricular nuclei were labeled, as well as individual cells encircling the third ventricle. Control and fasted animals showed little or no expression compared to refeled animals in brain stem and anterior hypothalamus, although ad lib. fed controls showed occasional c-fos expression around the dorsal medial nuclei in the caudal hypothalamus.

Our results show that feeding induces c-fos expression in specific brain nuclei at both the mRNA and protein level. Further studies are required to correlate c-fos expression in these neural areas to specific homeostatic and postingestive effects of food intake.

446.17 MEDIULLARY INPUTS TO THE FIFTH, SEVENTH, AND TWELFTH CRANIAL NERVE MOTOR NEURONS: H.T. Cunningham, J.H. and F.L. Sawchenko. The Sak Institute, Los Alamos, NM 87545.

Prior anatomical studies performed in the rat identified the region of the caudal medullary reticular formation immediately subjacent to the nucleus of the solitary tract (NTS) as the primary source of afferent inputs to the motor nuclei of the fifth (MoV), seventh (VII), and twelfth (XII) cranial nerves, which are involved directly in the control of oromotor behaviors such as deglutition and mastication. In this study, the sensitive fluorescent retrograde tracing technique was used to identify medullary areas innervating MoV, VII and XII, and to characterize the cells of origin of these projections. Discrete deposits of the anterograde tracer Fluorogold, Fluororo-dioxygenase, were then placed in implicated portions of the dorsomedial reticular formation, and the topography of labeled terminal fields within each of the cranial nerve motor nuclei were charted. The results may be summarized as follows:

1) The regions of the reticular formation innervating MoV, VII and XII are largely overlapping, and extend from the level of the MoV to the dorsal spinal cord. In each instance, the greatest concentration of retrogradely labeled cells lay at the level of the NTS.
2) Most inputs are bilateral with an ipsilateral predominance. The single exception is the largely contralateral input to motor neurons innervating the anterior digastic and mylohyoid muscles in the ventromedial portion of MoV. They also project to the intermediate and dorsal portions of VII, and to all subdivisions of XII regions that innervate a number of muscles involved in the initiation of deglutition. Thus, although the resolution of these techniques does not allow us to discount the possibility that a small proportion of neurons in the reticular formation might share characteristics of both populations, it appears clear that two distinct, though topographically contiguous, deglutitive and masticatory pathways arise from the reticular formation in the dorsomedial medulla.

Duodenal lipid infusions rapidly suppress sham intake of liquid diets and rapid stimuli. These effects were observed following sham gastric equipotent T.c. and duodenal cannula, maintained on a food deprivation schedule, and trained to ingest fluids while restrained in a chronic recording apparatus. Parabralachial gustatory neurons were identified using conventional recording techniques. These cells were tested with intralipid infusions (50 ul) of a concentration series of sucrose, as well as a single concentration of policy of the ileum, citric acid, and quinine HC1 before, during, and after duodenal infusions of a lipid emulsion (Intralipid) or saline. The neurons were tested during 3 different, 15-minute periods, before and after the duodenal infusions. The responsiveness of at least 7 taste neurons was assessed during each time period; 11 neurons were tested both before and after an infusion. During the first post-infusion interval (0-15 min), neural activity elicited by NaCl decreased to less than that produced by any concentration of sucrose. During the next time period (15-30 min), taste receptors responded to lower concentrations of sucrose, but increased their responsiveness to NaCl. During the last period (45-60 min), NaCl responses returned to pre-infusion levels, while sucrose responses increased. These data suggest that some neurons may switch their best response category depending on whether the animal is food deprived or satiated. Supported by DC-00047, DC-00240, MH-00653.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
CELLS WITHIN PONTINE PARABRACHIAL NUCLEUS COLLABORATE TO INHIBIT ACTIVATION OF PAGMUS AND OVERARCHING MEDELINA IN THE RAT: IMPLICATIONS FOR FUNCTIONAL INTEGRATION OF PAIN AND SATIETY. L. Belayance, P. L. Fanta, R. D. Hofbauer, and C. Gonzalez. Division of Neuroscience Research, University of Minnesota, Minneapolis, MN 55455.

The pontine parabrachial nucleus (PNB) receives input relevant to feeding and nociception, and may play an integral role in the synchronization of these different functional systems. In this part of the study, we utilized the minigrade tracers to label lateral and/or adjacent to the pontine parabrachial nucleus (PNB) and to determine if a single cell in the PNB collateralizes to innervate two distinct brain areas, thus increasing information relevant to feeding or nociception. After injection of rhodamine-conjugated latex beads into the dorsal medulla and injection of fluorescently into the hypothalamus, doubled labeled cells were located in the pontine parabrachial complex. This would suggest that some PNB cells collateralize to innervate both the dorsal medulla and the hypothalamus, structures involved in the regulation of feeding and nociception. This second part of the study was designed to look at the peptide content of the collateralizing PNB cells. We combined the retrograde fluorescing immunofluorescence technique to determine whether the PNB cells that collateralize also co-localize peptides implicated in the transmission of information relevant to feeding and/or nociception: cholecystokinin (CCK), neuropeptide Y (NPY), enkephalins. The results of these studies suggest that the PNB may utilize collateralization as an integrating system in addition to the more traditional interneuronal activities. Furthermore, the PNB may play an integral role in the synchronization of different functional systems, i.e. feeding and nociception.

Hyperphagia and obesity in cats, dogs, and primates with lateral amygdaloid lesions were observed by several investigators during the 1950's, 1960's, and early 1970's (e.g., Bunberg, 1955; Forsberg, 1971; Greenfield, E. 1997) and Clemente & de Groot, 1957). Interest in this extra-hypothalamic obesity syndrome disappeared when such effects were not observed after amygdaloid lesions in rats. In an initial part of the present study, we also found that large lesions of the amygdala (ylisis had not been completed at the time of submission) resulted in weight gains of 15-25 grams during the first 2-4 postoperative days. Daily food intake nearly doubled in some animals. In a subsequent controlled study, adult female rats with amygdaloid lesions gained 20-30% of their preoperative body weight in 30 days, compared to only 5% for animals with sham lesions. The amygdaloid-lesioned animals were unaffected when switched from a standard pellet diet to a high-fat diet and back again. It is hypothesized that the amygdala plays a major role in appetitive mechanisms.

Neuroanatomical studies have implicated the reticular formation (RF) lateral to the hypoglossal nucleus (xII) as a substrate interposed between brainstem orosensory and motor nuclei. This substrate may be important for producing ingection (licking and swallowing) or rejection (gaping) responses to gustatory stimulation. In the present study, rats were implanted with a chronic microdevice that advanced a bundle of fine wires into the RF lateral to the hypoglossal nucleus. A total of 80 single cells (8 multi-unit responses) were recorded from 18 preparations. Thirteen preparations had recording tracks through the center of the solitary tract (NST) and the RF lateral to xII from a level 0.2 mm rostral to obex to the rostral pole of xII. Electrode tracks ranged from the lateral border of xII to 0.5 mm lateral to the nucleus. Five preparations had electrode tracks extending from the rostral pole of xII to a level 2.5 mm rostral to obex and from 0.4 - 1.0 mm lateral to the midline. Oro-nasal responses to intraoral fluid stimulation were recorded from all preparations (43/80 cells) except two, the medial or the lateral larynx. Responses specific to swallowing were recorded dorsal to oro-lymphatic structures in 5 preparations and were located in the NST at levels ranging from 0.4 - 1.4 mm rostral to obex. Thus it would appear that the caudal NST and the RF ventral to it (lateral to xII) mediate different aspects of the ingestive sequence. Supported by DC04147.

**D. DOPAMINE RECEPTOR ACTIVATION INDUCES SOCIAL REACTIVITY IN MICE SELECTIVELY BREED FOR AGGRESSION.** M.H. Leskic, L.L. Garvey, P. Gendreau, M.A. Mayleden, D.E. Nichols, R.B. Mulimani, B.H. and Development Research Center, 11th, Dept. of Psychology, Psychology and University of North Carolina, Chapel Hill, N.C., 27599 and School of Pharmacy, Purdue University, West Lafayette, IN, 47907.

Robust social behavior has been examined in mice bred for selective breeding ICRC mice for high and low levels of aggression. As previously shown, when paired with a non-selected, group-housed partner mouse, NC900 mice exhibit increased levels of aggression, whereas NC100 mice fail to attack, but rather freeze upon social contact. Previous studies have established that NC100 mice have lower dopamine concentrations in nucleus accumbrans and caudate nucleus, with increased dopamine receptor density in these brain regions. Thus, we wished to determine the effect of administration of a dopamine receptor agonist on social behavior. Mice of both lines were administered 0, 1, 3, or 10 mg/kg (s.c.) of the agonistic, full efficacy, dopamine receptor agonist dDAVP and their behavior assessed in a social interaction test. Dihydrexidine dose-dependent reduced aggression in NC900 mice. Instead of aggression, these animals displayed a marked reactivity to mild social stimuli, as measured by increases in escape behavior, reflexive kicks, and vocalizations. Dihydrexidine had no systematic effect on the freezing behavior characteristic of the low-aggressive line, but did induce social reactivity in these animals, albeit to a lesser degree. In independent experiments, mice were pretreated with either the D2 agonist SC123190 (0.1 mg/kg) or the selective D2 agonist remoxipride (1.0 mg/kg), after which they received dihydrexidine (10 mg/kg) and were tested as above. The effect of dihydrexidine on social reactivity (both NC900 and NC100) and attack (NC900) were significantly antagonized by SC123190 but not attenuated by remoxipride. These studies suggest an important role for D2 dopamine receptors in mediating social stimuli (Supported, in part, by PHS Grants MH45371, MH54587, and MH42765).

**INTRACRANIAL SELF-STIMULATION ON FR15 PRODUCES A BEHAVIORALLY SENSITIZED RESPONSE TO LOW DOSES OF COCAINE HYDROCHLORIDE (COC) IN THE RAT.** E.R. Hartley* and D.E. Reilly.

Department of Psychology, Emory University, Atlanta, GA 30322.

In a previous study (Neurosci Abst, 1990) we report that rats performing ICSS at L8 electrodes on an FR15 schedule showed a complete cessation of responding when administered low-dose AMPH unlike animals trained on an FR1 schedule. The FR15 rats developed increasing levels of stereotypic behavior over the course of the 20 minute session and a dose-response analysis revealed a left shift in FR15 as compared to FR1 rats. To determine if the above behavioral augmentation occurred outside the operant environment, rats were assessed in their home-cage environments. No differences in stereotypy ratings between groups were observed.

In a separate study, the cocaine Coc was examined. A similar response suppression was observed in rats performing on the FR15 schedule though the stereotypy that was observed was qualitatively different as it was statically different to the AMPH-induced stereotypy. Dose-response analysis of Coc revealed a left shift in FR15 rats but, unlike AMPH, there was some response suppression at all doses. A home cage assessment between groups revealed no differences in the stereotypic response to COC and measures of locomotor behavior obtained immediately following ICSS were also no different.

We propose that the FR15 schedule induces an elevated DA release only within the context of the operant environment and that the addition of the AMPH or COC results in an elevated baseline resulting in the development of stereotypic behaviors that compete with the performance of the lever press response.

**EFFECTS OF DOPAMINE BLOCKADE ON THE HYPERACTIVITY PRODUCED BY DRUG INJECTIONS INTO THE MEDIAN HIPPOCAMPUS.** L.S. Kiro and C. Mcshaffer, Dept. Psychol., Univ. Ill at Chicago, Box 4348, Chicago, I1 60680.

We have shown previously that injections of GABA and opioid agonists into the median raphe nucleus (MR) result in large increases in both locomotor activity and dopamine turnover within the nucleus accumbens. In experiments conducted, we examined the possibility that the MR's influence on locomotion might be mediated by alterations in dopamine release. Hyperactivity was induced by injections of intrar- MR injections of DAGO or DIPPE. In contrast, haloperidol, at a dose of 0.4 mg/kg, was able to abolish the hyperactivity induced by systemic amphetamine or by intra-MR injections of DAGO or DIPPE. In haloperidol, hyperactivity was without effect on the response to intra-MR injections of muscimol or baclofen. These results suggest that dopamine may be involved in the response to intra-MR injections of intrar- MR, but is unlikely to play a critical role in the response to GABA agonists. These data also suggest that different populations cells may mediate the locomotor responses to intra-MR injections of GABA and opioid agonists.
447.7 DIABETIC RATS DISPLAY BLURRED BEHAVIORAL RESPONSE TO D-AMPHETAMINE OR DARK PHASE; IMPLICATIONS OF ALTERED DOPAMINE (DA) FUNCTION. Q. AHMAD AND Z. MERALI* Sch. of Physiol. & Dept of Pharm. Univ. of Ottawa, Ont. Canada, K1N 8B9.

The behavioral response of spontaneously diabetic Wistar BB rats (SDR) (maintained on insulin) and matched controls (CTL) to systemically administered d-amphetamine (d-AMPH) was compared. Diabetic rats (4-6 months) and long-term (8-12 months) stages of diabetes, was assessed. Each stage comprised of a different set of animals. Behaviors monitored for 1 h per day included locomotion, general activity, rearing frequency and duration. During the early stage, d-AMPH (0.3, 0.5, 10 mg/kg) induced a dose dependent increase in behavior of CTL rats. The SDR group only responded to the higher doses (0.5 and 1.0 mg/kg of d-AMPH and with a smaller magnitude than the CTL group. At the intermediate and long-term stages, the SDR again displayed a shift to the right of the d-AMPH dose response curve. Similarly blunted behavioral activity was also noted in the SDR during the dark phase of the light cycle. Specifically, the SDR displayed lower levels of activity at light offset or before light onset. Thus the altered response of the SDR may be related to the impairment of synthesis and/or release of DA. This contention was tested in SDR (intermediate state), using microdialysis. Extracellular levels of DA at the nucleus accumbens were monitored every 20 min during the dark phase, in behavior animals. The SDR had a higher basal level of DA as compared to CTL. However, the SDR displayed blunted fluctuations in DA levels, as compared to CTL. Thus the diabetic state may be related to altered DA release pattern and/or altered post synaptic responses to DA.

In two studies, freely moving male rats were observed after they had varying amounts of copulation followed by injection apomorphine (AP); 60 mg/kg; a dopamine agonist), or vehicle. As expected, APO increased erections and yawning in males that had no antecedent sexual contact. Surprisingly, three iterations of one ejaculation produced erections even in vehicle-treated males, which did not differ from APO-injected copulating males. Sexually exhausted rats had no APO-induced changes, a significant depression relative to the other groups. Copulation did not affect yawning in either study. Stretching was rarely seen and may not be a reliable component of the syndrome. We infer that ejaculation has a dopaminergic effect on the erectile component of the PE/SYS, mediated in part by changes in neurochemical activity that are specific to brain systems involved in erection, or at least do not include systems that regulate yawning. [Supported by HD-08933.]

447.10 RESERPINE-INDUCED ORAL DYSKINESIA IN RATS: EFFECT OF DOSE AND COMPARISON TO TETRAZEPINE. J. L. Neuwanger*, E. Canabalos, and D. A. Davis. Department of Psychology, Arizona State University, Tempe, AZ 85287-1100.

Repeated administration of reserpine (1 mg/kg) in rats produces a severe depletion of monoamines, and induces the development of oral dyskinesia that reaches a maximal level within 3 days. To examine whether lower doses of reserpine would result in a slower development of oral dyskinesia, rats were injected SC with 0, 0.01, 0.05, 0.1, and 1 mg/kg reserpine every other day for 60 days. Oral dyskinesia was measured 24 hr after injections by recording the incidence of tongue protrusions during 30 min. Rats treated with 0.01 mg/kg developed TPs within 3 days, whereas rats treated with the 0.05 mg/kg developed TPs after 10-20 days, and rats treated with 0.1 mg/kg had not developed TPs by 60 days of treatment. These findings suggest that a large dose of reserpine may result in a slower development of TPs, similar to the prolonged development of tardive dyskinesia in humans. Furthermore, we suggest that a severe depletion of monoamines induce neurochemical changes similar to those that underly tardy dyskinesia, but at an accelerated rate. We also examined whether tetrazepam, another monoamine depleting agent, would induce oral dyskinesia. Rats were injected with either vehicle, reserpine (1 mg/kg, SC, every other day), or tetrazepine (3 mg/kg, SC, either once or twice daily for 21 days). TPs, grooming, and locomotor activity were measured on days 30-32 after the last injection. Both reserpine and tetrazepine treatment produced an increase in TPs. Tetrazepine, however, also produced an increase in grooming and locomotor activity relative to the other groups, suggesting the increase in TPs produced by tetrazepine may be due to an increase in overall activity rather than a dyskinesia. Reserpine produced a more severe depletion of monoamines (86-94%) relative to tetrazepine (28-58%). Reserpine also produced a 450-900% increase in dopamine and serotonin turnover as measured by neurochemical metabolite ratios, whereas tetrazepine did not alter turnover. Relationships between changes in brain monoamine levels and behavior will be discussed.

We have previously shown that the activity of schedule-induced polydipsia (SIP) was persistently depressed in a bilateral symmetrical locus coeruleus lesions and ventral tegmental area lesions in succeesion. The hypothesis that central catecholaminergic neurons modulate SIP behavior is supported by findings that the changes in the overall dopaminergic system observed in SIP may be due to the changes in the dopaminergic system of the nigrostriatal, mesocorticolimbic, and mesolimbic systems. The current study assessed the regional turnover of monoamines in SIP and control rats. It was found in the SIP that NA and DA levels and DA synthesis and utilization in the limbic area were increased and that NE synthesis in several pontine cerebrospinal-NF projections, e.g., subicampus, cortex and pons, were also increased. Conversely, the NE-metabolism in the hippocampus was decreased in SIP rats. In the same areas were decreased in the SIP rats. We therefore concluded that enhanced actions of both DA-limbic system and NE-cerebrospinal system are important in the process of SIP establishment.

447.12 DOPAMINERGIC CONTROL OF MALE CUMULATORY BEHAVIOR IN QUAIL. RECEPTOR AUTORADIOGRAPHY AND PHARMACOLOGICAL STUDIES P. A. L. W. D. E. Ball, I. M. G. and I. A. D. Laboratory of General and Comparative Biochemistry, University of Liège, Belgium, Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD 21218, USA.

In quail, dopamine (DA) turnover in the medial preoptic nucleus (POM) is higher in males than in females. In the POM, is a key site of testosteron (T) on sexual behavior, this suggests that DA may be involved in the control of this behavior. Also, tyrosine hydroxylase-immunoreactive fibers innervate the preoptic area and hypothalamus. The behavioral effects of dopamine were analyzed by in vivo pharmacological manipulations. In a first experiment, the D1 agonist acid, apomorphine (AP), 10 mg/kg, did not change the behavior induced by T in castrated (CX) males. Inhibition was statistically significant for doses higher than 10 mg/kg and complete at 1 mg/kg. In a second experiment, repeated injections of AP (0.1, 0.01, 0.001 mg/kg) had no effect on the behavior, except for the dose of 1 mg inhibited the behavior in less performed 10 min after the injection. Several reports have indicated that AP can modulate sexual behavior in male rats. The inhibitory effects observed here may reflect a higher density or higher sensitivity of the D2 dopamine receptors in male rats compared to female rats. The effect of AP on the sexual behavior was measured using behavioral effects of AP in quail pretreated with apomorphine, a specific D2 antagonist. Apomorphine (0.03 mg/kg) should enhance sexual behavior and completely blocked the inhibitory effects of AP. These data suggest that sexual behavior in male quail is mediated through D2 receptors.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
448.1 HIGH-PEAK BLOOD EThANOL CONCENTRATIONS RESULTING FROM POSTNATAL EXPOSURE TO ETHANOL AFFECT MEMORY-BASED BUT NOT CUE-BASED DISCRIMINATIONS IN THE INFANT RAT. J. L. Diaz-Granados*, P. L. Greene, G. Y. Espinosa, & A. Ameral. Department of Psychology & Institute for Neuroscience, University of Texas, Austin, TX, 78712.

We have previously shown that postnatal exposure to ethanol that produces high-peak blood ethanol concentrations in infant rats, results in significant deficits in hippocampal neuroanatomy and discrimination learning based on the memory of singly alternated rewarded (R) and nonrewarded (N) trials (Greene, et al., Behav. Neurosci. 106:51, 1992). In the present experiment, we tested infant rats, artificially reared and exposed to ethanol from postnatal day 4 to 9, in a straight alley in a discrimination using rough and smooth floor textures as cues. On day 4 postpartum, pups were fed with gastric cannulas and a nutritionally adequate diet was infused intragastrically for 15 minutes every hour. In 4 consecutive morning feedings one group of pups received an ethanol-adulterated diet while postnatal controls received an isocaloric diet. (A third group was raised normally in a litter.) The remaining 20 feedings for all pups were with undiluted diet. On days 17-18, animals were tested on one of three discrimination schedules: single alternating S and N, random R and N, or random R and N followed by a discrimination reversal. The ethanol-exposed animals were not different from the normals or the artificially-reared controls in either alternating, or the random or reversed discriminations. These results indicate that the deficit in discrimination reported earlier in ethanol-exposed, hippocampally damaged animals is a memory deficit and not a general deficit in discrimination, since pups discriminate normally when external cues are made available. Supported by NIAAA grant AA07052.

Fetal Alcohol Syndrome is associated with altered sleep and feeding patterns in newborns. This experiment investigated persistent effects of in utero alcohol exposure on circadian rhythms in adult offspring. Male and female rats born to either control, pair-fed or alcohol-exposed dams were monitored for body temperature and activity using a telemetry system under various LD schedule conditions. Baseline (12:12 LD) or 14:10 LD measurements were affected by prenatal treatment, but females were more active, had higher mean body temperature, and had higher maximal temperatures that peaked earlier than males. Under a free-running schedule (LL), alcohol-exposed males were less active than controls; females did not differ by treatment. Mean and maximum temperatures were higher in alcohol-exposed males and lower in alcohol-exposed females than same sex controls, thus no longer displayed the typical sex-dependent pattern. Although all subjects demonstrated phase advancement, alcohol-exposed subjects lagged behind controls. Chronometric analysis of the volume of the SCN was inconclusive. These results suggest that the stress of a free-running schedule revealed underlying thermoregulatory dysfunction caused by prenatal alcohol exposure. (Supported by NSDA AA088050)

448.5 ETHANOL CONSUMPTION SUPPRESSES IMMUNE RESPONSE IN FETAL ETHANOL-EXPOSED RATS. J. Weiberg* and T.B. Jerpells, Dept of Anatomy, Univ of British Columbia, Vancouver, BC V6T 1Z3, Dept of Cellular Biology & Anatomy, Louisiana State Univ, Shreveport, LA 71130.

Ethanol consumption during pregnancy may alter immune function of offspring. Our previous work found that fetal ethanol-exposed (E) animals had decreased thymus number, decreased splenic lymphocyte response to concanavalin A (Con A), and a functional defect in T-cell response to a secondary stimulation by IL-2, as compared with pair-fed (PF) and control (C) animals. Importantly, deficits occurred in E males but not females. In the present study we examined the vulnerability of E offspring to the immunosuppressive effects of ethanol exposure in adulthood. Adult Sprague-Dawley males and females from prenatal E, PF and C conditions were assigned to E or PF adult treatment groups. Six groups were thus formed, with Prenatal–Adult treatments as follows: E–E, E–PF, PF–E, PF–PF, C–E, C–PF. Adult E or PF treatment was continued for 4 wk.

Sex differences in treatment effects were found. For females, C–PF animals had higher thymus and spleen weights than other groups. There were no differences among females from the 3 prenatal groups in splenic lymphocyte response to Con A, although adult ethanol consumption had some suppressive effects on responses in E and C animals. For males, thymus weights were lower in E–E than in E–PF animals; no other treatment groups showed this differential response. In addition, both E–E and E–PF males exhibited a suppressed lymphocyte response to Con A; males from prenatal PF and C conditions showed no suppression unless exposed to ethanol in adulthood. Supported by AA07789 (JW) and AA07731 (TR).

Learning and memory deficits after prenatal alcohol exposure occur both during development and in adulthood. Sleep deficits are also prominent in neonates and rats. Data from our previous findings demonstrate that paradoxical sleep and memory are correlated in several mammalian populations, suggesting that the possibility that deficits in paradoxical sleep will accompany deficits in memory in adult rats prenatally exposed to alcohol. We address this issue, pregnant Sprague-Dawley rats were fed a liquid diet including 35% ethanol-dereived calories, or were pair-fed an isocaloric diet from gestation days 8-19. Sleep (0h) records via continuous EEG and EOG, revealed a decrease in paradoxical sleep and an increase in stage 2 sleep. To address this issue, pregnant Sprague-Dawley rats were fed a liquid diet including 35% ethanol-dereived calories, or were pair-fed an isocaloric diet from gestation days 8-19. Sleep (0h) records via continuous EEG and EOG, revealed a decrease in paradoxical sleep and an increase in stage 2 sleep.

448.6 ACUTE ETHANOL EXPOSURE DEPRESSES STIMULATED GLUTAMATE RELEASE IN THE HIPPOCAMPUS OF THE DEVELOPING GUINEA PIG. J. P. Reynolds, J. V. Milligan, and W. B. Yager, Dept. of Pharmacology and Toxicology, and Dept. of Physiology, Queen's University, Kingston, Canada, K7L 3N6.

It has been proposed that glutamate (Glu) mediates ethanol (E) teratogenesis in the hippocampus. Our objective was to elucidate the effect of acute E exposure on spontaneous and potassium ion (K+)-stimulated release of Glu in the hippocampus of the near-term fetal and adult guinea pig. GLU release was measured as efflux in 300-μm thick, transverse, hippocampal slices. Acute in vivo E exposure involved oral intubation of 4 g E/kg body weight in near-term pregnant and adult male and female guinea pigs, which were sacrificed 2 hr after dosing. Acute in vitro E exposure involved incubation of tissue slices with 48 mM E, the apparent maximal blood [E] at 1 hr after 4 g/kg body weight. E did not affect spontaneous Glu efflux. In vitro E decreased K+-stimulated Glu efflux in the fetus and adult. In vivo E and in vitro E decreased K+-stimulated Glu efflux in the fetus, but not in the adult. These data indicate that (a) in the near-term fetal guinea pig, acute E exposure decreases stimulated Glu release in the hippocampus, and (b) in the adult guinea pig, tolerance develops to the depressant effect of E on stimulated hippocampal Glu release after a single E dose. (Supported by the MRC of Canada)
448.7 THIAMINE-DEPENDENT ENZYME CHANGES IN THE BRAINS OF ALCOHOLICS: RELATIONSHIP TO THE WERNICKE-KORSAKOFF SYNDROME. R.F. Butterworth, 1, 2 Kipf and C. Harper, 3 Neurosciences Research Unit, A-V CRC Hospital, St. Luc, University of Montreal, Montreal, Quebec, Canada H3X 3J7 and Dept of Psychiatry, University of Sydney, Sydney, Australia.

Previous studies in experimental animal models suggest that the cerebral dysfunction and cell death in the Wernicke-Korsakoff Syndrome (WKS) results from reductions of thiamine-dependent enzyme activities in brain (Butterworth, Alcohol & Alcoholism, 23, 271-279, 1989). As part of a series of studies of the role of thiamine in WKS in humans, activities of the thiamine-dependent enzymes pyruvate dehydrogenase (PDH), α-ketoglutarate dehydrogenase (αKGDH) and transketolase (TK) were measured by standard spectrophotometric procedures in samples of frontal cortex and cerebellum of 10 alcoholic patients who died in hepatic coma with no clinical or pathological evidence of WKS, 2 alcoholic patients with neuropathologically confirmed WKS and 10 control subjects free from neurological disease.

Reductions of TK (by 75%), PDHC (by 82%) and αKGDH (by 90%) were observed in the brains of WKS patients. Activities of the non-thiamine-dependent enzyme glutamate dehydrogenase were within normal limits in brain tissue in all alcoholic patients vs. WKS. Activities of all three thiamine dependent enzymes were unchanged in the brains of alcoholic patients dying in hepatic coma. These findings demonstrate, for the first time, a direct link between reductions in activities of thiamine-dependent enzymes and WKS in humans.

(Funded by The Medical Research Council of Canada).

448.8 NEUROAL AND ASTROCYTIC RECEPTOR CHANGES IN AUTOPSIED BRAIN TISSUE FROM ALCOHOLIC PATIENTS WITH HEPATIC ENCEPHALOPATHY. J. Lavoie*, G. Girard, D.K. Leong and R.F. Butterworth, Neurosciences Research Unit, Andre-Vallée Clin. Res. Centre, Hospital St-Luc (University of Montreal), Montreal, Quebec, Canada H3X 3J4.

As part of a study of neurochemical mechanisms in alcohol-related brain damage, neuronal and astrocytic binding sites for specific radioligands were measured in autopsied brain tissue from 9 cirrhotic alcoholic patients and an equal number of control subjects free from neurologic disease. Neuropathological examination excluded the presence of WKS in humans. Densities of GABA-Benzodiazepine receptors were observed using [3H]-muscimol, [3H]-flunitrazepam or [3H]-Ro 15-1788. Binding parameters for the gluta matic receptor ligands [3H]-kainate or [3H]-MK801 were likewise unaltered in the brains of alcoholics. Densities of muscarinic cholinergic receptors, evaluated using [3H]-quinuclidinyl benzilate ([3H]-QNB) were increased by 48% in frontal cortex of alcoholic patients. Similar changes in [3H]-QNB binding were observed in rat brain following portacaval anastomosis (Giguere et al., Brain Res. 562, 1992) suggesting that these changes result from chronic liver disease rather than alcohol per se. These findings suggest that (i) neuronal loss in alcoholic brains in hepatic coma is restricted to a modest loss of cortical cholinergic neurons and (ii) chronic liver disease results in increased binding of [3H]-quinuclidinyl benzilate, benzodiazepine and muscarinic cholinergic receptors.

(Funded by The Medical Research Council of Canada)

448.9 CHRONIC INTRAGASTRIC INFUSION OF ETHANOL RESULTS IN THE PRODUCTION OF TOLERANCE TO ETHANOL IN MICE. W. Cao, T.K. Landa, A.C. Collins, Institute for Behavioral Genetics, Univ. of Colorado, Boulder, CO 80303.

The present study characterized chronic intragastric infusion as a method for developing tolerance to ethanol in mice. The selectivity bred long sleep (LS) and short sleep (SS) mice were used. Male mice were anesthetized and were surgically prepared with a catheter in the stomach. The mice were infuse d every 6 hours with physiological saline or ethanol (3.0 or 4.0 g/kg). Potential tolerance to ethanol was determined by measuring the effects of challenge doses of ethanol on body temperature, open field and Y-maze activities. In addition, the mice were given an anesthetic dose of ethanol (6.0 g/kg for SS, 3.5 g/kg for LS) and the duration of sleep times was measured 6 hours after termination of infusion. Chronic infusion resulted in tolerance to virtually all the effects of ethanol in both mouse lines. However, the LS developed tolerance more readily (after shorter periods of infusion) and to a greater degree. Chronic infusion did not result in changes in the rate of ethanol metabolism in either mouse line which suggests that this procedure results in pharmacodynamic tolerance to ethanol's effects. Thus, the intragastric infusion method, which allows for very precise regulation of dose and dose interval, is a useful technique for producing tolerance to ethanol in mice. Supported by AA-06391 and DA-00116.

448.10 FURTHER CHARACTERIZATION OF AN ANIMAL MODEL OF ETHANOL WITHDRAWAL "KINDLING". H.C. Becker and R.L. Hale, VA Medical Center and Medical University of South Carolina, Charleston, SC 29401.

We have previously demonstrated that animals exposed to ethanol (EtOH) for a total of 48 hrs exhibit more severe withdrawal seizures if exposure is divided into three 18 hr intoxication/6 hr abstinence cycles than when the 48 hrs of exposure occurs in a single bout. This pattern of results supports the "kindling" hypothesis of EtOH withdrawal in that repeated episodes of EtOH withdrawal result in a progressive intensification of withdrawal seizures. The present study was designed to further characterize this animal model of EtOH withdrawal "kindling" and examine whether such a "kindled" response is still evident when withdrawal testing is conducted following an additional intoxication bout. Adult male mice were chronically exposed to EtOH via intragastric infusion in vapor chambers for 40 hrs prior to withdrawal testing. Prior to this 40 hr bout of intoxication, one group (Multiple Withdrawal; MW) received 3 cycles of 16 hrs EtOH exposure separated by 8 hrs periods of abstinence; a second group (Continuous Exposure; CE) received the same total EtOH exposure (48 hrs) without interruption; and a third group (Single Withdrawal, SW) did not receive any EtOH exposure prior to the 40 hr test cycle. A control (C) group was included that did not receive any EtOH exposure throughout the experiment. Blood EtOH concentrations (BEC) following the 40 hr period of EtOH exposure were 100-140 mg/dl for all EtOH-exposed groups. Mean areas under the 24 hr curve for handling-induced convulsions after the 40 hr EtOH exposure period for MW, CE, SW, and C groups were 33±5, 18±4, 3±1, and 0±0, respectively. These results indicate that differences in the severity of EtOH withdrawal seizures due to differences in prior withdrawal experience can be demonstrated even when later EtOH exposure patterns are equated. Supported by the VA Medical Research Service and NIAAA.

448.11 EFFECT OF ETHANOL ON ADENOSINE RECEPTORS CONTRIBUTES TO THE DEVELOPMENT OF THE WITHDRAWAL SYNDROME. S.M. Reszka, C.J. Walters, and J.L. Lal, Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX, 76107.

It has been hypothesized that stimulation of adenosine receptors is involved in ethanol (ETH) intoxication and the development of tolerance. We investigated an ethanol withdrawal symptom ("asthenia-like" behavior) using the elevated plus maze (EMP) paradigm (Laï et al., Alcohol 8, 687, 1991). Long-Evans hooded rats were given a balanced liquid diet containing 12% ETH for 40 hrs. After this period, animals were allowed to show a base line EMP response (CPT, 0.05-0.16 mg/kg, ip) during the last 6 days of ETH diet administration. Twelve hours after a final ETH dose (3g/kg, po), rats were tested in the EMP. We observed a significant reduction in the open-arm activity and an increase in the ataxic responses indicative of ETH withdrawal. Pair-fed treatment with an A1 adenosine agonist, R-(+)-N6-(2-phenylisopropyl)-adenosine (PA, 0.08-0.32 mg/kg, ip, 15 min), had little effect on performance in the EMP during ethanol withdrawal. Acute treatment with an A1 adenosine antagonist, 8-cyclopentyl-1,3-dimethylxanthine (CPT, 0.02-0.16 mg/kg, ip, 60 min), exacerbated ETH withdrawal with a further reduction in open-arm activity. Chronic treatment with CPT (0.04-0.16 mg/kg, ip) during the last 6 days of ETH diet administration resulted in a dose related increase in the amount of time spent in the open-arms of the EMP, but had little effect on the number of total arm entries. These data support the hypothesis that an ethanol stimulated increase in adenosine receptor activity may be associated with the development of dependence and that blockade of adenosine receptors during ethanol withdrawal will attenuate the display of "asthenia-like" behaviors during ethanol withdrawal. Supported by NIAAA Grant AA06980.

Studies examining post-training ethanol's effects on memory have found conflicting task-dependent results. Recent work suggests that this apparent contradiction may be due to an inherent aversive component of ethanol. According to this hypothesis, treatment with ethanol results in the loss of aversive information to the pretreatment stimulus complex, altering retentive performance. Low levels of chronic ethanol exposure using a helium-oxygen (heliox) gas mixture has been shown to antagonize a number of ethanol's acute and chronic behavioral effects. The present study investigated whether hyperbaric exposure antagonized ethanol's aversive effects on appetitive task memory. Male C57BL/6J mice were individually trained to find a cheese pellet. Mice were immediately injected i.p. with saline or 0.5, 1.0, or 2.0 g/kg ethanol (20% v/v). They were then returned to their home cage and exposed to 1 ATA air, 1 ATA heliox, or 12 ATA helium for 2 hours. Retention performance was measured 24 hrs after training in the non-drug state. Helium-air control mice ate the pellet significantly quicker after training, while all other mice exhibited a non-significant increase in latency, suggesting amnesia. However, habituation of locomotor activity and pellet approaches in all groups indicates that memory of the environment remained intact, while grooming data suggest that the amnesic response in the heliox and ethanol groups reflects a subtle aversive effect of these treatments. Collectively, it appears that post-training exposure to heliox, like ethanol, is aversive and does not impair memory storage processes. Further studies are necessary to determine the mechanism of heliox's aversive effect which may be related to hypobaric pressure that can antagonize the aversive effect of ethanol in this task. (Supported by NIAAA grants AA03972 & AA05234).
448.13
ANTAGONISM OF ETHANOL-INDUCED CONDITIONED PLACE PREFERENCE BY THEOPHYLLINE. C.L. Cunningham*, D.H. Malott, P.O. Risberg. Oregon Health Sciences University, Portland, OR 97201-3098
Acute exposure to ethanol (EIOH) elevates adenosine levels in brain, and it appears that adenosine may be involved in the central depressant actions of EIOH. The present study examined the role of adenosine in mediating EIOH's rewarding effects by assessing the impact of a nonselective adenosine antagonist, theophylline, on ethanol-induced conditioned place preference. Intoxicated (BAC 2%) were exposed to a Pavlovian discriminative conditioning procedure in which a distinctive floor (tactile) stimulus (CS+) was paired four times with either EIOH (2 g/kg, IP), theophylline (30 mg/kg), or the combination of theophylline and EIOH. A different floor stimulus (CS-) was paired only with saline. Conditioning trial duration was 30 min and the theophylline pre-treatment interval was 30 min. Preference testing was conducted in the absence of either drug. Both EIOH and theophylline increased general activity on conditioning trials and their combination produced greater activity than either drug alone. As expected, EIOH alone resulted in conditioned place preference.
However, theophylline alone produced conditioned place aversion. The group receiving the combination of theophylline and EIOH showed no evidence of place conditioning, suggesting these drugs cancelled each other's hedonic effects. This outcome may not appear to represent a pharmacological antagonism, but seems more readily interpreted as an instance of behavioral or "functional antagonism."

EFFECT OF ETHANOL AND GLUTATHIONE ON REACTION TIME IN RATS. Z.M. Post*, P.K. Randall, S.W. Leslie and C.K. Erickson. Dv. of Pharmacol., Coll. of Pharm., Univ. of TX, Austin, TX 78712
Ethanol (EIOH) and NMDA similarly stimulate calcium uptake into dissociated brain cells. However, ethanol (EIOH) inhibits only GSH-stimulated uptake, perhaps because GSH blocks its purported site of action, the glycine site on the NMDA receptor complex. The interaction between GSH and EIOH has proven to be behaviorally significant in the rat given a hypothetical dose of EIOH regained the righting reflex sooner when pretreated with intracerebroventricular (ICV) GSH. The purpose of this study was to determine whether GSH pretreatment would also lessen EIOH-induced impairment of a reaction time (RT) task in rats. On week 1 of a simple crossover design, behaviorally tolerant rats (n=12) were administered EIOH (i.g., 2.8 g/kg, 20% w/v in water) 15 min after ICV GSH (10 µl, 20 mM) or vehicle (10 µl artificial cerebrospinal fluid); on week 2, EIOH followed the alternate ICV agent. Although EIOH by itself impaired normal speed and speed of response (85 v. 96% and 312 v. 240 ± 11 ms at 30 min, respectively), performance after GSH was no different from vehicle. In a second experiment, EIOH-naive rats (n=10) were given 2.4 g/kg EIOH after ICV GSH or vehicle. Again, EIOH alone impaired response (63% success and 453 ± 29 ms) but GSH-treated rats were not protected. This lack of effect is probably due, at least in part, to the fact that the animals are highly practiced by the time drugs are administered. Also, there is great incentive to perform successfully, and thus, compensatory behavior is developed rapidly. It would be appropriate to test a behavior of intermediate demand which measures motor control, but to which less behavioral tolerance to EIOH develops. (Supported by funds from the Univ. of TX.)

449.3
Effects of nicotine (1.5 mg, i.v.) on cerebral metabolic rates for glucose (CMRglc) are being studied in human volunteers, including cigarette smokers and nonsmokers. CMRglc is measured by positron emission tomography using the [15O] water methodology. Subjective and cardiovascular responses are also recorded.
Preliminary results indicated that smokers showed globally higher CMRglc than nonsmokers in the placebo condition, and that both groups showed a widespread decrease of about 10% in response to nicotine. Smokers gave higher subjective responses than nonsmokers to questions about drug liking (e.g., "Did the drug have good effects?") or "How much did you like the drug?"). There were no differences between smokers and nonsmokers on ratings of drug strength (e.g., "How strong was the drug effect?" or "How much did you feel the drug?"). Smokers showed more tachycardia than nonsmokers, presumably due to tolerance. The findings suggest that nicotine resembles other drugs of abuse in that it reduces CMRglc. Relationships between CMRglc and effects on mood are under investigation.

BEHAVIORAL EFFECTS OF NICOTINE CONSUMED BY RATS. C. Kair* and G. Mellor, Department of Psychology, University of Wyoming, Laramie, WY 82071
Rats that had not consumed water for 24 hr were placed into 41 x 41 x 30 cm clear acrylic chambers with a 10-ml drinking tube in one corner. Each rat remained in the chamber for one hour, and activity was recorded using an Omnitech monitor. Water was given in the home cages for 2 hr after each session. By the 7th day all rats drank all 10 ml of water in the test chamber within 5 min. On the 8th-14th days the drinking tube contained 10% sucrose with 10 µg/ml nicotine. At first there was no apparent effect on locomotor activity, but over the 7 days of nicotine testing the total distance moved during the hour increased more than threefold. Subsequent test days alternated between presentation of 10% sucrose alone or sucrose plus nicotine. A significant dose-effect relationship was found with locomotor activity increasing in response to 5, 10 and 20 µg/ml nicotine solutions. Pretreatment with 1.0 mg/kg mecamylamine 20 min prior to tests with 10 µg/ml nicotine had no effect on volume consumed or time to drink, but did reduce the locomotor response.
Rats will drink 75 ml/day of 10 µg/ml nicotine in 10% sucrose in 24 hr, 2-bottle drinking tests with plain water in the 2nd bottle. Those rats quickly stop drinking significant amounts of nicotine either when the sucrose is removed from the mixture or when a third bottle is presented containing 10% sucrose without nicotine. Thus, we have been unable to demonstrate that rats develop a dependence on nicotine after consuming this sucrose-nicotine mixture. These findings call into question theories of drug dependence that tie reinforcing properties of drugs to their locomotor stimulant effects.
449.5

There is evidence to suggest that increases in dopamine in the nucleus accumbens mediates the rewarding effects of psychomotor stimulants and that D2/D3 dopamine antagonists can reverse stimulant-induced changes in mesolimbic dopamine activity. Previous work from our laboratory has shown that MDL 28,133 (MDL) can attenuate the reinforcing effect of d-amphetamine and cocaine. The present study assessed the ability of MDL 28,133 to attenuate or block nicotine-induced facilitation of brain stimulation reward. Rats implanted with bipolar ventral tegmental area electrodes were administered 1.0, 3.0, or 6.0 mg/kg MDL (IP) 1 hr prior to testing. MDL alone did not produce any change in responding. However, when co-administered with nicotine (0.4 & 0.8 mg/kg IP, 45 min post-MDL), MDL produced a dose-dependent reversal of the threshold lowering effect of nicotine. Analysis of response rates indicated that MDL did not interfere with the animal's performance, as do other compounds with dopamine antagonist properties (i.e., haloperidol). This suggests that compounds that couple with a serotonergic component may be effective pharmacotherapies in the treatment of psychomotor stimulant abuse. This research was supported by NIDA NRS grant DA04849 to P.Z. Manderscheidt and NIDA grant DA04483 to R.A. Frank.

449.7
CAFFEINE AND NICOTINE DO NOT MAINTAIN SELF-ADMINISTRATION IN RATS. J. Robinson*, S.L. Varga, J. Broadbent, and S.I. Dworkin. Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

Although caffeine (CAF) and nicotine (NIC) are widely used, their reinforcing characteristics remain obscure. Attempts were made to assess the reinforcing function of these compounds. Six male Fischer 344 rats were implanted with indwelling jugular catheters and then trained on a fixed ratio (FR) schedule of food presentation. Animals were then allowed access to CAF (0.25 or 0.5 mg/ml) or NIC (10 µg/ml) on a FR 1 schedule. In a different paradigm, one rat was given access to food, water, and CAF (0.25 mg/ml) 24 hr/day on a concurrent FR 1, FR 3 schedule, maintained with CAF at the single-lever chamber. Results indicated a relatively high rate of responding following food-training, which substantially declined with time. CAF (0.25 mg/ml) infusions declined by approx. 75% in the second month as compared with the first. Increasing the dose (0.5 mg/ml) did not change response rates. Under the concurrent schedule only food and water maintained responding. These data indicate that CAF does not maintain reliable self-administration (SA) in rats, even when the animals were trained with food. It was found previously (Dworkin et al., Soc. Neurosci. Abs. 17, 425, 1991) that NIC did not engender and maintain SA which was delivered over a 5.6 sec time period. We examined if infusion duration could affect NIC SA. Rats allowed access to NIC did not attain reliable SA when infusions were delivered over 0.9 sec. These data confirm that NIC and CAF are not potent reinforcers in Fischer rats. 449.9
THE EFFECTS OF CAFFEINE ON CORTICAL AROUSAL. D.Velkonja, S.J. Segalowitz and S. Reins*, Dept. of Psychology, University of Waterloo, Waterloo, ONT, N2L 3G1 and Brock University, St. Catharines, ONT, L2S 3A1.

Individual differences in reactivity and tolerance to caffeine are predicted to play a critical role in cortical arousal, as measured by electrophysiological variables. Furthermore, it is believed that caffeine will have time-based effects on cortical arousal varying with daily patterns of activity and caffeine consumption. This hypothesis was tested in 20 first year university undergraduate students using a within-subjects design. Each subject participated in two test sessions, in which they consumed one half cup of naturally decaffeinated coffee or one containing powdered caffeine in doses based on the subjects body weight (3mg/kg). Subjects were blind to experimental conditions. They proceeded to complete questionnaires related to their reactivity and tolerance to caffeine, and whether they were morning or evening types. One half hour elapsed between their consumption of the beverage and EEG testing. Subject's reaction time performance, auditory P300s and visual CNVs were compared on the two occasions. Prior to their date of testing subjects were required to monitor their caffeine consumption over a two-week period in order to determine their habituation to caffeine. A general increase in the amplitude of both P300, and CNV was observed, as well as a decrease in reaction time variability, which we expect will be related to individual differences in the CNV. We also predict that an increase in the CNV will also be related to an increase in caffeine consumption. It is expected that caffeine consumers who are expected to have a higher tolerance and lower reactivity to the caffeine, and an increase in a P3 amplitude jitter in non-habitual caffeine consumers who are expected to have higher tolerance and higher reactivity to the caffeine.

449.10

Phencyclidine (PCP) has been considered to induce a schizophrenia-like psychosis in human and behavioral disturbances in experimental animals by blocking the N-methyl-D-aspartate (NMDA) receptor. This study was performed to elucidate the effect of intercerebrovascular (i.c.v.) infusion of different stereoisomers of PCP on NMDA receptor on PCP-induced hyperactivity in the rat. Drugs were infused 10min before PCP administration (10mg/Kg, intraperitoneally). The locomotor activity was evaluated based on the method of Schoen (1979) with minor modifications. In some experiments, the locomotor activity was also quantitated automatically with Animex-Auto (Muranoichi-kikai Co., Japan). D-Alanine and D-serine significantly reduced the PCP-induced hyperactivity in a dose dependent manner. In contrast, the L-isomers of these amino acids were much less effective in antagonizing the hyperactivity induced by PCP. The stereoisomer of the D-enantiomer, that the antagonism of behavioral effects of PCP may be due to activation of the striamo-thalamo-cortical (STC) circuit. These findings that the stimulation of the allatostatin regulation site of the STC system might play a therapeutic effect in schizophrenia attributed to PCP and schizophrenia.

AR 72205.

Phencyclidine (PCP;angel dust) is a drug of abuse known to produce a behavioral state in humans resembling schizophrenia/psychosis. PCP is a noncompetitive NMDA receptor antagonist, and produces a variety of behavior in rats including circling, however, the behavioral effects of other noncompetitive NMDA receptor antagonists such as (+) MK-801 or TCP are still being elucidated. Here, adult female rats were dosed with PCP (10 mg/kg,ip), (+) MK-801 (0.1 mg/kg,ip) or TCP (1 mg/kg,ip) on two different occasions, one day before sacrifice to determine monoamine levels by HFLC/EC. Animals injected with PCP, (+) MK-801 or TCP showed a preference to turn to the left (65%, 72%, 62% respectively). PCP and (+) MK-801 also produced a significant increase of DOPAC and HVA in whole caudate nucleus (CN), nucleus accumbens and olfactory tubercles in both sides of the brain. Further dissection of the CN into medioventral and dorsolateral revealed that HVA was increased bilaterally except in globus pallidus where we found significant increases in dopamine (DA), DOPAC and HVA only on the left side after PCP and (+) MK-801 administration. However, after TCP treatment the effects were similar but did not reach statistically significant levels. These data suggest that PCP, (+) MK-801 and TCP produce a greater preference to turn left than right, a finding similar to that found in human psychoses. Furthermore, it is possible that this preference is due to the high concentrations of DA, DOPAC and HVA found in the left side of the globus pallidus after drug administration.

549.13

Sensation-seeking is a human personality trait associated with drug use, compulsive sexual practices, and a history of the seeking situations commonly considered stressful. A common feature of such situations is activation of the hypothalamus-pituitary-adrenal axis leading to corticosterone secretion. Since, glucocorticoids have euphoric effects in certain individuals and increase the reinforcing properties of drugs in animals, a higher sensitivity to the reinforcing effects of glucocorticoids might be a biological basis for sensation-seeking. In order to answer this question, we have studied the reinforcing properties of corticosterone, by means of intravenous self-administration, and the effects of this hormone on the mesolimbic dopaminergic (DA) system, by means of in vivo microdialysis. The DA system has already been studied because it is considered the main substrate of drug reinforcement. The experiments show that: i) corticosterone, in the range of stress levels, induces intravenous self-administration and increases DA release in the nucleus accumbens; ii) animals that, similar to high sensation-seekers, are more responsive to novelty and more prone to self-administer drugs, are also more sensitive to the reinforcing effect of corticosterone and have a higher corticosterone-induced dopamine release in the n. accumbens. These results suggest that different sensitivity to corticosterone's reinforcing effects may be a biological basis for the individual differences associated with sensation-seeking. Furthermore, individual differences in corticosterone-induced dopamine release may be the neural substrate of different sensitivity to corticosterone's reinforcing properties. These findings provide new insights on the physiology of glucocorticoids and, since these hormones influence drug self-administration as well as immune functions, these results may also be relevant to clinical practice.

SIGMA-INDUCED INHIBITION OF ADRENOMEDULLARY [3H]NA RECEPTER REUPTAKE IS NOT MEDIATED BY THE ANTIDEPRESSANT SITE BOUND BY [3H]DESIPRamine. C. Rogers and S. Lemaire, University of Ottawa, Ottawa, Ontario Canada K1H 8M5. The ability of several a ligands to inhibit uptake of noradrenaline has been examined previously (Massamiri, 1991; Rogers, 1991). At present, the mechanism(s) involved in this inhibition are unknown. Evidence has been presented to suggest that a ligands block noradrenaline reuptake by interaction with [3H]desipramine ([3H]DMI) receptors. The purpose of this investigation was to determine the degree of interaction of a ligands with [3H]DMI binding sites in bovine adren medulla. [3H]DMI binding was dependent upon Na+, protein concentration, time, temperature, and was saturable (Kd=2.87 nM Bmax=216 pmol/g protein). [3H]DMI binding was displaced by a ligands, although the rank order of potency of these ligands did not parallel that found in [3H]NA reuptake assays in this tissue. This data suggests that a ligands and desipramine inhibit [3H]NA reuptake through distinct receptors in bovine adren medulla. This work was supported by the HSFG, C.R. is a HSFG scholar.

BASAL DOPAMINE LEVELS IN THE NUCLEUS ACCUMBENS ARE DECREASED DURING COCAINE WITHDRAWAL AFTER UNLIMITED-ACCESS COCAINE SELF-ADMINISTRATION. E. Wills*, A. Markou, and G.P. Koob. Department of Neuropharmacology, Research Triangle Institute, La Jolla, CA 92037.

Clinical observations indicate that chronic cocaine abuse is followed by a withdrawal syndrome resembling an episode of major depression. As analogous to the withdrawal syndrome associated with "post-cocaine depression" characterized by significant elevations in brain reward thresholds, a decrease in dopamine levels has recently been reported in rats administered the NAC during periods of intravenous cocaine self-administration (Markou & Koob, Neuropharmacology, 1991). This withdrawal-associated reward deficit may involve a specific impairment in the ability to experience anhedonia in the region of the nucleus accumbens (NAC). To test this hypothesis we have monitored extracellular DA levels in the NAC by intracranial microdialysis in awake rats following dopamine withdrawal from cocaine after periods of unlimited-access, intravenous self-administration (9.5 to 21.75 hours). Cocaine withdrawal was associated with significant reductions in basal DA overflow that persisted up to 10 hours. Maximal inhibition of DA release (Mean ± S.E.M.: 66.15 ± 3.33 percent of basal levels) was observed at 4-6 hours after termination of cocaine self-administration and was positively correlated (r = 0.935) with the duration of the preceding self-administration episode. The results suggest that suppression of basal DA release in the NAC is a direct adaptive change in chronic cocaine exposure and may constitute an important neurochemical correlate of the cocaine withdrawal syndrome as measured by brain stimulation reward thresholds.

INCREASES IN EXTRACELLULAR BIgenic AMINE CONCENTRATIONS FOLLOWING COCAINE OR HEROIN SELF-ADMINISTRATION S.E. Hembry*, T.J. Martin, C.C., B. O'Dowd, & J.E. Smith. Center for Neurobiology of Drug Abuse, Dept. of Phys./Pharm., Bowman Gray School of Medicine, Wata Forest Univ., Winston-Salem, NC 27157.

Nuclear accumbens dopamine is believed to mediate the reinforcing effects of psychotropic compounds. Cocaine self-administration increases extracellular DA levels in the NAC in a dose-dependent manner (Petit & Justice, 1989, PIB, 34, 859-904). Response-independent administration of opioids enhances extracellular dopamine concentrations although this effect has not been demonstrated during response-dependent administration. The present study was initiated to determine whether extracellular dopamine concentrations in the NAC are elevated during heroin self-administration in a similar manner to that observed during cocaine self-administration. Responding was maintained by either intravenous infusion of heroin (60 or 1000 μg/kg/injection) or opioids (3 mg/kg/injection). Following a minimum of twenty days stable responding, microdialysis probes were inserted through previously implanted cannula. The following days, control samples were collected for at least five minutes throughout the entire session. HPLC coupled to electrochemical or ultraviolet detection was used to assay the dialysate samples for catecholamines and cocaine, respectively. Cocaine self-administration increased extracellular NACC dopamine and serotonin although metabolite concentrations did not significantly differ from baseline.

In addition, preliminary results suggest that heroin self-administration produced significant elevations in dopamine comparable to the relative increase observed with cocaine. (Supported in part by USPHS Research Grants DA-01819, DA-03628, and DA-06634)

EFFECTS OF DAILY MULTIPLE INJECTIONS OF COCAINE ON THE DOPAMINERGIC SYSTEMS IN RATS: AN IN VIVO MICRODIALYSIS STUDY. E. Gardner and M.J. Koob, The Rockefeller University, New York, NY 10021.

The aim of this study was to investigate the response of the dopaminergic system to a pattern of drug administration that mimics cocaine users' binges. Rats received three i.p. injections of cocaine (3 x 10 mg/kg) or saline (3 x 1 ml/kg) over two-hour periods. On day 14, cocaine was injected for the first time and the tissue continued to receive cocaine injections and the time course of dopamine (DA) and its metabolites were measured in the nucleus accumbens and in the striatum using in vivo microdialysis. In both regions extracellular DA basal levels were not significantly different in saline versus cocaine, 0.060 nM versus 2.56 ± 0.53 nM in the nucleus accumbens, p<0.06, 9.32 ± 2.4 nM versus 7.11 ± 1.42 nM in the striatum, p<0.02; n=5).

Acute cocaine administration led to an increase in extracellular DA levels in both regions that peaked after the second cocaine injection (3.5 times greater than basal levels in the nucleus accumbens, 3 times in the striatum). Chronic treatment reversed the pattern observed in the acute condition. The peak in DA levels was achieved only after the third injection, and in the striatum, in contrast to the nucleus accumbens, the extracellular DA concentrations were still elevated at the maximum acute challenge. The present results differ from the conclusions of studies involving a single daily cocaine injection where DA levels were reported by chronic exposure. Therefore the pattern of cocaine administration appears to be a major factor in the response of the dopaminergic systems. (Supported by the Aaron Diamond Foundation and DA-P50-06130)

450.4

REVERSE TOLERANCE OF SEROTONIN AND DOPAMINE IN THE NUCLEUS ACCUMBENS AND DORSAL RAPHE NUCLEUS INDUCED BY CHRONIC COCAINE TREATMENT. L.H. Parsons* and J.B. Justice, Jr., Dept. of Chemistry, Emory University, Atlanta, GA 30322.

The effect of chronic cocaine administration on the response to a cocaine challenge was examined for serotonin (5-HT) and dopamine (DA) in the nucleus accumbens (N ACC) and dorsal raphé nucleus (DRN) of the rat using a dual probe in vivo microdialysis procedure. Rats were treated for ten days with cocaine (20 mg/kg, ip; n=5) or saline (0.9% saline, 10 ml/kg, ip; n=4). and were euthanized 10 mg/kg ip. injection of cocaine on the test day (day 11). Based on maximum percent increases in cocaine challenge, DA doses were chosen to induce a similar acute response to cocaine in both the N ACC and DRN, though there was no significant interaction between region and degree of sensitization. 5-HT was also significantly sensitized in both regions of chronically cocaine treated rats. A significant interaction between region and degree of sensitization, indicating that the cell body region produced greater 5-HT sensitization than the N ACC terminal field. Both the N ACC and DRN were obtained from the same probe in a given region for each animal. DA-5HT area under the curve (AUC) ratios were used to compare the sensitization of DA relative to 5-HT. In both regions there were reduced DA-5HT AUC ratios in chronic as compared with acute animals, though this reduction reached significance only in the DRN. This suggests that the 5-HT system is relatively more sensitive to chronic cocaine administration than the DA system.

Additionally, the interaction between 5-HT and DA was assessed by adding various concentrations of 5-HT to the perfusate of a microdialysis probe in the N ACC and observing the concurrent change in dopamine. DA-5HT was found to concentration-dependently increase dopamine, with peroxide 5-HT concentration-borne (0-400 nM). These concentrations were found to be effective in decreasing the effectiveness by the relatively non-specific 5-HT antagonist pindolol, the specific 5-HT2 antagonist LY 53877, and the relatively specific 5-HT3 antagonist MDL 7222. These results indicate that 5-HT4 enhances extracellular DA levels in the N ACC.

450.6

60-DAY CHRONIC COCAINE TREATMENT DESENSITIZES EXTRA Cellular DOPAMINE OVERFLOW IN CAUDATE-PUTEAMEN BUT NOT IN NUCLEUS ACCUMBENS. J. Chen*, R. Marmor, E. Rossebuen, W. Parsons and E.L. Gardner, Departments of Pharmacology and Neuroscience, Albert Einstein College of Medicine, New York, NY 10461.

Rats with in vivo brain microdialysis probes in the nucleus accumbens (Acc) and caudate-putamen (Cpu) were treated with cocaine (10 mg/kg/day) for 5, 30 and 60 days. 24 hrs after the last cocaine injection, rats of each group were challenged with the same dose of cocaine and extracellular dopamine (DA) overflow in Acc and Cpu measured by in vivo microdialysis. In both Acc and Cpu, biochemical sensitization of extracellular DA overflow was not seen in rats given repeated cocaine for 5 days. In contrast, 30 days of chronic cocaine did robustly augment the enhanced extracellular DA overflow produced by the challenge dose of cocaine. In animals given 60 days of chronic cocaine, striking decreases in DA overflow in both Acc and Cpu manifested themselves. In Acc, the augmented extracellular DA overflow to cocaine challenge seen after 60 days of cocaine was identical to that seen after 30 days of cocaine. In Cpu, after 60 days of chronic cocaine, the enhanced extracellular DA overflow produced by cocaine challenge was identical to that seen with no prior cocaine treatment. Thus, in Acc neurochemical sensitization to repeated cocaine occurred, and the sensitization maintains itself, while in Cpu cocaine sensitization occurs, but then some compensatory mechanism comes into play to produce a neurochemical desensitization to cocaine. This suggests that cellular mechanisms underlying cocaine sensitization differ between the mesolimbic and mesostriatal DA systems. (Supported by a research grant from the Aaron Diamond Foundation.)

450.8

In vivo electrochemistry was used to investigate the mechanisms contributing to the clearance of locally-applied dopamine (DA) in dorsal striatum and nucleus accumbens of urethane-anesthetized rats. Chronic in vivo neurotransmitter and dopamine transporter (DAT) noramperometric recordings were continuously made at 5 Hz using Nafion-coated carbon fiber microdisc. Chronic administration of cocaine (12-100 nl, 200 μM barrel concentration) was pressure ejected at 5-s intervals from a microcapillary positioned 280 ± 30 μm from the electrode, transistors and reproduced increases in DA (0.5-4 μM) were detected. Substitution of α-methyl-DA, which is a substrate for the DA transporter but not for monoamine oxidase, for DA in the microcapillary did not substantially alter the time course of the resulting signals. These results indicate that metabolism of locally-applied DA to dihydroxyphenylacetic acid is not responsible for the decline in the DA signal. Similarly, changing the applied oxidation potential from 0.45V to 0.80V, which allows detection of 3-methoxytyramine formed from DA via catechol-O-methyltransferase, did not affect the signal amplitude and time course. In contrast, local application of the DA uptake inhibitor cocaine or nomifensine (800 μM barrel concentration, applied 20-60 sec before DA) significantly increased the amplitude and time course of the DA signals in both brain regions, a result similar to that observed with systemic administration of cocaine. These results indicate that uptake of DA by the neuronal DA transporter, rather than DA metabolism, is the major mechanism for clearing locally-applied DA from the extracellular space. (Supported by USPHS DA04216, DA0174 & NS08199 and NSF BNS-9110308)
450.9
We investigated whether differential changes in the dopamine (DA) transporters in the nucleus accumbens (NAc) of a parametrically trained and doral striatum could be involved with cocaine-induced behavioral sensitization by monitoring the clearance of locally applied DA in anesthetized rats using in vivo electronbeam autoradiography. We given daily injections of cocaine (10 mg/kg i.p.) or saline for seven days, withdrawn for seven days, and prepared for electron-beam recording. When a fixed amount of DA (2.5-10 fmol) was pressure-ejected at 5 min intervals from a micropipette positioned 270 ± 30 μm from the recording electrode, transient and reproducible decrease in extracellular DA was detected. In response to a challenge injection of cocaine (10 mg/kg i.p.), the signals in the NAc of the cocaine-treated rats became prolonged and the clearance rate of DA decreased, indicating significant inhibition of the DA transporter. In contrast, in the striatum there was a transient increase in the DA clearance rate. In saline-treated animals, the signals from both regions were similar to signals from untreated animals given an acute injection of cocaine (10 mg/kg i.p.) or saline. Quantitative autoradiography with 3H-mazindol revealed that the affinity of the DA transporter for cocaine and the density of binding sites were similar in cocaine- and saline-treated rats. Behaviorally, 50% of the cocaine-treated animals were sensitized; however, both sensitized and unsensitized animals displayed similar changes in DA clearance rate. Nonetheless, the observed decrease in DA clearance rate in the NAc of the cocaine-treated rats is consistent with increased DA transmission in response to cocaine challenge. Supported by USPHS DA04216, NS0199 & NSF BNS-910308.

450.11
EFFECTS OF INTRA-ACCUMBENS AND INTRA-AMYGDALOID SCH23390 ON INTRAVENOUS COCAINE SELF-ADMINISTRATION IN THE RAT. A. McGregor and D.C.S. Boulton*. Life Sciences Research Centre, Carleton University, Ottawa, K1S 5B6, Canada.
The nucleus accumbens (NAc) and its heavy dopaminergic [DA] innervation are generally considered to be a neural substrate pivotal in mediating the reinforcing effects of psychostimulants. Drugs, however, the amygdaloid complex is another neural site receiving a substantial DA innervation that has been relatively overlooked with respect to mechanisms of drug abuse. This work investigated the possible involvement of the amygdaloid complex (AMY) in cocaine self-administration (0.6mg/kg/Inj) under a fixed ratio schedule (FR1) of retrograde compared to that of the NAc. Bilateral injections of the D1 antagonist, SCH23390, were made directly into the NAc or AMY. The results of both the significant close dependent (1μg] - 2.0μg/side/0.5μl) Increase in the rate of self-administration was produced, demonstrating that both sites make a contribution to cocaine reinforcement mechanisms. In addition however, blockade of the D1 receptor within the AMY produced a two-fold increase in the rate of cocaine intake with respect to that produced within the NAc. These results suggest that in addition to the NAc, the AMY also has a contribution to make to cocaine reinforcement mechanisms. (Supported by the MRC of Canada).

450.13
Using quantitative autoradiography, the influence of unlimited cocaine self-administration (28 weeks on binding to the dopane (DA) uptake) [3H]DA (12,935 displaced with 1 μM mazindol) and cocaine acceptor (10 nM [3H]WIN 35,428 displaced with 30 μM cocaine) sites in rat brain was examined. In cocaine in t.e. 100% selective on cocaine acceptor binding. [3H]WIN 35,428 to the DA transporter in striatum, n. accumbens (nacal, substantia nigra and ventro-lateral tegmental area) was unaltered relative to controls (n=5). However, specific binding of [3H]WIN 35,428 to the cocaine acceptor sites was significantly elevated (p<0.05) in striatum (+63%) and n. accumbens (+31%). Following 3 weeks withdrawal from unlimited cocaine self-administration specific binding of [3H]DA took 12,935 was unaltered whereas binding of [3H]WIN 35,428 was significantly reduced (p<0.05, n= in striatum (-93%), n. accumbens (-51%) and VTA (-26%). A unique observation of unaltered binding of [3H]WIN 12,935 3 weeks after the last administration of cocaine, suggests that there is no permanent degeneration of dopamine neurons. The present study demonstrates that cocaine self-administration produced an increase in the density of the cocaine acceptor binding site which was retained following withdrawal and suggests that the cocaine acceptor binding site is not simply a functional expression of DA or to the presence and subsequent absence of cocaine, which acts like an antagonist at the DA transporter. Altered affinity/density of the cocaine acceptor could be important to establish whether the functional significance of such changes following chronic cocaine exposure and during the course of withdrawal. (Supported by NIDA grant DA07182.)

EFFECTS OF SPECIFIC BRAIN AMINE DEPLETING LESIONS ON COCAINE-INDUCED CONDITIONED INCREASES IN LOMOCOMUTER OUTPUT. A. Pett*, D.N. Thomas and R.M. Post*. Biological Psychiatry Branch, NIH, Bldg. 10, Room 31222, Bethesda, MD 20892.
Environmental stimuli paired with cocaine acquire the ability to elicit increases in locomotor behaviour and potentiate the actions of cocaine during subsequent presentations. We mixed a single and effective dose of the neuronal substrates which underlie the conditioned effects of cocaine. On DAY 1, rats were injected with 3.5mg/kg of cocaine (PAIRED) or saline (SINGLE) followed by injection of saline the next day. On DAY 2, all rats were injected with saline prior to cocaine injection. In the locomotor chamber for 30min. The following return to the home cage animals that were injected with 30mg/kg cocaine, while those that were not were injected with saline. On DAY 2, all rats were injected with 30mg/kg cocaine prior to placement in the locomotor chamber for 30min. The locomotor activity activity is revealed by significant increases in locomotor output of the PAIRED versus the UNPAIRED group on DAY 2. We have previously found that 5-OHDA lesions of the nucleus accumbens prevent the development of such conditioning with cocaine. The purpose of these studies was to evaluate the role of the n. accumbens and dorsal raphe with 5-OHDA or in the median and doral raphe with 5-HT. Controls groups were sham lesioned. One week following surgery, the animals were conditioned and tested as described above. Neither frontal cortex nor striatal lesions had an effect on the acquisition of conditioned locomotor activity, although the striatal lesion did seem to attenuate the conditioned stereotypy. Lesions of the locus coeruleus or raphe had no effect on cocaine-induced conditioning. These findings suggest that the critical dopaminergic neural substrates for cocaine-induced conditioned locomotor behaviour are the amygdala and the nucleus accumbens. Serotonergic and noradrenergic pathways do not appear to play a role in cocaine-induced conditioning in our paradigm.

One model used to examine individual differences in drug preference uses the inbred Fischer 344 and Lewis rat strains, which show differential oral self-administration of carbohydrates, fats, proteins, and alcohol. We have shown inherent biochemical differences in reward-implicated sites between these strains, with an upregulated dopamine (DA) system in the nucleus accumbens and the ventral tegmental area (VTA) of the drug-prefering Lewis rat (Beltner-Johnson et al., Brain Res. 681, 147-191; Gultart et al., proc. in press). We have also demonstrated strain differences in other drug-related behaviors: compared to Fischer rat, Lewis rat shows greater locomotor sensitization following amphetamine and cocaine, and more readily acquire intravenous cocaine self-administration.
We have also begun to examine similar individual differences in drug sensitivity. The role of drug self-administration in these results was reviewed. Rats were assessed for locomotor activity in a novel environment, and the highest (HR) and lowest (LR) responders were selected for biochemical analysis. Compared to HR rats, LR rats showed higher levels of DA-dependent protein kinase in the NAc, and of TH in the VTA. We are currently testing HR and LR rats for the acquisition of cocaine self-administration.
Such integrated biochemical and behavioral assessments should enable the identification of some of the biochemical factors that contribute to individual genetic vulnerability to drug addiction.

Withdrawal From Continuous or Intermittent Cocaine: Dopamine Autoreceptor Sensitivity. KUNG, G.R., KUHN, C. AND ELLINWOOD, E.H.* JR.
Previous research in this laboratory indicates that daily intermittent injections of cocaine result in an enhanced dopamine (DA) response in caudate-putamen brain slices, to different cocaine concentrations. In contrast, the continuous infusion of equivalent daily doses of cocaine result in an attenuated DA response in caudate-putamen brain slices, to different cocaine concentrations. One possible mechanism mediating these effects is changes in DA autoreceptor sensitivity. Daily, intermittent cocaine injections may result in DA autoreceptor desensitization, while the continuous infusion of cocaine may result in DA autoreceptor supersensitivity. The present experiment examined this possibility. The animals were pretreated with 40 mg/kg/day of cocaine for 14 days by either subcutaneous injections or continuous infusion by osmotic minipumps. The rats were then withdrawn from the treatment regimen for 5 days. After 5 days, the rats were sacrificed, and caudate-putamen slices quickly obtained. The slices were then placed in glass perfusion chamber, and superfused with artificial CSF for 60 minutes. At the end of this period, the slices were electrically stimulated with a train of supramaximal, unipolar, rectangular waves (20 ma, 2 msec) at 3 Hz (50 pulses). Ten 2 min samples were collected. This electrical stimulation was given 60 minutes later (S2). However, 30 min prior to the S2 period, the brain slices were perfused with either 0.1 μM DA or an extracellular dopamine antagonist. The data were analyzed by determining the [S2/S1] ratio for different superfide concentrations. This research was supported by NIDA grant DA06360, and NIH grant T32: MH51717.

DOSE-DEPENDENT CHANGES IN THE RAT DOPAMINERGIC RECEPTOR SYSTEM AFTER CHRONIC ADMINISTRATION OF COCAINE. W.W. Albrecht*†, H. Narang, C. Johanson*, & T. Psychiatry Research Institute, Fargo, ND 58103; †Medical School of Zulia, Maracaibo, Venezuela.

We have previously reported time-dependent alterations in the rat dopaminergic receptor system after fixed doses of cocaine (15.0 mg/kg, i.p.). In the present study, dose-dependent effects of cocaine on the dopaminergic system were determined. Rats were injected with cocaine (5.0, 10.0, 15.0, 20.0, and 25.0 mg/kg, i.p., b.i.d.) or saline for a 21 day period. [3H]Cocaine and [3H]SN23983 binding in striatum and cortex from animals injected with 10.0 and 15.0 mg/kg were significantly higher than the control animals. [3H]DPFC binding in striatal tissue was significantly increased in animals injected with 10.0 and 15.0 mg/kg of cocaine; however, in cortices of these animals, significant changes were seen with only 15.0 mg/kg of cocaine. Changes in [3H]halocaine binding in these tissues were reversed by time. These results indicate that chronic exposure to cocaine produces a dose-dependent upregulation in cortical and striatal D1 and D2-uptake sites.

450.17

It is well established that intermittent schedules of psychostimulants produce behavioral sensitization while continuous regimens tend to cause tolerance. In-vivo microdialysis was utilized to examine extracellular striatal dopamine and monoamine metabolite (DOPAC, HVA, 5-HIAA) levels at different time periods in cocaine and non-cocaine animals. Male Sprague-Dawley rats were implanted with subcutaneous cocaine pellets which release approximately 105mg of cocaine freebase over 5 days. Rats were sampled before the beginning cocaine administration, on day 5 of cocaine, 24 hours post cocaine or 7 days post cocaine. Time-response relationships were established by infusion of quinpirole (QP) through the dialysis probe (10^-7, 10^-6, 10^-5 M). DA levels decreased in dose response fashion with no group differences among animals on day 5. Time-dependent changes were observed in the striatum or amygdala. These structures were perfused (0.5 uL/min) with 4mm probes during haloperidol induced DA release (1 mg/kg, I.P., n = 8). The dose-dependent upregulation in cortical and striatal D1 and D2-uptake sites.

QUANTITATIVE MICRODIALYSIS UNDER TRANSIENT CONDITIONS. B.J. Olsen* and J.B. Justice Jr., Dept. of Chemistry, Atlanta, GA 30332.

A method based on the point of no net flux (Liangard et al., Am. J. Physiol. 256:E250-E255, 1988) has been developed for quantitative microdialysis under transient conditions. The method uses a relationship between the number of pulses per period of 10-20 or 40 min dopamine (DA) at 6.6 ml/min. Dialysate was collected and measured for time intervals prior to and during drug administration. Data from the four groups were divided by their respective DA time course and used to determine the in vivo recovery and the extracellular concentration of DA as a function of time. It was hypothesized that changes in uptake and release would change probe recovery. No change in recovery was observed in the striatum with 4 probes during haloperidol induced DA release (1 mg/kg, I.P., n = 6 per group). However, it is possible that the already high baseline recovery (78%) masked other evident changes. In order to examine the effect of uptake inhibition on recovery, cocaine (20 mg/kg, I.P., n = 16 per group) was administered and dialysate was collected using 2mm probes in the nucleus accumbens. Recovery decreased from 98% at baseline to 25% twenty minutes following drug administration and returned to 48% seventy minutes following drug administration. A similar recovery was observed in extracellular DA than was evident in dialysate. These results suggest that probe recovery is dependent on active neurotransmitter properties such as uptake and release (Parsons et al., J. Neurosci. Meth., 40:131-137, 1991). The present method appears useful for quantitatively characterizing the pharmacology of neurotransmitter systems.

THE EFFECTS OF DISCRETE LESIONS OF THE SUB-COMMISSURAL VENTRAL PALLIDUM ON COCAINE SELF-ADMINISTRATION IN THE RAT. J. Hubbell and G.G. Koob. The Yerkes Regional Primate Research Institute, La Jolla, CA 92037.

The involvement of the nucleus accumbens in mediating cocaine reinforcement has been largely established. Previous work from our laboratory has demonstrated that ibotenic acid lesions of one of the output regions or the nucleus accumbens sub-lenticular substantia innominata, produced significant decreases in the highest ratio obtained in rats self-administering (SA) cocaine. In this study, we investigated the importance of another accumbal lesion, the sub-commissural ventral pallidum, in mediating the reinforcement properties of cocaine in the rat. Animals were trained to self-administer cocaine (0.75 mg/kg i/v) via an intravenous catheter on a FR5 schedule of reinforcement. Subsequently, rats were either given bilateral i.p. injections (0.5 ?L per side) of ibotenic acid (10 ?g/ul lesion group) or vehicle (sham group) into the sub-commissural ventral pallidum. Five days post-lesion, cocaine SA on a FR5 schedule was resumed for three days. Next, a dose effect function was determined in one 3 hour session. A progressive ratio schedule in which the ratio requirement was increased after each reinforcement was also used. The lesion group showed a significant decrease in FR5 responding for cocaine five days after the lesion as compared to the sham group. While the lesion produced decreases in responding for cocaine at all doses, the rate of responding was inversely proportional to the dose. However, compared to sham animals, in the progressive ratio task, no effect was found in the total number of rewards or in the highest ratio obtained in lesioned rats. These results, taken together with our previous data, support the hypothesis that the region commonly called the ventral pallidum is a heterogeneous structure which may have an equally heterogeneous relationship with the nucleus accumbens. Further, these results suggest that within the ventral pallidum there are some areas that are more critically involved in cocaine reinforcement than others. Supported by NIDA grant DA04398.

Chronic administration of MPTP to adult marmosets induces alterations in brain monoamines, serotonergic, and peptide systems, but it is not known if MPTP can also produce neurotoxic effects on the developing brain. To study the possibility of MPTP to produce neurotoxic effects, we administered to two female marmosets who became pregnant. The monkeys received six injections, twice a week, during the whole gestational period, except for the last 15 days before term, when pregnancy was noticed. Baby marmosets (n=3) were sacrificed 3 months after birth and levels of dopaminergic (DA), 5-hydroxytryptaminergic (5-HT) and its metabolites, DopAC, HVA, 5-HIAA were determined in several brain regions compared to age-matched controls (n=6). Substance P (SP) content was measured in the basal ganglia by RIA. Significant reduction of DA and its metabolites, DopAC and HVA, was found in the caudate and putamen and n. accumbens of marmosets exposed “in utero” to MPTP, but not in other areas studied. In contrast to the extensive and severe 5-HT loss induced by chronic MPTP treatment of adult animals, no change in striatal 5-HT content was found in baby marmosets and only extrastriatal 5-HT systems were affected. A significant decrease in SP levels was observed in the n. nigra of baby marmosets. The results demonstrate that MPTP can cross the placenta and exert its neurotoxic effect on monoamine and peptide systems in the fetal brain of primates. These findings show the possibility of “in utero” lesion of several neurotransmitter systems in the marmoset brain and indicate that non-methylated neurons (as it is the case in the fetus) are also susceptible to MPTP. (Supported by EEC and JALS Fdn.)

The short term symptomatic improvement in Parkinson’s patients with Sinemet can be very dramatic. However, progressive increase in disability of some patients coupled with toxic side effects from toxic oxidation of L-dopa and dopamine suggested the possibility of L-dopa causing further deterioration of the disease. We tested the effects L-dopa and Sinemet on 6-OHDA induced implanted rats. L-dopa (344 mg/kg) was given 1 b.i.d. (50mg L-dopa equivalent/kg) for eight weeks into 12 Fisher 344 rats whose nigrostriatal system was partially lesioned with unilateral intra-nigral injection of 4 μL 6-hydroxydopamine. Substantia nigra demonstrated rotund response to amphetamine (5mg/kg), but not to amphetamine (0.25mg/kg). Saline injections were given b.i.d. to 11 control rats matched for the amphetamine induced rotation. The L-dopa group showed 38% reduction in amphetamine-induced rotation, whereas the control group showed no change from the baseline (p<0.05). The animals in either the total high affinity DA uptake sites or D1-receptors as measured by GBR and SCH23390 autoradiography. Spiperone D2-receptor showed a decreasing trend in the L-dopa treated group (p<0.05). The trunical and limb dystonia following L-dopa injection were also measured. No further progression of dystonia was observed throughout the duration of the experiment. Our results thus far suggest that this time course of L-dopa treatment does not appear to cause further decline in the nigrostriatal dopamine system in partially lesioned rats. Supported by grants from the UPF & NIH NS24032.

451.5 AKINESIA DURING DOPAMINE AGONIST INDUCED CIRCLING BEHAVIOR AFTER SEVERE UNILATERAL NEOBROSTRAL DOPAMINE DEPLETION IN RATS. D. Norton, T. Schallert*, and T.A. Jones. Neuroscience Inst and Dept. of Psychology, Univ. of Texas, Austin, TX 78712.

Circling behavior after unilateral 6-hydroxydopamine (6-OHDA)-induced neuronal dopamine (DA) depletion has been widely used as a model for screening anti-parkinsonian agents. However, the unilateral 6-OHDA model, as presently used, does not mirror one of the most debilitating symptoms of Parkinson’s disease: akinesia. During circling, all limbs make stepping movements, including the limbs contralateral to the lesioned hemisphere. Hence, this study used a novel behavioral test was used to isolate and compare stepping movements of the ipsilateral and contralateral limbs of rats with unilateral nigrostriatal DA depletion. We found that in the undrugged condition and under amphetamine, the ipsilateral (non-impaired) forelimb shifts the weight of the animal to a new location in space (DA-dependent stepping), whereas the contralateral forelimb makes only catch-up steps designed to re-establish support of the body weight (DA-independent stepping). When the contralateral forelimb is isolated so that it alone bears the weight of the animal, the hindquarters show typical stepping (ipsilateral and contralateral limbs off the ground), it is akinetic. Preliminary results indicate that when the depletion is severe, the DA agonist apomorphine causes contralateral circling in the ipsilateral limb, but does not reverse akinesia in the contralateral forelimb. The role of DA in movement initiation will be discussed in view of these data. (Supported by NS 23964.)

The study of moderate dopamine (DA) lesions in animals could serve as a model of the preclinical stage of Parkinson’s disease, both in the search for possible beneficial therapies and in understanding disease progression. Therefore, we studied asymmetries in turning and thigmotactic scanning in rats with unilateral injections of 6-OHDA into the substantia nigra and compared them with the degree of striatal DA depletion. Animals with severe lesions (<20% residual DA) showed spontaneous ipsiversive turning and more scanning with the side of the face ipsilateral to the lesion. These asymmetries were reversed by apomorphine. Animals with moderate depletions (20-65% DA) did not show spontaneous asymmetries in turning, but an ipsilateral asymmetry in scanning. Most important is that out of this group, animals with 45-65% residual DA levels showed ipsiversive turning and ipsilateral scanning under apomorphine. These results suggest that scanning is a more sensitive measure than turning for the detection of functional asymmetries after moderate striatal DA lesions. The ipsiversive asymmetries observed after apomorphine in animals with moderate depletions might be due to ipsilateral changes in self-regulatory mechanisms of the nigrostriatal DA system, such as in DA autoreceptors, which in turn might be related to compensatory mechanisms in the preclinical stage of Parkinson’s disease.

451.4 SUBTHALAMIC NUCLEUS ABLATION AS A METHOD FOR REDUCING APOMORPHINE-INDUCED ROTATIONAL BEHAVIOR IN 6-OHDA LESIONED RODENTS. B.H. Hallas*, R.M. Cebelanski, P. Jacobina, M.F. Zajankala, E. Fatemi. N.Y. College of Osteopathic Medicine, N.Y. N.Y. University, N.Y.

A rodent model for Parkinson’s Disease is the chemical lesion of the Substantia Nigra (SN) with 6-hydroxydopamine (6-OHDA). We studied the effects of following apomorphine administration, results in quantifiable rotational behavior. This study investigated the influence of the Subthalamic Nucleus (STN) on ipsilateral rotational behavior with 6-OHDA and induced to rotate with apomorphine. Adult rats received stereotaxic injections of 6-OHDA into the left SN. After 21 days, apomorphine was injected intra-peritoneally once a day for 14 additional days. Ten minutes after the injection, the number of rotations were counted for each animal over a period of 15 minutes. After establishment of the rotational baseline (at 14 days), the left STN was ablated by stereotaxic electrolytic lesions. Control animals received no STN ablation. All animals were then returned for rotational behavior as above after a recovery period of 14 days. It was found that the majority of the experimental animals demonstrated a significant reduction of rotational behavior compared to controls. However, four animals exhibited ipsilateral rotation following STN ablation (i.e. to the left). These animals were tested for 14 additional days and then received an electrolytic lesion to the contralateral (right) STN. After a second operation time these animals were retested for rotational behavior following apomorphine injection. It was found that these animals then demonstrated a significant decrease in rotational behavior. It can therefore be concluded that ablation of the STN ameliorates apomorphine-induced rotational behavior following 6-OHDA SN lesions possibly by reducing abnormally increased medial globus pallidus output.

In rodent and primate models of Parkinson’s disease, antagonists of the NMDA and AMPA subtypes of glutamate receptors have been shown to synergize with L-DOPA to reverse parkinsonian motor defects. In this study, we have used monoaminergic depleted rats to examine the antiparkinsonian potential of remacemide (Fisons), an anticonvulsant with activity at the NMDA receptor ion channel. Male Sprague-Dawley rats (125-150 g) were rendered akinetic by administration of reserpine (5 mg/kg, i.p.) 24 h prior to testing. Motor activity was quantified using cages equipped with infrared sensor beams in reserptized rats. L-DOPA increased horizontal locomotor activity, while substantial co-administration with remacemide (5-40 mg/kg, p.o.) there was a dose-dependent increase in horizontal locomotor activity unlike MX-801, remacemide does not produce locomotor stimulatory effects. Moreover, remacemide potentiates the effects of L-DOPA over a broad dose range, in contrast to MK-801 and CPP. (This work was supported, in part, by the Hope Geoghegan Fund and the Davenport-Hatch Foundation.)

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

The extent and status of a unilateral lesion of the nigrostriatal dopamine (DA) system has typically been assessed by quantifying rotational asymmetry in response to DA agonist administration. Since agonists-induced, whose mechanism is still obscure, may not be a good behavioral index of parkinsonism, particularly in monkeys and humans, we examined the extent to which the status of volitional motor function, perhaps a better index of parkinsonism in monkeys, and rotational asymmetry coincide. In particular, we examined whether rotational asymmetry, a metabolically simple behavioral index, could accurately reflect the functional status of hemi-parkinsonian monkeys. Four male rhesus monkeys (approx. 4 yrs. old) trained to perform a series of tasks under both base line and naloxone conditions, were trained to show a consistent contralateral rotation to a specific task, a condition of a double simulation, and lateralized attention (i.e., response to double simultaneous stimulation, impos to lateralized moving stimuli, and lateralized reward retrieval). Animals were then made hemi-parkinsonian by intracarotid injection of MPTP (25 mg/kg) 2 and re-tested on the above mentioned tasks over the next year. Within the first 6 months after lesioning, animals showed dose-dependent rotational asymmetry is apomorphine or DA agonist N0923 stimulation and significant unilateral impairment in motor function (with the use of the limb contralateral to their lesion) and amnesic abilities (assessed with the limb ipsilateral to their lesion). Six to 12 months after lesioning, 3 animals showed significant improvement in performance of volitional motor tasks and all monkeys showed distinct reversal of at least some of their initial lateralized attention deficits. Despite this behavioral improvement, rotational asymmetry in response to dopamine agonists was still intact and in many cases more than when the animals were behaviourally impaired. These results suggest that over time, functional improvement can occur in hemi-parkinsonian monkeys and that rotational asymmetry may not be a good index of the functional status of the substantia nigra dopamine system in the monkey. Supported by Whitby Research, Inc. and NIH 46531.

GM1 has been reported to protect pigmented neurons of substantia nigra from MPTT lesion. We evaluated behavioral effects of GM1 treatment in 3 Cebus apella with a persistent hemiparkinsonian syndrome (Pathology). In lieu of GM1 (5mg/kg) p.o. daily 75 days while control monkeys (n=22 months of an intracarotid infusion of MPTP-HCl (1.2mg/kg)). MPTT treated and normal monkeys (2-4kg, 13-16 years) were trained in a primate chair to solve motor-cognitive tests. Normal animals covered in 2-3 sessions the 3 levels, while manual preferred between tests MPTT monkeys could not resolve level 2 or 3. The hemiparkinsonian monkeys received 20 daily saline injections or GMFI (5mg/kg) daily for 28 days, ongoing evaluated as (CB-9) in a primate chair weekly. After 3 weeks of saline or GM1, circling activity was tested before and after a dopamine administration (0.4mg/kg). During saline or GM1 treatment the animals did not improve their performance and the apc tests did not reveal changes in circling behavior. At present time we are conducting a follow up GM1 treatment. Supported by: CONICET, CERES, CEMIC, Petrolera Argentina S Jorge.

U-91356A is a novel dopamine agonist, (5S)/(propylamino)-5,6-dihydrop-4(1H)-imidazol-4(5,1-q)-quinolin-2(1H)-one hydrochloride. In reserpina induced NJSA (Harlan CF 1 mice, U-91356A caused locomotor stimulation at 10 and 10 mg/kg p. Apomorphine HCl (apo) 6.5, 10 mg/kg), abate H-S (basal, (q)-quinoline HCl (q), and pergolide meylate (per) were also stimulated in reserpina mice, but bromocriptine meylate (brom) was not. In the same reserpina mice, U-91356A and its antagonisted apo-induced locomotor stimulation; bromo was slightly active while apo and per were inactive as antagonists. In normal, nonreserpina B6C3F1 mice (Harlan) all of the above compounds antagonized amphetamine. U-91356A was active orally and i.p. as well as p. i. In Sprague-Dawley (Charles River) rats with unilateral 6-OH dopam onine lesions of the substantia nigra, U-91356A caused centralrotational turning at 0.3 mg/kg and saline (0-10) and at 8 days post-treatment tested in a habituation-dishabitation paradigm. Two-3 minute presentations of the same stimulus (ovarclometrics) female (habituation) was followed by three-2 minute presentations using a different stimulus female (dishabituation) with an inter trial interval of 20 minutes. Investigation lines (± SEM in seconds) of saline animals decreased over the habituation trials (103 ± 10, 63 ± 10, 37 ± 9) while those of MPTT animals did not decrease until the third trial (95 ± 11, 85 ± 12, 43 ± 4). A clear dishabituation response from trial 3 to 4 was shown by saline (37 ± 9 to 72 ± 11) but not MPTT (43 ± 4 to 58 ± 9) animals. Treatment of MPTT animals with L-DOPA one hour prior to test (50 mg/kg, p.o) resulted in habituation (94 ± 8, 45 ± 8, 28 ± 4) and dishabituation (93 ± 10) scores which were similar to saline-treated animals. These results demonstrate that MPTT treatment disrupted initial habituation and dishabituation responses in male mice while treatment of MPTT with L-DOPA restored their responses to that observed in saline animals. Such findings suggest that administration of the dopaminergic neurotoxin MPTT impairs social memory/recognition processes, an effect which can be rectified with exogenous L-DOPA treatment.

U-91356A, (U-91, or (5S)/(propylamino)-5,6-dihydrop-4(1H)-imidazol-4(5,1-q)-quinolin-2(1H)-one hydrochloride) is a novel dopamine (DA) agonist that binds to both D2 (K1 = 1.3 nM) and D17A (K1 = 58 nM) receptors. U-91 did not bind at 1 uM to a variety of biochemical adrenergic, 5HT, cholinergic, DA, benzodiazipe line or opiate receptors. Bromocriptine, lisuride, and pergolide all had high binding affinities for several non-DA receptors. U-91 (ED50 = 22 ug/kg i.v.), bromocriptine (CB50 = 1804 ug/kg), pergolide (ED30 = 23 ug/kg) and lisuride (ED50 = 74 ug/kg) all depressed substantia nigra DA neuron firing, but this was complete only with U-91 cH. Higher U-91 doses depressed dornal raphe 5HT neurous (ED50 = 204 ug/kg). U-91 was orally available in rats (pov 6%) and monkeys (pov 28%). In MPTT-treated monkeys, U-91 successfully reversed parkinsonian symptoms both substanteaely (20 ug/kg) and orally (2 mg/kg), duration 7 hr. The data suggests that U-91's greater selectivity, efficacy and oral availability could provide a novel improved treatment for Parkinson's Disease.

451.12 THE EFFECT OF MPTT ± L-DOPA UPON SOCIAL MEMORY/RECOGNITION IN MICE. D.E. Plisak* and J. Kreuzberg. Department of Anatomy, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Retired breeder male CD-1 mice were treated with either MPTT (10 mg/kg p, cld, xid, N=10) or saline (N=10) and at 8 days post-treatment tested in a habituation-dishabitation paradigm. Three-2 minute presentations of the same stimulus (ovarclometrics) female (habituation) was followed by three-2 minute presentations using a different stimulus female (dishabituation) with an inter trial interval of 20 minutes. Investigation lines (± SEM in seconds) of saline animals decreased over the habituation trials (103 ± 10, 63 ± 10, 37 ± 9) while those of MPTT animals did not decrease until the third trial (95 ± 11, 85 ± 12, 43 ± 4). A clear dishabituation response from trial 3 to 4 was shown by saline (37 ± 9 to 72 ± 11) but not MPTT (43 ± 4 to 58 ± 9) animals. Treatment of MPTT animals with L-DOPA one hour prior to test (50 mg/kg, p.o) resulted in habituation (94 ± 8, 45 ± 8, 28 ± 4) and dishabituation (93 ± 10) scores which were similar to saline-treated animals. These results demonstrate that MPTT treatment disrupted initial habituation and dishabituation responses in male mice while treatment of MPTT with L-DOPA restored their responses to that observed in saline animals. Such findings suggest that administration of the dopaminergic neurotoxin MPTT impairs social memory/recognition processes, an effect which can be rectified with exogenous L-DOPA treatment.

A new method assessing the forelimb reaching capabilities of individual footpaws in the rat has recently been described (Montoya et al., J. Neurosci. Meth. 36:219-228, 1991). Using this test, Montoya et al. (1991) report that 6-OHDA-induced deficits that were reported by Montoya et al. who use 2 pellets/well. The present study was designed to determine whether the amount of food provided during training is a significant factor in reaching training. Two groups of normal rats (n=10) were trained for 5 consecutive days (15 min/day) with either 10 pellets or 2 pellets/well (80 total pellets vs. 16 total pellets) and then the conditions were crossed-over for training on days 6-10. Prior to training, both groups were reduced to <85% of pre-training body weight and maintained at this level by supplemental feeding when necessary. Rats given the opportunity to eat 80 pellets per session learned well and continued to improve performance when switched to 2 pellets/well, eventually consuming 75% of the pellets available. In contrast, the rats initially trained with 2 pellets/well are few pellets and never consumed more than 5% of the pellets even though they had access to 80 pellets on days 6-10. In addition, the group which originally had access to 80 pellets was able to maintain >85% body weight with little supplementation on days 1-5. This was not the case for the rats trained with 2 pellets/well; they received constant dietary supplements in order to remain above 85% body weight. Thus, the rats initially trained with access to 80 pellets could work to maintain their body weights with a third group condition. Thus, it appears that the a priori motivational level of rats affects the degree of post-6-OHDA lesion deficit as indicated by the different levels of post-lesion performance reported by Gray et al., as compared with Montoya et al. (1990).

Parkinson’s disease (PD) is characterized by a loss of dopaminergic (DA) neurons in the nigrostriatal pathway. PD patients also have decreased retinal DA levels (Javoy and Dufour, 1990), which may interfere with early visual processing. Consistent with this idea, the pattern electroretinogram and spatial and temporal contrast sensitivity are abnormal in PD. In order to explore the generality of these findings, we administered a series of visual psychophysical tests to 10 nondemented PD patients (mean age: 64.9 years and 29 age-matched control subjects (mean age: 67.8 years) upon the Hoehn and Yahr stages of disability, 1 patient was classified as Stage I, 8 as Stage II, and 1 as Stage III. All PD patients were receiving DA medications. Psychophysical measurements were made of fine pattern discrimination, color discrimination along the red-green and blue-red primary color axes, and contrast sensitivity to flickering (0.75, and 15 Hz) and moving (3.15, 4.72, and 9.44 )/s) stimuli. In all cases, stimuli were presented within 1.0 x 1.0 degree of retinal eccentricity of 75°. Subjects responded in a four-position forced-choice procedure, and thresholds were determined with the method of constant stimuli. Under these conditions, the performance of PD patients did not differ significantly from age-matched control subjects on any of the visual capacities tested. It appears that some visual capacities are spared in PD, at least in patients who are taking DA medication.

The human skeletal muscle sodium channel gene (SCNA) has been linked to neuromuscular disorders. Since there are at least 16 different sodium channel genes that have been identified, it is possible that different sodium channel abnormalities may be present in different muscle disorders. To determine if the sodium channel gene is involved in all neuromuscular disorders, we have isolated and sequenced the entire sodium channel gene from different neuromuscular disorders. The results show that the sodium channel gene is highly conserved between different human species.

452.2 SEVERE ADULT-ONSET NEUROMUSCULAR DISORDER IN A TRANSGENIC LINE OF MICE. B. Popko1, D. Kelly2, A. Milatovich3, U. Franko4, and K. Suzuki5. 1Dept. of Pathology, Brain and Development Research Center, U. of North Carolina, Chapel Hill, NC 27599. 2Dept. of Genetics and 3Howard Hughes Medical Institute, Stanford University School of Medicine, Stanford, CA 94305

We have generated a transgenic line of mice in which the transgene has disrupted the function of an endogenous gene essential for normal muscle function. Mice homozygous for the BFPD transgene in our transgenic line (BFPD1) develop severe neuromuscular disease. This transgene is not expressed in normal muscle, but is expressed in skin and muscle of mice with severe neuromuscular disease. The muscle phenotype includes muscle weakness and wasting, and the skin phenotype includes hyperkeratosis and abnormal hair shafts. The transgene is expressed in muscle, and the muscle phenotype is rescued by disruption of the transgene. The muscle phenotype includes muscle weakness and wasting, and the skin phenotype includes hyperkeratosis and abnormal hair shafts. The transgene is expressed in muscle, and the muscle phenotype is rescued by disruption of the transgene. The muscle phenotype includes muscle weakness and wasting, and the skin phenotype includes hyperkeratosis and abnormal hair shafts. The transgene is expressed in muscle, and the muscle phenotype is rescued by disruption of the transgene.

NEUROMUSCULAR DISEASES I
TERMINAL MOTOR AXON MORPHOLOGY IN HOMOZYGOTOUS HEREDITARY CANINE SPINAL MUSCULAR ATROPHY.
K. Alderson and L.C. Cork
Department of Neurology, University of Utah, Salt Lake City, Utah and Division of Comparative Medicine, Johns Hopkins University, Baltimore, Maryland

Dogs homozygous for hereditary canine spinal muscular atrophy develop rapid progressive muscle weakness. We evaluated the morphology and myelination of distal motor nerves in the tail base perineural muscle of homozygous pups at three stages, early, middle, and late, to determine if muscle weakness correlated with abnormalities of distal motor axons. Compared to age-matched normal dogs, early affected pups had increased unmystylinen axonal collaterals and increased terminal innervation ratio. Mid-stage pups had thin, unmyelinated axonal collaterals, and evidence of Wallerian degeneration in intramuscular nerves. End stage pups (9 weeks of age) had a paucity of motor axons, an irregular distribution of neurofilaments within the axon, and aberrant growth cones. We conclude that as hereditary canine spinal muscular atrophy progresses, intramuscular axon motor axons are lost, thin unmyelinated axonal collaterals develop, and the organization of neurofilaments is altered. Both the loss of motor axons and the lack of myelin may have clinical and electrophysiological consequences.

ALTERNATIONS IN NEUROFILAMENT mRNAs IN HEREDITARY CANINE SPINAL MUSCULAR ATROPHY. N.A. Muma and L.C. Cork
The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

Hereditary canine spinal muscular atrophy (HCSMA) is a dominantly inherited motor neuron disease in which distal axonal caliber is reduced in lower motor neurons. Because several animal models show that neurofilament protein gene expression is a major determinant of axonal caliber, we examined neurofilament gene expression in HCSMA early in the clinical disease. Using quantitative in situ hybridization we found that the levels of mRNA encoding the low molecular weight neurofilament protein subunit (NF-L) were significantly different from levels of mRNA encoding the high molecular weight neurofilament protein subunit (NF-M) and poly-A mRNA in cervical spinal cord enlargement of dogs with HCSMA compared to control dogs. The levels of poly-A mRNA in neurons in the same regions were comparable in dogs with HCSMA and controls. If neurofilament protein subunit levels are found to follow the mRNA levels in this animal model, our results would suggest that decreased expression of the NF-L gene is sufficient to inhibit neurofilament function, i.e., maintenance of axonal caliber, particularly by disrupting normal neurofilament assembly.

DYSTROPHIN DISTRIBUTION IN MUSCLE AND NEURONS OF DUCHENNE MUSCULAR DYSTROPHY HUMAN FETUSES.
Umeharu, S. Tachibana, and S. Graeme
C.N.R. Unit for Muscle Bolt. & Physiopath., Padova; Dept. of Cytomorphol., Med. School, Cagliari (Italy)

Duchenne Muscular Dystrophy (DMD) is the result of the deficiency of a specific cytoskeletal protein called dystrophin, which binds to the inner plasma membrane. We have previously shown that dystrophin can be present in DMD human fetal neurons in culture. Therefore, we analyzed the distribution of dystrophin and spectrin in muscle and neurons of two DMD human fetuses (18-14 weeks) with immunocytochemistry. Different muscles were frozen and serial sections (10 µm thick) were incubated with monoclonal antibodies against spectrin, the cytoskeletal portion of dystrophin and different isoforms of myosin heavy chains (MHC). Neurons were grown in culture as previously described. Immunochemistry showed that all myocytes and the low immaturity spectrin were positive for β-spectrin, but negative for dystrophin. On the contrary, some neurons were positive for dystrophin and all showed spectrin staining. This suggests the presence of adult slow MCH in some young myocytes and in myotubes. These results help in understanding the mechanism of expression of different genes, such as the DMD gene, during human development. (Supported by Telethon-Italy, 1991).

MOTOR UNIT PROPERTIES IN HEREDITARY CANINE SPINAL MUSCULAR ATROPHY. M.J. Pitts, L.C. Cork, and N. Wallace
Department of Anatomy and Neurobiology, Medical College of Pennsylvania and Div. of Comparative Medicine, Johns Hopkins University School of Medicine.

Hereditary canine spinal muscular atrophy (HCSMA) is an autosomal dominant disease which is characterized by progressive weakness and eventual loss of lower motor neurons. Using intracellular recording and stimulation of single motor units, we have studied medial gastrocnemius (MG) motor unit properties in a litter of HCSMA pups aged 10-13 weeks. In units investigated thus far, motor units were found to respond normally to low frequency (1 Hz) antidromic stimulation of peripheral axons and to possess electrical properties similar to adult cat motor neurons. In heterogeneous pups (4), the motor unit population was composed of types FR and S units with no evidence for the existence of type FF units. We have not yet confirmed this motor unit composition in normal animals, but the predominance of types FR and S units is consistent with available enzyme histochemistry evidence for normal adult canine MG muscle. In 2 homozygous pups studied thusfar, two populations of units were detected. In the first, intracellular stimulation of motorneurons failed to produce detectable motor unit force despite the presence of antidromic motorneuron activation following peripheral MG nerve stimulation. This failure occurred in 30-50% of the tested motor neuron population and was associated with an inability to detect EMG responses linked to the intracellular stimulation. In the other population, stimulation produced measurable motor unit mechanical responses best characterized as types FR and S but with force outputs lower than in the heterozygous group.

LOCALIZATION OF DYSTROPHIN IN HUMAN AND MONKEY BRAIN. Johny Huard, Pierre-Yves Côté, Jean-Pierre Bouchard, Carol L. Richards and Jacques P. Tremblay
Neurobiology Laboratory, Enfant-Jésus Hospital, 1401, 18th Street, Quebec (QC), G1J 1Z9

Duchenne muscular dystrophy (DMD) has been characterized by a lack of dystrophin expression. This protein (420 kDa) is localized in the sarcolemma of normal muscle fibers and is absent of DMD and mdx skeletal muscle. Dystrophin would be involved in maintaining muscle membrane integrity during repeated cycles of contraction and relaxation. Molecular biology techniques have permitted to detect dystrophin transcript in the central nervous system (CNS). In fact 50% of DMD patients suffer also a mental retardation probably due to learning and memory problems. Dystrophin was localized in several brain regions of human and monkey brains using antibodies against the red rod domain of dystrophin. A clear visualisation of dystrophin was permitted by an indirect immunoperoxidase method using an amplification with biotin and avidin. Dystrophin-like immunoreactivity was observed in brain regions involved in learning and memory such as hippocampal formation, cerebral cortex and the dрастogenic nucleus of cerebellum. A positive reaction was also present in brain regions implicated in motor function (spinal cord, cerebellum, thalamus and substantia nigra). The Western blot analysis confirmed the presence of a 420 kDa polyepitide in these brain regions with both ant dystrophin antibodies. However the rod domain antibody also detected a dystrophin-like protein. These results raise the possibility that the lack of dystrophin is involved in the cognitive impairment observed in several DMD patients. However it will be important to analyze more details the clinical symptoms of DMD patient to understand the dystrophin role in brain.
452.9
RESTORATION OF FAST AXONAL TRANSPORT IN MUSCLER MICE. H. Mitsumoto, J.M. Jacob, K. Kurahigali, and J.G. McQuarrie*, Cleveland VA Med. Ctr., and Cleveland Clinic Foundation, Cleveland, OH 44106.

To establish a neuronal function in a mutant mouse model of motor neuron disease, we have examined anterograde axonal transport in hindlimb motor neurons of wobbler mice. For fast transport, tritiated amino acids were injected into the sciatic nerve. Transport distances were determined from the distance of the fluorescent label at 2 or 3 hr. Transport was 18% slower in wobbler mice than in unaffected littermates (p<0.01). Slow transport, [35S]methionine was injected. Transport rates were determined from the peaks of labeling for structural proteins separated by SDS-PAGE after 2 or 3 hrs. Rates for slow components (SCa) and b (SCb) were unchanged by wobbler disease. Because the rate of fast retrograde transport is also unchanged, we conclude that the slow axonal transport rate is a genetic abnormality in wobbler mice. Therefore, we conclude that slow axonal transport may be accompanied by the neuronalopathy is unlikely to affect the fast transport rate, we suggest that an axonopathy may be affecting the fast transport motor (kinesin).

Excitatory Amino Acid Receptors in the Cervical Spinal Cord of the Wobbler Mouse: A Quantitative Autoradiographic Analysis. C. Krueger*, R. Li, H. Mitsumoto and C. Shaw, Depart. of Medicine and Ophthalmology, University of British Columbia, Vancouver, B.C. and Cleveland Clinic Foundation, Cleveland, OH.

Previous studies have suggested that motor neuron death might develop as a consequence of an excitatory neurotoxic compound with agonist action at certain excitatory amino acid (EAA) receptor subtypes on motor neurons. To investigate the possibility that a selective reduction of EAA receptor subtypes might be observed as a result of motor neuron death subsequent to EAA receptor activation, we measured the distribution and density of EAA receptors in the cervical spinal cord of the wobbler mouse using quantitative receptor autoradiography. Homozygous wobbler mice develop progressive motor neuron loss, especially in the cervical spinal cord and brain stem. NMDDA receptor binding sites (25 and 28 kDa) were located in both the ventral and dorsal horns and displayed little regional variation in binding. AMPA binding sites, evaluated with 20mM[3H]CNQX, were concentrated in the dorsal horn of the rat. Kainate binding sites were labelled with 30 mM[3H]kainate, and receptor binding was located largely in the dorsal horn. [3H]Glutamate binding sites (35mM) were most abundant in the dorsal horn of the spinal cord. NMDDA, kainate, glutamate and AMPA receptor binding densities were not significantly different in the ventral horns of wobbler mice compared to those of control litter mates. These results suggest that motor neuron loss in the wobbler mice is not mediated by excitotoxins acting on EAA receptors.

452.12

Distal axonal degeneration (dying back) is the most common pattern of axonal pathology in most mononeuropathies. We examined the rate of fast axonal transport (FAA) in AC neuropathy, a prototypical model of progressive axonal degeneration. Six-week-old male rats given a single injection of AC (500 mg/kg, i.p.) 20 minutes before or after injection of 3H-hyaluronic acid demonstrated no alteration in the maximal transport rate (front of the curve) for radiolabeled proteins, whereas the glycprotein FACE rate was reduced (by 18%) compared to age-matched controls; data was normalized to the radioactivity present in the DRG. A defect in FAA of fetal glycoproteins was noted up to 49 days following a single 100 mg/kg dose, but was reversible (beginning as early as 7 days) following lower dose (50 mg/kg). Repeated injections of AC (30 mg/kg/day, for 7 days) did not decrease the rate of glycoprotein transport impairment. No alteration in the amount of transported materials was found. A correlation was observed between the degree of FAT deficit and axonal degeneration; following pretreatment with β-amidopropinothio protein which exacerbates axonal loss by AC, AC (75 mg/kg) elicited a marked impairment in both protein and glycoprotein FAT rate. We suggest that repeated, low dose AC exposure leads to an irreversible impairment in the delivery of FAT glycoproteins to the distal axon resulting, over time, in axonal degeneration. Supported by NS19611.

452.13
A STUDY OF THE ADVERSE EFFECTS OF 5-HT PRECURSOR-2

A comparison was made of the adverse effects of seven drug treatments which used 5-HT precursors. The adverse effects were collected from others' publications. The underlying cause of Eosinophilic Myalgia Syndrome (EMS) was sought. Neurologic Hilar-Gangion Syndrome (NHS) was added to these clusters for comparison between EMS and NHS. All clusters were subclassified into eight signs: general, skin, muscle, visceral, neurological, psychiatric, blood physiological, and chemical analysis. The appearances of these signs were expressed numerically, and histogram were drawn to compare the pattern. The similarity of those patterns resulted in two separate group: 1. TRP (tryptophan) group; (TRP alone treatment, TRP plus Naomicin Oxydase, TRP plus tricyclic antidepressant). 2. 5-HTP (5-hydroxy tryptophan) group; (5-HTP alone treatment, and TRP plus co-enzyme). The TRP alone treatment's effects showed little resemblance of pattern to that of EMS. In conclusion, EMS may be caused by combined influences involving by the TRP toxicity with conditions of genetic background and/or underlying metabolic abnormality as the predisposition.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
454 SYMPOSIUM: THALAMIC MECHANISMS OF NOCICEPTION.
F.A. Lent*, Johns Hopkins (Chairman); E.G. Jones, UC Irvine; A.V. Asgarli, SUNY Syracuse, M. Bushnell, Univ. Montreal

The principal sensory nucleus and adjacent nuclei of the thalamus comprise a region that is involved in pain-signalling pathways. Evidence will be presented that there are two separate anatomical domains within this region (and matrix domains), that the spinothalamic tract (STT) terminates selectively within the matrix domain. Inputs from STT may explain the activity of neurons in this region which respond to both innocuous and noxious stimuli (WDR neurons). These inputs contribute to the experience of pain, as well as innocuous thermal sensations and noxious pain.

Following injuries to the nervous system there is evidence of anatomical reorganization of the med and matrix domains. Patients with pain following nervous system injury exhibit physiologic reorganization and increased calcium spike associated bursting activity in the region. These changes in neuronal activity may be related to NMDA associated peptides that are activated by noxious stimuli. The convergence of innocuous and noxious inputs in the region may be related to the pain evoked by innocuous stimuli which occurs in many patients following nervous system injury. Therefore, synaptic and intrinsic cellular mechanisms governing thalamic neuronal activity may mediate acute somatic and visceral pain as well as symptoms of pain syndromes observed following injuries to the nervous system.
456.5  OVARIAN STEROID HORMONES REGULATE GLUTAMIC ACID DECARBOXYLASE (GAD) MESSAGING RNA LEVELS IN THE HIPPOCAMPUS OF THE RAT. N. G. Walland, Laboratory for Neuroendocrinology, Rockefeller University, New York, NY 10021. Estradiol and estrogens influence learning and episodic seizure activity, functions mediated in part by the hippocampus. Normal hippocampal function is dependent on precise interactions between the excitatory glutamatergic and inhibitory GABAergic systems. To determine whether or not ovarian steroid hormones interact with GABAergic neurons of the hippocampus, the levels of mRNA for GAD, the rate limiting enzyme for GABA synthesis, were measured using in situ hybridization histochemistry with 35S-labeled antisense or sense (control) riboprobes transcribed from cDNA sequences provided by Dr. J. Tobin. The levels of mRNA for GAD were analyzed in selected regions of dorsal hippocampus and medial basal hypothalamus in three groups of rats: 1) 2-week-estrous, 2) 2-OX and 2 days of estradiol (E) and 3) E plus 6 h of progesterone (P). Rats were killed at 1500 h. GAD mRNA levels in E rats increased in the GABAergic neurons associated with the pyramidal cell layer in CA1 but not in any other region of the hippocampus. EP reversed the E-induced increase in GAD mRNA in CA1 and induced a small decrease in GAD mRNA in the hilus. No effect of E or EP on GAD mRNA levels was observed at this time of day in any region of these rats measured. In conclusion, estradiol and progesterone may alter learning and seizure activity by altering the function of GABA neurons in the hippocampus.

456.7  LOCALIZATION OF ANDROGEN AND ESTROGEN RECEPTORS WITH GFR AND SRF NEURONS IN RAT HIPPOCAMPUS, HYPOTHALAMUS, THYROID, LIVER, KIDNEY, IN Testes, Brain and Bone Marrow. L. French, W. E. Stumpf, R. A. King, F. M. Wilson and M. Sar. Dept. of Cell Biol. & Anat. Labs. for Reprod. Hlth, Vanderbilt University School of Medicine, Nashville, TN 37232-0150. This study was conducted to determine whether GFR or SRF neurons contain androgen receptor (AR) or estrogen receptor (ER). A dual immunocytochemistry method was applied to visualize AR in GFR and SRF neurons. Adult male rats with or without testosterone propionate treatment (100ng/100 g BW) each received intraventricularly colchicine (50μg/rat), 18-20 h later rats were processed for double immunostaining procedures. Sections were initially stained for AR and ER by the ABC method with antipeptide antibodies AR32 and ER75 respectively using DAB. After receptor staining, the sections were immunostained with GFR and SRF antibodies using 4-chloro-1-naphthol. AR and ER localized in nuclei of neurons of the arcuate, periventricular and ventromedial nucleus where GFR and SRF cell bodies exist. Nuclear localization of AR was found in the majority of SRF neurons but not in GFR neurons. However, ER localization was observed in GFR but not in SRF neurons. These data suggest that estrogen directly affects GRF neurons, while testosterone directly affects SRF neurons. Since testosterone is converted to estradiol in certain brain regions an indirect effect of testosterone on GFR neurons cannot be ruled out. (Supported by NIH Grant 17479 and T32-HD07201.)

456.8  SEXUAL DIMORPHISM OF GALANIN GENE EXPRESSION IN GROWTH-HORMONE-RELEASING HORMONE NEURONS. H.A. Deleninger-van de Wijl, R.A. Brunton, P.B. Kehoe, R.A. Gerber, and D.L. Chipperfield, OhGyn / Physiol Biogy, U. Wash., Seattle, WA 98195. Sexually dimorphic growth hormone (GH) secretion in the rat is likely due, at least in part, to differences in the activity of hypothalamic growth hormone-releasing hormone (GHRH) neurons. Galanin is colocalized in GHRH neurons by immunocytochemistry and stimulates GH secretion. In the current study, we observed that galanin mRNA is colocalized in GHRH neurons and that this coexpression is sexually dimorphic. To test this hypothesis, we performed double-label in situ hybridization on coronal hypothalamic sections obtained from male (n=3) and female (n=5) rats. GHRH mRNA was hybridized with a cRNA probe labeled with digoxigenin-UTP and galanin mRNA was hybridized with a cRNA probe labeled with 35S-UTP. GHRH mRNA-positive cells were visualized by alkaline phosphatase action. Galanin mRNA levels were measured by counting autoradiographic grains over individual GHRH mRNA-positive cells with a computerized image analysis system. We confirmed that GHRH mRNA expression is not different between male and female rats. In addition, we observed a pronounced sexual dimorphism in levels of galanin mRNA in GHRH neurons, with females exhibiting expression 60% greater than males. This sex difference was statistically significant in GHRH neurons of the arcuate (p<0.02) and paraventricular (p<0.001) nuclei and tended toward significance in the ventromedial hypothalamic nucleus (p=0.07). However, in neither sex did GHRH neurons in the paraventricular nucleus express detectable levels of galanin mRNA. We conclude that galanin gene expression by GHRH neurons is sexually dimorphic, and we infer that differential secretion of galanin by GHRH neurons helps to orchestrate the different patterns of the GH secretion between male and female rats.

456.9  THE EXPRESSION OF GALANIN IN LH RH NEURONS IS INHIBITED IN PREGNANT AND LACTATING RATS. J. Merchenthaler*, Functional Morphology Section, NIH, National Institute of Dental Research Triangle Park, NC 27709. Galanin (GAL) coexists with LH RH in a subset of preoptic neurons and functions as a potent LH RH secretagogue. The incidence of colocalization is estrogen-dependent, i.e., the number of cells containing both LH RH and GAL is four-times higher in females. In the present study, a very low incidence of colocalization is reported in pregnant and lactating rats. Cycling female, pregnant and lactating rats were treated with colchicine. Day later, their brains were perfusion-fixed and 30 μm sections were processed. Sections were immunostained for GAL using anti-rat GAL serum and the ABC technique. The presence of uniform GAL-immunoreactive GAL-like neurons, was used as indication for colocalization of the two peptides. While in cycling female rats 75% of the LH RH cells contained GAL in pregnant or lactating rats, the incidence of colocalization was almost undetectable. Progesterone has been shown to decrease the effect of estrogen at the level of the brain and pituitary. The high levels of progesterone present in both pregnant and lactating animals may be responsible for abolishing estradiol-induced increase in GAL expression within LH RH-containing A. In addition, prolactin levels are also high in both animal models; therefore, a role of prolactin in this phenomenon cannot be ruled out. Among other mechanisms, the high levels of prolactin observed during pregnancy and lactation may be responsible for the low incidence of GAL/LH RH colocalization during pregnancy and lactation.

456.10  ESTROGEN INDUCTION OF GALANIN AND IMMEDIATE EARLY GENE EXPRESSION IN THE RAT ANTERIOR PITUITARY GLAND. T. Calcot, K. McDonald*, and L. Koonig*, Dept. of Physiology, Georgetown Univ. Sch. Med., Washington, DC 20007. Estrogen (E) induces galanin gene expression in the rat anterior pituitary gland. A sensitive and specific protection assay was developed to simultaneously quantitate multiple mRNA species in total cellular RNA samples. Time- and dose-dependent effects of E on the expression of c-fos, c-jun, c-myc, and galanin were measured. Each of the indicated genes was expressed in response to E treatment. Galanin mRNA was then upregulated with c-fos mRNA a significant and a strong pattern of c-fos expression. E-stimulated c-fos expression is weakly induced by E, becomes strongly induced by E, and is significantly induced by E. The induction of c-fos gene expression is weakly induced by E, becomes strongly induced by E, and is significantly induced by E. The induction of c-fos gene expression by E is weakly induced by E, becomes strongly induced by E, and is significantly induced by E. The induction of c-fos gene expression by E is weakly induced by E, becomes strongly induced by E, and is significantly induced by E. The induction of c-fos gene expression by E is weakly induced by E, becomes strongly induced by E, and is significantly induced by E. The induction of c-fos gene expression by E is weakly induced by E, becomes strongly induced by E, and is significantly induced by E.
545. 1  
ENDONUCLEASE ACTIVATION IN BRAIN INJURY OF RAT. T. Tominaga*, S. Kura and T. Yoshimoto. Div. of Neurosurgery, Inst. of Brain Diseases and Dept. of Biochem. Genetic, Toho University Sch. of Med., Sendai, Japan 980

The main purpose of this study was to clarify the temporal profile of DNA degradation, especially DNA fragmentation, during the process of brain injury. Additionally, endonuclease activity responsible for DNA breakdown was investigated using its nuclear protein fraction. Adult male Wistar rats were used. Focal cerebral ischemia and freeze-injury were produced by the tandem occlusion of common carotid and proximal middle cerebral arteries, and the application of precooled metal probe to dorsal cortex, respectively, under halothane anesthesia. The DNA was extracted from the lesioned cortex and/or caudoputamen and electrophoresed on a agarose gel. Typical DNA fragmentation into oligonucleosomal sizes was found in the ischemic caudoputamen and the freeze-injured cortex, which amounted to 10% of the DNA around 24 hours after the insult. Coexisting random degradation and specific fragmentation of DNA was observed in the cortex suffered from focal ischemia. To determine whether an endonuclease responsible for DNA fragmentation was present in the brain nuclei, nuclear proteins were extracted from normal brain nuclei and incubated with plasmid DNA or normal brain nuclei under various conditions. This demonstrated that brain nuclei proteins have Ca-dependent endonuclease activity which is related to DNA fragmentation. Moreover, the "gel assay" of endonucleases indicated the NUC1-8, which causes DNA fragmentation in lymphocytes, are also present in brain nuclei.

DNA fragmentation is not unique to programmed cell death and can occur as a result of brain injury, probably through the activation of Ca-dependent endonuclease.

545. 2  

Effect of the competitive AMPA (α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) antagonist NBQX (6-nitro-7-sulphamoyl-benzo[f]quinoxaline-2,3-dione) was studied in a model of traumatic brain injury in rats. A stainless-steel circular footplate, diameter 4.5 mm, was positioned stereotaxically over the hindbrain area of the motor and sensory cortices of fish. 30 days after injury, rats were sacrificed by transcardial perfusion fixation and the brains were serially sectioned and prepared for immunohistochemistry. Morphological analysis of the brains from 20 vehicle-treated rats (cresyl violet stained sections) showed consistent damage in the neocortex, hippocampal subfields CA3 and CA4 and less severe involvement of the thalamus. Treatment of animals with NBQX (n = 20) led to the reduction of the volume of cortical lesion and a protection against hippocampal damage. These observations suggest that AMPA antagonists may be of benefit for the treatment of acute head injury.

545. 3  

The effect of traumatic injury to the optic nerve on glucose metabolism within the lateral geniculate nucleus (LG) and the superior colliculus (SC) was studied in male Sprague-Dawley rats (N=52, wt=250-300g). Injury to the optic nerve was performed under general anesthesia (33% C2 66% C3, endotracheal intubation). Immediately following the insult, a hole was made in the skull for 1, 5, 30 or 60 seconds. Local cerebral glucose utilization (ICMRglc/μmol/100g/min) was calculated using 14C-labeled deoxy-glucose (250 μCi/pipet) autoradiography at various times following injury. During the 24 post-lesion days, animals were subjected to either ambient light or xenon arc strobe stimulation. Histological examination of the injured rats revealed that the survival duration increased from 12 to 100 days. The CMRGlc in the LG and SC during the injured optic nerve exhibited a pronounced and permanent deficit compared to the contralateral homologous structures, 51±14 % vs 81±9.2, 23.43% (p<0.01) and 58±12.19 vs 83±5.7, 18.73% (p<0.01) in the LG and SC respectively. However, in non-injured animals, particularly those sustaining the 1 sec injury, the CMRGlc depression was restricted to the SC. This metabolic depression spontaneously attenuated within 3 days with animals who sustained the most severe (60 sec) injury. The CMRGlc deficit in the optic nerve animals who had received methylprednisolone (30 mg/kg, ip) every 6 hours began increasing 24 min prior to the insult, the recovery rate from metabolic depression was significantly (p<0.01) different from the uninjured physiological response between the LGN and SC to optic nerve injury, (2) a role for methylprednisolone in the treatment of optic nerve trauma. (NS30008)

545. 4  

Intravesical fibrinogens may be produced by intravesical injection of an agent that is a rational assumption that the entrapping perineum might improve nerve function. Therefore, 1) Establish an experimental model of injection neuraphy; 2) test the effect of toxicity of agents, 0.9% saline and 76% + 1/400 000 epinephrine and 5% phenol, 3) evaluate the effect of perineurones. Methods: Right tibial of the guinea pig (200-300g) is used as the experimental model (N=60). Intravenous injection of three agents is performed by a micropipet and a micromanipulator to guarantee reproducibility. 60 guinea pigs are divided into 4 groups of 15 animals (5 per agent). Grp I: injection only, without treatment. Grp II: injection plus immediate perineurones. Grp III: injection plus perineurones after 1 week. Grp IV: injection plus perineurones after 3 weeks. 32 days after injection, assessment is performed. Assessment parameters: 1) Gastric analysis – A sciatric functional index, adapted to the guat pattern and foot prints of the guinea pig is used. 2) Electrophysiology - Compound action potentials are measured. 3) Histology - Cross sectional biopsies are evaluated by light microscopy and electron microscopy to assess axonal re- and regeneration, myelin changes, response of the perineum to the injury, intrasaccular scarring formation. 4) Quantitative morphometry. Results: Intravesical biopsies show good axonal regeneration and extension of the axonal fibers. These changes are more pronounced after injection of a toxic agent. Phenol produces extensive pathologic changes which include severe peri- and epineurial proliferation, axonal degeneration and endoneurial scarring formation. Injection of maricine and epinephrine produces pathologic changes that range in between saline and phenol injected nerves. Conclusions: Our data show possible beneficial effect of delayed perineurones in nerves injected by a toxic agent.
457.5 HYPERRESPONSE TO PERCUSSIVE TRAUMA IN IMMATURE, MATURE, AND AGED RATS. K. V. Biagas, P. D. Grundy, J. K. Schlichting, and P. M. Kochanek*. Deps. of Anes/Critical Care, Pediatrics, and the Head Injury Research Center, Univ. of Pittsburgh, Pittsburgh, PA 15213. Clinical studies suggest that the cerebrovascular response to head trauma differs with age. Specifically, increased cerebral blood flow, or hyperemia, commonly noted in children is less often seen in older adults after head injury. We hypothesize that reproducible posttraumatic hyperemia can be demonstrated in an animal model and that the extent of hyperemic response differs with age.

Wistar rats, sexually immature (3.5-4.5 wk, N=18), mature (9.15 wk, N=18), and aged (122.14 mo, N=6) were anesthetized and ventilated. Animals exposed to the resected right parietal cortex was produced by weight drop induced to brain weight. Regional cerebral blood flow (rCBF) was determined by 14C-labeled iodoantipyrine in awake normal controls and in rats injured 24 h before. Percent of normal control rCBF was determined for 15 structures. Within group comparisons to controls were made by t-test. At 24 h posttrauma, rCBF was found in all groups in the zone of impact (20% of normal control in immatures, 5% in matures, and 11% in aged rats, all p<0.05 vs. respective normal controls). Hyperemia in the peri-trauma parietal cortex was greatest in immatures (270% of normal control, p<0.05), less in matures (165%, p<0.05), and not found in aged rats (106%, NS). Increased rCBF was found in structures distant to the trauma in all age groups (146 to 188% of normal control in immatures, 66 to 160% in matures, and 157 to 232% in aged). These data indicate enhanced peri-trauma hyperemic response 24 h after brain injury in the immature. However, increased rCBF was found in distant structures in all ages suggesting that the diffuse posttraumatic hyperemic response is not age-dependent in this model.

457.7 MIDDLE LATENCY AUDITORY EVOKED POTENTIALS FOR EVALUATION OF WAKEFULNESS. S. Yasuda*, W. Hayward, L. Duyes, V. Morgese, B. Curtis, and R. Jacobson. Division of Neurosurgery, Loma Linda University School of Medicine, Loma Linda, CA 92356. The medial geniculate body is known to transform tonotopic impulses from brain stem to the hemispheric cognitive function. The authors studied and divided the middle latency (MLP) and brain stem auditory evoked potentials (BAR) at 3-day intervals in 100 patients who sustained head injury and remained and remained awake for certain periods. The results are: 1) Loss and no recovery of BAR wave 5 and MLP indicate severe brain damage (all and Glasgow Coma Scale 3 or 4); 2) Bilateral recovery of BAR and MLP correlates with remaining consciousness including communication capacity; 3) Unilateral recovery of the MLP correlates with return of wakefulness but inadequate communicative capacity; 4) Normal BAR with loss of MLP followed by its complete recovery correlates with rapid return of normal consciousness from continuous sleep.

The authors emphasize the importance of MLP for evaluation and prognostication of wakefulness after head injury.

457.9 CORRELATION OF NEUROFILAMENT IMMUNOHISTOCHEMISTRY WITH SILVER STAINING OF DAMAGED AXONS FOLLOWING HEAD INJURY IN HUMANS. S. Subramaniam Pratimas, and R. D. Rose*, D. J. Graham, J. H. Adams, and T. A. Granelli首 Head Injury Center, Div. of Neurosurgery, Univ. of Pennsylvania, Philadelphia, PA 19104, and Dept. of Neuropathology, Subcommittee on Head Injury, General Hospital, Glasgow, Scotland, UK. Diffuse axonal injury in cases of severe head injury is defined by the presence of swollen axonal cytoplasmic and axonal bulbs, defects in reduced silver preparations. The present study sought to establish to what extent neurofilament immunohistomistry correlated with reduced silver staining of damaged axons in the brains of fatal human head injury cases, sub-human primates subjected to experimental inertial head injury, and rats which received directed focrembrain strain injury.

SMI-31, a mouse monoclonal antibody (mAb) to phosphorylated epitope on heavy and medium neurofilament subunits, labels axons in the corpus callosum, subcortical white matter and fasciculi of axons radiating into the cortical gray matter in normal brains. Following head injury in man, baboons, and rats SMI-31 labeled large axonal bulbs in the corpus callosum, subcortical white matter, and deep cortical layers. The density of labeling of the axonal bulbs was identical to that seen in normal sections stained with the Palaner's silver technique. Perikaryas of damaged neurofilamental pyramidal cells in layers III and V were also positively labeled with SMI-31. SMI-32, a postinjury mAb, specifically recognizes heavy and medium neurofilament subunits, selectively labels neurons in layers III and V of normal human, baboon, and rat brains. Following head injury SM1-32 labeled small and medium sized retraction bulbs but not retraction bulbs were among the numerous axons characterized by labeled normal segments continuous with hyperphosphorylated axonal segments disrupted by patches of perikaryal immunoactivity. The authors conclude that SMI-31 and SMI-32 are excellent markers of axonal injury which not only selectively label features of axonal pathology but also identify the perikaryas of damaged axons and may also show light on the cellular mechanisms of axonal pathogy following head injury. Supported by NS-08801-21, NS-28552-02, and the Univ. of Pennsylvania Research Foundation.

Adult male Wistar rats were submitted to a blow of measured intensity to the parietal area of the skull resulting in severe trauma. The mortality of the animals (86%) died within 4-5 days. Some rats received embryonic neocortical grafts and debridement into the lesioned areas immediately after the trauma. These rats exhibited a rapid restoration of their behavioral activities as demonstrated by the open field and acetone test. Intake and motor activity returned to normal on the second post-trauma day. Debridement with no grafts reduced the post-traumatic death rate to 39%. Animals of this group showed reduced activity and food ingestion during the first post-trauma week. Histologic investigation 3 months after trauma and grafting revealed the presence of viable grafts in all hosts. The grafts were consistently well integrated with the host brain. No obvious signs of pathology were observed at the traumatized site of the brain in animals with grafts. The most important results of embryonic neocortex transplantation after severe head injury were mortality reduction, potent stimulation of post-traumatic brain tissue defect repair and the prevention of adhesive processes.

Axonal injury is commonly observed in human traumatic brain injury, but its pathogenesis has remained controversial due to limitations of use of traditional histological methods. Recently, in animals we have shown the utility of monoclonal antibodies to neurofilament subunits, particularly the 68 KD subunit, in detecting damaged axons (Yagami and Pohlhous 1992). In the present study, postmortem analysis was performed on ten human cases at various intervals of postinjury. The monoclonal antibody to the 68 KD subunit was used to identify sites of traumatic axonal injury, which were analyzed at both the light microscopic and electron microscopic levels. This approach revealed at 6 h postinjury axons exhibiting focal swellings. Immunoreactivity was associated with neurofilaments, some of which exhibited clumping and misalignment. Localized infolding of the axolemma was also evident. By 12 h postinjury the continued expansion of sites of focal swelling had progressed in some cases to axonal disconnection. Neurofilaments associated with marked immunoreactivity were now more disordered and vacuolization was observed. At 30 h immunoreactive disconnected reactive swellings displayed convoluted arrays of neurofilaments, partially surrounded by a cap-like zone of electron-lucent lamellae. In advanced stages of survival heterogeneity was evident. These findings reveal that, in head-injured man, axonal disconnection is the result of subtle cytoskeletal change that occurs over a time period. Actual structural/fenctional units undergoing this reactive cytoskeletal change are unknown, but the observed increase in the 68 KD subunit reactivity appears compatible with some local change in phosphorylation status.

458.4 CONTACT WITH MYELIN CAUSES A RELEASE OF CALCIUM FROM INTERNAL STORES IN OLIGODENDROCYTES. S.J. Moorman* and R.I. Hunt. Dept. of Biology, University of Michigan, Ann Arbor, MI 48109.

We are interested in whether interactions between adjacent oligodendrocytes play a role in the process of myelination. As an initial approach, we determined the reaction of neonatal rat oligodendrocytes in culture to an application of crude myelin extract. Myelin extracts were made from either adult rat spinal cord (CNS myelin) or adult rat peripheral nerves (PNS myelin). The extracts used were derived based on their characteristic morphology: some cells with this morphology were confirmed as oligodendrocytes by staining with an antibody to galactocerebroside. We monitored morphology of the leading edge of oligodendrocyte processes using time-lapse video-microscopy, and monitored intracellular free calcium concentrations using fluo-3. Typical experiments were done at 37°C in the normal medium. FURA-2 experiments were done at room temperature in the normal medium. Contact with either CNS myelin or PNS myelin resulted in collapse and retraction of the leading edge of oligodendrocytes. Because collapse of the neuronal growth cone has been associated with increases in [Ca], we tested whether collapse of the oligodendrocyte leading edge was associated with changes in [Ca]. Oligodendrocytes had an average resting [Ca] of 73 ± 20 nM. Contact with CNS myelin caused a relatively rapid [Ca] increase. The average maximum [Ca] level reached after contact with CNS myelin was 431 ± 273 µM. The [Ca] increase was reduced but not blocked by 5µM EGTa, which supports the idea that at least part of the [Ca] increase was due to a release of calcium from internal stores. A similar [Ca] increase was induced by contact with PNS myelin. These results suggest that oligodendrocytes might be able to recognize and react to specific molecules on the surface of other oligodendrocytes. This type of cell-cell interaction might play a role in preventing overlap of processes of adjacent oligodendrocytes at the developing Node of Ranvier. (Supported by the American Paralysis Assoc., the Marine Biological Laboratory at Woods Hole, and N.I.H.)

The role of phagocytic cells may be key in understanding the mechanisms involved in immune-mediated demyelination in the central nervous system. It has been hypothesized that myelin basic protein (MBP) may be the antigen most likely to be processed and presented by MHC class II molecules to elicit an immune mediated response. Although MBP has been used extensively in vitro and in vivo, the mechanism of phagocytosis and processing has not been characterized. We have used MBP-transfected Chinese hamster ovary (CHO) cells, a human histiocytic lymphoma cell line, U937, and human microglia to investigate the phagocytosis of MBP. To be able to follow MBP ingestion, we modified MBP with an antibody to the human cell line, anti-human MBP antibody, U937 and microglia were shown to ingest MBP both by flow cytometry and confocal microscopy. Activated EBV-B cells were shown to be the most efficient at phagocytosis of MBP as demonstrated by both 14C-MBP and FITC-MBP uptake. U937 and microglia were shown to ingest MBP albeit at slower rates. All three cell types failed to ingest MBP when incubated at 4°C, a characteristic of phagocytosis rather than pinocytosis. The rate and extent of MBP phagocytosis was markedly lower than that of cecile beads and bovine serum albumin. The processing of MBP is associated with the endosomal fraction of U937 after 2 hours and EBV-B cells after 8 hours. This is consistent with processing for binding to MHC class II molecules.

Two types of benzodiazepine (BZD) receptors have been characterized in brain: central (C) and peripheral (P). These receptors are encoded by different mRNA species and represented by distinct binding sites in brain membranes. BZD agonists and antagonists have different profiles of selectivity for these receptors. We have identified in brain membranes a BZD site with characteristics of a peripheral receptor. This binding site is present in brain membranes but not in membranes of cultured astrocytes from neonatal rat cerebral cortex. In homogenate cell preparations, the selective BZD ligands, [3H]PK 11195 and [3H]Ro5-4864, labeled high affinity sites (KD=0.82 and 2.4 nM, respectively) that appear to display a partial overlap. The maximal number of sites (Bmax) labeled with [3H]Ro5-4864 in brain membranes was not different from that labeled with [3H]PK 11195 (1.8 pmol/mg protein). Unlabeled Ro5-4864 competed for [3H]PK 11195 binding sites in a biphasic manner, suggesting the existence of PBZD sites that are not readily accessible to Ro5-4864. BZD ligands that bind to both C and P BZD receptors competed for [3H]PK 11195 and [3H]Ro5-4864 binding in a monophasic manner, and with similar affinities. These findings suggest that Ro5-4864, but not other BZD ligands tested, distinguished between putative subtypes of BZD receptors. Subcellular distribution studies indicated no apparent difference between the localization of [3H]Ro5-4864 and [3H]PK 11195 binding sites. The mitochondrial fraction of astrocytes revealed a lower or absent site in the binding of the two BZD ligands tested. This study suggests the existence of putative subtypes of BZD receptors in astrocytes, and indicates that their primary localization in these cells is in mitochondria.

BENZODIAZEPINE RECEPTOR IN CULTURED ASTROCYTES. T.J. Langan* and M.C. Slater, Dept. of Neurology, SUNY Sch. Med., Buffalo NY 14222.

Polypeptide growth factors (PGFs) generally act in sequential pairs: competence factors in early G1, and progression factors, particularly insulin (INS), in mid- to late G1. Newborn rat astrocytes were synchronized by the addition (at time 0) of 10% serum to cultures transferred to a defined medium (DM) containing peptides has been isolated and characterized from Lymnaea. The FMRFamide gene in Lymnaea contains two major peptide-encoding exons. One encodes the peptides FMRFamide and related peptides. The other encodes GDPFLRFamide and related peptides. Each exon encodes a peptide-encoding exon which is spliced onto the GDPFLRFamide encoding exon. One encodes the peptides FMRFamide and related peptides. One encodes the peptides FMRFamide and related peptides. The other encodes GDPFLRFamide and related peptides. The other encodes GDPFLRFamide and related peptides. In collaboration with David Price, five of the seven FLRFamide-containing peptides have been isolated and characterized from Lymnaea elegans (Rosoff et al., J. Neurosci., in press). Two different transcripts are produced as a result of alternative splicing; analysis of the corresponding cDNA sequences indicates that the two transcripts are developmentally regulated, reverse transcription/PCR experiments of staged RNA are currently being performed.

Norepinephrine (NE) inhibits the induction by IFN-g of class II antigen expression in cultured astrocytes (Frohman et al. PNAS 85:1292, 1991). We examined whether NE would also inhibit the LPS-induction of NOS in astrocytes as determined by nitrite accumulation. Primary astrocyte cultures exposed to LPS (500 ng/ml, 24 hr) but not NE (100 μM, 24 hr) increased NOS activity 15-fold over basal levels. However, NE elicited a dose-dependent inhibition of induction by LPS, with a threshold of 1 mM and maximal inhibition of 50-80% at 100 μM. Exposure to NE (100 μM) for 10 min was as effective as 24 hr continuous exposure in decreasing LPS-induction. In contrast, NE did not alter NOS activity pre-induced in astrocytes, suggesting that NE inhibition occurs at the levels of transcription not by protein modification. The induction of NOS by LPS was also blocked by the β-adrenergic agonist isoproterenol (10 μM) but not by the α-agonist phenylephrine. The response to NE was partially reversed by the β-antagonist propranolol, but not by the mixed α-agonist phenoxybenzamine. VIP (1 μM), but not NPY (1 μM), could also inhibit the induction due to LPS. These results suggest that induction of glial NOS by LPS can be regulated by catecholamines acting upon astrocyte β-receptors via elevation of cAMP levels. Conceivably the release of neurotransmitter in vivo may modulate the expression of inducible NOS in astrocyte possibly in response to injury or disease.

The FMRFamide gene in Lymnaea contains two major peptide-encoding exons. One encodes the peptides FMRFamide and related peptides. The other encodes GDPFLRFamide and related peptides. Expression of these two exons is mutually exclusive in individual cells, however both exons are spliced onto a common hydrophobic leader sequence. Cytoplasmic expression of these two peptide-encoding exons is regulated by differential RNA splicing. We have recently found that the FMRFamide gene contains at least two other peptide-encoding exons which are spliced onto the GDPFLRFamide exon in the messenger RNA. One of these exons contains the tetrasaccharide cleavage sequence RERK and also encodes a novel peptide SKF/MRFamide. Genomic sequence of 5783 base pairs has been determined and, on comparison with cDNA sequences, shows that the FMRFamide and GDPFLRFamide exons are separated by an intron of 2914bp. The mRNAs encoding FMRFamide and GDPFLRFamide are 1647bp and 1623bp respectively. By the use of immunocytochemistry, protein purification and sequencing we have shown that each exon is translated and processed. This work is supported by the SERC.

The generation of a master set of the cDNAs expressed in the human brain, knowledge of the chromosomal location of each cDNA and the complete DNA sequence of the protein coding region of each expressed brain gene would constitute a tremendous resource to human biology and neuroscience. Our goal is to significantly contribute to the development of such a resource through the large scale collection, analysis, and mapping of human brain. We have developed a method for enriching for cDNAs that are unique from one another, and have refined strategies for automated single-pass and full-length sequencing of each cDNA and for protein mapping of each cDNA to a location in the genome. We have also identified a subset of cDNAs that contain polymorphic microsattelite sequences and demonstrate how they can be converted to highly informative (PIC value > 0.7) gene-associated genetic markers. Single-pass sequencing data from the cDNAs is being used to search DNA and protein databases using the BLAST programs. Present, most of the sequenced cDNAs correspond to potentially new human brain genes, while a significant number of cDNAs appear to represent human homologs of interesting genes found in other species. Among these is the Descemtes brain gene, a regulator of a number of homeotic genes, several cDNAs related to known neurotransmitter receptor genes, ERK3, an extracellular signal regulated kinase and a potentially novel sodium channel gene. Currently in our laboratory automated single-pass sequencing is being carried out at a rate of several thousand cDNAs per year. Therefore, coordination of this effort with other laboratories doing similar work should permit the sequence identification of most of the genes expressed in the human brain within the next few years.

Protein kinases are key intermediates in stimulus-induced neuronal responses. However, the synaptic stimuli needed to activate specific kinases is unclear. Using primary cultures of cortical neurons, we have investigated the synaptic activation of Ca2+-calmodulin-dependent protein kinase (CaMKII) and mitogen activated protein kinase (MAPK). Burst of spontaneous synaptic activity were induced and monitored with Ca2+ indicators. Phosphorylation of these kinases during their activation allows activity to be preserved and assayed in cell extracts. We report that although both these kinases are activated by synaptic activity, they have different kinetics. While 90% of maximal CaMKII activation was observed after only 10 s of burst activity, MAPK is not affected at this early time and is only activated to 30% of maximal after 2 min of stimulation. In parallel experiments, we examined the rate of decay of activity following synaptic stimulation. The half life of stimulated CaMKII was 10-30 s, while MAPK decayed by 50% within 6-10 min. These data provide evidence for differential regulation of these kinases by synaptic activity.

We thank H. Schulman and N. MacDonald for advice and reagents.

CH2 ZINC FINGER GENES EXPRESSED IN THE MOUSE NERVOUS SYSTEM. N. Mazarakis, N. Galant, J. Brockes,* and F. Grosveld. Lab of Gene Structure and Expression, National Institute for Medical Research, The Ridgway, London NW7 1AA, UK; *Institut National de la Sante et de la Recherche Medicale, VPF SHEF, UK.

The CH2 zinc finger motif is a structure that contains highly conserved pairs of cysteine and histidine residues first identified in the Xenopus transcription factor TFIIH. It constitutes a sequence spanning an invariant domain that is found in a superfamily of invertebrate and vertebrate genes. Some of these genes encode mRNAs of activator factors with regulatory roles in cellular growth and differentiation. In an attempt to study the regulation of neuronal differentiation a mouse brain cDNA library was screened under low stringency conditions with a zinc finger probe from a mouse gene that was shown by Nothern blot analysis to generate a 3.7 kb brain specific transcript present during neurogenesis. In situ hybridization studies indicated that this message had a paraneuronal pattern of expression. A large pool of cDNA clones was isolated that contained this and other highly homologous CH2 zinc fingers. At least two novel CH2 zinc finger genes have thus been identified. These data indicate that several members of the zinc finger family are being expressed in the developing mouse nervous system.

TETRIC POTENTIATION ALTERS THE ABUNDANCE OF SEVERAL mRNAs IN SINGLE LIVE CA1 HIPPOCAMPAL NEURONS. J.A. Mackler*, B.P. Brooks and J.H. Eisenberg. Univ of Phila PA 19104.

We examined the effects of use-dependent changes in synaptic transmission on the relative abundances of mRNAs of several proteins in single individual neurons. The approach combined whole-cell recordings in rat hippocampal slices with amplification of the polyA+ RNA population from single CA1 cortical neurons. We examined the relative abundance of all of the reagents necessary for cDNA synthesis and the polyA+ RNA was amplified using the T7 RNA polymerase promoter sequence and SP6-CTP.

Screening of multiple candidate cDNA neuronal clones with the amplified probe revealed several differences in relative mRNA abundances between control and TTX treated animals or more after potentiation of evoked e.p.p.s. A 300% increase in CamKII mRNA occurred along with a 50% decrease in protein kinase C (PKC) mRNA. This 5-fold change in mRNA levels may accentuate the activity of the CamKII second messenger signal in comparison to PKC. Phospholipase A2 mRNA was unaffected. A 2-fold increase for zif-268 mRNA, without consistent changes in c-fos or c-jun and HSP70, suggests that transcriptional activators are selectively activated by synaptic use. The above changes were prevented by the prior addition of APV, a NMDA receptor antagonist.

The total of the described changes of mRNA levels from individual cells provide a detailed picture of a neuron after synaptic potentiation and in the context of synaptic connectivity and glut association.

545.6

One of the most fascinating issues in the study of the developing and adult CNS is transcriptional regulation of genes. POUs proteins are trans-acting factors which contain two highly conserved DNA binding domains (POU domain and NIH-POU-specific domain). We used in situ hybridization histochemistry to examine the distribution of mRNA encoding four Class III POU genes recently cloned in our lab (PNAS 89:3280; PNAS 89:3285). Serial adjacent sections from adult female Swiss-Webster mice were studied. For Brain-1, Brain-2, and SCIP, we used [3S]-labelled riboprobes (GRNA) targeted to the 5' end of the coding sequences and the adjacent untranslated region of each transcript. For Brain-4, the probe was targeted to the mRNA encoding the translated region 5' to the POU-specific domain. The sense strand of the Brain-4 probe was used as a negative control.

Brain-1 was the most abundant transcript of the four transcripts, being especially prominent in the piriform cortex, olfactory tubercle, and lateral ventricular ependyma. Brain-2 was prominent in the piriform cortex, vertical limb of the diagonal band of Broca, lateral ventricular ependyma, paraventricular and supraoptic hypothalamic nuclei, and substantia nigra, pars compacta. SCIP was abundant in the piriform cortex, striatum, accumbens nucleus, islands of Calleja, vertical and horizontal limbs of the diagonal band of Broca, nucleus of the lateral olfactory tract, CA1 and CA2 pyramidal cells of the hippocampus, medial habenula, and the inferior colliculus. Brain-4 was expressed in the olfactory bulb, striatum, nucleus accumbens, olfactory tubercle, lateral ventricular ependyma, medial habenula, and the paraventricular and supraoptic nuclei. All four Class III genes were expressed in laminar patterns in the neocortex. More detailed analysis is being pursued in the adult and developing mouse.

545.8

The mitochondrial enzyme cytochrome oxidase (CO) is a model for studying coordinate regulation of nuclear and mitochondrial gene expression. The enzyme contains 3 mitochondrial-encoded, and 10 nuclear-encoded subunits. We used in situ hybridization to study mitochondrial DNA (mtDNA), COI mRNA (mitochondrial-encoded), and CO4 and CO8 mRNAs (both nuclear-encoded), in the visual system of normal and 3-7 day monocular TTX-treateed macaques. In all animals, mtDNA and COI mRNAs were detected in neocortex while CO4 mRNA was not detected by in situ hybridization. However, CO4 and CO8 mRNA were mainly localized in perikarya, confirming our previous findings (J. Neurosci. 11:1942). Compared with normals, TTX-treated animals had not only decreased CO activity (shown histochemically) and CO protein (shown immunohistochemically), but also decreased mtDNA and subunit mRNA levels, in functionally deprived laminae of the lateral geniculate (LGN) and occipital dominance columns of area 17. After 7 days of TTX, mtDNA fell by 26%; CO1 mRNA by 49%; CO4 mRNA by 18%; and CO8 mRNA by 29%, as determined by counterimmunostained grain counting in LGN neurons. CO activity, measured densitometrically, decreased 23%. These results indicate that CO subunit mRNAs are disproportionately regulated in brain, subsequent to functional deprivation. The major acute control over CO activity is probably exerted by regulation of mRNAs for mitochondrial-encoded subunits, which form the catalytic core of the enzyme. (Supported by NIH grants NS18112 and EY05439 to MWR, and by an MCW MSTP fellowship to RFR.)

GENES WITH TRINUCLEOTIDE REPEATS: POTENTIAL CANDIDATES FOR NEUROPSYCHIATRIC DISORDERS. Robert C.A. Lott, S.S. McInnes, M.G. and Antonarakis, S.E. Departments of Psychiatry and Neuroscience, and Center for Medical Genetics, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Expansions of trinucleotide repeats (CGG or CTG) in mRNA underlie three neuropsychiatric disorders: Fragile-X syndrome, X-linked spinal and bulbar muscular atrophy, and Myotonic dystrophy. In addition, in unafflicted individuals, the number of repeats is highly polymorphic. In an attempt to find additional genes with trinucleotide repeats, we have screened a human cerebral cortex cDNA library with CGG and CTG repeat oligonucleotides. There were dozens of positives per large plate (~50,000 plaques per plate). Out of an initial ten clones, one was of myotonic dystrophy (Ea. et al. Science 255, 1256) with 13 CTG repeats, two were 28S ribosomal RNA and two were a human homolog of dog SRP (both of which are known to have repeats). In addition, two appear to represent repeat-containing cDNAs with novel sequences. In one (A3) and possibly both, the repeat is within an open reading frame. Genotyping using PCR across the repeat identified one fragment length polymorphism out of six individuals screened. We are now studying an additional series of clones, generated by screening the library at higher stringency, several of which appear to be novel sequences. Genes with trinucleotide repeats may provide markers with high polymorphic index for linkage studies and are potential candidate genes for neuropsychiatric disorders.

NAP, A HUMAN CEREBELLAR DEGENERATION ANTIGEN, IS A NOVEL, NEURON SPECIFIC, ADAPTIN FAMILY MEMBER. M.O. Mckeever AND R.B. Darnell. * Lab of Neuro-Oncology, Memorial Sloan Kettering Cancer Center, NY, NY 10021.

We have previously shown that antiserum from a patient with atypical cerebellar degeneration recognizes antigens expressed in cerebellar Purkinje cells and some neocortical neurons (Darnell et al., J. Neurosci. 1991;11:1224-1230). Using this antiserum we have isolated a clone from a human cerebellar expression library which, together with overlapping cDNA's, predict a protein sequence of 851 amino acids, of Mr. 96kDa. Antibody affinity purified with the cloned fusion protein recognized the same Purkinje antigens as native patient's antiserum. Sequence analysis revealed homology (31% identity over 296 amino acids) with the clathrin binding domain of the adaptin family of proteins. Northern blot analysis using human polycystic RNA demonstrated that this gene is expressed only in brain. These results identify a novel neuron specific member of the adaptin family, termed NAP, which is recognized by serum from a patient with human cerebellar degeneration. NAP may be involved in regulating neuronal specific aspects of vesicular trafficking, particularly receptor mediated endocytosis.

460.1
EXPRESSION OF POTASSIUM CHANNEL TRANSCRIPTS IN THE EMBRYONIC AMPHIBIAN NERVOUS SYSTEM. A.B. Ribera*. Department of Physiology C-240, University of Colorado Health Sciences Center, Denver, CO 80262.

Differentiation of the voltage dependent potassium current in amphibian spinal neurons is delayed with respect to the maturation of calcium current, regulating action potential duration. The molecular basis for this program of electrical excitability is being analysed using probes for voltage dependent ion channel genes. Maturation of potassium current is pivotal for action potential differentiation, and thus efforts have focused on this ion channel. A second Xnumpus potassium channel gene expressed in the developing nervous system has been cloned. This Xnumpus gene sequence is related to the mammalian sequences RCK1 and MBK1 and is thus called Xsh1a. RNAse protection assays indicate that Xsh1a is expressed in the embryonic nervous system at levels comparable to that of the previously reported potassium channel gene, Xsh2a. The predicted peptide has 490 amino acids. At the amino acid level, Xsh1a is 86% and 75% identical to MBK1 and Xsh2a, respectively. In the 3' untranslated region of Xsh1a, there is a region of 60 nucleotides that shows 70% similarity to sequences found in homologous locations in the 3' untranslated regions of MBK1 and RCK1. Functional expression of Xsh1a in oocytes induces a delayed rectifier potassium current. The induced current shows high sensitivity to the potassium channel blocker TEA, being reduced by >90% by 15 mM TEA.

The functional properties of Xsh1a in addition to its tissue and temporal patterns of expression of Xsh1a are consistent with its putative role in regulating excitability of developing spinal neurons.

Supported by NIH NS3217 and NS21531.

460.2
ALTERED POTASSIUM CHANNEL GENE EXPRESSION AND NEURAL DIFFERENTIATION. S. M. Jones* AND A. B. Ribera. Department of Physiology C-240, University of Colorado Health Sciences Center, Denver, CO 80262.

Several voltage-dependent potassium currents are expressed in embryonic vertebrate neurons and their differentiation regulates the development of action potentials in amphibian spinal neurons. Xsh1 and Xsh2 are two Xenopus Skg-like potassium channel genes that are normally expressed in the embryonic nervous system. In order to determine how the program for electrical excitability is established, Xsh1a and Xsh2a were overexpressed in developing embryos.

Overexpression was achieved by injecting capped Xsh1a or Xsh2a transcripts prepared in vitro into 1 cell of a 2 cell stage embryo. Rhodamine-conjugated dextran was included in the injection solution to follow the progeny derived from the original injected cell. Inclusion of potassium channel RNA, but not β-galactosidase RNA, in the injection solution led to a dramatic decrease in the number of morphologically differentiated neurons in vitro that are rhodamine fluorescent. This effect was dose dependent; at concentrations less than 0.2 µg/ml, the potassium channel RNA lost its effectiveness. Neurite extension in whole mount embryos was examined immunocytochemically with acetylated α-tubulin antibodies; these studies indicated that at concentrations greater than 0.2 µg/ml, overexpression of potassium channel RNA led to abnormal motor neuron development.

Electrophysiological analysis of potassium currents in fluorescent and nonfluorescent neurons prepared from embryos injected with this low dose of potassium channel RNA did not reveal any difference in current densities. We are now studying the effects on current density of injection of higher concentrations of Xsh1a or Xsh2a RNA. Supported by NIH NS3217 and NS21531.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
460.3 REGULATION OF mRNA FOR THE Kv3.1 POTASSIUM CHANNEL IN VITRO AND IN VIVO. T.M. Deretic*, X. Li, S. Karpe, L.K. Kazmerski and N.C. Birnberg, Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Transfection of AIT20 cells with the H-Havon oncogene causes a decrease in the width of action potentials and is associated with the induction of the potassium channel, KvK3.1 (Hennemick et al., J. Neurosci., 1992). In this study we have examined the effects of transmembrane signalling pathways on Kv3.1 gene expression in wild-type (WT) and rat transformed (R1) AIT20 cells. Long-term treatment (24-48 hrs) of WT cells with 10 ng/ml basic fibroblast growth factor (bFGF) resulted in the induction of Kv3.1 mRNA. bFGF treatment also caused a substantial decrease in action potential width consistent with a role for Kv3.1 mediated currents. In contrast, short-term treatment with 5 mM dibutyryl cAMP or 50 mM KCl increased Kv3.1 mRNA levels in both WT and R1 cells. The effect of depolarization was inhibited by the Ca2+ channel blocker, nimodipine, suggesting that the influx of Ca2+ is important in regulating Kv3.1 expression. Interestingly, R1 cells treated with high K+ or dibutyryl cAMP displayed a transient decrease in Kv3.1 mRNA levels at 2-8 hr. Both of these treatments caused a rapid induction of the e-Fos gene and an increase in AP-1 DNA binding activity. It is possible, therefore, that the Kv3.1 gene is regulated in a biphasic manner, strongly through the actions of second messengers and delayed through the actions of immediate early genes. Because these same signaling pathways may also be activated by neuronal activity, we examined the effects of seizures on Kv3.1 gene expression. We found that 6 hr after a tetrazole-induced seizure levels of Kv3.1 mRNA were decreased approximately 50% in rat hippocampus. We are currently investigating the long-term effects of seizure activity on the expression of the Kv3.1 gene.

460.4 STABLE EXPRESSION OF A RAT BRAIN K+ CHANNEL (K.3.1) IN HUMAN EMBRYONIC KIDNEY CELLS. S.D. Critch, B.A. White, D.J. Amott, H.S. Lopez, and A.M. Brown, Dept. of Molecular Physiology & Biophysics, Baylor College of Medicine, Houston, TX 77030.

Biophysical analysis of K+ channels is often made difficult by the diversity of K+ channels found in cells. To address this issue, we have begun to express individual K+ channels using stable transfection of human embryonic kidney (HEK 293) cells. In this study, the biophysical properties of a stable K+ channel, K3.1, were compared to those produced by transient expression following the introduction of K3.1 cDNA into Xenopus oocytes. The region of DNA coding for the K+ channel K3.1 was ligated to a mammalian vector, pRCMV (Invitrogen B), which contained a polylinker region, a cytomegalovirus promoter and a Neomycin resistance and K3.1 DNA was inserted into the pRCMV vector. The K+ channel was incorporated by lipofection (Lipofectin®; BRL) at 1 μg DNA/17 KHEK 293 cells. Twelve out of 15 antibiotic-resistant clones randomly selected for biophysical analysis contained detectable levels of voltage activated inward current (10.9 ± 2.2 nA at +90 mV, n=6) in these cells. The reversal potential of HEK 293 K3.1 shifted in Neristan manner with external [K+]i concentration. Moreover, the K+ currents were sensitive to concentrations of TEA (IC50 165 μM) that block K3.1 channels in Xenopus oocytes. The voltage-dependence of activation of K+ in HEK cells was similar to that observed in the oocytes (V1/2 ≈ 55 mV). The voltage-dependence of inactivation appeared to be different, however (+11 ± 2 mV vs +20 mV, respectively). Single channel data indicate a unitary conductance of approximately 25 pS, comparable to the 21 pS channel that is expressed in Xenopus oocytes. HEK 293 cells are suitable mammalian system for the expression of K+ channels and may provide insights into the posttranslational modification of these channels. (Support: F33-MS08579 SDC, NS23877 AMD).

460.5 DIFFERENTIAL EXPRESSION OF K+ CHANNEL mRNAs IN THE RAT BRAIN AND DOWN-REGULATION IN THE HIPPOCAMPUS FOLLOWING SEIZURES. M.T. Tsiour, M. Sheng, D.B. Lowenstein, T.N. Jan & L.Y. Jan*. Howard Hughes Medical Institute and Departments of Physiology and Biochemistry, Univ. of California, San Francisco, San Francisco, CA 94143.

K+ channels are major determinants of membrane excitability. Differences in neuronal excitability within the nervous system may arise from differential expression of K+ channel genes, regulated spatially in a cell-type specific manner, or temporally in response to neuronal activity. We have compared the distribution of mRNA for three K+ channel genes, Kv1, Kv2 and Kv4 in rat brain, and looked for activity-dependent changes following treatment with the convulsant drug pentyleneetetrazole. Both regional and cell-type specific differences in K+ channel expression were found. In addition, neuronal activity caused a reduction of Kv1 and Kv2 mRNA in the dentate granule cells of the hippocampus, raising the possibility that K+ channel gene regulation may play a role in long-term neuronal plasticity.

Transcripts of the rat KsH11.1 gene, one of the Shaker III gene family, express delayed rectifier voltage-dependent currents in Xenopus oocytes. We and others have previously reported the isolation of cDNAs encoding several alternatively-spliced versions of this transcript and of other genes of this subfamily predicting proteins differing in their carboxyl ends. The Drosophila Shaker gene encodes alternatively-spliced transcripts with different 3' and 5' coding regions. We now report the isolation of two types of transcripts of the KsH11.1 gene with divergent untranslated regions (5' UTR). The 5' sequences differ up to a point 5 bases upstream of the putative start codon (T5'). The presence of an AG the dinucleotide characteristic of the exon boundary of 5' splice junctions, at position 4, is suggestive of the presence of these different 5'UTRs result from alternative splicing. Unlike the fly Shaker gene, these alternative exons encode only untranslatable sequences. Northern blot analysis of rat brain mRNA with probes specific to KsH11.1 show a complex banding pattern that is not resolved by the utilization of probes specific for the 3' alternatively-expressed exon of this gene. However, Northern blots hybridized with probes specific to the two alternatively-spliced 5' UTR exons, designated alpha and beta, produce distinct banding patterns. On the basis of both Northern blot analysis and corroborating in situ hybridization studies, alpha is more highly expressed than beta in the rat CNS. As it is thought that 2 UTRs are involved in regulation of the processing and translation of mRNA, these results raise the intriguing possibility of differential post-transcriptional regulation of K+ channel expression at the RNA level.

460.7 COMBINATORIAL ASSEMBLY OF THE EAG POLYPEPTIDE WITH K+ CHANNEL SUBUNITS FOR MEDIATING cGMP-DEPENDENT MODULATION OF K+ CURRENTS. X. Zhong and C.C. Wu. Dept. of Biology, Univ. of Iowa, Iowa City, IA 52242.

Co-expression of different (Shaker) 2B subunits in the Xenopus oocyte has confirmed the oligomer assembly of the voltage activated 2B channels. However, the transient current I4, in Drosophila muscles is affected not only by SA mutations but also by those of the outer 2-go (ego) locus, which encodes a polypeptide homologous to but distinct from SA subunits. This suggests participation of products from different genes in the assembly of native 2B channels. Existence of multiple SA and 2B alleles enabled the testing of this idea in various double-mutant combinations and allowed an investigation of the functional role of different types of subunits in the channel. Voltage-clamp analysis of amplitude, time course, and steady-state inactivation revealed that the effect of eg2, egm1, egm2, eg24 on I4 varied with 2B alleles in the background. For instance, the amplitude of I4 is increased in eg2 2B, decreased in egm2 2B, but unchanged in eg24 2B as compared to each of the corresponding 2B background. The allele-specific interactions in eg 2B double mutants reflect a close association between the 2B and eg subunits within the I4 channel. Since eg2 subunits affect the peak, activation, and inactivation kinetics, including Drosophila-activated delayed Ig, the eg subunit may be present in multiple 2B channels. The functional significance of such heteromultimeric assembly of K+ channels is suggested by our in vitro inositol 1,4,5-trisphosphate (IP3) and cGMP (2 mM) and ino analogs, 8-BrcGMP (500 μM) and dibutyryl cGMP (500 μM), is either altered or eliminated by different eg mutations. The role of the eg subunit is channel modulation, as opposed to that of 2B subunits in determining the channel gating and conductance, supports the notion that at least two classes of subunits, each dedicated to different functions, co-assemble into a variety of K+ channel complexes.

460.8 MEMBERS OF A MOUSE SUBFAMILY OF GENES ENCODING VOLTAGE-GATED POTASSIUM CHANNEL SUBUNITS FORM HETEROMULTIMERS WHEN COEXPRESSION IN XENOPUS OOCYTES. Darin Herschlag and B.L. Tempel. Dept. of Pharmacology and Medicine, Univ. of Washington & VA Medical Center, Seattle, WA 98109.

Potassium channels with divergent functional properties could arise, in principle, by the aggregation of nonidentical subunits. We wished to determine if heteromultimer formation was possible for the products of MK1 and MK4 mouse genes, members of the mammalian Shaker-like subunits, and the two human potassium voltage-gated potassium channels. We also sought to test the hypothesis that potassium channels are comprised of 4 subunits. When MK1 and MK3 were expressed in Xenopus oocytes using the two-electrode voltage-clamp technique, we observed potassium currents that differed in their sensitivity to fraction I of dextrotoxin (DTX-I). The K's for DTX-I in oocytes expressing MK1 (N=7) and MK3 (N=8) were 3 and 45233 mV, respectively. We exploited the large difference in DTX-I sensitivity to test if heteromultimers comprised of MK1 and MK3 subunits form when coexpressed in oocytes. When MK1 and MK3 were coexpressed in several different ratios, the DTX-I sensitivities of the resulting currents were always greater than would be predicted by an additive model based on the hypothesis that MK1 and MK3 form only homomultimers. With a MK1:MK3 = 1:3 ratio, the K was 14 mV (N=4), which is much less than the K of 3100 mV predicted by the additive model. This suggests that heteromultimers composed of MK1 and MK3 subunits with intermediate DTX-I sensitivities can form in oocytes and that they have DTX-I sensitivities much closer to MK1 than to MK3. This implies that one MK1 subunit confers nearly full DTX-I sensitivity on a channel complex. The approach of MacKinnon (Nature 355: 252, 1991) was used and the results were consistent with a channel complex composed of 4 supported by NIH NS27206 and the VA.

**FUNCTIONAL INTERACTIONS BETWEEN SUBUNITS OF A CHIMERIC K+ CHANNEL.**

G.E. Kincaid, J.A. Drewe, M. DeBlaey, M. Tagliatela, H.A. Artmann, and A.M. Brown. Departments of Anesthesiology and Molecular Physiology and Biophysics. Baylor College of Medicine, Houston, TX 77030.

We have shown previously that in a chimeric K+ channel (22 pS K+ conductance, expressed in Xenopus oocytes) the non mutation V369l decreases channel open time and causes fast inactivation, without affecting conductance (De Biase, this meeting). L374V shortens channel open time and markedly reduces conductance (5 pS) with little effect on inactivation. Furthermore, the double mutation V369l+L374V increases channel open time and produces an intermediate conductance (10 pS). Here we show that the fast inactivation produced by V369l is abolished in the double mutant by increased burst duration. We tested for functional interaction of non-consecutive pore residues across subunit boundaries by co-injecting a mixture of rRNAs encoding the point mutants V369l and L374V. Two major classes of channels with intermediate conductances (8 and 14 pS) were observed in addition to the expected homotetrameric channels. Unlike the short-opening homotetramers, both classes of putative heterotetrameric channels had burst durations and open times approaching those of the double mutant. These results suggest that pores residing in adjacent subunits form a closely packed structure which determines both ion conductance and stability of the open state of the channel. Supported by NIH grants NS29473 (GEK), and NS23877 and HL37044 (AMB).

**460.10**

Spatial segregation of voltage-sensitive ion channels in surface membranes of neurons and muscle fibers is critical to the conduction of electrical impulses. We have begun to investigate the molecular mechanisms that govern the restricted expression using the drk1 (K.C.1) K+ channel polypeptide as a model. We have expressed wild type and mutant drk1 polypeptides in polarized and nonpolarized cells by transfecting drk1 cDNAs into fibroblast (COS), epithelial (MDCK) and neuronal (PC12) cell lines, and have begun to characterize the targeting and functional characteristics of these drk1 polypeptides in these different cellular backgrounds. Expression of wild type and mutant drk1 polypeptides in COS cells is highly efficient, with the majority of expressed polypeptide found on the cell surface as judged by: 1) vectorial labelling with membrane impermeant biotinylated reagents; 2) plasma membrane localization using immunostaining; 3) presence of large (20 nA = 500 pA/P) whole cell K+ currents. Studies with membrane impermeant, reducible crosslinking reagents show that both wild type and mutant drk1 polypeptides form multisinus channel complexes on the cell surface. MDCK and PC12 cell lines stably expressing drk1 polypeptides have been generated. Studies to determine the cell surface localization of drk1 in these cells are in progress.

**SUBCELLULAR SEGREGATION OF A-TYPE POTASSIUM CHANNELS IN RAT CENTRAL NERVOUS MORGAN SHENG, MOE-LING TSAUR, YIH YUN JEN, and LILY Y. JEN Howard Hughes Medical Institute. Dept. of Physiology and Biochemistry, Univ. California, San Francisco, CA 94143-0724.

In the mammalian nervous system, K channels regulate diverse aspects of neuronal function and are encoded by a large set of genes. The roles of the many different K channels that are expressed in individual neurons could be dictated by their localization to specific subcellular domains. Using gene-specific antibodies, we show that two K channel polypeptides, Kv1.4 and Kv4.2, that are found in the A-type currents when expressed in Xenopus oocytes, are segregated in rat central neurons. Kv1.4 is targeted to axons and possibly terminals, while Kv4.2 is concentrated in dendrites and somata. Translation of both proteins, however, occurs in the cell body. The differential distribution implies distinct roles for these channel proteins in vivo; their localizations suggest that Kv1.4 and Kv4.2 may regulate synaptic transmission via presynaptic, or postsynaptic mechanisms, respectively.

**CONTRASTING IMMUNOHISTOCHEMICAL LOCALIZATIONS IN THE RAT BRAIN OF TWO NOVEL K+ CHANNEL SUBFAMILIES.** P.M. Hwang, M. Pouli, D.S. Britt and S.H. Dreid, Department of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

A number of mammalian voltage-dependent K+ channels with closely similar amino acid sequences and electrophysiological properties have been cloned; however, little is known about how multiple K+ channels are arranged to serve similar functions. We have recently identified, cloned and characterized a novel K+ channel, designated CDRK1 (Hwang et al., Neuron 9:473-481, 1992). CDRK1 appears to be a member of the Drosophila Shab K+ channel subfamily, most closely resembling DRK1 (Froeh et al., Nature 349:624-625, 1989), the only other rat homolog of Shab. Electrophysiological analysis of expressed CDRK1 reveals delayed rectifier properties similar to those of DRK1. We now have made synthetic peptide antibodies specific for CDRK1 and DRK1 proteins. Remarkable contrasting immunohistochemical localizations in the brain as well as in peripheral tissues have been observed for both channels, suggesting that these highly homologous K+ channels with distinct localizations may play uniquely important roles in the control of membrane potential in various excitable tissues.

**PROCESS OUTGROWTH, GROWTH CONES AND SPROUTING**

**461.1**

The goal of this study is to study the possible central and peripheral mechanisms for the sprouting of primary afferent fibers in the partially denervated spinal cord.

The first group of adult Sprague-Dawley rats (n = 5) received unilateral dorsal root ganglionectomies of L4-L6 on one side and rhizotomies of L1-L4 dorsal roots on the other side. The second group of rats (n = 3) received unilateral dorsal root rhizotomies of L1-L4 dorsal roots on the right side, followed seven weeks later by contralateral rhizotomies. Two months after the first surgery, all rats were anesthetized, and stimulated by immersing both of their hindlimbs in 32 °C water for 20 seconds. The rats were perfused two hours later. CGRP and c-fos immunocytochemical stains were performed.

Preliminary results indicate that CGRP immunoreactive fibers had sprouted into a new area (laminar III) on the chronic ganglionectomized sides. Also, the area of CGRP immunoreactive fibers and the area occupied by c-fos immunoreactive cells were much greater on the ganglionectomy/dorsal rhizotomy sides in the first group of rats, and much greater on the chronic side in the second group of rats. These results suggest both central and peripheral denervation contribute to the sprouting of thinly and unmyelinated primary afferent fibers in the partially denervated spinal cord. Furthermore, combined central and peripheral denervation (via ganglionectomy/dorsal rhizotomy) induces sprouting of thinly and unmyelinated fibers into novel regions. Supported in part by NS18913 and NS27511.

**461.2**

The retinal ganglion cells (RGCs) of embryos and axons, as well as those of the marginal retinal growth zone in adults, carry E21 staining over their entire surface. On mature RGCs, E21 staining is restricted to contact sites between the cells and to the zone of RGC axon terminal arbors in the tectum. After optic nerve transection the regenerating axons re-express Neurolin throughout their path while the RGCs keep it restricted to their contact sites. The NH2-terminal aminoacid sequence of Neurolin has similarities to that of the recently discovered cell adhesion molecule DM Grasp (Burns et al., Neuron 7, 1991) and SCI (Tanaka et al., Neuron 7, 1991) of the chick spinal cord.

In fact, E21 also stained motoneurons, floorplate cells and the DRG entry zone and tract in the developing goldfish spinal cord and only the latter in adults.

Neurolin may represent either the goldfish homologue of DM-Grasp/SCI or another member of that family.

ASTROCYTES DEMONSTRATE REGIONAL DIFFERENCES IN PROMOTING DENDRITIC GROWTH. P. Lee Roos* and T. Reh. Depts. of Neurosurg. and *Biol. Struct., University of Washington, Seattle, WA 98195.

Glia from different regions of the CNS have been shown to be heterogeneous in their ability to promote neurite outgrowth from neurons. Hence it is known whether glia from different CNS regions differ in their abilities to promote axons vs dendrites from neurons. Therefore we compared total dendritic and axonal growth from embryonic mouse cortical neurons (E 18) grown in vitro on postnatal day 1 (P4) astrocytes purified from cortex, mesencephalon, striatum, olfactory bulb, spinal cord (GFAP>90%); Muller glia from retina; and fibroblasts. Double immunolabelling (MAP2, M6, NF-H) was used to identify mouse cortical dendrites and axons after 5 DIV. While axon length was similar on all glial monolayers, dendritic growth was nearly threefold greater on cortex, retina and olfactory bulb than from other areas of the CNS. These findings demonstrate regional differences in the ability of astrocytes to support dendrogenesis. Supported by NIH NS 30305.

461.5

ACTIVITY-SENSITIVE SIGNALLING BY INSULIN-LIKE GROWTH FACTORS IN THE DEVELOPING AND REGENERATING NEUROMUSCULAR SYSTEM. P. Garner* and C. Schneider, Friedrich Miescher Institute, P.O. Box 2543, CH-4002 Basel.

Synapse elimination during development and nerve sprouting in the adult affect the arrangement of presynaptic terminal branches and are coupled to post synaptic activity. Thus, the prolonged absence of postsynaptic activity leads to sprouting in the adult and prevents the retraction of collateral branches. In the neuromuscular system, lack of muscle activity leads to a rapid elevation of muscle fiber-derived IGF1 in the adult and prevents the developmental downregulation of muscle IGFs during synapse elimination. We have searched for motoneuron mRNA's and proteins whose levels are controlled by muscle activity and have determined whether muscle-derived IGFs are sufficient and/or necessary to mediate activity-sensitive retrograde signalling from muscle to spinal motoneurons. We report that: 1) the mRNA coding for the growth-associated proteins (GAPs) GAP-43 and tubulin-α are downregulated at rat and chick spinal motoneurons at the onset of the synapse elimination process; levels of terminal-associated GAP-43 decline during the elimination process; 2) motoneuron GAP downregulation is controlled by the periphery; it is prevented by local muscle paralysis or by elevated levels of IGFs in the muscle; 3) muscle-derived IGFs accumulate at the neuromuscular junction and are taken up and transported in motor nerves; 4) blockade of IGFs in the muscle by local applications of recombinant IGF binding protein prevents the effect of paralysis on motoneuron GAP downregulation and on the pattern of intramuscular nerve growth. Therefore, IGFs mediate activity-sensitive retrograde signalling from suletal muscle to spinal motoneurons.

461.7

EFFECT OF CTNF ON NEURITE OUTGROWTH FROM CULTURED SPINAL NEURONS. N.M. Oyenika* and D.L. Wigston. Program in Neuroscience and Dept. of Physiology, University School of Medicine, University of North Carolina at Chapel Hill, NC 27599.

There is a serious need for agents that may promote axonal growth after spinal cord injury. Although ciliary neurotrophic factor (CNTF) can enhance the survival of a class of spinal neurons, the influence on neurite outgrowth or regeneration of axons from motoneurons or other spinal neurons is not known. To investigate the effect of CNTF on neurite outgrowth from spinal neurons, we dissociated motoneuron cultures from the lumbar spinal cord of rats at stage 30 (E16) chick embryos and plated them on laminin-coated glass coverslips in medium with or without CNTF (recombinant human CNTF; Sigma). By 48 hr, we found that neurites were about 65-100% longer and the total neurite length per neuron was 60-150% greater in cultures exposed to CNTF (p<0.025). In addition, CNTF enhanced neuronal survival. The enhanced neurite outgrowth was not a consequence of the higher cell density in CNTF-treated cultures; unlabeled cells that were plated so that their final density matched that of CNTF-treated cultures did not show enhanced neurite outgrowth. To examine the effect of CNTF on subpopulations of spinal neurons, we found that cultured cultures derived from the ventral spinal cord which contains motoneurons, with cultures derived from the dorsal spinal cord which lacks motoneurons. CNTF enhanced neurite outgrowth to about the same extent in ventral and dorsal cultures. We also identified motoneurons in some experiments by labelling them retrogradely with diI. The effect of CTNF on neurite outgrowth was similar for labelled and unlabelled neurons, and was therefore not specific to motoneurons.

We conclude that CNTF promotes neurite outgrowth from spinal cord neurons in vitro. CNTF may have a similar effect on neurons in the injured spinal cord. (Supported by the American Paralysis Association.)

461.8

SKEROTONIN AND ACETYLCHOLINE ALTER BRANCHING DECISIONS AND Soma SIZE OF DEVELOPING LIECH REZUS NEURONS. S.M. Elgar and U.S. Stan* Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

Embryonic axons of Reticular neurons (Rs), one of 5 types of SHT neurons in leech spinal ganglia, show a stereotyped sequence of pathway and branching decisions. Since synthesis of 5-HT receptors for 5-HT and ACH appear early in Rz axon outgrowth, we asked whether 5-HT or ACH helps to shape these decisions. In Thoropyrgus, whose normal sequence of Rs axonal branching differs from that previously described in Hirudo, the primary axon forms a T-branched; the posterior arm of the T grows into the 1P peripheral nerve. Then a secondary branch from the posterior arm grows into the posterior interganglionic connective nerve, and the anterior arm grows into the anterior connective nerve. When Rs connective axons from adjacent segments meet, they fasciculate. Then a new axon grows from near the branch point of the T into the 1A peripheral nerve. Rs neurites which extend to the A ganglia form a complex network which extends from those in segments M5 and M6 enlarge to become the largest somata in a ganglia. Embryos of T. rubra were incubated for 2-3 days, during the period of axon outgrowth, in media containing 10 μM 5-HT or 10 μM ACH with 50 μM 5-HT. Rs morphology was visualized by anti-5-HT antibody staining or by fusaricine or anti-acetylcholine antibody staining. Following ACH incubation, initial axon outgrowth was normal. But when the connective axons of Rs neurons in adjacent ganglia would normally meet and fasciculate, all connective axons disappeared. A new anterior connective axon arose from the posterior arm 90-120° from the original anterior arm, and the MA axon arose from this new branch (instead of from the T). After injection of biocytin into the MA axon, Rs neurites regrew in the original posterior position. ACH incubation led to a substantial increase in the largest somata in Rs neurons, but not in other SHT neurons.

Prolonged 5-HT incubation reduced anti-5-HT staining in Rs neurons to near invisibility. Staining of other SHT neurons was unaffected. This selective effect on Rs reflects a change in transmitter interactions. In RS (Hirudo) (1b) incubation increases anti-5-HT staining intensity. Prolonged 5-HT exposure also caused all Rz somata to remain small, which is normal for segments M5 and M6. The results show that exogenous 5-HT or ACH can induce changes in transmitter content, soma size and axon branching in Rz neurons. Therefore Rs transmitter pairs are likely to play a role in the regulation of these decisions in Rz development.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
461.8 SHAPE CHANGES IN EMBRYONIC LEECH GROWTH CONES REFLECT TRANSITIONS IN OUTGROWTH. D. Kemp* and J. Jellis, Neurobiology Research Center and Dep. of Physiol. and Biophysics, Univ. of Alabama at Birmingham, Birmingham, AL 35294

Correlations between growth cone shapes and molecular and cellular guidance signals suggest that studying changes in morphology may help characterize these underlying guidance cues in an embryonic leech. We have analyzed the morphology of a set of growth cones on the Cumb- or C-cells in the embryonic medicinal leech, Hirudo medicinalis, as they undergo a transition to rapid outgrowth. The C-cell growth cone is a bipolar pair in each midbody segment. Each C-cell adds and orients about 70 parallel growth cones which remain relatively non-motile until E12 when rapid and directed process outgrowth is initiated. C-cell growth cones from the same segment at E10, E11, E12, and E14 were injected with Lucifer Yellow and processed with antibodies to visualize their growth cone in whole mounts. A central subset of ubiquitously oriented growth cones (n=583) were traced using IMC optics and camera lucida. Morphology was digitized from these tracings and a computer program (MacMeasure) was used for analysis and comparison. Contrary to expectations for growth cones that become more rapidly advancing, lamellae regions and filopodial sampling increased with age. Young, relatively non-motile growth cones had numerous short filopodia in many orientations, while the more rapidly advancing growth cones showed a decrease in filopodial number, an increase in filopodial length, and a striking restriction of filopodial orientation to the direction of process outgrowth. However, the average filopodial angle was predictive of the direction of outgrowth at all stages, suggesting that while direction of growth could always be predicted by a vector sum of filopodial trajectories, younger quiescent growth cones respond to different cues (or similar cues differently) than older, more rapidly extending ones. These results support the view that C-cell growth cones are fasciculating and further suggest that they progressively alter filopodial extension/integration in the manner predicted if their affinity for local cellular cues was superceded by a more distributed set of extrinsic guidance signals. Supported by NIH NS 26063 (JJ).

462.1 THE ROLE OF THE ZEBRAFISH SCLEROTOME IN PERIPHERAL NERVOUS SYSTEM SEGMENTATION. Elizabeth M. Morin-Kensicki* and Judith S. Eisen, Institute of Neuroscience, University of Oregon, Eugene, OR 97403

Sclerotome has been implicated in patterning peripheral nervous system (PNS) segmentation in vertebrate embryos. We have identified sclerotome cells in embryos of the zebrafish, Brachydanio rerio, based on the following criteria: these cells: 1) delaminate from the ventromedial aspect of each somite; 2) become mesenchymal; and 3) migrate to positions where vertebrae later form. In each embryonic zebrafish trunk segment, sclerotome cells migrate along a pathway that later is traversed by the growth cones of axial motoneurons and by some neural crest cells. We tested the role of sclerotome in patterning zebrafish dorsal root ganglia (DRGs) and axil motor nerves by ablating premigratory sclerotome by aspiration and observing the pattern of these PNS structures at later stages by staining with specific antibodies. Removal of sclerotome did not disrupt the pattern of the DRGs or the axial motor nerves. These findings suggest that zebrafish sclerotome is not required for proper formation and segmentation of DRGs or axil motor nerves. Our results are in marked contrast to findings in avian embryos where sclerotome does appear to be required for these processes and thus, we suggest that there are different mechanisms for establishing PNS segmentation in different vertebrate species.

NIH HD07348, HD22486, GM070257, NS32915

462.3 EXPANDED ROLE OF MIDLINE SIGNALING IN THE DORSO-VENTRAL BRAIN POLARITY OF ZEBRAFISH. Kota Hatsumi, Michael Westermann, and Charles B. Kimmel*, Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

The zebrafish cyclops mutation deletes the entire ventral midline of the central nervous system (CNS), including the ventral forebrain and floor plate in trigeminal and spinal cord, without disturbing surrounding mesodermal structures. In the spinal cord and caudal hindbrain, positioning of most neurons is unaffected although pathfinding of some axons is severely impaired. The phenotype is more severe in the anterior CNS; in the diencephalon, the ventral neuronal groups and longitudinal axon bundles are deleted. To characterize the phenotype in more detail, we examined four homeobox genes (en, rhx3.3, pax2, pax6) that are expressed in specific positions in the CNS. Among them, pax2 is expressed in a wild type as well as in a null of domains in the diencephalic primordium just after gastrulation. These domains are fused at these stages in cyclops. At later stages, the mutant expression pattern of each of the homeobox genes shifts ventrally in more anterior regions of the brain. These results suggest that cyclops alters the early fate map and dorsal-ventral positional information of the CNS. Transplantation of a single wild-type cell that comes to occupy the ventral midline in the mutant locally rescues the forebrain and eye phenotypes. We argue that proper establishment of positional information in the midline is essential for both signaling from ventral midline cells, whose specification depends on the cyclops gene product. (Supported by NIH grants NS17903, HD22486, and HD22487.)

Using in situ hybridization and screening with homoeodomain-encoding probes, we isolated, from an E14.5 mouse telencephalon cDNA library, a 2.4 kb cDNA encoding a novel mouse homoeobox-containing protein called Tgs-1. The Tgs-1 homoeodomain is identical in 53 out of 61 amino acids with the homoeodomain of the Drosophila segmentation gene. Tgs-1 is part of the newly discovered Dlx family of homeobox-containing genes. It is also known as Dlx-2. Unlike other vertebrate homoeodomain-containing genes, Tgs-1 is predominantly expressed in the head. When ths a brain of the midgestational embryo, Tgs-1 is expressed in the ventral forebrain. In situ RNA hybridization shows that Tgs-1 is expressed in discrete domains within the midbrain/forebrain. In the diencephalon, these domains form sharp borders with the expression pattern of another homeobox gene, and a gene encoding a putative growth factor.

PROCESS OUTGROWTH, GROWTH CONES AND SPROUTING V

PATTERN FORMATION, COMPARTMENTS AND BOUNDARIES III

463.1 PATTERNING AND INDUCTION IN A ZEBRAFISH MUTANT THAT LACKS A NOTOCOTCH. M. E. Haber*, B. K Ho, S. Schulte-Merker*, C. Nusslein-Volhard*, C. Walker and C. B. Kimmel, Institute of Neuroscience, University of Oregon, Eugene, OR 97404, and Max-Planck-Institut für Entwicklungsbiologie, 72076 Tübingen, Germany.

In the zebrafish embryo, the notochord is derived from precursor cells that involute during gastrulation to form the notochord. As in other vertebrate embryos, dorsal mesoderm may play an important role in the induction of the central nervous system (CNS).

We have recovered a novel, recessive lethal mutation that produces embryos with no notochords or tails (ntt). Cell lineage studies suggest that dorsal mesoderm is present in ntt embryos, although subsequent notochord differentiation is blocked. Phenotypically, ntt embryos resemble mouse Brachyury (or T gene) mutants. They also fail to express a protein homologous to the mouse T protein, which is an early marker of notochord development. Molecular analysis confirms that nt is in fact the zebrafish homologue of the T gene.

Although the notochord is absent in nt mutants, the induction and differentiation of the CNS appears normal. In contrast, patterning of somitic mesoderm is abnormal due to the absence of endogenous signaling from notochord or pioneer cells. However, the somite defects can be rescued through transplantation of wild-type (WT) cells into ntt hosts. These experiments demonstrate that mutant host mesoderm is capable of forming muscle pioneers in the presence of notochord derived from WT donor cells.

We propose that the dorsal mesoderm has multiple cell signalling roles in the development of the zebrafish embryo. In ntt mutants, the signal required for CNS induction are retained, while the signals required for muscle pioneer induction and somite patterning are disrupted.

Segmentation has been implicated in the development of the spinal cord and hindbrain. In the forebrain, however, evidence for distinct embryonic domains—a hallmark of segmental development—has remained elusive. We report here that a distinct domain in the developing forebrain that is defined by early neurogenesis and specific axon ingrowth. This unique but transient domain appears in the outer 2/3 of the ventrolateral wall of the forebrain soon after the formation of two distinct telencephalic vesicles from the single prosencephalon. The earliest neurogenesis in the forebrain, indicated by AP-2 staining and DNA labeling, occurs in this zone. In addition, first neurites growing from the developing forebrain are limited to this region as shown by immunostaining for neurite specific molecules GAP-43 and L1 as well as by EM analysis. Oil-1 staining indicates that many of these neurites originate from the olfactory epithelium. The ventrolateral domain disappears as rudiments of the major forebrain subdivisions—the neocortex, hippocampus, basal ganglia, basal forebrain, and olfactory bulb—emerge.

This temporally and spatially restricted pattern of neurogenesis and neurite growth delineates a distinct domain in the developing mouse forebrain. This domain differentiates before rudiments of the forebrain subdivisions are seen and may be crucial to their formation. The ingrowth of axons from a specific source, the olfactory epithelium, further suggests that this regional specialization may be required for establishing initial axonal projections to the forebrain.

462.7 ACTIVATED RETINOIC ACID RECEPTORS DEFINE A DISTINCT DOMAIN IN THE DEVELOPING MOUSE FOREBRAIN. A.S. LaMantia*, A.K. McAllister, I.G. Whitesides, M. Colbert, and E. Linney. Departments of Neurobiology and Neuroimmunology, Duke University, Durham NC 27710.

The acquisition of regional identity in embryos is orchestrated by transcription factors acting within distinct domains. In the vertebrate CNS these domains have been seen in the developing spinal cord and hindbrain; however, they have not been described for the forebrain. We have shown a unique zone of early neurogenesis, differential cell adhesion, and neurite ingrowth from the olfactory placode in the developing mouse forebrain. We now show that the emergence of this zone is temporally and spatially correlated with that of a transcription factor, the retinoic acid receptor, using a transgenic detector mouse (Balkani et al, 1991:PNAS 88:3437-3451). The transgene contains three copies of the retinoic acid response element, a basal promoter, and 5'-galactosidase as the reporter gene.

At the prospechene stage, cells in the ventrolateral zone of the forebrain and the olfactory placode are transgene positive based upon anti-β-gal immunostaining. At the early telencephalic stage, transgene activity is coexpressed with neuron-specific markers. Neurons are seen in the outer 1/3 of the epithelium, while transgene activity is limited to proliferative cells in the middle 1/3. Similarly, transgene positive cells are segregated from neurons in the olfactory epithelium. Transgene activity decreases as more postmitotic neurons are observed in the ventrolateral zone and olfactory epithelium, and by the forebrain rudiment stage it is absent in both places. These observations support a role for region-specific transcriptional regulation in the earliest subdivision, differentiation and intervation of the mammalian forebrain. A.S. LaMantia is supported by a National Down Syndrome Society Scholastic Award.

Previously we identified an aldehyde dehydrogenase present at high levels in the dorsal retina of the embryonic and adult mouse as the basic isomerase AHD-2 known to oxidize retinaldehyde to retinoic acid (RA). Comparative estimates of RA levels with a reporter cell line placed the retina among the richest organs in the early embryo; levels in ventral retina, however, exceeded dorsal levels. A zymography biosassay, the test of charge-separated protein fractions for RA synthetic activity with the reporter cells, revealed a different, acidic dehydrogenase in ventral retina. Affinity purification shows a 60 kD protein whose presence and amount parallels the ventral enzyme activity. Per protein amounts, this putative novel enzyme is several hundred-fold more powerful in RA synthesis than AHD-2.

The relative contributions of the two enzymes to total RA synthesis in the eye region vary with developmental age. The acidic dehydrogenase precedes AHD-2; alone it mediates the very active RA synthesis we see in the optic grove and surrounding tissue at E8.5. At E10 the acidic enzyme accounts for ~90% of synthesis in the eye region, at E14 for ~70% of synthesis in the retina, and at E17 for ~50%. In the adult retina the acidic enzyme is no longer detectable and all RA synthesis is mediated by AHD-2. The patterns in the expression of the enzymes suggest (1) that the acidic dehydrogenase plays a role in the determination of the eye as an organ, and (2) a particular cell population, created by the use of different dehydrogenases, is specifically targeted at the biochemical basis of positional information.

Retinoic acid (RA) in the embryo is generated from retinaldehyde by a series of dehydrogenases that differ in spatial localization and enzymatic characteristics including inhibitor susceptibility. In the early mouse embryo the retina and the spinal cord have the highest RA concentrations. Synthesis of RA to the retina is mediated by retinaldehyde dehydrogenase, which is mediated by different dehydrogenases, one in the dorsal, the other in the ventral retina.

In tests of dehydrogenases inhibitors on RA-synthesizing enzymes in vitro and for teratogenic effects in vivo, we found several reagents with relatively selective effects. In the retina, dial sulfate depressed preferentially dorsal RA synthesis in all species tested. The retinal enzyme was much less susceptible to sulfinilamid; in the mouse it was relatively inhibited by p-hydroxymercuribenzoate. A combination of inhibitors to the monooxygenation stage of retinoid synthesis, the most striking effect was in the trunk region; after very low concentrations of the drug the trunk was shortened and the notochord appeared swollen and wavy; higher concentrations produced in addition other phenotypes, including visceral anomalies. Inhibition of RA synthesis may be involved in malformations linked to disulfinilamid (=Antabuse®) in experimental animals and humans.

Members of the engrailed (en) gene family encode highly conserved transcription factors, containing five conserved protein domains, encoding a homeodomain. The murine en genes, En-1 and En-2, are initially co-expressed in a spatially restricted pattern across the presumptive mid/hindbrain junction. Later, the genes are expressed in restricted groups of neurons important for motor control. To examine En-2 function, a mutation which deletes the homeobox of the En-2 gene was made by homologous recombination in embryonic stem cells. Mice homozygous for this mutation, En-2, exhibit a reduced cerbellar granular layer and a distinct patterning defect of the cerebellar folia. Examination of the developmental profile of foliation has revealed that at the midline, the secondary fissure occurs in a more anterior position, causing a fusion of the pyramis and the uvula. As well, laterally, the amonoparamedial fissure fails to form a fusion of Crus II with the paramedial lobe. Analysis of a lobe-specific lacZ transgene marker also indicates that a lobe transformation within the mutant cerebellum. In an attempt to identify genes that interact with En-2, we have begun mapping complex mutants with other mutants such as weaver and unc connect (that affect the cerebellum). In addition, we are testing whether the mouse homologs of genes such as wingless (wg) interact with En. In Drosophila, wg acts as a target for this interaction in mouse, Wnt-1, a homolog of wg, is expressed in a similar domain as the En genes during early development. Mice homozygous for a Wnt-1 targeted mutation exhibit a deletion of the mid-hindbrain region projecting to the brain. Preliminary genetic and morphological evidence suggesting that Wnt-1 interacts with En-2 in the patterning of cerebellar foliation. We are currently examining the expression patterns of Wnt-1, En-1 and En-2 genes during cerebellar foliation to correlate their expression with the observed phenotypes.

WHY DO WHISKER-RELATED PATTERNS FAIL TO DEVELOP IN THE BRAINSTEM AFTER FETAL NGF INJECTION?

We (Henderson et al., Neurosci. Abstr. 17, '91) have reported that rats given 20 or 30 μg of NGF systemically on embryonic day (E) 15 and again on E18 failed to develop whisker-related, cytochrome oxidase patterns in the trigeminal (V) brainstem nuclei by the time of birth. Controls indicated that this effect was not due to surgical trauma, reduced body weight, or reduced metabolic rate. In the present study, untreated rats given NGF daily for up to 3 postnatal days also failed to develop brainstem whisker patterns. A series of experiments were designed to test 3 hypotheses: 1) naturally occurring V ganglion cell death is ameliorated by NGF injections; 2) elevated NGF levels alters ganglion cell projections to the whiskerpad and/or 3) to the brainstem. Stereological analysis indicated that V ganglion cell numbers were higher than normal at birth after NGF injections at E15 and again at E18 (± 12% of control, p < 0.05) and brainstem whisker patterns did not develop. One injection at E15 did not alter cell numbers at birth (97 ± 12% of control, p > 0.05) and brainstem whisker patterns did develop. In cases where patterns failed to develop, Dil- and Dia-labeled infraratular nerve fibers had normal trajectories and projections to the whiskerpad were not unusual. Yet, Dilaabeled V primary afferent projections to the brainstem did not exhibit whisker-related patches. Thus, naturally occurring ganglion cell death may be important for the patterning of central primary afferent projections. DE97754, DE79662, NS24679.

NERVE GROWTH FACTOR VI

463.1

A transgenic mouse line has been obtained which carries the prepro-NGF gene under a c-fos promoter. The expression of the transgene in the brain and spinal cord has been assayed in vivo, in correlation with ELISA estimations of the amount of NGF synthesized and secreted by both cell types. In transgenic astrocytes, basal intra- or extracellular amounts of NGF were not significantly different from normal despite the presence of high amounts of mRNA specific for the transgene. Stimulation of the promoter with phorbol esters (TPA) produced a 10-fold increase in the secretion of NGF by both normal and transgenic astrocytes. Stimulation of the cAMP pathway by dibutyryl-cAMP or forskolin induced a 2- to 3-fold increase in the secretion of NGF. In transgenic neurons, intra- and extracellular basal levels of the protein were respectively 4- and 2-times above normal ones. Fetal calf serum, which increased by 4 the levels of NGF secreted by normal neurons had no effect on transgenic ones. TPA, which increased by 10 the amount of NGF secreted by normal neurons had a slighter effect on transgenic neurons while dibutyryl-cAMP and forskolin increased the secretion of NGF by 10 in transgenic neurons and by 3 in normal ones. The possibility to selectively regulate the production of NGF in transgenic embryonic tissue offers new insights to the in vitro studies of the factor and to in vivo investigations by transplantation.

463.2
DIFFERENTIAL INFLUENCE OF NERVE GROWTH FACTOR ON NEUROPEPTIDE EXPRESSION IN VIVO - A NOVEL ROLE IN PEPTIDE SUPPRESSION?

In normal adult rat, approx. 50% of lumbar DRG neurons have high-affinity receptors for NGF. A role for NGF in these neurons appears to be maintenance of differented phenotype as denoted by the ability of excess or NGF to counteract loss of cell body and CPG following injury. To examine further at a cellular level possible mechanisms underlying the role of NGF in regulation of peptide expression in intact and injured neurons, particularly the right sciatic nerve was transected two weeks prior to sacrifice. In other animals, NGF was infused intracerebrally (125μg/hr) for 8 days following the two-week insecetive period. Cytokine sections were processed for receptor radioautography with radiolabeled NGF and for in situ hybridization with 35S-labeled oligonucleotide probes to detect α-CGRP, β-CGRP, SP, SOM, VIP, CCK, NPY and galanin (GAL) mRNA. In normal neurons α-CGRP, β-CGRP, SP, and SOM are also expressed and are regulated by NGF; whereas few neurons express CCK, NPY and GAL. Immunohistochemistry and in situ hybridization confirmed that NGF receptors are widely distributed in the adult rat CNS. The injury-induced increases in VIP, CCK, NPY and GAL mRNAs. These results indicate NGF can act in vivo to maintain and possibly augment, the regulation of peptide expression in intact sensory neurons. We suggest that NGF may be part of the signal that allows reversion to normal of responses to injury when axons regenerate into the intact sciatic nerve conduit, a rich source of NGF. 463.4

Mouse trisomy 16 (Ts 16) is an animal model of Down syndrome (DS). We have previously shown that fetal Ts 16 brain fascia transplant undergoes time-dependent, cholinergic neuronal atrophy similar to that seen in DS and Alzheimer's disease (AD). We now asked whether the transplants contained NGF receptors and would respond to NGF. We transplanted cell suspensions of fetal Ts 16 or control fascia into the hippocampus of young adult mice. Six months later, mice received continuous infusion of either NGF or vehicle for 2 weeks. Grains were examined by immunohistochemistry or in-situ hybridization to characterize neuronal morphology and gene expression. In both Ts 16 and control grafts, β-CGRP and SP mRNA were expressed in cholinergic neurons and not in the host mouse hippocampus. Similar to prior findings, Ts 16 cholinergic neurons appeared atrophic and were significantly smaller than controls (β-CGRP, Tu < 0.001). The decrease in all cholinergic neurons (Ts 16: 201 μ² (208 ± 29 μ²), p < 0.001). There was no evidence of Aβ deposition. NGF reversed neuronal atrophy in an animal model of spontaneous, age-related, neurodegeneration. We speculate that NGF may be reversing a neuronal death program and that expression of candidate death gene can be examined in this model.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
NGF RECEPTOR ACTIVATION AND INTERNALIZATION IN PC12 CELLS.
Mark Grimm* and William C. Mobley
Department of Neurobiology, University of California, San Francisco, CA 94143.

Neurotrophins interact with receptors on neurites to cause a response in the distant cell body. To understand how the signal is carried to the cell body, we have studied early events in the intracellular movement of NGF in neurons undergoing neurite outgrowth. Radiolabeled NGF was cotransfected with the NGF receptor (p75 NGFR) into PC12 cells. After 18 h, NGF was internalized into a large fraction of NGF was released in ligand. Neuronal membrane structures that escaped when the NGF was reimmobilized to cell-free conditions. When the NGF was reimmobilized to cell-free conditions, it was observed that the NGF is released from the PC12 cells. We conclude that the NGF, when internalized into early endosomes, and that transport vesicles arising from early endosomes accumulate in vitro. Preliminary experiments suggest that both p75 NGFR and trk are present in these vesicles.

Nerve growth factor (NGF) induces sprouting of injured adult rat focal cholinergic neurons and promotes their regeneration into nerve grafts and hippocampal formation. We have investigated the potential neurotrophic or cholinergic effects of NGF in the adult rat focal cholinergic septohippocampal system. 1) Animals received bilateral sciatic nerve grafts between the disconnected septum and hippocampal formation. A 4-week NGF infusion into the rostral lateral ventricle caused sprouting of cholinergic fibers in the dorsal lateral septum, which extended toward the ventricle. 2) In mice with nerve grafts and 2-week infusions with NGF into the fornix (proximal to the lesion and grafts), axons sprouted in the medio-dorsal septum, i.e. toward the infused fornix. However, no fibers were seen in the nerve, i.e. regrowing axons had reached near the NGF source. 3) NGF infusion into the contralateral ventralis of animals with a unilateral fimbria-fornix transaction but no graft, induced sprouting toward the midline of the septum but not in the normal side. 4) Infusion of a low NGF dose into the lesioned septum induced sprouting only along the infusate. Thus, the location of an NGF source (the location of the highest NGF concentration) can control the orientation of outgrowing cholinergic axons, indicating that NGF has neurotrophic effects in the adult animal, as it has for developing peripheral nervous system in vivo and in vitro. Support: NINCDS grant NS-18549 and 27047.

The neurotrophic family of growth factors includes several neurotrophins, which are the most potent members of the growth factor (NGF), all of which promote neuronal survival and differentiation. The biological actions of neurotrophins are exerted via activation of tyrosine kinase receptors. In addition, all neurotrophins are recognized by a different receptor molecule, known as p75, which is required for NGF signal transduction and is expressed in neurons as well as in some non-neuronal tissues. In the preovulatory ovary, non-neuronal p75 expression is localized to theca cells of developing follicles. Immunochemical characterization of p75 in embryonic rat ovaries using a specific monoclonal antibody (PG1 190) revealed that the receptor is expressed in mesenchymal cells. By gestational day 18, these cells begin to form stroma "pockets" which, as gestation proceeds, separate the presumptive pre-granulosa cells into discrete groups surrounding individual oocytes. This enclosure continues postnataally resulting in an abrupt formation of primordial follicles between 24 and 48h after birth. In vitro exposure of neonatal ovaries in organ culture to affinity purified NGF antibodies (2.4µg/ml), resulted in a striking reduction (>80%) in follicular formation quantitated 48h later. Unexpectedly, this was accompanied by widespread cell death confined to p75-positive stromal cells. The results suggest that NGF and/or other members of the neurotrophin family are essential components of the differentiation program that governs follicular formation. (Supported by NIH grants HD24670, HD74748, HD18185, RR01663)
The Lck A, Lck B and Lck C genes have been shown to encode a class of receptors for nerve growth factor, a neurotrophic factor, neurotrophin 3 and neurotrophin 4. We have sought to study the role of these tyrosine kinase receptors in a vertebrate model of neurodevelopment, the zebrafish Brachydanio rerio. Nucleotide sequence analysis of 120 clones derived from P1 hybrids revealed five distinct representatives homologous to Lck A, Lck B and Lck C. A lambda ZAP cDNA library has been constructed from day 1 embryo RNA and cDNA clones have been isolated. Southern blot hybridization has been shown to show that each of these Lck sequences represent a unique zebrafish gene. Northern blot analysis reveals that these zebrafish Lck genes are expressed early in embryonic development. Some of the novel Lck members identified in zebrafish may be the receptors for previously uncharacterized neurotrophic factors. These results suggest that one or two Lck genes have not yet been described in mammals.

Intracerebral implantation of cells genetically altered to secrete high levels of NGF has profound effects on local neuronal survival after excitotoxic or knife-cut lesions. The effects of such biological NGF delivery systems, specifically the induction of genes encoding protective enzymes or stress proteins in surrounding neurons or glia, has not been well studied. We chose to investigate the effects of an implanted NGF-secreting fibroblast cell line on local levels of acetylcholinesterase (AChE), the stress proteins c-fos, c-myc, heat shock protein-72 kDa (hsp72), and ubiquitin (UB), and the peroxidase enzyme catalase. Seven days after unilateral corpus callosum implantation of either a genetically altered NGF-producing (NGF+) or control (NGF-) fibroblast cell line, we stained tissue sections surrounding either the NGF+ or NGF- grafts using antibodies raised against c-fos, c-myc, or Ub, though both types of grafts stained faintly for c-fos. Both NGF+ and NGF- grafts induced a high level of hsp72 immunoreactivity in tissue immediately surrounding the grafts. AChE staining was unchanged in areas adjacent to the grafts, and though there was no fibroblast AChE staining, multiple AChE positive fibers appeared to be growing into or traversing the NGF+ grafts. In contrast to the above, NGF+ cells caused increased catalase staining in astroglial cells adjacent to the grafts. These catalase positive astroglial cells were not seen in areas distant from the NGF+ grafts, nor were they seen in brains implanted with NGF- cells. These results suggest that the local protective effects of NGF+ fibroblast grafts may be mediated through changes in peroxidative metabolism due to increased levels of catalase. If so, NGF-mediated protection and neurotropism in the adult brain may be caused in part by an increase in cell resistance to lipid peroxidation.

**Molecular Cloning and Developmental Analysis of Five Lck Genes in Zebrafish.**

S.C. Martin*, J.W. Wo and G. Heinrich

University Hospital and Boston University School of Medicine, Boston, MA. 02118

NGF has not been well studied. We chose to investigate the effects of an implanted NGF-secreting fibroblast cell line on local levels of acetylcholinesterase (AChE), the stress proteins c-fos, c-myc, heat shock protein-72 kDa (hsp72), and ubiquitin (UB), and the peroxidase enzyme catalase. Seven days after unilateral corpus callosum implantation of either a genetically altered NGF-producing (NGF+) or control (NGF-) fibroblast cell line, we stained tissue sections surrounding either the NGF+ or NGF- grafts using antibodies raised against c-fos, c-myc, or Ub, though both types of grafts stained faintly for c-fos. Both NGF+ and NGF- grafts induced a high level of hsp72 immunoreactivity in tissue immediately surrounding the grafts. AChE staining was unchanged in areas adjacent to the grafts, and though there was no fibroblast AChE staining, multiple AChE positive fibers appeared to be growing into or traversing the NGF+ grafts. In contrast to the above, NGF+ cells caused increased catalase staining in astroglial cells adjacent to the grafts. These catalase positive astroglial cells were not seen in areas distant from the NGF+ grafts, nor were they seen in brains implanted with NGF- cells. These results suggest that the local protective effects of NGF+ fibroblast grafts may be mediated through changes in peroxidative metabolism due to increased levels of catalase. If so, NGF-mediated protection and neurotropism in the adult brain may be caused in part by an increase in cell resistance to lipid peroxidation.

**Immunological and Ultrastructural Localization of Low- and High-Affinity NGF Receptors on Neuronal Cells.**

P. Spoerri*, L. Rettelli, E. Dal Toso and S.D. Shapira

Fidia Research Laboratories, Abano Terme, Italy.

Responsiveness of neural cells to NGF appears to require expression and ligand binding to both the low-affinity NGF receptor (LNGFR) and the protooxygenase product trk, the latter being a receptor tyrosine kinase. We recently described the immunolocalization of LNGFR on PCL2 phaeochromocytoma and C6 glioma cells using immunogold electron microscopy. We now demonstrate the immunolocalization of LNGFR and the high-affinity component of the NGF receptor, trk (HNGFR), on the former cells and cultured neonatal rat dorsal root ganglia neurons using a double labeling technique. Receptor-specific antibodies were utilized in conjunction with immunogold conjugated to colloidal gold particles of different sizes. NGF-treated cells displayed considerable colocalization of LNGFR-HNGFR immunoreactivity (IR). Gold particles associated with LNGFR were by far the more numerous, being frequently seen near 2-3 (or more) gold particles delineating the HNGFR. Positive trk-IR thus seems to colocalize with LNGFRs in at least these neural cells.

**Local Response to Intracerebral Grafts of NGF-Producing Fibroblasts: Induction of a Peroxidase Enzyme.**

D. M. Prim, I. Schuhmacher, M.P. Ston, J.O. Brooksfield and D. L. Jansen

Neuroregeneration Laboratory, McLean Hospital, Belmont, MA.; Molecular Neurogenetics Unit, Neurology and Neurosurgery Services, Massachusetts General Hospital, Boston, MA.

NGF has not been well studied. We chose to investigate the effects of an implanted NGF-secreting fibroblast cell line on local levels of acetylcholinesterase (AChE), the stress proteins c-fos, c-myc, heat shock protein-72 kDa (hsp72), and ubiquitin (UB), and the peroxidase enzyme catalase. Seven days after unilateral corpus callosum implantation of either a genetically altered NGF-producing (NGF+) or control (NGF-) fibroblast cell line, we stained tissue sections surrounding either the NGF+ or NGF- grafts using antibodies raised against c-fos, c-myc, or Ub, though both types of grafts stained faintly for c-fos. These catalase positive astroglial cells were not seen in areas distant from the NGF+ grafts, nor were they seen in brains implanted with NGF- cells. These results suggest that the local protective effects of NGF+ fibroblast grafts may be mediated through changes in peroxidative metabolism due to increased levels of catalase. If so, NGF-mediated protection and neurotropism in the adult brain may be caused in part by an increase in cell resistance to lipid peroxidation.

**Reversible Abolition of Visual Motion Processing Mechanisms in the Lateral Suprasylvian Cortex of the Behaving Cat.**

S.G. Lomberg, P. Comwell, J.S. Sun, M.A. MacNeil and B.R. Payne

Department of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA. 02118

The purpose of the present study was to test the hypothesis that the lateral suprasylvian (LS) visual cortex of the cat is critical for the identification of a stationary pattern partially obscured by a moving mask. Two cats were trained to perform a task involving the discrimination of different shapes. The task was performed with and without the moving mask. The results showed that the LS cortex was critical for the extraction of stationary patterns from a field filled with contours in motion. The absence of LS cortical activity this ability is abolished. (Supported by NIMH #4647 and the Comwell Family).
464.3 INTEGRATING VISUAL MOTION RESPONSES FROM NEURONS IN COR-TICAL AREA MT BY ADAPTIVE FILTER SELECTION. S. J. Newhall* and T. J. Siwczyk. The Salk Institute, La Jolla, CA, 92037.

Integrating the responses from multiple motion-sensitive neurons in the visual cortex of the monkey may improve motion perception. We have developed an algorithm that combines the responses of multiple motion-sensitive neurons in the MT cortex of the monkey to generate a single output signal that is more reliable than any of the individual neurons.

464.4 CORRELATED ACTIVITY OF NEURONS IN AREA MT. E. Zohary*, M. N. Shadlen, and W. T. Newsome. Dept. of Neurobiology, Stanford University, Stanford, CA 94305.

We have found that the activity of neurons in MT is correlated with the activity of other neurons in the same or different areas. This correlation is not due to chance, as the correlation is stronger when the neurons are in the same area, and it is weaker when the neurons are in different areas. The correlation is also stronger when the neurons are in the same layer, and it is weaker when the neurons are in different layers.

464.5 PREDICTING PSYCHO PHYSICAL PERFORMANCE FROM POOLED NEURONAL RESPONSES. M.N. Shadlen*, W.T. Newsome, K.H. Breen, E. Zohary and J.A. Movshon*. Dept. of Neurobiology, Stanford University, Stanford, CA 94305; Howard Hughes Medical Institute and Center for Neural Science, New York University, New York, NY 10003.

We have developed a model that predicts the performance of a population of neurons based on the activity of a single neuron. The model is based on the idea that the activity of a single neuron is a good predictor of the performance of the population because the activity of the single neuron is a good predictor of the performance of the population. The model is tested on data from monkeys performing a visual discrimination task, and it is found to be accurate.

464.6 RESPONSES OF NEURONS IN AREA MST DURING DIRECTION DISCRIMINATION PERFORMANCE: A COMPARISON OF NEUROLOGICAL AND PSYCHOPHYSICAL SENSITIVITY. Simone Ceolini and W.T. Newsome*. Dept. of Neurobiology, Stanford University, Stanford, CA 94305.

We have found that the activity of neurons in MST is correlated with the activity of other neurons in the same or different areas. This correlation is not due to chance, as the correlation is stronger when the neurons are in the same area, and it is weaker when the neurons are in different areas. The correlation is also stronger when the neurons are in the same layer, and it is weaker when the neurons are in different layers.
464.10

Extraocular visual auras are involved in motion vision. Focal tMS of striate cortex degrades spatial acuity for letter trigrams and Landolt-C stimuli. TMS of extrastriate cortex may also degrade spatial acuity for random dot stimuli. Subjects identified the direction that correlated dots moved, using a background located 10 deg to the left or right of fixation. Psychometric functions for this four-direction, forced-choice task were fitted. The percentage of correlated dots required to achieve 80-90% correct responses was determined. The test was then repeated with additional randomly interspersed trials at the determined percentage of correlated dots during which TMS was applied 50-250 msec after the onset of the 50 msec motion stimulus. TMS was applied with a 9 cm coil over the lateral posterior hemispheres at an intensity of 1.8 Tesla. In five subjects, TMS degraded the motion perception when applied 100-150 msec after stimulus onset. TMS produced a 36% mean decrease (range 33% to 44%) in correct responses when applied 125 msec after motion stimulus onset. In three subjects, little or no decrease was found when TMS was applied 50-75 msec or 175-250 msec after stimulus onset. This study was repeated over human extrastriate cortex transiently degraded motion perception and may be valuable in tracing pathways of visual information processing. (Supported by NEI E03387 and The Valley Foundation).

464.11

Transcranial magnetic stimulation (TMS) in healthy human subjects (N=42) can produce specific reversible defects of visual perception. Single TMS pulses are applied systematically to different locations over the central, temporal, parietal and frontal cortex using a Cadwell M10-10 magnetic stimulator device with a maximum output of 2 Tesla peak flux density. A number of different visual tasks have been employed. In a task with visual letters, the delay between stimulus onset and TMS, and type of magnetic coil have all been varied. In the motion perception task, for instance, a probe with a 14x14 dot matrix (0.01° x 0.01°) oriented parallel to the short term memory scanning, motion direction detection and color identification. The effects of visual stimulation (200 Hz) were studied on the visual evoked potential (VEP). The obtained VEP amplitude at the brain central level was measured.

464.12

Electrophysiological Concomitants of Apparent Motion in Man. R. Pfeffermann, V.G. Seminotti. Center for Neuroactive Drugs, Dept. of Motion Analysis, Institute of Neurosciences, Salk Institute, La Jolla, CA 92037; Institute of Cybernetics and Biophysics, CNR, Genova, 16132 Italy.

A Witheiser's paradigm is used to induce the visual perception of apparent motion was approximated on a VENUS Neuroscientific system by producing a bidimensional 5x5.9 deg image of alternating black and white sinusoidal vertical bars counterphasing at 0.5-8 Hz. Stimulation was at 0.4 or 5.0 cd/lm (or temporal frequency parameters used to produce (visual) retention and cortical evoked potentials in man. The signal was recorded 1.00.00.0 HI via dermal electrodes located on inferior eyelid (reference: contralateral upper and occipital area; ground; midfrontal), and processed offline (512 sample/second) by FFT. Eight healthy subjects were recorded; all agreed in reporting the expected perception of apparent motion with high probability at 2.0 Hz or 5.0-8.0 Hz temporal frequencies with visual evoked potentials at 10.0 and 5.0-5.0 cd/lm, respectively. Significantly higher amplitudes of the visual and cortical 2nd harmonic were observed at these temporal frequencies compared to higher or lower frequencies (512 Hz) when the percept was not reported to be as evident and the latency amplitude was higher than 2nd harmonic. The observation was consistent between and within subject, and suggests a potential concurrence of Witheiser's phenomenon with the spatial/temporal frequency-dependent functions of the visual system concurring in the generation of retention/cortical visual evoked potentials.

465.1

'H and 3P in Vitro NMR Studies of Chronic Hypoxia in FISHER 344 RATS. R. Kalonym* E. G. N. Exner, 3P. Lab of Neurology, University of Pittsburgh, Pittsburgh, PA 15261

Recent biochemical and clinical observations suggest that repeated, brief, mild energetic stress could, in some individuals, trigger molecular and metabolic mechanisms that result in the biochemical findings in the brains of Alzheimer disease (AD) patients. In this study, we investigated the biochemical responses of Fischer 344 rat brains by subjecting them to repeated hypoxia for 30 seconds for a period of two weeks. Three months and 10 days old animals were used to investigate age-dependent changes in metabolic changes under hypoxic stress. Of 3P NMR studies of the free clamped brains of controls and affected animals at the end of the two weeks indicate: (1) a nonsignificant increase in the level of the excitatory amino acid aspartate and glutamate in 3 month old animals. In the 10 days old animals, aspartate level was unchanged, whereas a 5% elevation (p=0.07) of glutamate was measured; (2) the inhibitory amino acid GABA is increased by 20% in 3 month old animals (p=0.04) and unchanged in 10 day old animals; and, 3P levels were decreased by about 9% in 3 month old animals (p=0.02) and by about 4% in 10 day old animals. These preliminary results indicate that aged animals are more susceptible to energetic stress than the young animals. Our 'H NMR results indicate a permanent alteration in some amino, 3P levels but not in others. However, 3P NMR results show no significant alteration in energy metabolism or membrane phospholipid metabolism indicating recovery of the brain from those energetic stress.

Glutathione Depletion Induces Heme Oxygenase-1 (Hsop2) mRNA and Protein in Rat Brain. J. P. Everin and M. D. Malins. Dept. of Biophysics, Univ. Rochester School of Medicine, Rochester, NY 14621

In mammals, heme oxygenase isoforms, HO-1 and HO-2, cleave heme to produce bile pigments. HO-1 is a stress protein (HSPO2) induced by chemicals in systemic organs the sensitivity of the rat brain. HO-1 mRNA and protein to cellular glutathione (GS) levels and provides the first evidence of reciprocal regulation of two antioxidant pigments: GSH and bile pigments in the rat brain. The treatment of rat brain with diethyl malate (DEM) (4.7 mmol/kg ip) caused a pronounced decrease in brain GSH levels. GS levels remained depressed for at least 24 hr post-injection. Northern blot analysis of DEM treated brain revealed an increase in HO-1.1-1.6 Kb mRNA up to 10-fold that of controls in a manner reciprocal to that of GS. Similarly, treatment of neonatal rats with buthionine sulfoximine (BSO, 0.5 mmol/kg ip; twice daily, 2-2 days of life) caused a marked decrease in brain GSH and a concomitant 10-fold increase in brain 1.6 Kb HO-1 mRNA above control levels. In contrast, the level of two homologous HO-2 transcripts (1.3 and 1.9 Kb) did not increase in response to either DEM or BSO treatment. Analysis of brain HO-1 immunoreactive protein following in DEM treated induced HO-1 protein in only select non-neuronal cell populations. Furthermore, the epidymal cell line expressing these proteins, Bergmann glia, cerebellum, leptomeninges lining brain and glia throughout brain responded to treatment by increasing HO-1-like immunoreactive elements.

We suggest that when glutathione induces HO-1 protein, hence increased capacity to form bile pigments, may be vital to those brain cells which normally depend on the triplepeptide for antioxidant defense. Supported by NIH Grants R37 ES03491, ES03968 and ES01247.

Society for Neuroscience Abstracts, Volume 18, 1992

Dept. of Biology, UCLA, Los Angeles, CA 90024. 

Catalytic, pharmacological and molecular studies have recently identified the genetically variable cytochrome P450IDI in mammalian brain. P450IDI (debrisoquine hydroxylation) is responsible for the metabolism of many drugs including neuroleptics, codeine and antidepressants. In addition, significant overlap was observed between substrates inhibitors for the dopamine transporter and for the P450IDI, for example, (-)cocaine, MPTP, methylenidate and d-amphetamine. In order to study this CNS P450IDI, we used PCR to detect the presence of P450IDI and cell marker RNA in immortalized cell lines. 10 of 15 centrally-derived cell lines were positive for the P450IDI RNA. Variation of RNA levels in 8 rat brain regions was also studied. In addition, 2 of 3 pancreatic cell lines and a fibroblast cell line also contained the P450IDI RNA. Studies of regulation, inducibility and enzyme activity are underway. Cell lines containing P450IDI should enable us to further our understanding of the role of the P450IDI enzyme in the CNS. (RFT is supported by the MRC of Canada)

The etiology of tardive dyskinesia (TD), a frequent and usually irreversible side effect of the chronic use of neuroleptics, remains unknown. Because available pathologic data do not support presynaptic hypotheses and implicate in the mitochondrial electron transport chain have recently been documented in several movement disorders, we thought it important to test the possibility that neuroleptics may affect mitochondrial respiration. Accordingly, adult rats received fluoxetine (Flu; 4 mg/kg) in saline daily for 30 days and were sacrificed 1.4 and 7 days after the last injection. Control animals received vehicle only. Chronic Flu administration caused significant changes in complex I, II, III and IV activities in both caudate-putamen and nucleus accumbens compared to controls. The effect of Flu on mitochondrial respiration was partially reversed as stratal complex I activity improved 7 days after the last injection, while the other complexes still exhibited some alterations. In addition, brain mitochondria prepared from naive rats and incubated with different classes of neuroleptics showed reduced complex I activity as compared to controls. Our findings with neuroleptics in rats may be relevant to the underlying pathophysiological mechanisms of TD.

465.7 *Kainate Receptor Expression Induces Toxicity in Fibroblasts and Hippocampal Slice Cultures.* L. Bergold, J. Casaccia-Bonnefil, and R. Pederson. SUNY-HSCB, Brooklyn, NY, and 4 The Albert Einstein School of Medicine, Bronx, NY. 

The CA3 region of the hippocampus is prone to damage by the excitotoxic kainate (KA) through potential mechanisms involving either recurrent excitation and/or the high expression of KA receptors. In order to develop a gene transfer system to study KA toxicity, a cDNA encoding the KA receptor subunit, gluR6, (provided by S. Heineman) was cloned into a defective HSV:1 viral vector, and used to transfer and express KA receptors in NIH3T3 fibroblasts and organotypic slice cultures. Fibroblasts infected with HSVgR6 became sensitive to KA toxicity, whereas infection with HSVlac, which expresses g-glutamidas, did not. This suggested that HSVgR6 efficiently transferred and directed expression of KA receptors, resulting in toxicity after exposure to KA. Slice cultures were infected by a 250ml microinjection of virus to the stratum pyramidale of CA1 or CA3. Infection with HSVlac resulted in expression of the reporter gene in 11-13 cells centered around the stratum pyramidale with no overt damage to the slice culture. In contrast, microinjection of HSVgR6 to CA1 and CA3 produced target site effect. The effect was limited to the site of injection, most CA1 pyramidal cells were killed, suggesting that recurrent excitation in CA3 may be an important transsynaptic excitotoxic mechanism.

465.8 *Excitotoxic Lesions in Organotypic Hippocampal Slice Cultures.* P. Casaccia-Bonnefil* and P. Bergold.4 Program of Anatomy and Cell Biology and Department of Pharmacology SUNY-HSCB, Brooklyn, NY 11203. 

Slow neuronal excitotoxicity is believed to underlie many chronic neurodegenerative diseases. A 36 hour treatment of organotypic hippocampal slice cultures in low concentrations of glutamate agonists or GABA-A antagonists results in loss of specific populations of both principal cells and interneurons three days after the drugs are removed. The loss of principal cells is detected by methylene blue staining, while subpopulations of interneurons are detected with anti-neuronal antibodies. GABA-A antagonists as well as calbindin D28K, parvalbumin, neuropeptide Y, somatostatin, and VIP. A complete loss of dentate granule cells and most hilar neurons is seen after treatment with 50μM glutamate. This treatment has no effect on CA1 or CA3. Application of concentrations of picROTOX up to 500μM does not appreciably increase the lesion. Exposure to 50μM kainate kills only CA3 piriform cells and hilar cells, and 10μM NMDA kills only CA1 neurons. Exposure to 1μM of either agonist has no effect. Co-application of both 50μM picROTOX and 1μM kainate, in contrast, destroys CA3, the hilus and the dentate gyrus. This suggests that specific patterns of delayed excitotoxicity can result from the synergistic action of both increased excitation and decreased inhibition.
465.9 CALPAIN INHIBITORS PREVENT CAPSAICIN-DEPENDENT NEUROTOXICITY IN DORSAL ROOT GANGLION NEURONS. P.S. Chordi1, J.R. Savidis, D. Bleasman & R.L. Miller, Dept. Pharmacol. and Physiol., Univ. of Chicago, Chicago, IL 60637.

Capsaicin (N-methyl-N-vanillyl-6-nonalamide) exerts a specific excitatory action on nociceptive sensory neurons resulting in elevated (Ca²⁺), and subsequent neuronal degeneration. A postsynaptic depolarizing current (iCa²⁺) with cell death is the Ca²⁺-dependent thiol-protease, calpain. In the present study we used cultured dorsal root ganglion (DRG) neurons. Inhibitors can prevent capsacain-mediated neurotoxicity. DRG neurons were isolated from 3-5 day old rat pups and grown in culture for up to 35 days. Two functional assays were employed to determine the number of capsacain sensitive neurons in the culture: (1) Calpain stimulated Ca²⁺-uptake; after exposure to 1-10μM capsacain for 20 minutes, in the presence of 5μM Ca²⁺, silver nitrate revealed that approximately 30-40% of neurons examined were sensitive. (2) Fura-2 based microfluorimetry; bath application of capsacain (1-10μM for 30-60 seconds) resulted in increases in [Ca²⁺] in 30-45% of DRG neurons examined. The capsacain response in both (1) and (2) were prevented by applying the capsaicin receptor antagonist ruthenium red (1μM), but were unaffected by the thiol-protease inhibitors E64 (10μM) or the calpain inhibitor MDL-18170 (10μM). Capsacain-mediated neurotoxicity was assessed by adding capsacain (1-10μM) to DRG cultures for 20 minutes in 5μM or 10μM extracellular Ca²⁺ ([Ca²⁺]o) and after 17-24 hours using propidium iodide/fluorescein diacetate fluorescence to determine the percentage cell survival. Capsacain treatment (30-100μM) in 10μM Ca²⁺, produced cell death in up to 30% of neurons. However, when either E64 or MDL-18170 (both at 10μM) were added to the media, the death produced by capsacain treatment was completely prevented in 5μM Ca²⁺ (p<0.001, n=4) and partially prevented in 10μM Ca²⁺ (p<0.001, n=4). [Ca²⁺]o (1-10μM extracellular Ca²⁺), preincubation with the Ca²⁺-chelator BAPTA-AM (50μM) or addition of ruthenium red (1μM) also prevented capsacain-dependent cell death. These experiments provide strong evidence that capsacain neurotoxicity is mediated via activation of the Ca²⁺-activated protease, calpain.

Forty rabbits were given either vehicle or ddc, by oral intubation, at a dose of 35 mg/kg/day for 24 weeks. The sciatic nerves were examined at 4 weeks intervals beginning at 8 weeks. Myelins splitting at the interperiodic line and intramyelinic edema were first evident at 16 weeks and closely correlated with enlarged mitochondria with abnormal ultrastructure. Analysis of a myelin fraction isolated from the nerves showed that ddc treatment did not affect protein distribution, lipid distribution or CNPase activity. No abnormalities were noted in neurons of dorsal root ganglia. We conclude that the primary effect of ddc is on mitochondrial function in Schwann cells with subsequent myelin degeneration.

The accessory radula closer muscle (ARC) and its innervation provide a model system for studying the role of neuromodulation and co-transmission. The ARC is innervated by two cholinergic neurons, B15 and B16, and a serotonergic modulatory neuron, the MCC. The motorneurons also contain modulatory peptide co-transmitters falling into four families. B15 contains the SCPs, buccalins, and FRPs, and B16 contains the buccalins and myomodulins. We have developed a method using RIA to directly measure SCP and buccalin release from the ARC following intracellular stimulation of a single motorneuron. We previously showed that SCP and buccalin are stored in the same dense core vesicles, and co-released in response to pharmacologically relevant patterns of B15 stimulation. Here, we report the effects of some of the modulators on peptide release from B15. Buccalin A, at 5×10⁻⁷M, decreased SCP release from B15 suggesting that buccalin released from B15 terminals can inhibit its own release, since SCP and buccalin are co-released. Furthermore, buccalin released from B15 may decrease the sensitivity of B15 because stimulation of the two motorneurons together produced less SCP release from B15 than stimulating B15 by itself. SCPs, at 10⁻⁷M, had no effect on buccalin release from B15, suggesting that SCP release from B15 does not affect buccalin release. Serotonin, at 5×10⁻⁷M produced an increase in SCP release from B15, as did stimulation of the MCC. These results suggest that the extrinsic serotonergic modulatory system can affect the intrinsic peptidergic modulatory system and that the intrinsic modulatory system can affect itself.

The peptides SCP and myomodulin (MM) are contained in the ARC motor neurons B15 and B16 and increase ARC contraction amplitude and relaxation rate. The mechanism by which these changes occur was investigated by SDS-PAGE and protein phosphorylation and phosphatase assays. We previously reported that synthetic peptide application to intact ARC muscle induced phosphorylation of a ±500 KDa protein. B15 neurons were stimulated intracellularly with individual current pulses at physiological rates for 10 min. Stimulated and non-stimulated muscle homogenates were phosphorylated using a back-phosphorylation paradigm with γ[³²P]ATP in the presence and absence of CAMP. Protein stimulation and the expression of the 70 kDa CAMP induced incorporation of [³²P] into a ±500 KDa protein in ARC muscle. Stimulation of B16 at physiological rates for 10 min also prevents CAMP induced incorporation of [³²P] into this protein. These results indicate that either B15 or B16 stimulation induces phosphorylation of this band. The phosphorylation could be due to either increased kinase activity or decreased phosphatase activity. Measurements of phosphatase activity following MM application show that phosphatase activity is not changed. Direct evidence implicating PKA in the phosphorylation of this band was provided by forward phosphorylation experiments in which muscle homogenates containing either SCP or MYO were treated with a specific peptide PKA inhibitor (P1K). P1K inhibited the phosphorylation of the ±500 KDa protein in a dose dependent manner. These results suggest that SCP and MM conjugate on the same substrate protein and utilize the same second messenger pathway.
**466.3** EFFECTS OF NEURON B16 STIMULATION AND MYODUOULIN APPLICATION ON cAMP AND PKA LEVELS IN ARC MUSCLE OF APISIA. S.L. Hooper, E.C. Cropper, W.C. Probst, I. Kuentzmann & K.-R. Wess. West Dept Physiology, M. Sinai Sch Med, NY, NY 10029. Ctr. Neurobiol. & Behav., Columbia U and NY Psych Inst, NY, NY 10023. The SCPs and myodoulins (MMs), modularly neuropetides present in the intestine of the ARC, exert similar action on ARC contraction amplitude and relaxation rate. The peak SCPs action at the PKA target site transduction pathway. Our studies (1990) on phosphodiesterase data (Probst et al., this volume) suggest that MM may also utilize cAMP and PKA as a second messenger system.

We now report that cAMP application to ARC muscles causes dose dependent cAMP increases, but to maximal levels only approximately one tenth that induced by SCP application. The maximum increases of cAMP levels following physiologically relevant stimulations of neurons B5 (SCP) and B16 (MM) are approximately the same. However, unlike SCP application or B15 stimulation, MM application or B16 stimulation show desensitization, with cAMP levels decreasing rapidly with continued B16 stimulation or MM application.

Unlike SCP, MM application to intact ARC muscles induces only small increases of active PKA in low speed super centrified muscle homogenates. However, MM induces large increases (though still small compared to those induced by SCP) in active PKA in both uncentrifuged homogenates and in resuspensions of the pellet fraction, suggesting that MM induces both PKA activation and translocation to the pellet. Taken together, these data indicate MM'S effects are likely mediated via the cAMP/PKA signal transduction pathway. The rapid dose dependent desensitization of MM induced cAMP augmentation may contribute to the depression of ARC contraction amplitude seen when high doses of MM act on the ARC.

**466.5** PEPTIDE IMMUNOREACTIVITY IN IDENTIFIED SENSORY AND MOTOR NEURONS OF MEDICAL LEECH EMBRYOS AND ADULTS. J.W. Bledsoe, I. Sellen and M.P. Nathanson. Neurobiology Research Center and Department of Physiology & Biophysics, Univ of Alabama at Birmingham, Birmingham, AL 35294.

Identified neurons in the medicinal leech, Hirudo medicinalis, are known to express several neuropeptides. Using an antibody against a synthetic peptide, crinacine pigmented dermopa (PDH) (Dirksen et al., Cell Tissue Res. 250:377, 1985), we have observed the PDH nerve cord for innervation. In the adult, the anti-PDH labels a large number of neurons in both the ventral and dorsal aspects of each ganglion. We used electrophysiological techniques and microinjection of the fluorescent dye Lucifer Yellow to identify some of the neurons and then double-labelled the preparations with anti-PDH, visualized with a rhodamine-conjugated secondary antibody. Of particular interest was the double-label of two well studied neurons, including a primary sensory neuron known as the lateral encapsope (NE) cell and the heat-activated (HE) motor neuron. There has been no previous data to suggest possible neurotransmitters or modulators for any of the primary sensory neurons. In contrast, the HE was previously shown to be cholinergic and to also express a FMRFamide epitope (Kuhlman et al., J. Neurosci. 5:2301, 1985). Certain other FMRFamide labeled neurons, including the dorsal excitatory motor neuron 3, showed no staining with anti-PDH. Other double labeled neurons include the nitropeptide and the inhibitory motor neurons 1 and 2. In embryonic Hirudo, the N-cell appears to be the first neuron labeled by anti-PDH, being distinguished by embryonic day 10 (E10). The HEs are identifiable using this antibody by E12, which is 3-4 days prior to the earlier FMRFamide labeling. Additionally, a cell that has been identified as a possible HE homolog in ganglion 2 labeled at the same stage of development as the definitive HEs. This staining pattern and temporal progression argue that the PDH-epitope is carried by a different antigen than that which precipitates a FMRFamide epitope. Supported by NSB3606D(U) and NS39463(MPN).

**466.6** OCTOPAMINE-IMMUNOREACTIVE NEURONS IN THE LOBSTER CNS. H. Schneider, B.A. Trimmer, J. Rapus, M. Eckert & E.A. Kravin*. Harvard Medical School, Neurobiology Dept., Boston, MA 02115, and University Jena, Tierphysiologie, 07580 Jena, FRG.

With an antibody directed against an octopamine-gluteraldehydethioglycol complex we detected about 86 immunoreactive neurons within the entire CNS of 4th stage larval of the American lobster, Homarus americanus. The cells are distributed as follows: brain - 12, circumoesophageal ganglia - 2, suboesophageal ganglia - 38, thoracic ganglia - 6 each, and abdominal 4th and 5th abdominal ganglia - 2 each. All the octopamine-immunoreactive cells are paired and located along the dorsal or ventral midline. Of the 86 neurons, 24 have been identified as neurosecretory cells, and 32 are intersegmental ascending thoracic, ascending abdominal, or descending interneurons. The neurosecretory system is arranged segmentally and located entirely within the thoracic and suboesophageal ganglia. The projections of these neurons elaborate extensive varicose fibres along the proximal regions of 2nd thoracic and suboesophageal roots. These neurons are complementary to 2 pairs of large serotonin-containing neurosecretory neurons found in the fifth thoracic and first abdominal ganglia. The sets of neurosecretory neurons are arranged differently: the serotonin cells are intersegmental while the octopamine cells are segmental. Using a biochemical assay, the cell bodies of octopamine-immunoreactive neurosecretory cells in the thoracic segment of the nerve cord were found to contain 40-100 fmol of octopamine, while control neurons had none. Supported by NHI and DFG Sch 568/1-1.

**466.7** IDENTIFICATION OF A DROSOPHILA HISTIDINE DECARBOXYLASE GENE REQUIRED FOR PHOTORECEPTOR SYNAPTIC TRANSMISSION. J.Y. Berkey*, R.J. M. Solek, D.W. Ch. Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN and Dept. of Ophthalmology, Northwestern Univ. Med. School, Chicago, IL.

Histamine has been proposed to be the synaptic transmitter used by interneuronal photoreceptors, including Drosophila. Using genetic and molecular cloning approaches, we identified a Drosophila gene encoding histidine decarboxylase (HDC), the enzyme which converts histidine to histamine. Drosophila predicts from a single copy predicted to have a 60% identity to homologs in mammals. The Drosophila cDNA hybridized to an 0.4 region of the polytene chromosomes, to which the hdc gene was mapped. Using an antibody recognizing the HDC protein, antibodies to this gene that this gene encodes. The hdc gene is expressed in the insect eye. Expression is detected in the eye and in adults. Northern blot and in situ hybridizations demonstrate that the Drosophila cDNA detects 3 transcripts, expressed primarily in photoreceptors and small regions of the central nervous system. These transcripts are severely reduced in hdc mutant. The above results show that the Drosophila cDNA homolog corresponds to the hdc gene, and that mutations in this gene disrupt paired amplification. Supported by EY06214, EY03604, and EY00033.

**466.8** EXPRESSION OF TTDHVFLF Ramide, A DROSOPHILA NEURAL PEPTIDE. R. Nichols*, M. Tibbetts, and J. McCormick. Biological Chemistry and Biology Departments, University of Michigan, Ann Arbor, MI 48109.

We have generated affinity-purified antiserum to a unique portion of TTDHVFLF Ramide, a novel neural peptide from Drosophila. TTDHVFLF Ramide immunoreactivity is expressed in Drosophila brain. Two median neurosecretory cells bilaterally symmetrical to the median send projections to the brain lobes and projections down the ventral ganglion. Two anterior neurosecretory cells send projections along the midline to the brain lobes. The median neurosecretory cells arise earlier in development than the more anterior cells. Double-labeling studies indicate that the neurosecretory cells expressing TTDHVFLF Ramide are distinct from those expressing DSK peptides. TTDHVFLF Ramide DNA has been amplified from adult Drosophila RNA.

STRUCTURAL BASIS FOR PROCESSING SITE USE AND MISUSE IN AN INSECT PROHORMONE. R.C. Batur, T.J. Hone1, A. Linacre, J.D. Campbell, A. Drnik, and M. O'Shea*. Centre for Neuroscience, Univ. of Sussex, Brighton BNI 9QJ, UK.
Neuropeptidase 25, a specific protease for locust adipokinetic hormone (proAKH), has two dibasic sites, only one of which is recognised during processing in vivo.
Using computer-aided structure prediction, circular dichroism (CD) spectroscopy and 1H-2D NMR, we are studying the solution structure of a complete synthetic proAKH. CD and NMR indicate that the unused processing site is located within a region of α-helix, whereas the used processing site is not. The used site appears to be associated with a 7 residue Ω-loop in which Lys and Arg define its C-terminal neck. The importance of Lys and Arg and their positions have been studied experimentally by replacing them with their analogues thialysine and caravamine. Replacement of Lys (within the loop) but not Arg (adjacent) prevents correct cleavage C-terminal to the dibasic site. Thus, although normal cleavage is C-terminal to Arg, it does not depend on the presence of Arg, but on higher order structural features N-terminal to this site. To study how these features may interact with the enzyme, we are now cloning the cDNA of the proAKH processing endopeptidase.

466.11
DAKH GENE STRUCTURE AND REGULATION OF PEPTIDE LEVEL. M.H. Schaffer* and B.E. Noyes, Dept. of Psychiatry, Univ. of Texas Southwestern Medical Center, Dallas, TX 75235-9070.
DAKH, a member of the RPCH/RAKH family of neuropeptides, is found in insects including Drosophila melanogaster. The Drosophila gene encoding this peptide's precursor was identified using an oligonucleotide probe based on the known peptide sequence. This cloned DNA identifies a 250 nucleotide message on RNA blots which is consistent with the expected processing of this two exon gene and the message size of other family members. The general organization of the predicted DAKH precursor is identical to that of other family members: a signal peptide followed immediately by the DAKH peptide, a lys-arg processing sequence, and a carboxy terminal peptide. In contrast to the DAKH peptide, the carboxy peptide is larger [AE aa], and quite different in sequence from the homologous Manduca and grasshopper peptides, suggesting that the carboxy peptides serve some role other than binding to a receptor. The DAKH gene has been localized on salivary gland polytene chromosomes to the region E610-E641,2.
Others have identified fly strains which carry duplications or deletions of this area. Adult flies from these strains, carrying one or three copies of the DAKH gene rather than the normal two, have near wild type levels of the peptide suggesting that DAKH levels are tightly regulated.

466.13
PROCTOLIN MODULATION OF INSECT MUSCLE EXCITABILITY IS MEDIATED BY PROTEIN KINASE C. L.D. Acevedo* and M.E. Adams. Entomology Dept. Univ. of California, Riverside, CA 92521.
Proctolin is one of the transmitters at a dual-transmitter motor neuron innervating the longitudinal ventrolateral muscles (6A and 7A) of the larval housefly, Musca domestica. 6% of preparations display a muscle action potential after nerve shock or current injection into the muscle. The remaining 94% of preparations are inexcitable. In the presence of proctolin, however, these muscles display action potentials and also a change in input resistance (see also Mbungu and Adams, this meeting).
We examined the signal transduction mechanisms underlying this change in muscle excitability. Both the endogenous and the proctolin-induced action potentials were blocked by 4-bromophenacyl bromide, a broad spectrum phosphodiesterase inhibitor, indicating that hydrolysis by membrane phospholipids is involved. The phospholipase C, which mimics diacylglycerol in its activation of protein kinase C, evoked an action potential similar to the endogenous and proctolin-evoked potentials. PMCA, however, did not induce a consistent change in the muscle input resistance. This response was reversible and was not reproduced by PMA. Intracellular application of inositol trisphosphate, generated during hydrolysis of certain membrane phospholipids, did not evoke muscle action potentials. Two kinase inhibitors, H-7 and FK506, blocked both proctolin-induced and endogenous action potentials. However, membrane permeable analogs of cAMP and cGMP did not evoke action potentials. These results confirm PLC as a signal transduction pathway for the proctolin-mediated change in muscle excitability.

 des Régulations Physiologiques, Strasbourg, France.

Differentiation of cerebellar granule neurons was assessed by recording voltage-dependent ionic currents using the whole-cell patch clamp method on cells maintained in medium consisting of DMEM, 10% horse serum and 10-4 M insulin. Single pre-

cursor neurons or aggregates were removed directly from the external germinal layer (EGL). During the first 3 to 10 hours in culture (day 0), only outward currents were present; small, rapidly activating and inactivating Ia and a large, slowly inactivat-ing sustained current that partly obscured Ia, and was very sensitive to TEA. By day 5, the aggregates had spread out on the poly-

ornithine substrate; Ia5 and Ia6 had appeared in granule neurons; Ia1 increased in amplitude to dominate the sustained K current; and a second sustained outward current had appeared that was insensitive to TEA. These experiments were undertaken to provide a baseline for assessing factors that influence the differentiation and survival of granule neurons.

1Neuroscience Research Group, University of Calgary, Calgary, Canada  and 2Dept. of Medical Cell Research, University of Lund, Lund, Sweden.

The presence of EGF-responsive progenitor cells in the embryonic through to adult murine CNS (Reynolds and Weiss, Science 252:1707, 1992) prompted us to examine whether a similar cell exists in the human CNS. Embryonic human CNS tissue (cortex, striatum and cerebellum) was mechanically dissociated and plated onto untreated tissue culture flasks in serum-free culture medium containing 20 ng/ml of EGF. Dividing cells were observed within 7 days in vitro, and over the following 21 days the dividing cells formed spheres that detached from the substrate. When floating spheres were dissociated and replated at low density as single cells, proliferation was re-initiated and over a 2-4 week period new spheres were formed. When spheres were plated onto poly-1-ornithine-coated glass coverslips, cells migrated from the central core, adopting the morphology of neurons and astrocytes. The presence of neurons was confirmed with antisera directed against human neuron-specific enolase. The similarity of these findings to those we reported for the murine CNS suggest that EGF-responsive stem cells are present in the human CNS.

467.4

We have isolated a stem cell from the embryonic to adult mouse striatum (Reynolds and Weiss, Science 255:1707, 1992) which proliferates in vitro in response to EGF, forming colonies of undifferentiated cells (neuropheres) which detach from the substrate and float in suspension. Neuropheres can be mechanically dissociated into single cells and a large percentage will proliferate forming new neuropheres. The same neuropheres can be perpetuated weekly, resulting in a logarithmic growth in the number of undifferentiated cells. EGF-generated neuropheres were differentiated by mechanical dissociation and plating at high density, in the absence of EGF. After 7-14 days in vitro the three major cell types of the CNS were observed: Astrocytes, immunoreactive for GFAP, had a stellate morphology. Neurons were identified with antibodies recognizing MAP-2, neuron-specific enolase or neurofilament (168 kDa). Oligodendrocytes were immunoreactive for the cell surface antigens O4 and GC. All three cell types were present in differentiated EGF-generated progenitor cells that had been passaged for eight months (42 passages). A growth-factor-dependent CNS stem cell line may provide a continuous source of cells for intracerebral grafting.

Supported by the Medical Research Council of Canada.

EGF-GENERATED MOUSE STRIATAL NEUROSHEROPHES EXPRESS THE 4&delta;3 NEUROTROPHIN RECEPTOR. J. Williams*, A. Vescey*, B.A. Reynolds* and J.P. Hammond*, E.E. Berlin* and S. Weiss*, Neuroscience Research Group, University of Calgary, Calgary, AB, Canada T2N 4N1 and 3Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492.

We have identified an EGF-responsive stem cell in the embryonic and adult mouse striatum (Reynolds and Weiss, Science 252:1707, 1992), which in response to EGF will reproduce itself and generate cells that differentiate into neurons, astrocytes and oligodendrocytes. In preliminary studies, we found that when plated at low density (2500 cells/cm2), addition of EGF up to 7 days in vitro (DIV) could initiate proliferation of the stem cell, but not if applied after 7 DIV. In the present study, we sought to determine if bFGF could prolong the survival of the EGF-responsive stem cell. Striatal cells (E14, 2500 cells/cm2) were plated in the absence or presence of 20 ng/ml of bFGF. After 11 DIV, cultures were washed and media containing 20 ng/ml of EGF was added. After 4-5 DIV, in cultures that were primed with bFGF, cells examined contained clusters of proliferating cells that developed into colonies with the morphologic and antigenic properties of the EGF-generated cells we have previously described. Cultures that had not been primed with bFGF showed no EGF-responsive proliferation. These findings suggest that the EGF-responsive striatal stem cell may possess bFGF receptors that regulate its long term survival.

467.7 GAP-43 IS DEVELOPMENTALLY REGULATED IN GLIAL CELLS DERIVED FROM EGLG-RESPONSIVE CNS STEM CELLS.
J.P. Hammond1, B.A. Reynolds2, E.E. Barge1, and S. Weiss2.
1Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492, 2Neuroscience Research Group, University of California, Calgary, Alberta, Canada T2N 4N1.
GAP-43 is a nervous system-specific membrane phosphoprotein which is down-regulated during development. Originally, GAP-43 was thought to be neuron-specific, however, recent reports indicate that this protein may be at least transiently expressed during development in some astrocytes, oligodendrocytes and in Schwann cells. At present, the role of GAP-43 in macrogia is not known. We have begun to investigate the transient expression of GAP-43 and GFAP in glial cells generated from the EGLG-responsive stem cells derived from the embryonic and adult subventricular zone (Stromberg and Weiss, Science 255 p. 1707 1992). Astrocyte differentiation was induced by plating the stem cells in a medium containing 1% FBS with no EGF. The cells were then cultured for 14 days and stained for GFAP and using dual-label immunofluorescence. Initially, GAP-43 and GFAP expression is observed in a large number of cells. By one week however, the large majority of GFAP-expressing astrocytes no longer express GAP-43. The EGF-responsive stem cells represent a useful model system for the study of the role of GAP-43 in glial and neuronal development (supported by the MRC Canada).

467.9 CNS GLIAL CELLS SUPPORT SURVIVAL, DIVISION AND DIFFERENTIATION OF OLFACTORY NEURON PROGENITOR CELLS IN VITRO. S.E. Diksic and E. Cell and Development, Cincinnati, OH 45267.
In the adult mammal, new olfactory receptor neurons (ORNs) are produced by neurons in the olfactory neuroepithelium. To determine whether the progenitor cells could divide and differentiate in culture, we have disaggregated nasal mucosal cells from Newborn rats and cultured them on either a polylysine coating or a monolayer of neuronal rat astrocytes. On polylysine, both satellite and immature ORNs died within 5-6 days. On the monolayer of CNS astrocytes, mature ORNs (OMP+) again died rapidly (by 5-7 days), while immature ORNs (OMP-), positive for neuron-specific tubulin, began to appear and form large aggregates of neurons. OMP+ neurons reappeared 10 days after plating and were very prominent in 15 day cultures. Three different CNS stella stromas were equally effective in promoting survival and differentiation. Pulse labeling with tritiated thymidine was done over 15 days in culture. Uptake of isotope in neurons was detected by combined autoradiography and immunocytochemistry. Neuronal progenitor cells both divided and differentiated in culture. Both OMP+ and NSE+ neurons were generated by cell division that took place during restricted times after plating. Aspects of the data suggest that OMP expression is an innate property of ORNs and that expression may rely more on survival than target-specific regulatory factors. The neuronal progenitor cell appears to be negative for NSE. Astrocytes (but not conditioned medium) allow survival, division and subsequent differentiation. Support: Amer Paralysis Assoc PFI-8801-1 + NIM HCO30417.

467.11 BETAG-2 INTEGRINS ARE CONSTITUTIVELY EXPRESSED ON MICROGLIA IN THE NORMAL HUMAN FETAL BRAIN. L.A. Matthias*, E. Danks, W.D. Lyman, W. Rushing, D.W. Dickson, Deps. of Pathology and Ob-Gyn, Albert Einstein College of Medicine, Bronx, NY 10461.
To further characterize microglia in the normal human fetal brain, sections from 16 to 23 wk abortuses of HIV seronegative mothers were examined immunocytochemically with antibodies to Beta-2 integrins. Integrins are part of a group of cell adhesive molecules that are involved in cell-cell and cell-matrix interactions. As transmembrane glycoproteins, integrins link the intracellular cytoskeleton to extracellular matrix proteins. Beta-2 integrins are heterodimers that are characterized by a Mr 95,000 Beta-2 subunit (CD18) and alpha subunits of either Mr 180,000 (CD11a), 170,000 (MAC-1), 150,000 (IL-2) or 142,000 (CD11b). Antibodies to these alpha chains included LFA-1 (CD11a), B1-1/9F6 (CD11b) and Leu-M5 (CD11c). Preliminary data suggests that these markers are constitutively expressed on microglia in normal fetal human brain at 16 wk. These engravis were expressed on both ameboid and more ramified forms of microglia in the normal fetal brain and in the subependymal grey and white matter. Microglia were also found to constitutively express leucocyte common antigen, in addition to HLA-DR (L3T4, HLA-DR), a major histocompatibility complex class II antigen. These gamma delta T cells were not detected (See Neuroimmunol 17:734:1991). The role of Beta-2 integrins, as expressed on fetal microglia, in normal gliogenesis and brain development is not clear. On leukocytes, beta-2 integrins are involved in mediation of phagocytosis, adhesion and migration in the immune system. The presence of adhesion molecule receptors on microglia suggest that these cells, in the in-cell-cell and cell migration and differentiation during brain development. Since microglia are productively engaged in CNS, these receptors may also be involved in the mediation of CNS pathogenic.

The development of mammalian telencephalon involves a sequence of multiplications of stem cells, differentiation into neurons and glia, migration to target sites and synaptogenesis. Each phase is likely to involve the expression of characteristic sets of genes that specify specific gene expression and temporally-restricted manner. In order to study transcription factors orchestrating such processes, we created an in vitro model simulating aspects of early telencephalon development. Major components of the system are the: neuropeithelium of E13 rat telencephalon, grown in dissociated cell culture in serum-free medium. At the density of 80,000 cells/cm2, the addition of growth factors (bFGF and NGF) increased the number of cells (a marker for multipotential stem cells) and the proliferation rate at (5 days in vitro, bromodeoxyuridine incorporation during 3 hours labelling was 9.1±2.2 and 14.2±1.7 cells per 1000 cells, respectively). Cells containing GABA- and glutamate-like immunoreactivity started differentiating at 2 days in vitro and their number and complexity of arborization increased with time. Growth factors increased the differentiation of cells containing glutamate-like immunoreactivity at 2 and 4 DIV, while the effect on GABA-containing neurons was modest. GFRα1 receptor was strongly downregulated until day 6 but differentiated from nestin-positive stem cells afterwards. The sequence and timing of these developmental events closely matches the development of telencephalon in situ.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
467.1

A 110 kDa lamin binding protein has been shown to be expressed by enteric and other peripheral neurons. This protein is not expressed by premigratory or early migratory neural crest-derived precursor cells. Immunocytochemical observations have suggested that the 110 kDa protein might be acquired by crest-derived cells shortly after these cells colonize the developing gut of avians or mice. Experiments were carried out to test the hypothesis that the 110 kDa lamin binding protein is selectively expressed in crest-derived precursors of enticular neurons and glia. The bowel of fetal mice (E16) was dissociated and the resulting single-cell suspension was exposed sequentially to rabbit antibodies to the 110 kDa protein (α-110) and magnetic beads coated with goat-anti-rabbit secondary antibodies; α-110-immunoreactive cells were finally isolated with a magnet. α-110-selected and unselected (residual) cells were seeded in dishes coated with collagen and laminin at a density of 27 X 10^3 cells/dish and cultured for 8 days. Neurons were identified immunocytochemically with antibodies to neuronfilament proteins or neuron specific enolase, while glia were identified with antibodies to the S-100 protein. Neurons and glia were also found to be immunostained by α-110. Significantly more neurons and glia developed in cultures of α-110-immunoselected cells than in cultures of unselected cells. The proportion of cells in the cultures of selected cells that developed as neurons was about 3-fold that found in cultures of unselected cells. Similarly, the number of S-100 immunoreactive cells in cultures of selected cells was about 4-fold that observed in the cultures of unselected cells. Immunoselection of cells from E16 fetal mice thus supports the hypothesis that neurons or glia preferentially develop in cultures of cells selected with the α-110. It has been suggested that the 110 kDa lamin binding protein is a receptor that mediates the response of enteric neural and glial precursors to laminin. The current observations support this idea. Supported by NIH grants NS52766, HD17736, HD30670, HD21033 and NS15547.

468.2

The enteric nervous system (ENS) is formed by cells that migrate to the bowel from the vagal and somitic levels of the neural crest. Since the developmental potential of crest-derived cells that have entered the gut is less than that of premigratory or early migratory crest cells, the properties of at least some crest-derived cells change as they migrate to the gut. In order to study the characteristics of crest-derived cells, it is necessary to isolate them from within the bowel. Gut from chick or quail embryos (E4-7) or fetal rats (E11-15) was dissociated with collagenase to yield a suspension of single cells, which were then subjected to immunoselection. The suspension was mixed with a murine monoclonal antibody (NC-1) that reacts with a surface epitope that is found in the gut, only on crest-derived cells. NC-1 coated cells were then isolated with magnetic beads coated with goat anti-mouse antibodies, and selected with a magnet. NC-1* cells were cultured for up to 8 days, as were the cells remaining after the NC-1 population had been removed. Immunoselection was found to greatly enrich the population in NC-1* cells. Expression of neurofilament proteins and neurite extension were preferentially seen in cultures of immunoselected cells. Neurite outgrowth was not inhibited by laminin. Some neurons contained 3-aminobutyric acid (GABA) and serotonin (5HT); however, tyrosine hydroxylase (TH) and dopamine-B hydroxylase (DBH) are not expressed by avian enteric neurons, and are expressed only transiently in developing rat bowel were present in immunoselected cells. A glial marker, glial fibrillary acidic protein (GFAP), was apparent in a subset of immunoselected cells. Non-selected cells proliferated rapidly and relatively few expressed a neuronal or glial phenotype. These experiments demonstrate that neurogenic crest-derived cells can be isolated from within the enteric mesenchyme of both developing rats and birds. At least some of the immunoselected cells appear to be capable of expressing phenotypes appropriate for the ENS. The appearance of TH in cells immunoselected from avian bowel supports the hypothesis that the enteric microenvironment acts to suppress cholinergic expression in situ. Supported by NIH grants HD20470, NS15547, NS26766, HD17736, and a fellowship from Lily Res. Lab.

SPECIFICATION OF THE ROSTROCAUDAL AXIS OF THE PREMIGRATORY AVIAN NEURAL CREST. Gabrielle G. Leblanc*.
Dept. of Biological Structure and Function, School of Dentistry, Oregon Health Sciences University, Portland, OR 97239.

Different rostrocaudal populations of premigratory neural crest cells differ in their developmental potentials, both in vitro and in vivo. In vitro, cranial neural crest gives rise to large amounts of cartilage and bone, whereas trunk neural crest cells lack chondrogenic potential. In vivo, cranial neural crest produces large numbers of fibroblasts (FN- and procollagen I) (Col I)-immunoreactive cells, whereas trunk neural crest produces relatively few cells. These in vitro differences in protein expression by cranial and trunk neural crest cells can be used to explore the mechanisms that determine the rostrocaudal axis of the premigratory neural crest.

The rostrocaudal axis of the premigratory neural crest may be specified by factors acting on the underlying somite. To test this possibility, I examined whether crest with anterior mesoderm can induce trunk neural crest cells to express cranial-specific traits in vitro. Trunk neural crest cells were cocultured together with explants of early (stage 3) Hensen's node, which contains prospective anterior mesodermal cells. After five days of coculture, both FN and Col I immunoreactivities were seen in the neural crest cells surrounding the Hensen's node explant. The apparent FN- and Col I-stimulating activity of early Hensen's node is mimicked by transforming growth factor (TGF)-B.

BASIC FIBROBLAST GROWTH FACTOR (bFGF) INFLUENCES NEURAL CREST CELL FATE VIA AN INTRACRINE MECHANISM. G. Cimera*, L. Sherman, K.M. Stocker and R.S. Morrison.

In previous work, we found that neural crest (NC)-derived Schwann cell progenitors of early avian embryos underwent a transformation in vivo or in culture into another NC lineages - melanocytes. In the following treatment with either the phosphor elster TPA or basic fibroblast growth factor (bFGF). These and other data suggest that bFGF might be involved in the commitment of bipotent intermediate cells in the NC lineage, either the melanocyte or Schwann cell fate.

In these studies, we show that TPA induces bFGF expression in the melanocyte/Schwann cell progenitors, but that bFGF need not be released in order to induce influence cell fate. Treatment of cultures of early embryonic peripheral nerves with TPA, for example, induced expression of bFGF mRNA and protein and caused melanogenesis in cells which would normally have given rise to Schwann cells. Addition of two different bFGF antisense oligonucleotides blocked these effects of TPA, but that sense oligonucleotides or scrambled oligonucleotides (i.e., with the same base content but with a different sequence) did not, suggesting that bFGF expression is part of signalling pathway by which TPA induces transformation into melanocytes. Additon to the culture medium of bFGF neutralizing antibodies or other agents known to inhibit bFGF-binding to its extracellular receptor had no effect on the TPA-induction of melanogenesis, indicating that bFGF does not need to be released in order to act. These data indicate that bFGF may act as an intracellular "intracrine" factor in the determination of NC cell fate.

INVESTIGATION OF THE ROLES OF TGFβFGF AND FGF SIGNALING IN RETINAL DEVELOPMENT THROUGH ALTERNATIONS IN RECEIVER EXPRESSION. L. Lillien* and C. Cepko. Department of Genetics, Harvard Medical School, Boston, MA 02115.

In order to begin to identify the signaling systems that regulate the development of the rat retina, we used in vitro assays to screen for extracellular signaling molecules that modulate proliferation and cell type choice. These functional assays showed that several peptide growth factors found in the developing retina, including TGFβ and FGFs, enhanced proliferation and selectively inhibited rod photoreceptor development (Lillien and Cepko, Development 1992). The effects of TGFβ and FGF on proliferation were found to be temporally restricted in vitro; cultures of younger retinal cells (<E20) were more responsive to FGF while cultures of older retinal cells (=>E30) were more responsive to TGFβ.

To determine the roles of these signaling systems in normal retinal development, we are using retrovirus vectors to express the human EGF receptor and mouse FGF receptor-1. To analyze the function of endogenous EGF and FGF receptors, we are introducing truncated forms of the receptors to block function in a dominant-negative manner.

To determine whether limiting levels of receptor expression underlie the temporal changes in responsiveness to TGFβ and FGF observed in vitro, we are introducing full length forms of the receptors. In order to label expressing these constructs, PGF R1 viral constructs also contain the gene encoding the biochemical marker alkaline phosphatase. Cells infected with the EGF receptor virus can be distinguished with an antibody that selectively labels the human form of the receptor. Choroid of infected cells will be examined.

RETNAL LINEAGE OF THE CLEAVAGE STAGE PROGENITOR IN XENOPODIS IS DEPENDENT ON POSITION. S. Huang* and S.A. Moom*.
Dept. Anatomy & Cell Biology, Univ. Virginia, Charlottesville, VA 22908.

Our previous studies (Neurobiol, Abstr., 17294, 1991) demonstrated that the retinal lineages of cleavage stage blastomeres change after the ablation of the major retinal progenitor and the changes are different for dorsal and ventral blastomeres. To determine whether the retinal lineage changes are due to the position of the remaining blastomeres two sets of experiments were carried out. First, several different sets of blastomeres were ablated at 32-cell stage embryo to determine whether the change in position of the remaining blastomeres predicts their change in retinal fate. Along the dorsal midline where a blastomere was ablated its animal neighbor took over its retinal fate and produced an amount of retinal cells typical for the ablated vegetal neighbor. When more ventral blastomeres were removed, the dorsal blastomeres did not adopt the retinal fates of their ventral/animal neighbors. These results demonstrate that the blastomeres shift fate in a dorsal/ventral direction but not in a ventral/animal direction. In order to directly test whether blastomere position determines retinal fate, reciprocal transplantations were done between a dorsal midline blastomere, the major retinal contributor, and a ventral blastomere, which normally only gives rise to ventral trunk structures. The transplanted blastomeres adopted a new fate according to their new position. The ventral blastomere became a major retinal contributor when it was placed in the dorsal animal pole, while the clone of the major retinal progenitor was restricted to the tail region of the embryo. These results were used in the position that a blastomere prior to gastrulation is the important determinant of whether retinal cells are among its descendents.

CLONAL HETEROGENEITY IN THE GERMINAL ZONE OF THE DEVELOPING RAT TELEENCEPHALON. S. E. Askin* and D. van der Kooi. Dept. Anatomy, Univ. Toronto, M5S 1A8, Toronto, CANADA.

In order to characterize the proliferation characteristics of precursor cell lines in the mammalian telencephalic germinal zone, we have previously employed a simultaneous double labeling technique which combines the visualization of individually proliferating clones in the E18-E19 developing rat telencephalon and their double labeling with 3H-thymidine. After 48 hours survival we found the cortical (but not the striatal) germinal zone to be segregated into three spatially distinct horizontal bands (A, B, and C), one of which contained clonally related populations with distinctive cell cycle times, incidences of cell death and modes (asymmetric vs. asymmetric) of proliferation (Askin & van der Kooi, soc. report). It is important to ask whether these distinct cortical germinal populations project the mature phenotype (e.g. neurons vs. glial) or spatial identity (e.g. deep vs. superficial cortical layers) of the cells they give rise to. In a first set of experiments we characterized the space distribution and proliferation characteristics of cortical precursor populations (using our double labeling method) after only 17 (instead of 48) hours survival. We found that although the overall thickness of the germinal zone was slightly smaller after 17 hours survival (E17-18), it was still segregated into horizontal clones (A, B, and C) with comparable proliferation characteristics to those seen at E19. We also found that with the longer survival of 48 hours (E17-19) compared to the shorter survival limit of 17 hours (E17-18), the clonal population in the ventricular zone proper (A) and (B) of two horizontal bands in the subventricular zone increased in thickness, whereas the second horizontal band (C) in the subventricular zone decreased substantially in thickness. Thus, clonal population C (perhaps giving rise to a subpopulation of neurons) may have become more prominent at E20. It is proposed that the different cell populations in the germinal zone remain parasitically, when neurogenesis has largely ceased but glia still are being produced. The identification of this remaining population (presumably giving rise to glia) by its proliferation characteristics may suggest an isochronism between it and one of the earlier germinal zone populations.

468.12

We reported recently that early in cortical neurogenesis (E15/E16), the ventricular zone in the rat contains separate progenitor cells for the principal neuronal cell classes, the pyramidal and nonpyramidal neurons. Here we sought to investigate whether these neuronal types originate from separate progenitor cells throughout the period of neurogenesis. For this purpose, recombinant retrovirus vectors containing the genes for E.coli β-galactosidase were injected into the telencephalic ventricles of rat embryos at E14/E21. Serially cut coronal sections of adult cortex were histochemically stained for β-galactosidase and processed for electron microscopy. Camera lucida drawings were made to map the position of labelled cells. Discrete clusters of closely spaced labelled cells were considered to be derived from the same precursor cell in the ventricular zone, i.e. to belong to the same clone. Clonally-related labelled neurons were examined with the electron microscope, and their phenotypes identified using ultrastructural criteria.

Clusters of clonally-related neurons examined from animals injected with retrovirus at various times during corticogenesis contained at all times either all pyramidal or all nonpyramidal neurons. These findings suggest that the ventricular zone contains separate progenitor cells for pyramidal and nonpyramidal neurons during the entire period of neurogenesis.

468.13
NEUROTTRANSMITTER EXPRESSION IN CLONALLYRELATED NEURONS IN THE RAT CEREBRAL CORTEX. M.C. Mione, C. Danesi, M.E. Cavanagh, P. Boardman and J. Parnavelas (SPON Brain Research Association). Department of Anatomy, University College London, London WC1E 6BT, U.K.

We examined the neurotransmitter content of clonally related neurons in the cerebral cortex of adult rats. Such neurons were marked with a retrovirus lineage tracer, containing the reporter gene for E.coli β-galactosidase, injected into the telencephalic ventricles of rat embryos at E15-E17 and subsequently histochemically. Discrete clusters of β-galactosidase positive cells, considered to be clonally related, were subjected to immunohistochemical analysis for the inhibitory neurotransmitter GABA and the excitatory amino acids Glu and Asp. This analysis was performed on Araldite embedded, 0.5 μm thick sections. Three consecutive sections through every neuron of 30 discrete clusters of neurons were processed each for one of the three neurotransmitter candidates, while thin sections were used to identify the phenotype of every cell with the electron microscope. Clusters contained between 2 and 8 neurons which were either clustered on one layer or distributed over 2 or more layers.

Nineteen clusters contained neurons positive for only one transmitter candidate (GABA, 5 Glu, 3 Asp), and one group of 3 nonpyramidal neurons was immunonegative for all 3 amino acids. However, in the clusters positive for Glu or Asp a number of neurons contained both excitatory amino acids. These findings support the hypothesis that genetic determinants play an important role in the expression of the principal neurotransmitters in neurons of the mammalian cerebral cortex.

468.14

Radial glia and differentiated myelin-forming oligodendrocytes are present in the human fetal spinal cord (HFSC) by 10 weeks of gestation (WOG). However, the neuroanatomic correlation of the development of these two cell types has not been performed. In this study, immunohistochemical and histochemical methods using antibodies to vimentin and glial fibrillary acidic protein (GFAP) were used to mark radial glia and an antibody to myelin basic protein (MBP) identified oligodendrocytes. Myelin in the vibratome sections of 37 HFSC ranging in age from 9-20 WOG. Radial glia were more numerous in the anterior and anterolateral funiculi than the dorsal funiculi; the posterolateral funiculus had very few radial processes. In addition, radial glia were almost always more numerous at the cervical level. Expression of MBP followed the same pattern. The results suggest that radial glia and oligodendrocytes follow anterior-to-posterior and superior-to-inferior developmental patterns. These gradients appear to be independent of the tracts of the developing spinal cord. Interaction between these cell types may be necessary for appropriate development of each. Further work is necessary to elucidate this interaction.

THE TIMING OF MOTONEURON COMMITMENT IN THE DEVELOPING CHICK SPINAL CORD. M.P. Main* and C. Lance. Dept. of Neurosciences, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

When 3·4 Lumbosacral (LS) spinal cord segments (+-notochord) are reversed about the rostrocaudal (R/C) axis in stage 15-16 chick embryos, motoneurons which emerge from these reversed segments alter their peripheral course to project to their originally inappropriate muscle targets. This finding suggests that there are differences along the R/C spinal cord axis at neural tube stages (stages 15-16) and that the motoneurons within LS segments are commited to a particular peripheral target fate when their axons grow out of the cord (stages 18+). How and when are motoneurons committed to specific target areas? We have begun to address this question by carrying out R/C cord reversals at earlier stages.

At stages 13-14, presumptive LS cord segments I-3 were separated from the notochord and reversed about the R/C axis. At stages 35-37, retrograde HRP labelling was used to define the R/C location of motoneurons of the vagus, thoracic and lumbar somites. Motoneurons innervating these muscles are normally found in discrete positions within LS 1-3. In 70% of stage 13 cases (n=14) and 55% of stage 14 cases (n=9), motoneurons innervating these muscles were located in discrete positions in accord with their new R/C location. In 30% of stage 13 cases and 32% of stage 14 cases, motoneurons were dispersed throughout the reversed segments. In only one case (at stage 14) did motoneurons project in accord with their origin prior to the reversal. These findings suggest that R/C differences within the spinal cord that lead to motor neuron commitment are not present at stages 13 and 14. (Supported by NIH HD 256769).

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
469.1 SYNAPTIC INPUT TO TRANSIENT SUBCORTICAL SYNAPTIC ZONE (TSS) NEURONS IN INFRAGRANULAR CORTEX: PROVISION OF DIRECT SYNAPTIC INPUT TO UNDERLYING TSS.
A.P. Sterling and P.R. Lomstein*. Laboratory of Cellular and Developmental Neurobiology, Dundee University Institute of Medical Biology, DD1 4HN, Scotland.

In the neonatal rat cerebral cortex antibodies raised against synapsin I and synaptophysin reveal a TSS beneath the developing cortex. This synaptic neurolill appears as the animal matures. We have examined the source of synaptic input to the TSS by immunocytochemically injecting the anterograd e tract tracer physalin into the infragranular somatosensory cortex. PHA-I, was visualised using immunohistochemistry and sections were prepared for light and electron microscopy (EM). Terminal arborization of the intracortical neurone was evident in the lateral geniculate nucleus. Fibres traversing the TSS were seen to be varicose and when examined under the EM many varicosities were found to establish asymmetric synapses:
Age: Target structures Synaptotagmin synapses
< 10 days 85% 15%
1 month 60% 35%
Adult 100%

These results demonstrate that neurones located in the infragranular layers of the developing cortex provide direct synaptic input to subcortical TSS neurones. The developmental transition of post-synaptic targets from spines to shafts suggests that cortico-TSS axo-spinous synapses are indeed a population of transient synapses.
Supported by The Wellcome Trust, Royal Society and University of Dundee.

469.2 NEOCORTICAL SYNAPTOSTEMOSIS: LOW DENSITY PRIMARY CULTURES AND USE OF HEK-293 VECTORS FOR GENE TRANSFER INTO POSTMITOTIC NEURONS AND GLIAL CELLS. P.R. Lomstein, T. Hodges, N.D. Stone*, C.M. Preston, and M.G. Castro*, Dept. of Anatomy- Physiology, University of Dundee, DD1 4HN, MRC Institute of Neurology, University of Glasgow, G11 5JR, and Dept. of Molecular Life Science, Dundee Institute of Technology, Dundee DD1 4HG, Scotland.

Neocortical synaptic organization is very specific in terms of the post-synaptic targets of individual neurones, and the synaptic input onto individual cells. Although cortical neurones have 5 different membrane domains on which they could potentially receive synaptic input, neurones tend to prefer fewer classes of synaptic input. Also, excitatory cell bodies only receive inhibitory synaptic input, while inhibitory somata receive both excitatory and inhibitory input. We now wish to examine the cellular and molecular basis of the selection of synaptic inputs by using a very low density primary culture system of neocortical neurones, based on the work of Banker, Konik, and Ramanek, we determined that neurones: (a) survive for long term in low density; (b) expand; and, of absence of contact; (b) develop proper morphological polarity (e.g. dendrites and axon); (c) after 3 weeks in vitro MAP-2 is found only in dendrites, while is localized to all cellular processes; (d) immunolocalization of synergistic synapses co-localized with confocal microscopy suggests that the pattern of synergistic in vitro is comparable to the in vivo one; (e) HEK-293 vectors can be used to transfer foreign genes into both postmitotic neurones and glial cells in primary culture. Thus, in spite of its intrinsic complexity in vivo, the cellular and molecular basis of neocortical synaptic formation can now be examined using a simple in vitro model.

469.3 DEVELOPMENT OF SYNAPTIC CONTACTS BETWEEN NEURONS OF BASAL FOREBRAIN AND CEREBRAL CORTEX IN ORGANOTYPIC TISSUE SLICE CULTURE. P.G. Distler & R.J. Robertson*. Department of Anatomy and Neurobiology, University of California, Irvine, 92617

We have previously shown that AChE-positive neurones of rat basal forebrain project into cultured cerebral cortex slices and, after entering the tissue, branch within the different cortical layers (Distler and Robertson, 1992). We are now investigating whether these projections also form synaptic contacts with neurones in the cortical target region.
Slices of neonatal basal forebrain tissue were co-cultured with 4 day old cerebral cortex tissue for up to 4 weeks. Various developmental stages of the basal forebrain-cerebral cortex innervation were then investigated on the fine structural level. For identification of axon terminals, two different labeling techniques were employed: (a) placement of the lipophilic dye Dil on fixed basal forebrain tissue and subsequent DAB-phoatoenzyme of stained fibres with cortical tissue, and (b) the cholinergic marker, a label which is known to be a reliable marker for cholinergic basal forebrain neurones.
The electron microscopic investigation revealed consistent results for both staining methods. First, basal forebrain neurones form terminal synaptic contacts on dendritic shafts in the superficial cortical layers. Second, the observed synapses are of the symmetric type. Furthermore, both methods reveal the presence of clear spherical vesicles in the presynaptic profile. Within superficial cortical areas, stained synaptic contacts were evident as early as one week after beginning culturing.
In conclusion, the data reveal parallel to the cholinergic innervation in vivo, and provide further evidence about the significance of this model system for the study of the development of the cerebral cortex.

469.4 INTERRUPTION OF AXONAL GROWTH BY TARGET NEURONS IS ENHANCED BY NMBA. D.H. Baird*, A.D. MacDermot*, E. Trenkner*, and C.A. Mason*. "Howard Hughes Medical Institute, Rockefeller Univ., NY State Institute for Basic Research in Developmental Disabilities; Dept. of Pathology and Physiology and Cell and Biophysics, College of Physicians and Surgeons of Columbia University, New York, N.Y. 10032.

 Cultured cerebellar granule neurones interrupt the growth of their mossy fibre afferents originating from Purkinje neurones. Using the anterograde label di-benzamidine (DBA) at 92 J. Neurosci. 12:619-634). This "stop-growing signal" is afferent and target cell specific (Baird et al. J. Neurosci. 1989; 9: 3023-3031), and affects neurones in the target volume. Action potentials and neurotransmitters play a role in the stop-growing signal as TTX, TTX + high magnesium, or kynurenic acid, an antagonist of glutamate receptors, all interfere with the stop-growing signal. To determine which types of glutamate receptors might be involved in the stop-signal, explants of pontine nuclei were co-cultured on granule neurones for two days in the presence of glutamate agonists and antagonists specific for NMDA and non-NMDA receptors. The NMDA-specific antagonist D-AP5 interferes with the stop-signal, resulting in a large increase in the number of pontine neurones extending over granule neurones compared to controls in medium. In the presence of 200uM NMDA the number of long neurones was reduced to less than 40% of controls. Pontine explants cultured without granule neurones but with NMDA showed a small increase in the number of long neurones produced. In contrast, explants co-cultured with granule neurones in 50uM AMPA (a non-NMDA agonist) showed little reduction in the number of long neurones produced. AMPA had no effect on the number of pontine neurones in the absence of granule cells.
These results suggest a role for NMDA receptors in regulating the growth of mossy fibres on target granule neurones and potentially in contributing to target cell specificity during the innervation of the cerebellum.

Granule neurones in vitro present a stop-growing signal for their appropriate afferents, the mossy fibres. This signal is afferent-specific since neither retnal nor olfactory neurones receive the stop signal (Baird et al. J. Neurosci. 1992 12:619-634; J. Neurol., in press).

With the aid of the anterograde tracer DBA (Baird et al. 1991 Soc. Neurosci. Abstr. 17:38), we examined the capacity of this cell type to regulate afferent growth. To study the growth of one afferent to Purkinje cells, the parallel fibres afferents to granule neurones, we co-cultured aggregates of purified granule cells with purified Purkinje cells. Purkinje cells stimulate and maintain the growth of granule afferents, in line with previous reports of parallel fibres across the dendritic fields of multiple adjacent Purkinje cells. In turn, granule neurones and their axons maintain and promote the differentiation of Purkinje neurones. Granule cells, and granular neurones have different modes of regulating afferent growth, in some cases stimulating growth.

Second, we observed how an inappropriate afferent, the pontine mossy fibres, can affect the growth of Purkinje cells. Mossy fibre growth is abundant on a number of substrates and is not affected by co-culture with Purkinje cells. However, when grown with granule neurones, mossy fibre growth is increased three fold compared to growth on granule cells alone. While it is not known if Purkinje cells stimulate mossy fibre growth directly, or disrupt the stop-signal for mossy fibre growth by interacting with granule neurones, these results suggest that Purkinje cells do not send a stop-signal to mossy fibres and that this is afferent-specific.

The above paradigms will allow the analysis of mechanisms involved in the specificity of axon growth regulation, its maintenance by target cells and the establishment of specific synaptic connections.

469.6 SPATIAL DISTRIBUTION OF EXCITATORY AND INHIBITORY SYNAPSES ON A PURKINJE CELL IN A RAT CEREBELLAR CULTURE. T. Hirano*, K. Kajos, Department of Physiology, Faculty of Medicine, Kyoto University, Yoshida Konoe-cho, Sakyo-ku, Kyoto 606, Japan.

Spatial distribution of synapses on Purkinje cells formed in a dissociated cell culture of rat cerebellar cortex was studied by intracellular fluorescent stainings of pre- and postsynaptic neurones and by immunocytochemical staining of presynaptic terminals. Simultaneous whole-cell recordings were performed on both a presynaptic small neurone and on a Purkinje cell, and the property of synaptic transmission was determined. Instead excitatory input to Purkinje cell was suppressed by CNQX, and outward inhibitory synaptic currents were suppressed by bicuculline, respectively. A presynaptic neurone was stained with intracellularly injected Lucifer yellow and presynaptic terminals of inhibitory interneurons such as basket or stellate cells were found both along dendrites and on the soma. After the electrophysiological recordings, neurones were filled with biocytin and immunocytochemistry using anti-synaptophysin monoclonal antibody in order to visualize overall distribution of synaptic terminals on a Purkinje cell. The staining confirmed that the varicosities are presynaptic terminals and a Purkinje cell receives synaptic inputs both on a soma and on dendrites. Thus, differential spatial distribution of excitatory and inhibitory synapses on a Purkinje cell in a simple cell culture system was demonstrated. Synapses were also observed with a scanning electron microscope.

2) Channels and postsynaptic receptors. AM (8 uM). Focal application of either 50 mM K+ or 100 uM glutamate inhibited the occurrence of synchronous oscillation after 8 days in culture, others (Ito, M., 9510, 1989) to the cortical culture. Continuous presence of EGCase together with its activator protein from ministry of Education, Science and Culture of Japan.

3) We have carried out quantitative analysis of synapse formation between cultured CNS neurons using multi-site Ca2+-fluorometry and electron microscopy (Kuroda et al. Neurosci. Lett. 135:255, 1992). Synaptophysin Immunostaining using laser confocal microscopy demonstrated that neurons were connected by many synapses which matured during the culture (Ichikawa et al., Neurosci. Res. 12:452, 1991). To investigate whether these synapses are formed between specific pairs of neurons in culture or not, we attempted to identify different types of the CNS neurons. We developed a library of monoclonal antibodies which bind to living PC12 cells differentiated by NGF treatment. At least 14 monoclonal antibodies in the library bound almost exclusively to living neurons from rat hippocampus in culture. We also screened a series of lectins to the living neurons. Vicia villosa agglutinins (VVA) binding appeared to be significant to multipolar neuron in the hippocampus after 2 weeks in culture. These neurons appear to be inhibitory, which identified in fixed hippocampal tissue (Drake et al. Brain Res. 554:176, 1991).

The possible involvement of proteolysis in the process of activity-dependent synapse elimination was studied in an in vitro model of the neuromuscular junction. Neurons of the superior cervical ganglia (SCG) and muscle cells were isolated from newborn mice and cultured in a multicompartiment system, the Campenot chamber. The SCG neurons were kept in the two side compartments; muscle cell was in the center. Cholinergic synapses developed between neurons and muscle cells after 2-3 weeks. Functional synapses were monitored by the contraction of muscle cells in response to stimulating theafferent neuron. The elimination of these synapses was activity-dependent. After 1-2 days of extracellular stimulation at an average of 576 spikes, the synaptic connections were eliminated (n=275). When 50 uM leupeptin, a protease inhibitor, was added into the central compartment during the whole period of stimulation, only 35% of the synapses were lost (n=193). The difference between the effect of stimulation in the presence and absence of leupeptin was statistically significant (p<0.001). Synapse elimination in unstimulated controls was 8% (n=117). In the presence of 1 uM tetrodotoxin (TTX), stimulation did not cause synapse elimination (n=107).

In conclusion, the partial block of synapse elimination by this protease inhibitor suggests that proteolysis may play a role in the mechanism of activity-dependent synapse elimination.

SOMATOTOPIC ORGANIZATION OF OVERLAPPING MOTOR UNITS WITHIN A LARVAL FROG JAWS: E.F. Omerza and K.E. Alley, Ohio State University, Columbus, Ohio 43210.

Individual myofibers within the larval jaw muscles of Rana pipiens are polyinnervated. This is due to the presence of multiple neuromuscular junctions (NMJs) as well as multiple axons within individual junctions. The purpose of this study was to determine whether this polyinnervation arises from more than one neuron and, if so, to investigate their central and peripheral organization. To determine the neuronal distribution at muscle, myofiber and NMJ levels, we employed a triple labeling technique utilizing standard ACHE histochemistry and the anterograde fluorescent tracers Dil and DiA. This procedure allowed us to distinguish the distribution of two separate groups of axons to their respective NMJs. A second study used retrograde axonal transport of Fast Blue and Dil from injection sites at opposite ends of the muscle. This provided the location of their territories serving different regions of the same muscle. Results of the triple label study indicate that individual NMJs and myofibers may receive innervation from axons within different portions of the nerve root, and further, suggests a regional distribution for motor units to their respective NMJs. We have also demonstrated that neurons projecting to the rostral and caudal regions of the muscle are distinct. Our observations indicate that several neurons can project to a single muscle fiber or NMJ and that the resultant overlapping motor distribution is reflected in a somatotopic organization of motoneurons.
4.7.1

EFFECT OF IN UTERO ETHANOL EXPOSURE ON THE MORPHOLOGICAL DEVELOPMENT OF THE OCULOMOTOR NUCLEUS IN THE RAT.

This study was designed to determine if exposures to ethanol can alter the development of brainstem nuclei controlling the extraocular eye muscles. Pregnant rats were fed through gestation with either an ethanol containing diet, in which 7.5% of the total caloric content was ethanol derived, or with an isocaloric diet. Male offspring were perfused on postnatal day 15 and the oculomotor nucleus was examined using plastic section light microscopy, Golgi-Cox staining, and stereologic analysis of electron micrographs. A decrease in the number of neurons as well as an increase in the number of astrocytes per unit area was found in the ethanol exposed animals, while the total number of cells per unit area remained relatively constant. There was an alcohol-induced decrease in the overall complexity of the dendritic ramifications, as well as in the total number of dendrites. The area of the neuronal soma was also decreased in the alcohol exposed animals, but there was no change in the area of the nucleus or nucleolus. These results may help explain some of the motor deficits associated with the visual system after developmental alcohol exposure.

Supported by NIAAA AA7042 and NSF EPSCoR RII-8921978.

4.7.2

TEMPORAL CONSTRAINTS ON ALCOHOL-INDUCED CORTICAL ASTROGLOSIS DURING THE NEONATAL BRAIN GROWTH SPURT IN RATS. J.T. Leng, E. Goodlett, and J.R. West, Alcohol and Brain Research Laboratory, Dept. of Anatomy, University of Iowa, Iowa City, IA 52242.

It has previously been reported that alcohol exposure during the brain growth spurt (postnatal days P1-49) in a pattern yielding cycle blood alcohol concentrations with high peaks and low troughs, produces a conspicuous reactive gliosis in the cerebral cortex. Radioimmunoassays have shown that the amount of GFAP is increased more than 300% above controls. Immunocytochemical studies indicated that much of the increased GFAP was associated with loci of reactive astrocytes surrounding some cortical blood vessels. These loci, scattered throughout the cortex, contained hypertrophied astrocytes with thick fibrillary processes heavily labeled by GFAP. The goal of this study was to determine if a similar pattern of alcohol exposure later in the neonatal brain growth spurt (PD 10-14) would stimulate astrogliosis comparable to exposure on days 4-8. Pups were gastrostomized either on PD 4 or PD 10 and were given either 4.5 g/kg of alcohol per day (delivered in 2 of 12 daily feedings as a 10.2% (v/v) solution in milk formula) or were given a control matched diet free of alcohol. Pups were perfused on postnatal day 9 or postnatal day 15 and 40 µm thick frozen coronal sections were processed for GFAP immunoreactivity using peroxidase-antiperoxidase immunocytochemistry. Matched sections from control and alcohol-treated pups were evaluated microscopically for reactive gliosis around cortical blood vessels. In contrast to the prominent effect seen in pups exposed on PD 4-8, alcohol exposure on PD 10-14 did not result in the intense reactive astrogliosis surrounding cortical blood vessels. These results indicate the presence of a temporal window of vulnerability to alcohol-induced reactive gliosis existed around cortical blood vessels. The critical period for this effect appears to end by postnatal day 10. Supported by grants AA 070313 and AA 05523.

NUTRITIONAL AND PREGNATAL FACTORS: ALCOHOL

4.7.4

ALTERED DEVELOPMENT OF DOPAMINERGIC NEURONS IN THE RAT SUBSTANIA NIGRA FOLLOWING PRENATAL ETHANOL EXPOSURE. A.K. Shetty, R.C. Burrows, and D.E. Phillips, Dept. of Biology, Montana State University, Bozeman, MT 59717.

The development of dopaminergic neurons of substantia nigra pars compacta (SNc) was investigated following prenatal ethanol exposure. Pregnant rats were either fed with an ethanol containing liquid diet (6.7% v/v) or were pair fed an isocaloric diet throughout gestation. Offspring were sacrificed on postnatal day 15 and the morphology of neurons was assessed by tyrosine hydroxylase (TH) immunocytochemistry and by Golgi-Cox staining. Compared to control offspring, ethanol exposed offspring had more densely packed and smaller TH positive cell bodies, fewer dendrites, and fewer TH positive fibers, reduced numbers of second, third and fourth order dendrites, fewer total dendritic segments per cell, and an altered dendritic branching pattern. The results also indicate that ethanol exposure causes retardation of the development of SNc neurons, especially of the growth and branching of dendrites. The underdevelopment of dendrites could result in altered development of neuronal circuitry which in turn could contribute to the abnormal motor functions reported after developmental alcohol exposures. Supported by NSF EPSCoR RII-8921978 and NIAAA AA7042.

EFFECTS OF ALCOHOL EXPOSURE DURING DEVELOPMENT ON THE NEUROCHEMISTRY OF THE AMygDA.LA. Sandra J. Kelly. Department of Psychology, University of South Carolina, Columbia, SC (U.S.A. 29008).

Previous work from this laboratory has suggested that the amygdala may be affected by exposure to alcohol during the early postnatal period. This period is similar with respect to brain growth to the third trimester in humans. The alcohol exposure is given via an intracerebral rearing procedure in which rats are exposed to either 0, 0.5, or 3 g/kg/day of ethanol from postnatal days 4 to 10. Control groups consist of rats naturally reared but not exposed to alcohol and rats reared normally by dams. At 21 days of age, the rat brains were killed and their heads were immediately immersed in liquid nitrogen. The amygdala region was dissected free, sonicated in 0.2 M perchloric acid, and frozen until time of assay. At that time, the sonicated tissue was thawed and centrifuged for 15 min. The supernatant was analyzed for noradrenaline, dopamine, DOPAC, HVA, 5-HT, and 5-HIAA content.

Exposure to alcohol during development alters the amygdala in 21 day old rats. Males were in rats of both sexes and the 5-HT levels were increased in female rats. There were also a number of effects of artificial rearing on neurochemistry. (Supported by NIAAA Grant AA08380)

EXPRESSION OF LHRH mRNA IN THE C57Bl/6J MOUSE FOLLOWING ACUTE IN UTERO ETHANOL EXPOSURE. B.C. Scott*, R.T. Zoeller, P.K. Ruden, Department of Anatomy and Neurobiology, University of Missouri School of Medicine, Columbia, MO 65212.

Previously we have shown that an acute dose of ethanol on gestational day 7 (G7) alters the number of neurons immunoreactive for LHRH peptide (Scott et al., Dev. Brain Res. 66:119, 1992). The effect of an acute dose of ethanol on G10 on the expression of LHRH mRNA was examined in this study. G10 corresponds to the day of development when LHRH neurons begin to differentiate as a single neuronal population in the medial olfactory placode of the mouse (Wray et al., Proc. Natl. Acad. Sci. U.S.A. 86:3132, 1992). C57Bl/6 mice were exposed to two doses of 25% ethanol (2.9 g/kg body weight) on G10. Control pups were intubated with water. Animals were sacrificed on G18 and frozen coronal sections cut at 12 μm. In situ hybridization histochemistry was used to identify individual neurons containing LHRH mRNA. A Bioquant MEG IV image analysis system determined the area covered by grains for each neuron expressing LHRH mRNA in the diagonal band of Broca/medial preoptic area. Fetal ethanol exposure does not appear to interfere with LHRH gene expression when given during an important period of LHRH neurogenesis. (Supported by NIAAA grants AA07458, AA05893 and AA00107)

648.8

Maternal alcohol consumption (36% ethanol-derived calories during the last two weeks of gestation) produces a long-lasting alteration in stress-induced neuroendocrine and neuro-behavioral responses and in basal (non-stressed) neuroimmune responses in the offspring. In order to determine the effect of FAE on stress-induced LHRH expression in the male Sprague-Dawley FAE and control rats were exposed to swim stress (5 periods of 3-min swim in 37°C water over 30 min, with tails weighted). One hr later thyroxines were removed and their proliferative response to Concanavalin A was tested. The thymoproliferative response of swim-stressed control rats dropped by 69% compared to unstressed controls (p<0.01), while it decreased by only 40% in unstressed FAE rats. The ontogenic and temporal profiles of this FAE-induced difference in cellular response to stress are currently under investigation. (Supported by VA Medical Research Service.)

THE INFLUENCE OF CHRONIC PRENATAL ETHANOL EXPOSURE ON CHOLINERGIC DEVELOPMENT IN THE SEPTOHIPPOCAMPAL SYSTEM OF THE RAT. D.J. Swanson, D.D. Walker, and M.B. Heggen*, University of Florida College of Medicine and V.A. Medical Center Gainesville, FL, 32610.

In animal models of Fetal Alcohol Syndrome (FAS) the hippocampus has been shown to be especially sensitive to the effects of prenatal ethanol exposure, exhibiting neuronal loss and alterations in neurotrophic factor elaboration. We have begun to characterize the influence of chronic prenatal ethanol exposure on the development of the cholinergic neuronal population which projects to the hippocampus, the medial septal nucleus and nucleus of the diagonal band (MS/DB). On gestation days 12 pregnant dams were either fed an ethanol containing liquid diet, pair-fed a calorically equivalent sucrose containing diet, or given rat chow ad lib. Preliminary evidence shows that chronic ethanol exposure produces a significant decrease in MS/DB ChAT activity at postnatal day 1 (P1; 18% reduction in ethanol exposed pups compared to pair-fed pups). Subsequently, at P7 ChAT activity expression in ethanol exposed pups approximately equaled that of pair-fed and chow control pups. Further experiments are in progress to examine additional developmental time points as well as the anatomical basis for this alteration in ChAT developmental expression. These studies will determine whether the early decline results from a developmental delay, or whether a reduction in cholinergic neurons coupled with up-regulation of ChAT expression may occur. (Supported by AA05332, AA02000, a grant from the A.B.M.R.F., and the Dept. of Veterans Affairs.)

648.9

ETHANOL EXPOSURE INCREASES GFAP mRNA AND PROTEIN IN DEVELOPING RAT CORTEX AND CULTURED CORTICAL ASTROCYTES. T.L. Fletcher* and W. Shan, School of Public Health, The University at Albany and Wadsworth Center, Albany, NY 12201.

Prenatal exposure to ethanol can result in Fetal Alcohol Syndrome (FAS). We have shown that brief ethanol exposure causes changes in expression of a limited number of genes in the developing rat CNS. We describe here ethanol's effect on glial fibrillary acidic protein (GFAP) expression. Artificially-reared rats pups received 3.3 g/kg/day from postnatal days 5-7 resulting in peak blood alcohol levels of 180 mg/dl. Artificially-reared control pups received an isocaloric diet. Suckling control pups were reared by their dams. Two hours after the last dose of ethanol, mRNA was isolated from three brain regions of some pups. Other pups were fostered to control dams and mRNA was isolated at 14, 21, or 90 days of age. Northern and slot blot analyses demonstrated a transient 3-fold increase in GFAP, but not β-actin, mRNA in cortex. No changes in GFAP were observed in the hippocampus. Western blot analysis of 7 day cortex showed a comparable increase in GFAP protein. To determine if this increase was due to a direct action of ethanol on glial cells, primary cultures of cortical astrocytes were exposed to ethanol exposure in media containing concentrations equivalent to pup ethanol exposure. Ethanol exposure increased GFAP expression parallel to the in vivo observations. These results suggest that ethanol directly disrupts the regulation of specific genes in astrocytes during CNS development. (Supported by AA-07472)

648.10

THE EFFECT OF EARLY POSTNATAL ETHANOL EXPOSURE ON LIGHT-DARK PREFERENCE IN PREWEANING RATS. Jamie H. Wilson* and Sandra J. Kelly. Department of Psychology, University of South Carolina, Columbia, SC 29008.

This experiment examined the influence of early postnatal ethanol exposure on light-dark preference and the effect of home-cage shavings versus clean shavings on this preference. Rats were artificially reared and exposed to either 3 or 5 g/kg/day of ethanol from postnatal days 4 through 10. Control groups consisted of rats artificially reared but not exposed to alcohol and rats normally reared by dams. All rats were reared by dams from postnatal day 12 to the time of testing on postnatal day 16. The testing apparatus consisted of two chambers: one was made of black Plexiglas and completely enclosed and the other was made of white Plexiglas and open to bright lighting. A small door connected the two chambers. Each animal was placed in the black chamber facing away from the dark chamber. Latency to enter the dark chamber and total time spent there were recorded.

The presence of home-cage shavings resulted in more time spent in the white chamber. It is plausible that the presence of home-cage shavings reduced the stress associated with a novel environment such that the animal leaves the shelter of the black chamber. There was a distinct sex effect in that males spent more time in the dark chamber than females. High-dose and low-dose animals spent less time in the dark chamber than animals reared by dams. Both control groups spent the same amount of time in the dark chamber. Early postnatal exposure to ethanol may cause a decrease in the adaptive alternative explanation is that there was an increase in exploratory behavior due to ethanol during development. (Supported by NIAAA Grant AA08080 to S.J.K.)
470.11 AUDITORY BRAINSTEM RESPONSES (ABR) IN RATS PRENATALLY EXPOSED TO ALCOHOL: EFFECTS OF CRITICAL PERIODS. M.W. Church*, G.W. Overbeck, P. Holmes, J. Tilak. Fetal Alcohol Research Center, Dept. Ob/Gyn, Wayne State University School of Medicine, Detroit, MI 48201.

Prenatal alcohol exposure can cause sensory disorders and other nervous system morbidity. Our interest concerns the auditory system. For example, children with the Fetal Alcohol Syndrome (FAS) have a variety of hearing disorders (Church & Garkin, Pediatrics 82:147-154, 1988; Church & Eldis, Alc. Clin. Exp. Res. 16:380, 1992). Using an animal model, we have also observed congenital hearing loss (Church, Alcohol 4:231-239, 1987) and developmental delays in auditory maturation (Church & Holloway, Alc. Clin. Exp. Res. 8:258-261, 1984) as evidenced by the ABR. The degree and type of morbidity caused by prenatal drug exposure depends, in part, on the gestational age at the time of exposure. To study the effects of "critical periods" of exposure, Sprague-Dawley rats were prenatally exposed to alcohol by administering liquid diets containing either 0% or 35% ethanol-derived calories to pregnant dams from gestation day 7-14 or 15-22. Untreated control groups were also used. The earlier (organogenesis) period of exposure proved more critical in producing ABR maturation delays in the offspring than the latter (histogenesis) period. Supported by NIAAA Grant AA07606.

471.1 GLIA AND OTHER NON-NEURONAL CELLS IV

Cervical spinal cords from premature infants were obtained at autopsy and immersion fixed in Zamboni's fixative. Transverse 60μm vibratome sections were cut and stained with antibodies to human neuron, chondroitin-4-sulfate (CS-4), vimentin (VIM) or glial fibrillary acidic protein (GFAP) using a biotin-avidin-peroxidase protocol.

In developing white matter, radially-oriented astrocytes are both GFAP and VIM positive before 33 weeks of gestation. Few satellite astrocytes are evident in the white matter prior to that time. Later, the predominant white matter astrocytic type is tall and appears to express GFAP only. The distribution and density of these cells correlate with the degree of myelination. GFAP-positive astrocytes are evident in the gray matter at 28 weeks, but are more numerous and more ramified by 33 weeks.

CS-4 is distributed throughout white and gray matters at the gestational ages examined. In the regions of the unmyelinated corticospinal tract, CS-4 Immunoreactivity is associated with septae. These septae are also GFAP and VIM positive prior to 33 weeks of gestation, but only GFAP positive at later times.

We have previously demonstrated that embryonic neurons growing in a substrate ofmitocerebral cortical astrocytes were selectively labeled with the vital dye 5(6)-carboxy fluorescein diacetate (CFDA). Neurons displayed brilliant green somata as well as intensely labeled processes while the glial monolayer showed only a dim level of fluorescence. Using optical recording methods, we demonstrated that both neurons and astrocytes hydrolyze CFDA to the fluorescent free acid. However, once CFDA is removed from the medium, the astrocytes rapidly expel the dye with a time course of minutes as opposed to neurons which retain the dye for several hours. This has allowed the selective labelling of neurons with CFDA. When astrocytes are rinsed at 4°C, they retain the dye for several hours, suggesting that an active pump is responsible for the exclusion of the dye. The exclusion of the dye is also inhibited by reserpine in a concentration dependent fashion. Immature astrocytes were not able to expel the dye. However, the ability of embryonic astrocytes to pump fluorescent dyes develops during the first week in vitro. Moreover, the immortalized V1 cell line from embryonic mouse hypothalamus, which expresses several mature astroglial properties, is able to expel the dye. This cell line will be used to investigate the properties of this membrane transporter. Supported by NIH NS 24168.

471.3 NEURONS FAIL TO INDUCE BRAINSTEM ASTROGLIAL CELL DIFFERENTIATION IN VITRO. D.L. Cooper and M.E. Hamburger. Department of Psychology and Center for Neurobiology and Behavior, Columbia University, New York, NY 10032.

Tumors derived from cells of astrocytic lineage are the most common and devastating of the mammalian brain. Previous in vivo analyses, in which cerebellar astroglia and granule neurons were purified from early postnatal cerebellum and combined, demonstrated that neurons provide a control mechanism for astroglial growth, inducing cerebellar astroglial glial differentiation via an extracellular neurotrophic activation of TGFβ. In the present study, we examined whether astroglial cells from the brainstem, a more primitive brain region where neuronal layers do not form, respond to neuronal regulatory signals and TGFβ-induction of glial differentiation.

When neurons, purified from either brainstem or cerebellum, are co-cultured with brainstem astroglial cells, the neurons bind poorly to the astroglial cells and do not induce glial differentiation. Although neurons do not induce brainstem astroglial differentiation, brainstem glia had an augmented response to the TGFβ. In the absence of neurons or TGFβ, brainstem astroglia showed a 2-3 times higher than that of cerebellar astroglial DNA synthesis. Addition of TGFβ to 85 or 1(10 ng/ml) resulted in a 50-60% reduction in DNA synthesis in brainstem glia as compared to the 26-61% reduction seen with cerebellar astrocytes. At similar concentrations, both TGFβ induced glial differentiation, measured by Northern blot analysis of GFAP expression and the glial fibrillary acidic protein (GFAP) expression.

These experiments demonstrate the ability of TGFβ, but not neurons, to induce differentiation of brainstem glia, and suggest that the failure of neurons to induce differentiation may be related to neuron-glial binding.

The studies reported here were aimed at establishing an antigenic marker specific for olfactory nerve glia throughout development. We have recently developed a monoclonal antibody (I58) that recognizes both myelinating and non-myelinating Schwann cells in the chick (Bhattarcharya, et al. 1991) but does not recognize astrocytes, oligodendrocytes or neurons. In the current study, we used the I58 antibody and the avidin-biotin-HRP technique (Vectastain) on tissue sections of embryonic and adult chickens. I58 immunostained olfactory nerve glia both in early embryos and in adults indicating that olfactory nerve glia may be more closely related to non-myelinating Schwann cells than other glial cells types. Further, the pattern of immunostaining we obtained is consistent with the idea that most, if not all, progenitors of olfactory glia are derived from the olfactory placode rather than the neural crest. We also observed that immunostained glia were initially distributed along the perimeter of the olfactory nerve (late E4). By the end of E5, I58-immunostaining was found throughout the nerve. Finally, glia appear to enter the olfactory bulb with the olfactory nerve. In the adult, a thin rim of I58 immunopositive cells can be observed around the edge of the olfactory nerve layer. This work was supported by NIH grants NS30047 (RBN) and NS27277 (RB and NR).

X-irradiation is a useful tool for manipulating the cellular composition of an organ and exploring the developmental consequences. Exposure of the spinal cord to a single 3-day-old x-ray exposure induces a profound and incomplete depletion of astrocytes and oligodendrocytes (J. Neupath. Exp. Neurol., 22:294-301, 1963). Exp. Brain Res. 75:513-522, 1989). This in vitro study addresses issues related to the vulnerability of specific cell phenotypes and maturation of normal embryonic spinal cord of rats were irradiated and removed within one hour to establish the cultures. Non-irradiated spinal cord from littermates provided the control cultures. Cells were cultivated for 8 days in serum-free medium. Immunohistochemical markers were used to characterize the cultures. In cultures derived from x-irradiated tissue, growth was markedly diminished and a significant portion of the surviving cells were GFAP-positive astrocytes. These cells were either primary or epithelial, and some were colocalized in the majority of the epithelial cells. Galactocerebroside, a marker for mature oligodendrocytes, was immuno-localized in an abundant population within control cultures but was virtually absent in cultures from x-irradiated rats. However, a small population within cultures from x-irradiated rats exhibited immunolocalization of A2B5 and 2,3-CNP, markers of early oligodendrocytic lineage. This primary study demonstrated reduced survival and viability of glia in cultures derived from x-irradiated spinal cord. Moreover, the absence of mature oligodendrocytes suggested a specific vulnerability of a stage in this cell lineage.

IMMUNOCYTOCHEMICAL AND ULTRASTRUCTURAL CHARACTERIZATION OF GLIAL CELLS IN LONG-TERM CO-CULTURES. C. Andersson, J. Brunsle-Behnold, and M. Tytell. Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27101.

We examined a mixed glial culture containing type 1 astrocytes and 0-2A lineage cells in fetal calf serum at 5 days in vitro (DIV). 12 DIV, and 30 DIV, using cell-specific immunocytochemical markers and electron microscopy. The flat type 1 astrocytes were polygonal, and GFAP+, GalC- and A2B5- (specific markers for natural astrocytes and oligodendrocytes, and 0-2A cells) at all three time points. From 5 to 30 DIV, the type 1 astrocytes increased in cell size. Ultrastructurally, the stochastically processed axons dramatically changed over time, with the numbers of glial filaments increasing and microtubules decreasing. At 5, 12, and 30 DIV, the 0-2A lineage cells were multipolar, and A2B5+, GFAP-, and GalC-. Ultrastructurally, the 0-2A lineage cells could not be regarded as either astrocytes or oligodendrocytes. These cells had a dense cytoplasma, a very small number of intermediate filaments, and a large number of vacuoles and dense bodies. At no time were the differentiated type 1 astrocytes immunoreactive for HNK-1 and NCAM. 0-2A lineage cells were HNK-1- and NCAM-, further suggesting cellular immaturity.

The cytoskeleton of cultured type 1 astrocytes seems to develop comparable to astrocytes in vivo. Under these culture conditions, 0-2A lineage cells were multipolar, but immature, and appear unable to differentiate.

INSULIN-LIKE GROWTH FACTOR 1 (IGF-I) INDUCES ASTROCYTES TO ACQUIRE A RADIAL GLIAL-LIKE MORPHOLOGY IN VITRO. A. Casey and B.J. Duff. Dept. of Anatomy, University of Saskatchewan, Saskatoon, SK, Canada S7N 0W0.

Insulin and IGF-I are known to have neuroprotective effects; however, they can also affect astrocyte function. For example, Dugan and Blankenhorn have shown that they both affect glycogen metabolism (1992, J. Neurounch. Sci. 53:311) and have shown that they affect astrocyte neuroprosthetic activity (Ang et al. 1992, J. Neuroi. Sci. in press). Since astrocyte morphology is independent of astrocyte function, our objectives were to determine whether insulin, and in particular IGF-I affected astrocyte morphology. Rat type 1 astrocytes were isolated using the McCarthy and de Vellis method. After two weeks in a serum-containing medium, the cultures were maintained on Bottenstein's G5 medium minus the insulin. In this medium the astrocytes maintained their flat fibroblast-like appearance. Treatment of insulin (1-5 ng/ml) or IGF-I (10-100 ng/ml) resulted in a dramatic change in astrocyte morphology. In contrast, IGF-II (10-100 ng/ml) had no effect on astrocyte morphology. The insulin and IGF-I induced morphology consisted of a distinct soma from which one emerged long prominent and sometimes several long processes of narrower caliber. The processes were tightly packed with GFAP-containing intermediate filaments, whereas the soma had a lesser density of intermediate filaments. This morphology is very reminiscent of that of radial glial cells. In the CNS, IGF-I mRNA as well as IGF-I receptors are expressed by both neurons and astrocytes in a stage-specific manner, i.e. the highest level of IGF-I expression occurring in embryonic and fetal development. It is likely, therefore, that IGF-I can act in a permissive as well as an autocrine fashion in the brain. We postulate that possibly IGF-I plays a role in the differentiation of radial glial cells. Furthermore, these packets and/or autocrine effects of IGF-I may be involved in the relationship of developing neurons and radial glia, which affects both neuronal migration and the differentiation of neurons and astrocyte. We thank Dr. B. Bhaumik for the gift of IGF-I and IGF-II.

1011.0 THE ISOLATION OF A NOVEL OLIGODENDROCYTE SPECIFIC c-DNA
C. Schefer, N. Schenaer-Wenzler, C. Decaner, and M. E. Schwab.

Brain Research Institute, University of Zurich, Auguste-Porel Str. 1, 8029 Zurich – Switzerland.

Myelin contains a variety of unique proteins (e.g. MAG, MBP, PLP, CNPase). Only a few proteins seem to be selectively expressed by central nervous system (CNS) oligodendrocytes as compared to peripheral nerve Schwann cells. Myelin disorders that are specific for the CNS exist, however, and oligodendrocytes play important additional roles in CNS development and regeneration by their expression of neurite growth inhibitory proteins. Here we demonstrate the isolation of a c-DNA encoding a novel oligodendrocyte specific clone. The c-DNA corresponds to a c-RNA of 4.9 kb. The presently available c-DNA (3.4 kb), including the poly-A tail, does not show homology to any known oligodendrocyte or CNS c-DNA. The expression is restricted to the postnatal CNS. The encoded protein is expressed in astrocytes (PNS), liver, lung, thymus, heart, kidney, spleen, skeletal muscle, testis, and is higher at P10-20 than in the adult spinal cord. In situ hybridisation shows a stronger expression in oligoden- drocytes in myelinating regions of the brainstem, cerebellar white matter and corpus callosum. In cultured optic nerve oligoden- drocytes P111 expression was localized in galC-positive oligoden- drocytes.

471.11 THE GLIOARCHITECTONICS OF THE HUMAN NEOCORTEX. T.J. Mandryk. Department of Pathology and Laboratory Medicine, University of Cincinnati and Laboratory, Cincinnati, OH 45267-0529.

It is well known that the normal cortex shows few fibrillary astrocytic fibers. In the molecular layer of these areas, the astrocytes are associated with external glial limiting laminae. In the disease process in Alzheimer's disease of the molecular layer. This might be associated with gliosis, but in the aged individual, and in Alzheimer's disease, the astrocyte's molecular layer displays fibrillary fibers which penetrate down to the II and III layers. The astrocytes in the molecular layer are also seen in the thalamus, cortex, and thalamus.

471.12 MULLER CELL PHENOTYPE PRECEDES SENEQUENCE OF VIRALLY TRANSFORMED CHICK NEURORETINAL CELLS. G.M. Siegel, E.L. Emperador, J.T. Hansen, and M.F.D. Notter. Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642.

The phenomenon of senescence has been an obstacle in obtaining permanent Rou's sarcoma virus-transformed avian cell lines. Our previous studies analyzed this senescence phenomenon in Rou5 sarcoma virus-transformed chick neuroretinal cells (L29NR) and demonstrated a decreased mitotic index accompanied by loss of transformed phenotype (Siegel and Notter, submitted, JVI 384-92). After four to five months in culture, new cell death, unusual process formation is observed in L29NR cell populations. We have now characterized these morphologically differentiated cells as immunoreactive for glial fibrillary acidic protein, S-100 antigen, and vimentin, while predominantly negative for neuron-specific enolase, as detected immunocytochemically. Electron microscopic observations revealed large, vacuolated cells packed with longitudivally-oriented intermediate filaments, extensive smooth and rough endoplasmic reticulum, as well as occasional myelin-like figures, characteristic of normal retinal Muller cells. However, unlike normal Muller cells, retinal Muller cells have been described to be intracerebrally and extracellularly. From these data, we conclude that despite continued retroviral expression, senescence L29NR cells exhibit a Muller cell phenotype as a state of terminal differentiation at the end of their mitotic lifespan in culture.

During metamorphosis in Prosopha, the central nervous system (CNS) is extensively remodelled. Adult nerves arise from the embryonic glial layer and in the nerve formation is extensive pathfinding. Some glial cells may serve as landmarks to define pathways for developing neurites. At the boundary between the nerve and cortex, unique glia cells have an affinity for Notch antibodies (Ab) in third instar larvae (Pellon et al., J. Cell Biol. 113:657). In early pupae, Notch Ab affinity is most prevalent in the glial cells at the neurite where the neurites are forming. By 48h, the affinity decreases and is barely evident at 72h; this period is coincident with final leg nerve formation. Related miotic activity, typical for many other Notch-positive cells, is absent in these glia. These neurone glial cells are distinguished by intense synthetic activity in parallel with the peak Notch affinity (48h pupae), as indicated by extensive rough endoplasmic reticulum.

In this study we have modified techniques for culturing neurons of pulmonate molluscs to obtain populations of cells having glial-like characteristics. The cells were isolated from the cortical regions of the central ganglions of snails Lymnaea stagnalis and Helisoma trivolvus using protease (see Ridgway et al., J. Neurobiol. 22: 377-390, 1991). The isolated cells were then cultured under sterile conditions in 36C Leibowitz (L-15) medium on various substrates. The putative glial cells displayed an elongate morphology (75-100 μm in length and 10-15 μm in width), the nucleus being situated midway along the cell axis. Lamellipodial processes extending from the perimeter of the cells correlated with a high degree of motility in the first 6-12 h after plating. This motility was substrate specific: on adhesive substrates (e.g., poly-L-lysine) cells decreased in motility after 12 h, whereas those plated on less adhesive substrates (e.g., bovine serum albumen) were motile for 48-72 h. Electrophysiological recordings made from motile cells revealed resting membrane potentials ranging from -40 mV to -50 mV. The cells were responsive to both dopamine (0.1-1.0 μM) and noradrenaline (0.1-0.1 μM). Cells could be maintained for 4-5 days whereupon they became pycnotic and lost their membrane potentials; reasons for this cell death are under study.

While early animal models of schizophrenia addressed primary changes in striato-limbic dopamine activity, they did not account for other phenomena associated with the illness (e.g. congential temporal-limbic abnormalities, cortical deficits, vulnerability to stress, postpubertal onset). We have reported that ionotonic acid ventral hippocampal (vH) lesions in adult rats affected DA-related behaviors in a manner consistent with increased mesolimbic DA activity. These changes were paralleled by biochemical indices suggesting enhanced DA transmission in the nucleus accumbens, a reduction in the medial prefrontal cortex, and an increase in corticosterone levels in hippocampal CA1 (Brain Res., 1992). The behavioral response to pharmacological (FG-7142) or environmental (swim stress) stressors was not affected. In contrast, locomotor activity and response to amphetamine of rats lesioned as neonates (PD7) did not differ from controls 4 weeks after the lesion (PD35). However, 3 weeks later (PD56), the same rats became hyperactive in these conditions. Moreover, neonatal lesioned animals were hyperactive in stress, in contrast to rats with neonatal lesions of VH, augmented activity developed only after puberty. Neonatal but not adult-induced lesions also produce an exaggerated response to stress, with increased serum corticosterone levels.

Homologous mechanisms could be involved in schizophrenia.

471.2 DEVELOPMENTAL EXPRESSION OF PARVALBUMIN mRNA IN THE CEREBRAL CORTEX AND HIPPOCAMPUS OF RAT. Leena Luu de*, Eduardo Soriano*, Jose A. del Rio, Sonia Formigari**, University of Cordoba, Dept of Neurobiology, 14004 Cordoba, Spain.

Parvalbumin is a calcium binding protein that is thought to play a major role in calcium buffering in metabolically active fast-firing cells. In adult cortex, parvalbumin is expressed in a subset of cholinergic GABAergic interneurons. The pattern of parvalbumin mRNA expression during the postnatal development of rat cerebral cortex and hippocampus was examined by means of in situ hybridization with an oligonucleotide probe. In animals aged P0-P14, no signals of expression were detected in the adult cortex and hippocampus, with the exception of a few low numbers of motor neurons in motor and somatosensory cortices and in the hippocampus. By P12, parvalbumin expressing cells were detected within all cortical regions. At P14 an overall increase both in the number of positive cells and in the intensity of labeling was observed. A further maturation pattern was seen at P16-P21 stages, which lead to the appearance of an adult like distribution in cortex and hippocampus. The appearance of parvalbumin mRNA expressing cells does not follow the usual inside out sequence of cortical maturation. Instead, hybridization is first observed in the middle cortical layers to thereafter expand to the immediate adjacent layers. Count of silver grains revealed that hybridization signals increased progressively during postnatal development. In adult neocortex and hippocampus, the distribution of parvalbumin mRNA containing cells is consistent with our previous immunocytochemical findings in rodent cortex. These data suggest that the developmental pattern of expression of parvalbumin is similar to that of calcium buffering and may reflect the functional maturation of cortical interneurons.

The neurological deficits found in infantile hydrocephalus have most often been explained by pathological changes in cerebral cortex. It has been the primary objective of our studies to discover a cellular basis for these residual neurological deficits observed even though surgical intervention may have relieved the effects of ventriculomegaly on the cerebral cortex (McAlister et al., 1980). We have shown significant structural changes in cerebral cortex, basal forebrain region, especially in septal nuclei, and hippocampus. A primary difference in the structural alterations within these regions was the minimal increase in extracellular space in the hippocampus. In the present study we compared the ependymal surface adjacent to the cerebral cortex, basal forebrain region, and hippocampus. Kaolin injection induced hydrocephalus; aldehyde fixed sections were stained coronally with subsequent staining for cells and fibers. The ependyma underlying the cerebral cortex was thinned but appeared to remain intact. In contrast, the ependyma adjacent to the hippocampus was not altered in comparison to control tissues. The cuboidal shape as well as surface projections appeared normal. The potential relation of these structural differences to extracellular space in the neuropil is discussed. Supported by AA091031,RMK-NH/HD215572, JPM.

471.4 CYTOARCHITECTURAL, NEUROREL MOPHOL O GIC AND MOLECULAR ASPECTS OF HUMAN HIPPOCAMPAL DEVELOPMENT. Steven E. Arnold* and John D. Trojanowski, Departments of Psychiatry and Pathology, University of Pennsylvania School of Medicine.

Cytoarchitecture, neuronal morphology and the expression of various neuronal cytoskeletal proteins were examined in human hippocampal fixed sections from the hippocampal formations of 18 cases 10 weeks gestational age through 2 years were stained with cresyl violet for cytoarchitecture and immunophenotypic analysis and processed for immunohistochemistry. Monoclonal antibodies (mAb) used were directed at components of the neuronal cytoskeleton that are believed to be important determinants of neuronal polarity. These included microtubule-associated proteins (MAPs), MAP2, MAP3 and tau, alpha and beta tubulins, and poorly, moderately and highly phosphorylated MAPs. Immunostaining was performed on sections from five human fetal brains. Differential patterns of cytoarchitecture and neuronal morphology were noted across time and both between and within anatomic regions. The expression of MAP2, MAP3, alpha and beta tubulins, MAPs, and MAPs was evident at the earliest time point studied and persisted throughout development. Immunoreactivity to tau and NFP-F-* appeared at subsequent points, with tau diminishing in intensity later on in development. MAP2, MAP3 and NFP-F immunoreactivity allowed recognition of nascent dendrites and pyramidal shaped neurons prior to their definition with conventional cresyl violet staining. At all times, there were differences in intensity of immunoreactivity between the different amaminergic, subicular and entorhinal subfields. (Supported by NIH grant 1 R01 MH09708-01)

471.5 CALBINDIN-D28K DISTRIBUTION IN HIPPOCAMPAL FORMATION OF LATE GESTATION FETAL SHEEP IS INDEPENDENT OF PLASMA GLUCOCORTICOID CONCENTRATIONS. T.J. McDonald & R.H. Wasserman, Department of Physiology, Cornell University, Veterinary Research Tower, Ithaca, NY 14850.

Glucocorticoids regulate the appearance of Calbindin-D28K in the granule cells of the dentate gyrus of adult rats with adrenalcausing complete loss of immunoreactivity in the granule cell layer after 4 weeks (Jacopo and Rosado, 1990; Aronson et al., 1980). In late gestation, fetal sheep undergo a logarithmic rise in peripheral plasma cortisol concentration that starts at approximately 125 days of gestational age (DGA) with baseline concentrations of 10-15 ng/ml peak at term with concentrations over 100 ng/ml" (Magee et al. 1981. J.Ster.Biol: 14:1091-1099). This cortisol rise is driven by the pituitary and hypothalamic paraventricular nuclei and is indispensable for parturition to occur at term (Liggin et al., 1979; Recq et al., 1981; 1983; McNamara & Nalaniek, 1991. Am.J.Obstet.Gynecol: 165:764-770). In this study we analyzed the fetal sheep at 105, 125, 135, 147 (in labor) DGA and newborn lambs were examined immunocytochemically. While Calbindin-D28K was found in diverse areas of the brain, e.g. brainstem, cerebellum, neocortex, basal ganglia and hypothalamus, no Calbindin-D28K immunoreactivity was detected in the dentate gyrus or Ammon's horns at the ages examined. However, many Calbindin-D28K immunoreactive cells were found in the subiculum at all ages, but intensity of staining appeared to be independent of gestational age. It is concluded that unlike in adult rats, abstract image glucocorticoids have no effect on the weaner immunocytochemical distribution of Calbindin-D28K in the hippocampal formation of the late gestation fetal sheep.

471.6 NEUROGENESIS OF THE VASOPRESSIN NEURONS IN THE BED NUCLEUS OF THE STRIA TERMINALIS AND MEDIAL AMYGDALOID NUCLEUS OF THE RAT. H.A. Al-Shammari & G.J. De Vries, Program in Neuroscience and Behavior, Univ. of Massachusetts, Amherst, MA 01003.

The vasopressin-immunoreactive (AVP-ir) neurons of the bed nucleus of the stria terminalis (BST) and medial amygdaloid nucleus (MA) share many neurochemical and anatomical characteristics, e.g., in their neurotransmitter content, cell morphology, and steroid sensitivity. It is unclear, however, how BST and MA neurons develop these similar characteristics. To get more information about the development of these cells, we determined the day of birth of these AVP-ir subgroups with the cell birth marker bromo-2-deoxy-5-uridine (BrdU).

Pregnant Long-Evans rats received intraperinatal injections of BrdU on one of gestational days 14-20, day 1 being the day that a copulatory plug is found. At three months of age, the male offspring of these treated females were sacrificed and their brains were processed for both BrdU and AVP immunostaining. Approximately 20% of the cells in the BST and MA were also immunoreactive for BrdU, the majority of which were found in the BST and MA of animals exposed to the cell birth marker on embryonic day 16. In this study, the preliminary findings are in agreement with earlier studies using [H]thymidine autoradiography which suggest that most of the cells in the divisions of the BST and MA that contain the AVP-ir neurons are born on embryonic days 15-16 and 14-15, respectively.
472.7

Zones containing post-mitotic cells and neurons forming neurites express proto-oncogenes. The change in the expression of c-fos, c-neu, c-sis, and c-ras, was examined using immunobots. Tissue from the frontal pole of rat cortex was harvested at various ages (between gestational day 16 and postnatal day 52) and in 3- to 5-month-old rats. Blocks of tissue were disrupted in buffer containing detergent and proteinase inhibitors. Standard gel electrophoresis and transfer techniques were used in probing for immunobots. Anti-c-fos identified 2 proteins, one with a molecular weight of 64 Kd and the other 80 Kd. c-fos expression of both proteins appeared on G16 and was peaked at P5 and on G18. Anti-c-neu also labels 2 proteins, 65 Kd and about 185 Kd. The temporal expression of the 65 Kd protein was similar to that of c-fos. On the other hand, the 185 Kd protein appeared on the day of birth (P0) and virtually disappeared by P8; peak expression occurring on P3-P6. Anti-c-sis identifies a doublet with molecular weights of 53 and 62 Kd. The expression of both proteins begins as early as G16 and persists beyond P9. This expression was rather stable throughout this period. Trace amounts of all of these proto-oncogenes were detectable in the adult rat. The pattern of c-ras expression is different for it builds during the postnatal period to adult levels by P21. Based upon timing, the data are consistent with the concept of a cascade of events, c-neu being related to cell proliferation or neuronal migration, c-neu and c-fos being related to neuronal differentiation and or death, and c-ras being related to neurite outgrowth, synaptogenesis, and the maintenance of neuronal integrity. Funded by DE 07734, AA 06916, and AA 07568.

472.8
MIGRATION OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) IMMUNOREACTIVE NEURONS TO RAT CORTEX. M.W. Miller*, Res. Serv., Iowa City V.A.M.C., and Dept. Psychiatry & Pharmacology, Univ. Iowa Coll. Med., Iowa City IA 52242.

Most neurons migrate to cortex from the transform inside-to- outside sequence. Accordingly, neurons in deep cortex are generated before those in superficial cortex. In visual cortex, this migrational pattern is followed by cortico-cortical projection neurons and by GABAergic local circuit neurons. A combined autoradiographic-immunohistochemical method was used to determine the time of origin of VIP immunoreactive neurons. VIP is expressed by a subpopulation of local circuit neurons, mostly small bipolar neurons, which do not co-localize GABA, nor of neurons in a layer of cingulate cortex (areas 24 and 29), somatosensory cortex (area 3), and visual cortex (area 17) was examined by administering [3H]thymidine on gestational day 13, 15, 17, 19, or 21 and sacrificing the pups on postnatal day 30. Although the timing differed slightly in each cytoarchitectonic area, the basic pattern of neuronogenesis was similar in all areas. VIP-positive neurons with a particular time of origin were not distributed in a tangential band of cortex; rather such neurons were distributed through the full depth of cortex. Such a pattern was evident regardless of the time of origin. Thus, VIP immunoreactive neurons migrate into cortex via a mode other than the standard inside-to-outside sequence. Funded by DE 07734, AA 06916, and AA 07568.

472.9
POSTNATAL DEVELOPMENT OF PROTEIN KINASE C GAMMA EXPRESSION IN RAT BRAIN. R. Burwida, C. Nyakas, E.A. van der Zee, S. Cazabon, P.M. Luiten*. Dept. of Animal Physiology, University of Groningen, PO Box 74, 9700 AA, The Netherlands.

Findings of sexual dimorphism in the rat corpus callosum, using gross size measures, prompted the use of electron microscopic techniques to view ultrastructural parameters. Since neonatal handling was found to enhance certain differences between gross measures of female and male rat callosa, both handled and nonhandled rats were used to study this phenomenon. All rats were transcerebrally perfused at 110 days of age, and mid sagittal sections were obtained. Based on previous findings, sampling was restricted to the first 20% of the genu, although the posterior portions of the callosa have been retained and embedded for possible analysis. Preliminary findings indicate a greater quantity of unmyelinated axons than myelinated axons in the areas sampled, and a distinct Sex x Handling interaction in total number of unmyelinated axons.

472.10

472.11

A novel Antp-class homebox gene has been isolated from a human 11 W fetal brain cDNA library. PCR with two sets of oligonucleotide primers (specific for highly conserved regions of the Antp-class homeobox) was used to amplify portions of the gene present in the fetal brain library. Sequencing 100 clones identified 2 novel Antp-class genes. Screening the fetal brain library for a probe specific for one of the novel genes led to the identification of a 1.7 kb cDNA containing the novel homeobox sequence. This clone encodes a protein of approximately 327 amino acid residues. By Northern analysis, this cDNA detects multiple transcripts in the developing human CNS as well as other tissues. These observations suggest that in early mammalian development this homebox gene may act as a spectrum of control functions in a variety of organ systems including the CNS.

472.12

We introduce a developmental neuronalontological database from J.L. Cohen as a potentially useful framework for computational models and analysis of the developing human brain to 6 years and its relation to developing behaviors. We have investigated the relation between functions related to gyral and anatomical measures of cortical thickness, cell density, cell body length, cell body width, f of axons/ unit area across all layers and over 40 gyri. Using the analytical method, Optimal Multi layer hidden layer network, inputs consisting of the 6 variables per gyrus per layer were used to find the best separation of the gyral functions used the diverse variables. We wished to see which variables, layers and gyri maped to gyral functions found at least similar possible. We wished to see which variables, layers and gyri mapped to gyral functions found at least similar possible. Results will be presented. Also presented are data on total critical thickness, figure 1 graphs the total cortical thickness in mm., for the 37 loci for all eight age-groups in this age range. The correlation is not smooth, with many loci showing episodes of reduction in cortical thickness despite the general tendency to increased thickness with age. Figure 2 graphs the slope rates of change in cortical thickness per mm. per month of the values for total cortical thickness, for the seven age-blocks the graph showing that all loci show appreciable change in cortical thickness, either positive (increasing to thickness) or negative (decreasing to thickness) over the age-block 0-1 month, with the rate of change of total cortical thickness per month generally decreasing with age.
473.1

CHOLINE ACETYLTRANSFERASE IN THE CEREBRAL CORTEX OF NBM-LESIONED RATS RECEIVING CHROMAFFIN CELL GRAFTS. S. A. Weiner* and Z. C. Koyt. Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal, Quebec, Canada H4H 1R3.

Lesions of the nucleus basalis magnocellularis (NBM) in rats produce spatial memory deficits as well as changes to cholinergic markers in the cerebral cortex, the target area of projections from the NBM. We have previously reported that adrenal chromaffin cells transplanted to the cerebral cortex of rats with NBM lesions are able to ameliorate lesion-induced spatial memory deficits and increase acetylcholinesterase (AChE) staining in the host cortex (Weiner et al., Brain Research, 527: 163, 1990). In the present experiment, we tested the hypothesis that grafting chromaffin cells to the cerebral cortex of NBM-lesioned rats will have an effect on a different cholinergic marker in the cerebral cortex, choline acetyltransferase (ChAT). At various time points post-grafting, Sprague-Dawley rats received bilateral partial lesions in the NBM and, two weeks post-lesion, either were left unoperated or had suspensions of adrenal chromaffin cells grafted to six sites in their frontal and parietal cortices. A group of unoperated rats served as controls. ChAT activity was measured at 2, 6, 12 and 16 weeks post-graft. In the lesioned-alone group it was found that ChAT progressively decreased over time, whereas in the lesion plus graft group, ChAT levels were significantly decreased at 6 weeks and appeared to be increasing at the 11 and 16 week time points. These results support previous findings that the cholinergic system of cerebral cortex following grafting of chromaffin cells to the cortex of NBM-lesioned rats is increased. (Medical Research Council, Canada & Fonds de la Recherche en Santé, Québec.)

473.2

FOCAL FIBROBLAST GROWTH FACTOR IN CHROMAFFIN CELL GRAFTS TO THE CEREBRAL CORTEX OF NBM-LESIONED RATS. E. S. Zucol, Z. C. Koyt and S. A. Weiner. Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal, Quebec, Canada H4H 1R3.

Chromaffin cell grafts to the frontal and parietal cortices of nucleus basalis magnocellularis (NBM)-lesioned rats can ameliorate the spatial memory deficits which result from the lesions; this is accompanied by an increase in staining for a cholinergic marker in the host cerebral cortex (Weiner et al., Brain Research, 527: 163, 1990). Lesion of chromaffin cells of the adrenomedulla are known to contain basic fibroblast growth factor (bFGF), a known neuroprotectant, it is of interest to determine whether bFGF may be involved in the grafted effect. As a first step, it is necessary to test whether bFGF is present in these grafts at various time points post-grafting. Taz-mained rats were unoperated and then administered bFGF as a control or chromaffin cell grafts, two weeks post-lesioning. Rats were retstoned on the Taz-mate at various time points post-graft; subsequently, the density and distribution of bFGF in grafts and the area surrounding the grafts was measured using immunocytochemical techniques. Whereas the host cortex is virtually devoid of staining, bFGF was clearly visible in chromaffin cell grafts. As expected, kidney cell grafts contained no bFGF. Further, the presence of bFGF in the grafts correlated with groups that showed behavioral recovery of spatial memory, as measured in the Taz-mate. These results indicate that bFGF may be involved in producing the effects of chromaffin cell grafts to cerebral cortex. (Supported by the Alzheimer Society of Canada and the Medical Research Council of Canada.)

HYPERTHALAMIC ANATOMICAL CORRELATES OF GraftING IN THE HIPPOCAMPAL FORMIC OR THE CORPUS STRIATUM. R. E. Cost and T. E. Zuccol. UCLA, Santa Monica, CA 90404.

Grafting of embryonic neural tissue into the adult brain has been shown to be a viable method for treating a variety of neurological disorders. This study examines the histological effects of grafting on the thalamus, hippocampus, and corpus striatum. Grafts were made unilaterally into the thalamus of adult rats, and then the rats were sacrificed at various intervals post-grafting. The histological effects of grafting were examined by staining the tissue with hematoxylin and eosin. The results showed that there were no significant histological differences between the control and experimental groups. However, there was a trend towards an increase in the number of neurons in the grafts compared to the control tissue. This trend was more pronounced in the thalamic grafts than in the hippocampal or corpus striatal grafts. These findings suggest that grafting may have a beneficial effect on the development of the host brain, possibly by promoting neuronal growth and survival.
473.5

The major input to the basal ganglia is the excitatory input from the cerebral cortex to the medium spiny striatal neurons. The purpose of this investigation has been to reconstruct the cortical pathway by using fetal cortical tissue transplants. Frontal cortical grafts were performed by aspiration in adult rats. After 15 days animals received grafts of 16-day gestational cortical tissue into the lesion site. Connections from the graft to the host striatum were studied after 6 weeks using immuno-staining for neurofilaments and anterograde tracing with Dil. SMI-31 and SMI-35 immunoreactive neurites were found crossing the interface with corpus callosum and striatum with a relatively high frequency (13.7 and 29.8 /mm of interface respectively, but only rarely entering the adjacent cortex. Dil tracing demonstrated a large number of graft-derived neurites projecting from 0.5 to 0.8 mm into the host caudate putamen. It is concluded that fetal cortical grafts in adult animals send limited projections into the host caudate-putamen.

473.6

Several studies demonstrate that fetal neocortical tissue will survive, grow and form axonal connections with the host brain after transplantation into newborn rats with cortical aspiration lesions. In the present study fetal neocortical grafts were transplanted into Long-Evans, black hooded rats that sustained hypoxic-ischemic brain damage at 7-8 days of age by permanent right common carotid artery occlusion under methoxyfluorane anesthesia followed by hypoxic exposure (8% oxygen) for 2-2.5 hr. Twenty-one out of 25 animals survived this procedure. One week later, 1-2 mm^{3} neocortical grafts obtained from E13 fetuses were transplanted into the right hemisphere of these animals just caudal to the coronal suture at 1-2 mm from the midline. All animals survived the transplantation procedures and were sacrificed at 2 (n=8), 4 (n=6) and 6 (n=7) weeks after transplantation. Brains were cut frozen at 30 mm and processed for acetylcholinesterase (AChE) immunocytochemistry and Nissl stain. Generalized atrophy and shrinkage of the right cerebral hemisphere was seen in 20/21 animals. Various degrees of ischemic brain lesions with neuronal loss were observed in several structures including the cerebral cortex, thalamus, hippocampus, and striatum. Well developed transplants were found adjacent to the ischemic area. AChE positive fibers were seen crossing the transplant-host interface proving evidence that the grafts became integrated into the host brain circuitry.

(Supported by NIH Grant 13230 and the Potts Foundation)

473.7

Monoaminergic neural transplants to the rat frontal neocortex have been demonstrated in our laboratory to alleviate depression in animal models. These findings suggest that neural transplants may provide a long term source of monoamines to correct the central imbalance of serotonin (5-HT) and noradrenergic (NE) functioning implicated as the cause of depression. In order to support this suggestion, grafted monoaminergic tissue must survive well and continue to produce high levels of monoamines. Using electron microscopy the ultrastructural characteristics of 5-HT-containing pineal gland tissue, NE-containing adrenal medulla tissue, grafted pineal and adrenal medulla tissue and control tissue were examined at least six weeks following transplantation. The transplanted pinealocytes maintained their characteristic in situ features of numerous and dense mitochondria, a highly convoluted nucleus and the presence of lipid droplets. Similarly, transplanted adrenal chromaffin cells retained their in situ cuboidal morphology and displayed numerous granules. Neither type of graft was highly vascularized. The grafted transplants contained collagen matrices separating the pinealocytes from the chromaffin cells. Immunohistochemical studies indicated that the surviving chromaffin cells continued to produce tyrosine hydroxylase and dopamine-β-hydroxylase and the pinealocytes continued to produce 5-HT. Sixth month old pineal implants also appeared to sprout densely into the surrounding host parenchyma. These results demonstrate that the monoaminergic tissues retain many features of their in situ morphology when transplanted to the frontal neocortex of rats.

473.8

Previous findings in our laboratory have indicated that the transplantation of monoaminergic tissue into the frontal neocortex of rats can reduce behavioral deficits in rodent depression models. If the reduction in behavioral deficits by the transplants is due to the release of neurotransmitters, it should be blocked by specific monoaminergic antagonists. We have shown that both alpha and beta adrenergic antagonists not only reversed the effects of the transplants on the behavior but in fact exacerbated the deficit, suggesting changes in receptor sensitivity. This study investigates this effect at the receptor level. Monoaminergic tissue (adrenal medulla, pineal gland, or a combination of both) was transplanted into the frontal cortices of separate saline- and scopolamine-treated animals prior to transplantation as controls in other groups. Each group was treated with imipramine (15 mg/kg/day; ip) for six weeks. Six weeks later animals were tested for behavioral deficits using the forced swimming test. Following testing, a small section (5 x 5 x 7 mm) of cortex was removed from around the transplant of each animal and the transplant was discarded. The remaining tissue underwent receptor binding studies. 8-hydroxy-2-(di-n-propylamino)tetralin was used as a ligand to investigate alpha-1 binding sites while [125I]iodocyanopindolol was used for beta binding sites. In these initial studies, K_{d} concentrations of pindolol were used to screen for any changes in binding site sensitivity or concentration. No significant differences in binding were seen between transplant and control groups for either ligand (pindolol: 3.6-4.1 fmoles/mg tissue wet wt, pindolol: 4.5-5.4 fmoles/mg tissue wet wt). However, binding was significantly reduced in imipramine treated animals. These results suggest that the previously noted behavioral and pharmacologic changes in the transplanted animals are not associated with a corresponding change in the number of monoaminergic receptor sites.

473.9
Morphological assessment of grafted cortical neurons, J. Link*, M. Wood and D. J. Clarke. Dept. of Human Anatomy, University of Oxford, South Parks Road, Oxford OX1 3QX, U.K.

The morphology of cortical neurons grafted near/or into the rat striatum was studied by means of intracarier Lucifer yellow injections in fixed slices. Rat donor cortical tissue (from postnatal day 1 old rats; AO strain) as well as mouse donor cortical tissue (prenatal E 19; C3H/EH strain) was grafted as solid pieces (a 4 mm of 4 mm of donor tissue was inserted via a Hamilton syringe) in 8-12 week old rats (AO strain). Animals were immunostained with antibody against the HNK-1 receptor. 40-60 days postoperatively animals were perfused with buffered 2% paraformaldehyde and 1% glutaraldehyde. 120 μm vibratome sections were taken at the site of the transplant. The graft could be identified by a surrounding rim of astrocytes after incubation of the slice in the DNA-stain DAPI for 10 min. Cortical neurons (over 50 neurons in each transplant) were intracarier filled with Lucifer yellow, DAB-photoreactive, embedded in resin, photographed and drawn with the aid of a camera lucida. In addition, tissue was prepared for electron microscopy to study the ultrastructural morphology and synaptic inputs of the injected neurons. In general, no cortical lamination could be observed in the grafted cortical tissue, but neurons were loosely packed throughout the graft. Two major cell types could be identified. The majority were spiny neurons (95%), of which some could be described as pyramidal-like with somata, ranging in size between 10-20 μm in diameter. The remaining 5% represented non-spine neurons with a basket-like morphology. dendrites of both cell types were never seen to cross the astrocytic border, but some main axons and axonal collateral were found to leave the graft. On the basis of light microscopic observations no difference was found between mouse and rat grafted cortical neurons. In conclusion, we have shown that grafted neurons retain some characteristic features of cortical neurons, although there appears to be a greater preponderance of spiny neurons. This may reflect an immaturity of the graft tissue or a response to the aural environment.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

THURSDAY AM

In normal animal light flashes suppress acoustic startle reflexes. In light blinded animals inhibition is lost and replaced at certain intervals by an amacrine peak of excitation, which is not seen in enucleated rats. Fischer 344 rats were blinded by exposure to continuous fluorescent light and half of the animals were gifted with dissociated fetal retinal cell into 1 eye. Compared to non-grafted controls, grafted rats showed both statistically significant reductions of amacrine facilitation and increases in inhibition (Exp: 1: del Cerro et al, Neuroreport, 1:259, 1991). To test for the specificity of this effect, grafted rats were gifted with fetal retinal cell homogenates (Exp: 2: N=20), or dissociated perinatal cerebellar cells (Exp. 3, N = 19), with control rats left untransplanted in each experiment. In contrast to the grafted rats of Exp. 1, the grafted animals in Exp. 2 and 3 were not different from their controls. Histologically, clusters of photoreceptor cells were consistently found in the retina of Exp. 1 animals, but not in those of Exp. 2 or 3. We conclude that only retinal grafts of living fetal retinal cells partially repair the blindness caused by the action of continuous light exposure.

474.3 HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL CHARACTERISTICS OF Y79 RETINOBLASTOMAS IN VIVO. D. D. HORROTT, T. C. C. DEL CERRO, M. DEL CERRO, AND C. H. CHADLER. Department of Neurobiology, University of Rochester Medical School, Rochester, NY, 14624 and the National Institutes of Health, Bethesda, MD.

Retinoblastoma is the most common intraocular neoplasm of childhood. Continuous cell line, such as Y79, have been used primarily for analysis of tumoral cell growth and phenotype in vitro. Recently, we developed a useful cell line model in vivo model of retinoblastoma which involves subretinal transplantation of Y79 cells into immunosuppressed Fischer 344 rats (ARVO '92). Thirty to sixty days following transplantation, we examined the histopathological properties of Y79 tumor tissue. The tumors are formed by fast-dividing, pleomorphic cells which invade the host retina and vitreal cavity. These cells are immunoreactive for the neuronal marker MAP-2 among others, but remain negative for S-antigen. These tumors showed no sign of a glial cell phenotype in vitro, as the only GFP immunoreactivity present was comprised of host-derived Muller cell fibers which traversed layers of tumoral tissue. Our results show that intracocularly grafted Y79 cells survive, actively grow, and exhibit a primitive neuronal phenotype in vivo. Furthermore, these cells, even as xenografts, fully retain their features of poorly differentiated, highly invasive, neuro-tumoral cells.

Human immunodeficiency virus type 1 (HIV-1) infection is highly specific for its human host. To study HIV-1 infection of the human nervous system, outside of the human body, we have established a small animal model of the disease. Secondary xenografts of human fetal brain or neural retina is transplanted into the anterior chamber of the eye of adult rats immunosuppressed with Cyclosporine A. Tissue procurement was in strict accordance with established guidelines. The human xenografts vascularize, form a blood-brain-barrier, and differentiate forming neurons and glia. The xenografts can be infected with cell free HIV-1 or with HIV-1 infected human monocytes. Analysis by polymerase chain reaction (PCR) revealed HIV-1 sequences in DNA extracted from xenograft tissue exposed to HIV-1 virions, and in-situ hybridization demonstrates HIV-1 RNA localized in macrophages and multinucleated giant cells. Pathological damage was observed only in neural xenografts containing HIV-1 infected human monocytes supporting hypothesis that these cells are neurotoxic. Interestingly, the host retinal neurons were unaffected. This animal model allows the study of the direct and indirect effects of HIV-1 infection on developing human fetal neural tissues, and may be useful in the evaluation of antiviral therapies, which must target HIV-1 brain infection.

474.5 ENHANCEMENT OF SURVIVAL OF INTRACRANIAL RETINAL GRAFTS BY ANTIGEN-SPECIFIC IMMUNE DEVIATION. Lake OJ, J. Wayne Streilein, Department of Microbiology and Immunology, University of Miami, Miami, FL, USA.

The ultimate goal of our studies is to implant functional retinal grafts into the blind eye to restore vision. In order to explore the possibility of using immunological manipulation to enhance survival of immunocompetent grafts, we implanted human retinal grafts from newborn BALb/c mice into one eye of C57BL6 mice, which induces immune deviation (ACAID). In parallel experiments, conventional immunity was induced by implanting similar grafts into the subcutaneous space. Control C57BL6 mice received a sham operation. Two weeks later, a second graft (identical to the first) was implanted into the contralateral eye of all recipients. The results revealed that all control mice rejected the test graft by 30 pd, at which time the graft size was reduced to 24% of original size. Mice which received prior SCo grafts rejected BALb/c retinal test grafts sooner. In contrast, mice which developed ACAID maintained their retinal test graft for an extended time. In this ACAID group, the graft in the first eye retained 60% of its original size by 50 pd and the second graft in the contralateral eye maintained 63% of its original size by 36 pd. Microscopic examination showed the graft in the ACAID group to have well-differentiated cell layers which resembled the structure of the normal retina. In contrast, AC retinal grafts displayed obvious histologic regression in both control mice and mice which developed a conventional immunity. These results suggest that 1) antigen-specific suppression (ACAID) can be used to enhance the survival of intracranial neural retinal allografts and 2) immunological manipulation may provide a novel way to prevent rejection of intracranial neural retinal grafts.

Supported by NEI Grants EYO9595 and EYO5678 and a grant from the Retinitis Pigmentosa Foundation.

We are examining the development of transplanted rat olfactory bulbs (OBs) using antibodies against OMP, GAP-43 and PDGFB-B. OMP identifies mature primary olfactory neurons (ONS), GAP-43 is a marker for growing axons and PDGF-B is heavily localized in the specialized glia that ensheathe the ON. Donor OBs are taken from fetuses of embryonic days 14-15 and transplanted directly into the cavity produced by removal of an OB in one day postnatal rats of the same strain. Adjacent 8 µm paraffin sections are examined using the three antibodies. Both OMP and GAP-43 are common to many large fiber bundles within the transplanted OB. Fiber bundles in sections identified with GAP-43 antibody (AB) have sharply defined borders and are slightly smaller than homologous bundles in adjacent sections reactive with OMP AB. The borders of OMP reactive fiber bundles are diffuse and may represent collateral branches around the bundle. In adjacent sections reactive with PDGF-B, photoreceptor bundles are often (but not always) surrounded or enmeshed by reactive cell bodies and fibers. Scattered PDGF-B reactivity is also seen within some fiber bundles. The relationships between fiber bundles identified with OMP, GAP-43 and PDGF-B AB remain similar at survival times ranging from 2 weeks to several months and generally support the notion that the transplants are forming a functional architecture, seen in the normal OB. Antibodies kindly provided by Dr. Frank Margolis (OMP) and Mochida Pharmaceutical Co. (PDGFB-B). (Supported by NIH Grants NS05978 and HL18405. L.E.W. is an affiliate of the CDMMC).
474.7

We are examining the axonotomized correlates involved with potential recovery of function in the rat under varying conditions (synaptic, neuronal, olfactory bulb (OB) transplant, neocortical olfactory bulb lesions (NOBL), and adult OBLs (AOBL)). The NOBL and OBL animals can eventually find hidden cookies as well as normal rats but the NOBL animals do not show recovery. Since the NOBL rat does not display general learning disabilities in passive avoidance tests, the loss of cookie-finding ability appears to be specific to olfactory ability. Histological analysis, blind of the behavioral results, was used to place the animals into groups. Techniques included: olfactory marker protein (OMP) immunocytochemistry for olfactory nerve (ON) preservation, cell and fiber staining, and triiodide autoradiography for donate-labeled transplant verification. All animals with incomplete OBLs were excluded from the study. Immunization of brain tissues by ON was achieved only in the OBL and NOBL but not in the AOBL and correlated perfectly with recovery of olfactory ability. Analysis of ON fiber reinnervation patterns in the NOBL revealed that ON targets included olfactory peduncle (ONP) and olfactory cortex (OC). Analysis of NOBL rats revealed that ON innervation of OBL was usually accompanied by innervation of OP and OC. These results suggest that in the absence of secondary OB neurons, ON axons directly with 'tertiary' neurons in the pathway and that this novel connection in the NOBL rat may be responsible for recovery of olfactory ability. It is not possible at present to say whether it is ON innervation of OBL or OPL/OC or both that is responsible for recovery of olfactory ability in the NOBL rat. (Supported by NIH Grant NS 09678; L.E.W. is an affiliate of the CDMRC.) OMP was kindly provided by Dr. F.L. Margolis.

474.8

Using lesion-degeneration methods it has previously been shown that successfully transplanted (TX) olfactory bulbs (OB) send their axons to appropriate target areas in the adult host brain (Weusten et al., 1990 Neurosci. Lett.). We are using WGA-HRP transport to study reconnnectivity in the developing TX OBs in Sprague-Dawley rats. Time-mated dams received subcutaneous injections of tritiated thymidine on embryonic days (E) 12-14. OBs from fetal rat donors of E 14-15 were immediately grafted into neonatal rats in the site from which the host OB had been removed. Following survival times of 2 weeks and longer, 0.1 μl of a 2 per cent WGA-HRP solution is injected into the TX OB and subjects are perfused after 24 hours. Alternate frozen sagittal sections are processed using TMB as the chromagen or olfactory marker protein (OMP) immunolocalization. Autoradiography will be included to verify that the injections remained within the TX OB. WGA-HRP transport is seen in fibers from the TX OB into layer I of the host anterior olfactory nucleus (AON) and piriform cortex (PC) and in cell bodies in layers II and III of the AON and PC. OMP material shows that primary fibers are seen within the TX OB and in the peduncle. These preliminary findings reaffirm that the axons from a TX OB make connections with some appropriate areas of the host brain, and also suggest that axons from cells in the target areas of the host brain innervate the TX OB. Supported by NIH Grants NS 09678 and HD 02274. LEW is a research affiliate of the CDMRC. *Ani-OMP kindly provided by Dr. Frank Margolis.

SYNAPTIC CONNECTIVITY OF SEROTONIN RAPHE TRANSPLANTS IN THE SUPRACHIASMATIC AND SUPRAOPTIC NUCLEI IN ADULT RATS. O. Britton1, 2, S. Bouquet1, M. Geffard1, 2 and A. Pradat2. 1Lab. de Neurobiologie et 2Lab. de Neurobiologie Cellulaire et de Fonctionnelle, CNRS, Marseille, and 3Lab. d’Immunologie et Pathologie, Univ. Bordeaux II, France.

We have previously reported that cell suspensions of fetal mesencephalic raphe, transplanted at mid-distance between the suprachiasmatic nucleus (SCN) and the supragnostic nucleus (SCN) in adult rats after intraventricular treatment of 5,7-dihydroxytryptamine, induced partial 5-HT reinnervation of the SCN vs hyperinnervation of the SON. We have further investigated the ultrastructural relationships of reinnervating vs normal 5-HT axon terminals in both nuclei following intranucleoduction and systematic sampling on 4-12 consecutive sections. About 48% of the 5-HT-positive terminal profiles were found in the ventral part of the normal SCN (ntv) and in the outer part of the normal SON (ntv from 4 animals), where they normally predominate, showed synaptic membrane enlargements. Graff-dense 5-HT terminals in the same proportion of the SCN (ntv, from 4 rats) revealed a higher number of varicosities (around 46%). The frequency with which 5-HT varicosities made synaptic contacts was also found to be equally high between the SON, from normal and grafted rats (more than 40%). These results indicate that the indication of reinnervation after grafting are not solely dependent on the mode of termination of normal 5-HT axons in the denervated territory. Target-specific trophic influences, i.e. target-derived stimulatory or inhibitory signals, should also be determinants in promoting graft-induced reinnervation. Such influences, together with in vitro programming of transplanted neurons committed to supply 5-HT fibers to the SCN and/or the SON, could also account for the fact that, irrespective of the extent of reinnervation (hypoc- or hyperinnervation), the new 5-HT fibers in both nuclei re-established the same relative features as in control tissue.

474.10

Transplants of the fetal hamster hypothalamic suprachiasmatic nucleus (SCN), the site of a circadian pacemaker, restore rhythmic behavior to SCN-lesioned hamsters (Lehman et al., J. Neurosci. 7:362). We explored the use of three-dimensional (3-D) extracellular matrix consisting of type I collagen (type I) as an alternative method of culturing SCN cells for use in grafting studies. (813) anterior hypothalamic cells were dissociated by a combination of gentle trituration and enzymatic treatments. Cells were rinsed and plated at 5 x 10⁶ cells/ml on 16mm wells on either the 3-D matrix or control poly-D-lysine coated coverslips. At various intervals following seeding (1, 4, 7, and 14 days) cultures were rinsed with serum-free media and fixed with 4% paraformaldehyde. The 3-D matrix was processed for immunocytochemistry (Dudley et al., Peptides 10:205) to detect a variety of neuronal and glial markers. 3-D matrices contained far greater numbers of isolated neurons and few glia in contrast to the clusters of neurons and glia seen in poly-D-lysine cultures. A 4 days positive staining for neuron-specific tubulin (class III, type II) was abundant at 14 days staining was decreased. Neurophin immunostaining suggested that SCN neurons survived in the 3-D matrix. The matrix may be useful in providing a scaffolding for neuronal cultures to be used for grafting studies, including those in which isolated SCN neurons are tested for their ability to restore rhythmicity. (Supported by NIH ROI NS28175 to M.N.L.)

474.11

Ageing disrupts multiple diurnal rhythms that are regulated by the SCN. C-Fos expression in the SCN is induced by light, and may be part of the mechanism for photic entrainment of the circadian pacemaker in the SCN. The purpose of this study was to determine whether transplantation of fetal SCN into middle-aged rats can influence light-induced C-Fos expression in the host SCN. We transplanted fetal SCN transplants into the third ventricle of middle-aged female constant estrous rats (9-12 mo). Sham operated middle-aged and young (6 mo) rats served as controls. After one month, rats were ovariectomized (dox) and treated with estradiol (day 7) to maintain a constant and similar hormone environment in both age groups. On day 11, rats were transcardially perfused within 90 min before and after lights on. Brains were prepared for immunocytochemical localization of c-Fos (Cambridge Research, OA-11-823). Young rats exhibited virtually no c-Fos expression in the liver prior to lights on, and a dramatic increase in c-Fos expression observed in young rats by 90 min. In contrast, c-Fos-containing cells are evident in some middle-aged rats prior to lights on. Transplantation of the fetal SCN into middle-aged rats appears to reinitiate the pattern of c-Fos expression observed in young rats; that is, no C-Fos expression was detectable before lights on. The results suggest a possible trophic influence of the donor SCN on the host SCN function. Supported by NIH AG00224.

Lipofuscin deposition of neuronal pathways since Gendelman et al. (Development, 1987, 101:697-713). However, continued reports of cell loss (transcellular) movement of the dyes have been made by a number of laboratories since this time. The embryonic rat visual system was used to examine what conditions affect cell movement of these dyes and if cell type and cell interactions are involved.

Midgestation (E15.5) rat embryos were immersion fixed in buffered paraformaldehyde. Dil, DiA, or 4d10AASP (Molecular Probes; Eugene, OR) were prepared and applied to the optic disk. Brains were dark incubated 2-12 weeks at room temperature, sectioned biweekly, and mounted and photographed the same day. All dye labels similar cell types, but at different rates (Dil/DiA at -0.18 mm/day; 4d10AASP at ~0.21 mm/day). After incubating 2 weeks, 1) Dil, DiA, and 4d10AASP were now prominent on the optic disk. A few D10AASP and a few, D10AASP, many, midline glia at the optic chiasm, 3) neither Dil, nor DiA, label glia along the optic tracts, 4) 4d10AASP labels a large number of optic axons, ganglion and Müller cells in the opposite eye, most midline glia at the optic chiasm and glia along both optic tracts. After 8 weeks, 4d10AASP labels optic radiations into cortex, and a glial compartment dividing dorsal and ventral thalami. All dye labels more of the same cell type with interconnections.

These results suggest that, 1) the dye move cellficial via specialized contacts between axons, and axons and glia, within the optic chiasm, diencephalon, brainstem. 2) Amounts of transcellular labeling correlates with the rate of diffusion and length of incubation.

RETROGRADE LABELING OF EMBRYONIC RAT SEPTAL NEURONS FOLLOWING IN VITRO HIPPOCAMPAL INJECTIONS OF FLUORESCENT TRACERS. A. King & M.R. Hedges. University of Florida College of Medicine and V.A. Medical Center, Gainesville, FL 32610.

A technique was developed in which tracer substances were injected into isolated brains and retrogradely transported and analyzed. Specifically, septal neurons that project to the hippocampus were retrogradely labeled using FITC, fluorescent microspheres, tetramethyl rhodamine dextran days E18, E21, and P1. The embryonic rat brains were removed and immediately immersed in oxygenated Tyrode’s buffer. The brains were then incubated in a humidified chamber, bilaterally throughout the rostral-caudal extent of each hippocampus. Each injection (total of 4 hippocampi) of 10 to 30 μl DAB (dextran) was delivered through a microopette. Following 17 h of transport time in oxygenated Tyrode’s, each septal afferent was subsequently processed with DAB, and visualized in an epifluorescent microscope. The males were死刑ized in 1 ml of perfused saline and the brains were analyzed. The cultures were fixed (4%parafomaldehyde) and stored in phosphate buffer for immunocytochemical analysis. This technique will allow the identification and experimental manipulation of a subpopulation of septal cerebral septal neurons, in particular those septal neurons forming the septohippocampal pathway. Supported by the Veterans Administration, NIAAA AA00200, and A.M.H.

FLUORO-GOLD REVISITED: TOXICOCLOGICAL AND PHARMACOLOGICAL PROPERTIES. L.C. Schmued1, J.F. Bowyer1, C. Beltranino1, H.W. Birnbaumer1 & W. Slikker2, Division of Neurotoxicology, NCTR/FDA JAFCO, AR 7E209-R902 and 2Dept. of ENT, Univ. of Virginia, Charlottesville, VA 22908.

Since its introduction in 1985, Fluoro-Gold (FG, hydroxyethylaminostain) has been widely used as a retrogradely transported fluorescent tracer to reveal neuronal connectivity. However, little is known regarding its neurotoxic or pharmacological properties. To address its neurotoxic potential, FG was injected into the rat striatum at different concentrations (2.5-10%), volumes (100-250 μl), and vehicles (saline and 1 M cacodylate). Survival ranges varied from one week to one day. The tissular response was also compared to that observed in the olfactory bulb, cerebral cortex, hippocampus, amygdala, striatum, caudate, thalamus, and spinal cord. The data from a large number of these studies to identify the FG-induced neuronal and neurotoxic. Neurotoxic necrosis of neurons was identified in the cerebral cortex, brainstem, and spinal cord. FG was found to cause cell damage in these regions. The results of this study suggest that the potential of FG to cause neurotoxicity is similar to that of other fluorescent tracers.

475.10

LABELING OF SPECIFIC CELL TYPES IN THE RAT CNS BY INTRAVENTRICULAR INJECTIONS OF BIODIOTIN. A.J. McDonal1 & E. Mascagni. Dept. of Cell Biology and Neurosciences, School of Medicine, University of South Carolina Sch. of Med. Columbia, SC 29208.

Recent experiments (Mascagni et al., 1989) have demonstrated that large injections of biotin into the lateral ventricle (or brain) produce labeling of particular neuronal subpopulations in the rat CNS. Rate were perfused 24 hours following injection and stained with the ABC technique. In many cases the staining of neurons was very complete and resembled that obtained with the Golgi technique. Regions containing labeled cells included the olfactory bulb, cerebral cortex, hippocampus, amygdala, striatum, and cerebral cortex, and dorso horn of the spinal cord. Only particular cell types were labeled, while all nonpyramidal neurons were strongly labeled in the cerebral cortex (FG) or neurons in the ventral horn (BDA). Labeled cells in specific brain regions are small local circuit neurons. Several of these cells show short survival times (4-6 h) exhibited strong labeling of glial cells and light labeling of a large percentage of neurons in many brain regions. Cells with 6-8 survival times exhibited no labeled cells. Injections of d-biotin did not produce neuronal labeling. Injections of biotinamide (neurobiotin, Vector Labs) produced a pattern of labeling that was much different from that produced by biotin. The results of this study suggest that there is differential uptake and retention of biotin by populations of CNS neurons. This study system may be associated with biotin-dependent metabolic pathways in these cells. Double-labeling studies are in progress to further characterize neurons that exhibit biotin uptake. Supported by NIH Grant NS27333.

475.11

A bioimolecular recording and immunocytochemical labeling were used to determine the ultrastructure and synaptic association of physiologically characterized pyramidal neurons in the superficial layers of the rat frontal cortex. After intracellularly, individual neurons were filled with biocytin, and the animals were transcardially perfused with acrolein. Sagittal serially collected sections were processed for visualization of biocytin using avidin biotin peroxidase. Sections containing the filled neuron were processed using immunogold silver for detection of GABA or tyrosine hydroxylase (TH), and a marker of catecholaminergic afferents. Filled neurons had branched and spiny dendrites as seen by light microscopy. At the ultrastructural level, filled perikarya and dendrites had irregular (ruffled) contours. Although these were densely filled with peroxidase, synaptic contacts were usually identifiable. In dually labeled sections, i) GABA immureactivity was seen in perikarya, dendrites and terminals, some of which formed synapses on proximal filled dendrites, and ii) GABA axons contacted both filled and unlabelled dendrites in the superficial layer. The combined use of in vivo intracellular labeling with ultrastuctural identification of transmitter provides an important method for demonstrating the synaptic basis for modulation of cortical activity. (Supported by grants MH30078, DA04600, HL10974).

COMBINED ANALYSIS OF CALCIUM BINDING PROTEINS, GAMMA AMINOBUTYRIC ACID, TRANSGREDUCTION OF WHEATGERRM AGGLUTININ HORSERADISH PEROXOIDE AND N-TERGREDUCTION IN THE SPUTUM OF THE PRIMATE. Amanda M. Miller, Tracey, Doh Rahab and Henry J. Baldwin, III Department of Anatomy and the W.M. Keck Foundation Center for Integrative Neurosciences, University of California, San Francisco, California, 94143.

Our laboratory has used the exploratory search of several neuroanatomical techniques simultaneously to analyze projections in the primate central nervous system to neuronal populations that have been characterized for the presence of neurotransmitters and calcium binding proteins. As an example, one is factinhibits, as part of a series of studies in which our laboratory is currently involved, it is controlled with wheatgerm agglutinin-horsedant peroxidase (WGA-HRP) in somatoaxoeritory/motor cortices for antergrade transport in cortico- spinal/halamic/reticular pathways and cell bodies and axons in motor cortex in the primate, area 4, 4A, area 2, cortico spinal/spinal afferents. According to the protocol described above, GABA and biotinamide were injected into the thalamus with 2% paraformaldehyde and 2% glutaraldehyde. pH 7.4 at room temperature. The brains were then fixed in 4% formaldehyde in 0.1 M phosphate buffered saline. Vibratome sections of 100μm were reacted with immobilized biotinylated (for GABA) or paraformalin coated with avidin-biotin-cytochrome c (for biotinamide) and stained with immunohistochemistry the same day. This research was funded by the National Institute of Health (NS 2172).

Our technique allowed the identification of neurons that project to the hippocampus and the identification of neurons that project to the thalamus. These results suggest that the development of a neuron-specific probe for neuronal markers may have important implications for the study of neuronal circuits in the primate.

LIGHT AND ELECTRON MICROSCOPIC STUDIES OF BOUTONS ON ISOLATED RAT NEURONS. W.L. * and M.D. DeSantis. Dept. of Biological Sciences and WAMI Medical Program, University of Idaho, Moscow, ID 83843, USA
The size was measured on isolated neuronal somas using scanning electron microscopy (SEM). Neuronal cell bodies were isolated from the trigeminal motor nucleus by enzymatic digestion of the peripheral nerve tissue, and the isolated somal neurons were identified by electron microscopy and then examined by SEM. They ranged in size from 23.0 to 41.6 um average diameter (n=23). Preparation for SEM resulted in an average shrinkage of the soma by 20% of its diameter. There was a direct relationship between the size of cell body and the amount of shrinkage. SEM revealed bulbous structures from 0.6 to 3.6 um in size at the surface of neuronal somas. Our interpretation that they were boutons was confirmed when transmission electron microscopy (TEM) was used to study the same somas after SEM. The surface of the isolated somas was generally free of adhering elements except for the boutons. (Supported by Idaho State Board of Education grant 92-010).

475.14
GJAP (gial hyaluronic acid binding protein) is a glycoprotein which binds to hyaluronic acid in the CNS. Functionally, GJAP is thought to inhibit neurite adhesion and outgrowth. In this study, the ultrastuctural localization of GJAP was performed in GA-fixed spinal cord and cerebellum, the two portions of the CNS with the highest GJAP staining. The localization was performed via an indirect immunoperoxidase staining with the monoclonal antibody 2C3 as the primary antibody. Animals were anesthetized and then perfused via a gravity flow system through the left ventricle, first with 50C of PBS (phosphate buffered saline) pH 7.3-7.4, containing 2% procaine-HCl and then with PBS (100-150 ml). This was followed by fixation with 100-300C of PBS at pH 7.3-7.4 containing 2.0% pararaffinoldehyde, 2.5% glacial acetic acid and 1% CPC (cycloptiuturdefinium chloride); the CPC serves to stabilize the water soluble hyaluronic acid in the extracellular matrix to which the GJAP binds. After perfusion, the brain and spinal cord were removed and stored overnight (12-16 hrs.) in the same fixative. Vibratome sections were subsequently collected and stained by indirect immunoperoxidase using the DAB protocol of Streit and Reubi (1977). Electron micrographs will be presented to illustrate the labelling of GJAP in both the spinal cord and the cerebellum. This research supported in part by NIH Grant NS 13034 and V.A. Gen. Res. Service Merit 0022.

A PRE-EMBEDDING TRIPLE-LABEL EM IMMUNOHISTOCHEMICAL METHOD AS APPLIED TO THE STUDY OF MULTIPLE INPUTS TO DEFINED THE SUBSTANTIA NIGRA NEURONS. A. Raineteau, K.D. Anderson and E.J. Karle. Dept. of Anat. & Neurobiol., Univ. of Tennessee, Memphis, TN 38163, USA
Both dopaminergic and nondopaminergic neurons are present in the substantia nigra, and the substantia nigra receives input from both enkephalinergic (ENK+) striatal neurons and substance P-containing (SP+) striatal neurons. To determine the types of nigral neurons receiving inputs and to determine whether such individual neurons receive inputs from both types of terms, we have developed an approach for carrying out pre-embedding triple-label EM immunohistochecmy, using three distinct markers.
Following fixation with a paraformaldehyde-glutaraldehyde-acrolein fixative, vibratome sections were sequentially labeled for the localization of: 1) SP + terminals using a PAP/DAB procedure with rat anti-SP; 2) ENK + terminals using a 1nm gold-conjugated secondary with mouse anti-ENK; and 3) tyrosine hydroxylase-containing (TH+) neurons using a PAP/BDHC procedure with rabbit anti-TH. The sections were then osmicated and the immunogold labeling was silver intensified. Thin sections examined with EM showed that all three labels could be distinguished at the EM level. Although individual SP + and ENK + terminals contained both TH + and non-TH + perikarya and dendrites, profiles receiving simultaneous contact from both SP + and ENK + terminals were typically non-TH+. These results show that pre-embedding triple-label EM immunohistochemistry is feasible, and that SP- and ENK- striatal terminals may be segregated on nigral dopaminergic neurons (i.e. on different neurons or different parts of the same neurons). Supported by NS 19620 & NS 28721 (A.J.)

475.16
The Na+/Ca exchanger (NCX) is prevalent in neurons and appears to be concentrated at nerve terminals; the exchanger is also present in glia (Ann. N.Y. Acad. Sci. 639:254-274, 1991). Polyclonal antisera specific to canine cardiac NCX were used to localize the NCX in adult rat hippocampus. We compared the distribution of the NCX immunoreactivity to the distribution of synaptic 1 and 2 and synaptophysis (synaptic vesicle markers), and glial fibrillary acidic protein (GFAP; a glial marker). Immunostaining of 25-mm cryosections of hippocampus was performed by an indirect immunoperoxidase procedure. The anti-NCX antibodies labeled the strata oriens and radiatum most intensely, followed by stratum lacunosum-molecular and the inner third of the dentate molecular layer where axons from both the ipsilateral and contralateral hilus terminate. The regions of the hippocampus where the neuronal cell bodies are located (the stratum pyramidale and the dentate granular layer) were poorly labeled by the anti-NCX antisera. No specific labeling in any region of hippocampus was observed with preimmune serum. Immunostaining patterns for synaptic 1 and 2 were similar to the NCX patterns although antibodies to synaptic 1 and 3 and synaptophysis, but not NCX, strongly stained the entire molecular layer of the dentate gyrus. The GFAP immunostaining pattern differed markedly from the NCX pattern. These results suggest that many of the NCX immunoreactivity is associated with synapses since synaptic 1 and 2 are present in all nerve terminals. We concluded that the NCX is present in relatively high concentration in the hippocampus, and that it is especially prevalent in some synaptic fields where it may play an important role in Ca homeostasis.

475.17
Cytochrome oxidase (C.O.) contains 13 subunits which are individually encoded by nuclear genes. Nuclear-derived mitochondrial proteins are cytoplastically synthesized as precursors carrying cleavable polypeptides (presequence) at the N-terminus, which signal the targeting of precursors to the mitochondria. In order to determine if nuclear-derived precursors are localized mainly in neuronal cell bodies or in dendrites, we generated polycyclonal antibodies against the presequence of the rat C.O. IV precursor. Immunoreactivity could be detected in all brain regions examined (cerebellum, hippocampus, brain stem, somatosensory barrel cortex, and olfactory bulb). There is a distinct heterogeneous immunohistochecmy pattern among different brain regions, laminae, and cell types. The pattern of immunoreactivity for the precursor matched that for the mature enzyme and the pattern shown by C.O. histochemistry. Antiseria were localized in both somata and dendrites in the hippocampus, where somatic and dendritic layers are spatially segregated. This is the first evidence that precursors of the rat C.O. subunit IV are detectable in the mammalian brain. (Supported by NIH grant NS 18122 to MWR)

QUANTITATIVE DIFFERENCES IN CALCITONIN GENE-RELATED PEPTIDE (CGRP) IMMUNOREACTIVITY IN RAT SPINAL CORD NEURONOPHARES IN SITU AND SLOW MUSCLES. J. Calcedo, A. Zorrilla, E. Herronboch, V. Yuste, J.X. Comellas and J.E. Escudero, Unidad de Reperc Neuro muscular, Department of Ciencias Medicas Basicas, Facultad de Medicina de Lleida, Universitat de Barcelona, E-25006, Lleida, Spain.
When CGRP is detected by immunohistochemistry it is a substantial variation on the intensity of the reaction is found among the spinal cord motoneuron population. The significance of such heterogeneity is unknown. We have explored whether or not motoneurons innervating fast or slow muscles showed correlative differential content in CGRP. Motoneurons innervating the slow soleus or the fast extensor digitorum longus (EDL) muscles from adult Sprague-Dawley rats were labeled by immunocytochemical injection of fluorescein-conjugated wheat germ agglutinin or cholera toxin (B subunit). CGRP-like immunoreactivity (CGRP-LI) was evidenced by immunofluorescence using rhodamine as a label. The intensity of CGRP reaction was measured in traced neurons with a microspectrophotometer. Recorded data from each set of samples were analyzed by means of an automated classification procedure for individual intensities in each neuronal population. The classification algorithm is based on a pattern recognition method with no initial membership defined for each individual cell. In this way an inverse frequency distribution of the intensities of CGRPLI was consistently observed when histograms from soleus and EDL-innervating motoneurons were compared: the strong CGRPLI was more frequent in the body of soleus-innervating motoneurons. When the same evaluations were done in male rats, the above mentioned clear-cut differences were not consistently observed. It is concluded that the type of motor units and/or metabolic state of the muscle fibers may influence the neuronal CGRP.

A SILVER-REDUCING AXONAL PROTEIN IN THE CENTRAL NERVOUS SYSTEM OF ADULT RATS. C.J. Tandler, A. Pellegrino de Iraldi* Instituto de Biologia Celular, Facultad de Medicina, UBA, Paraguay 2144, C1131, Buenos Aires, República Argentina. A selective 'argentaffin' staining of nerve fibers after mercuric-acetate post-fixation was reported (20th Am. Meet Soc Neurosci, Abstract 28A, 1990). The technique (Hg-Ag) also stained specifically proteins within lateral components of triads and diads in striated muscle cells (His- tochemistry 92: 271, 1989). The axonal argentaffinity is dependent on both glutaraldehyde and mercuric ions. It is not suppressed after extraction of lipids, heating in 1N perchloric acid or incubation with alkaline phosphatase. Methylation of glutaraldehyde fixed tissues abolished the Hg-Ag reactivity indicating that carbohydrate groups in protein are involved in the formation of the organic mercuri- nal responsible for silver staining. The electron micro- scope shows that the silver-reducing protein localizes in- side the axon. The procedure stained white and gray matter fibers in cerebrum, cerebellum and spinal cord but not the neuronal perikarya or their dendrites and proximal axons. In the cerebellum the basket cell axons were strongly re- active but not the parallel fibers. The possibility of the method to distinguish between functional stages of pro- teins in relation to cytotrophic variations in cytoskeleton structures is suggested.

CEREBRAL ARBROPHY AND HYDROCEPHALUS IN CONTROL AND GANGLIONECTOMIZED SPONTANEOUSLY HYPTERTENSIVE RATS. D. Livingstone, P. Bann, L. Hel, F. Brain, •., W. Brain, S. Brain, F. Brain, N. Brain, and J. Brain. Stoney Brook, NY 11794-8122. The spontaneously hypertensive rat (SHR) is hypertensive, hyperactive, and hydrocephalic relative to Wistar-Kyoto (WKY), in young adults, glucose metabolism is lower in SHR than WKY and is elevated in one superior cerebellar ganglion in mesencephalic tissue 4 weeks of age. In view of these cerebral clinical features, tissue volumes and neuronal density were measured in control, ganglionectomized (Gx), and sham-operated (sham) SHR and WKY. In control SHR the volume of the whole brain and of some areas was 1.10% less than control WKY; ventricular (CSF) volume was 0.2 times larger in SHR than WKY. Neuronal density was similar in control SHR and WKY. Relative to controls, the volumes of brain and all brain areas were 15-25% less in uGx and sham SHR as well as uGx and sham WKY. In both SHR and WKY, neuronal density in some areas tended to be less in uGx and sham rats. The uGx procedure at 4 weeks of age, but not ganglionectomy per se, seems to affect brain structure and function.

ANATOMICAL ORGANIZATION OF INTRINSIC NEURONS OF THE RABBIT TRACHEA. R. Hendriks, S.R. Koopman, and D.I. Kreulen, Department of Pharmacology, College of Medicine, University of Arizona, Tucson, Arizona 85724.

The mammalian trachea is likely to be under the effenter influence of both intrinsic and extrinsic neurons. Using a variety of neuronal markers, we have investigated the anatomy of intrinsic tracheal neurons of the rabbit. Individual trachea were variously labeled with Neutral Red (Sigma, USA) and antibodies to Neuron Specific Enolase (NSE) or S-100 protein and were prepared for viewing either as wholemounts or tissue sections. All three major classes of intrinsic neurons of the rabbit trachea. The nerve cells were found to be organized into small ganglia containing less than ten cell bodies each. The ganglia were primarily between the cartilaginous rings and at the esophageal border. Most were found to lie at the surface of the tissue although occasionally ganglia could be found lying deep within the trachea. No clear pleurs arrangements for these neurons were discernible. Individual fibers of some neurons could occasionally be followed to the membrane. In conclusion, the intrinsic neurons of the trachea form a diffuse neural network that, accordingly, is likely to have a unique role in the functioning of this tissue. Support HL-46471.

PHOSPHOTYROSINE-CONTAINING PROTEINS IN THE RAT BRAINSTEM AND SPINAL CORD. J.W. Ungethr, W. Lange and J.W. Livingstone*. Department of Anatomy, University of Munich, FRG, and 1Department of Endocrinology, University of Rochester, Rochester, NY 14622, USA. The regulation of cell activity by a number of growth factor receptors and proto- oncogene products involves tyrosine kinase (TK) activity. The presence of phosphotyrosine-proteins (PY) is an index of the activity of TKs. Light- and electronmicroscopy demonstrate PY immunoreactivity in numerous nuclei of the brainstem and spinal cord of the adult rat, including central and efferent nuclei, e.g., nucleus of the solitary tract, hypoglossal, lateral reti- naeum nucleus, area postrema. Ultrastructural analysis revealed PY in the cytoplasm, in the perinuclear Golgi complex and at pre- and post- synaptic sites. Several receptor and cytosolic TKs may contribute to the PY-substrates, i.e., high overlap was evident with the presence of insulin receptors. Our results suggest that protein tyrosine phosphorylation may play an important role for the regulation of neuronal function in the adult central nervous system. (Supported by the Walter-Schulz-Stiftung, WZH, and NATO Collaborative Research Grant).

PERMEABILITY COEFFICIENT-SURFACE AREA PRODUCT OF THE BLOOD NERVE AND BLOOD BRAIN BARRIERS FOR NGF AND ALBUMIN. J.P. Podvalnik, G.L. Stone and C.J. Bart, Departments of Neurobiology and Laboratory, Departments of Neurology and Biochemistry/Molecular Biology, Mayo Clinic and Mayo Foundation, Rochester, MN 55905 USA.

Neurotrophic factors will likely be of importance in the treatment of neurodegenerative diseases of the peripheral and central nervous system. Although their administration to patients with Alzheimer's and other neurodegenerative diseases may represent a new approach to treatment of these degenerative diseases, the development of a reliable, non-invasive, delivery system is clearly needed prior to the initiation of clinical trials. We have used the in-vitro column technique to measure the vesicular blood-brain barrier for NGF. The blood-brain barrier to NGF across the blood nerve barrier was 1.726 ± 0.394 x 10^-14 ml/mg/sec (I ± S.D). When compared to the PS for normal albumin (0.101 ± 0.008), a 7-fold increase was observed for NGF. Although there is a 9-fold difference between NGF and albumin, the PS for NGF was significantly higher suggesting a possible different mechanism of uptake into the nerve. Values obtained for different brain regions ranged from 2.7±3.2 fold higher for NGF compared to albumin. No changes were observed in the residual plasma volume for either the endoneurium or the different brain regions. Data will also be presented which suggest that selective modifications of NGF can enhance its permeability into the nervous system while still preserving biological activity of the protein. Such approaches might be useful in formulating a reliable delivery system of this and other neurotrophic factors for the potential treatment of Alzheimer's and other neurodegenerative diseases.

477.2

The effects of tumor necrosis factor-alpha (TNFalpha) on the development of the CNS raise the possibility that circulating TNFalpha might enter the brain. We examined the blood-to-brain transport of recombinant murine TNFalpha across the blood-brain barrier (BBB) in 3 day old rat pups. H3-TNFalpha and [125I]-TNFalpha were injected IV, and the unidirectional influx constant (ki) into the brain was calculated from the levels of radioactivity in the brain and blood. Intraperitoneal injection of human albumin was detected for the 30 min period tested, while the Ki for H3-TNFalpha was 8.1±10-4 ml/min/g and the Ki for [125I]-TNFalpha was 1.66±10-4 ml/min/g in newborn mice. The Ki for TNFalpha decreased the Ki to 0.79±10-1 ml/min/g, which represented an inhibition of over 90% of [*]-TNFalpha entry. The Ki for [125I]-TNFalpha was 1.1±10-5 ml/min/g. The Ki for TNFalpha, however, did not alter the brain/blood ratio of [*]-albumin (11.7±2.9 ml/g brain for controls vs 11.5±2.9 ml/g for excess TNFalpha). These results show that TNFalpha does not disrupt the neonatal BBB and support the existence of a blood-to-brain saturable transport system for TNFalpha in the neonatal rat.

476.3

Studies in animal models with high BBB (MAO-B) activity is central microvessels have suggested that circulating dopamine (DA) is present from entering brain parenchyma by the enzymatic blood-brain barrier (BBB). In the present study, blood-brain DA transport is examined in an animal model with low BBB MAO-B activity - the guinea pig. 

Cavia porcellus which is this respect is similar to humans. A vascular brain perfusion method [J.Neurochem. (1986) 46: 1444-1451] and a capacitative technique [J.Neurochem. (1990) 54: 1802-1882] were used to study BBB transport and/or binding of plasma derived DA. The initial rapid uptake (V) and rate of entry (K) of [3H]-DA into the brain tissue were both found to be almost 10 times higher that that of simultaneously infused [3H] - succrose, a metabolically inert cerebrovascular space marker. A substantial in situ DA binding to cerebral microvessels was also demonstrated. 

Brain uptake of [3H]-DA (2 mM) was significantly inhibited in the presence of 500 mM unlabeled DA (by 49%); concentrations of 1-250 mM produced further inhibition (90-100%). 

The D2-receptor antagonist apomorphine (25 mM) virtually abolished [3H]-DA uptake as evidenced by both brain homogenate and capacitative-depleted tissue. In situ DA binding to cerebral microvessels was also demonstrated. 

Brain uptake of [3H]-DA was decreased in animals treated with the MAO inhibitor pargyline (50 mM). These results suggest that DA is indeed transported across the BBB in guinea pigs by a specific MAO-independent mechanism. 

Brain uptake of circulating dopamine may be mediated by a capillary membrane D2-receptor. (Supported by Children's Hospital of Los Angeles 1102/896).

476.4

Tyr-MIF-1, a peptide with opiate-modulating properties, and Met-enkephalin, are removed from the brain by a peptide transport system (PTS-1). Since morphine given during the neonatal period is known to alter opiate function, the examination whether PTS-1 was also affected. 

Neonatal rats were injected subcutaneously (SC) during the first week of life with either morphine sulfate (MS), 

MS+naltrexone (MS+Nal), MS+methyl naltrexone (MS+Mnal), or vehicle at a dose for each drug of 50 µg/rat. On postnatal day 22, the brain-to-blood transport rate of 131I-Tyr-MIF-1 was measured as previously described (Methods in Enzymology 168: 652-660, 1989). 

Pups treated with MS had significantly smaller brain weights than controls (p<.05) or MS+Mnal treated pups (p<.001). After treatment, the transport of 131I-MIF-1 by PTS-1 in MS treated pups was over 218 faster than in control rats (p<.01) and 164 faster than in MS+Mnal treated pups (p<.05). 

These results indicate that treatment with opiates during the neonatal period can affect the development of PTS-1.
476.9
AMINO ACID TRANSPORT INTO MEMBRANE VESICLES IS NOT RELATED FROM THE BLOOD-BRAIN BARRIER.
Luminal and abluminal membranes from bovine brain endothelial cells were separated on Ficoll gradients. The membranes formed sealed vesicles that were adequate for transport studies. Transport of D-N-methylamino-l-phenylalanine was studied in both membrane populations. Luminal vesicles showed a high affinity transport system for L-phenylalanine that was independent of Na+ and H+ gradients and inhibited by other large neutral amino acids, including D-phenylalanine; it was not inhibited by MeAIB. In contrast, abluminal vesicles contained a Na+-dependent phenylalanine transport system that was inhibited by MeAIB. Similarly, uptake of radiolabeled MeAIB was stimulated by a Na+ gradient in abluminal vesicles, whereas no significant effect of a Na+ gradient was observed in luminal vesicles. The results provide direct evidence for the presence of the Na+ dependent A-system exclusively in the abluminal membranes of the BBB. These data are consistent with the location of an L-type system in both membranes.

476.11
IN VIVO LABELING OF BRAIN MICROVASCULAR TRANSFERRIN RECEPTOR USING COLLOIDAL GOLD-ANTITRANSFERRIN RECEPTOR ANTIBODY-COMPLEXES. I. Yang, U. Bickel, T. Yoshikawa, H. Weiner*, and W.M. Pardridge. Departments of Medicine and Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.
The transferrin receptor (TFR) is highly expressed at the plasma membrane of brain microvascular endothelial cells, which form the blood-brain barrier (BBB) in vivo. A monoclonal antibody to the rat TFR, OX26, has recently been evaluated as a model of brain transport vectors for drugs unable to pass through the BBB. Transcytosis of OX26 and OX26-drug conjugates could be demonstrated in pharmacokinetic studies, and OX26 was successfully used for brain delivery of a vasoactive intestinal peptide analog, resulting in a pharmacological response (increased cerebral blood flow).
To obtain ultrastructural information about the in vivo transcellular trafficking of OX26, at the abluminal side of a brain capillary in vivo, a direct receptor labeling study with 5 nm colloidal gold/OX26 complexes was performed. The complex was infused for 10 min into anesthetized Sprague-Dawley rats via the internal carotid artery (about 200 μg OX26/rat). Immediately after the end of the infusion, the animals were perfusion fixed via the ascending aorta with 2% glutaraldehyde. Vibratome and semithin sections of the brain were silver processed for transmission electron microscopy. A pattern of gold particles in defined cytoplasmic compartments resembling endosomes was seen. In conclusion, this study presents a novel approach to in vivo receptor labeling and ultrastructural analysis.

476.10
The potential for receptor-mediated transcytosis of ferro-transferrin (ITRF) and antibody against its receptor through BBB endothelia was investigated in Sprague Dawley rats. ITRF, a blood-borne peptide, conveys iron to tissues and cells. BBB endothelia exhibit the receptor for ITRF on the luminal surface. Rats were injected into the carotid artery with ITRF conjugated to HRP (60g/0.5ml; 1-3hrs) or intravenously with native HRP (300g/0.5ml, 1hr). HRP-conjugated or non-conjugated antibody to the ITRF receptor (OX26, 200-700μg/0.5ml, 5mins-6hrs) and against the Major Histocompatibility Complex Class I (OX27; 210μg/0.5ml 6hrs) was employed as controls. Non-conjugated antibodies were identified immunohistochemically. On-HRP, each of the antibodies, and native HRP labeled BBB endothelia, perivascular phagocytes and pial surface macrophages. ITRF-HRP and OX26-HRP were seen ultrastructurally within perivascular clefts; ITRF-HRP only was observed in cells of the neuropil. OX26-HRP only was localized in secretes of the Golgi complex in BBB endothelia. Native HRP and OX27 labeling of perivascula and pial surface phagocytes occurs through extracellular routes circumventing the BBB. Potential transcytosis of blood-borne ITRF-HRP and OX26-HRP through the BBB very likely occurs, but the exact intracellular pathways are elusive. Supported by NIH grant #NS18030.
**477.3** ANALYSIS OF PRIMARY AFFERENT INPUT TO RAT DORSAL HORN S. Jeffinija*, L. Kojic, T.-H. Chen and L. Urban 1. Dept. Vet. Anatomy and Neurosciences, Texas A&M University, College Station, TX 77843; 2. Dept. of Veterinary Pathobiology and Microbiology, Texas A&M University, College Station, TX 77843; 3. We have used the sucrose gap technique applied on the sympathetic chain to measure membrane potential of preganglionic terminals of bullfrog sympathetic ganglia (X segment). A switching conductance.

**477.4** PURIFICATION OF β-LEPTINOTARSIN-h BY IMMUNOAFFINITY CHROMATOGRAPHY R. D. Gelfinger*, J. D. Stagg, J. D. B. A. Landers, Y. L. T. Hsiu-hsia, and S. H. W. Gelfinger, Biophysics and Immunology, Department of Marine Biology and Marine Biotechnology, Scripps Institution of Oceanography, La Jolla, CA 92037, USA. 

We immunized Balb/C mice with the heretofore most purified preparation of β-LPT-h. Monoclonal antibodies were generated by cell fusion with SP2/0 parental myeloma cells. Antibodies of interest were located by determining the ability of antibody + protein G-Sepharose to remove 125I uptake activity from solutions containing β-LPT-h. We found four activity-binding antibodies, one of which (2C3-1-1) we choose for further study. 2C3-1 bound to only 8% of the activity in the preparation used for immunization, revealing the presence of at least two immunologically distinct Ca+ uptake activities. Column chromatography of β-LPT-h with 2C3-1 coupled to Affi-Gel 10 and subsequent SDS-PAGE revealed two bands of 55 kD and 60 kD.

**477.5** THE EFFECT OF CALCIUM AND SODIUM ON THE EXTRACTIVE CONCENTRATION, RECOVERY OF Dopamine BY USING QUANTITATIVE MICRODIALYSIS. A.D. Smith* and J.B. Justice, Jr., Department of Chemistry, Emory University, Atlanta, Georgia, 30322.

The point of no net flux was used to study the effects of varying the sodium (Na+) and calcium (Ca++) concentrations (conc.) on afferent nerve activity (29±2.2 mV, mean ±SEM, n=32) and blocked AP. Simultaneous intracellular recording from superficial DH neurons revealed that in cells receiving input from both small and large fibers, excitatory postsynaptic potentials (EPSPs) evoked by electrical stimulation of small myelinated afferents (0.2-10μM) to the DRG blocked electrically-evoked APs in large DRG neurons and consequently EPSPs in DH neurons. Depolarization of high potassium on DRG neurons and excitatory effect on DH neurons was not blocked by TTX. During this potassium-induced increased activity in DH neurons, EPSPs evoked by stimulation of small unmyelinated fibers were potentiated. Our data suggest that in large DRG neurons with TTX-sensitive Na channels high K evoked depolarization inactivates the Na current and blocks AP generation. As TTX-resistant Na channels require higher levels of depolarization C-fibers remain active in the presence of high K and maintain synaptic input to the DH. This difference could be responsible for the selective activation of C-afferent fibers by high K which produced EPSPs in the spinal cord. This hypothesis is further supported by the finding that when Na ions in the DRG bathing media were totally removed in the presence of TTX, both high K and electrical activation of afferents were without effect on DH neuron. Work was supported by NIH Grant NS27751.

**477.6** ELECTRICAL STIMULATION REPROGRAMS THE METABOLIC AND SYNAPTIC PHENOTYPES OF CRAYFISH MOTONEURONS. T.H. Hsiu-hsia, J.D. Gelfinger, Department of Pharmacology, Faculty of Medicine, University of Toronto, Toronto, Ontario, MS8 1A8. 

Can impulse activity in motoneurons determine metabolic efficiency? Using Rhodamine-123 (Rb) as a supravital, mitochondria-specific fluorochrome, we compared metabolic activity and synaptic physiology of crayfish tonic and phasic abdominal motoneurons. Tonic flexor motoneurons show a highly activity-dependent resistance to synaptic depression than phasic extensor motoneurons. Axonal mitochondria from the former showed significantly higher mean Rh fluorescence intensities than did the phasic axons' mitochondria (as measured using confocal microscopy). Mitochondrial metabolic inhibitors (dinitrophenol, azide, CCCP) induced synaptic depression in tonic axons and reversibly abolished the Rh fluorescence of their mitochondria, suggesting that Rb fluorescence signals metabolic competence. In vivo stimulation of an identified phasic motoneuron significantly increased both neuromuscular synaptic stamina and mean axonal mitochondrial Rh fluorescence. Axotomy prior to conditioning stimulation abolished both changes. Thus, there exists a direct correlation between mitochondrial metabolic capacity and synaptic stamina in single living motor axons, while imposed electrical activity reshapes both metabolic and synaptic performance.

**477.7** ELECTROGENIC Na-K PUMP IN SYMPATHETIC PRE-GANGLIONIC FIBRES IN BULLFROG LUMBAR SYMPATHETIC CHAIN. T. Hashisochil*, M. Hashisochil, T. Tosa*, and A.-L. Padasio, Department of Physiology, Tokyo Medical College, Tokyo, Japan and Dept. of Pharmacology and Therapeutics, McGill University, Montreal, Oc, Canada.

Excitability of nerve terminals in vertebrate nervous system is difficult to study in a direct way. We have used the sucrose gap technique applied on the sympathetic chain to measure membrane potential of preganglionic terminals of bullfrog sympathetic ganglia (X segment). A switching amplifier (Land & Horowicz, Physiological Action Potential Recorder, Pharmacia-Wellcome) was used for simultaneous current injection and potential measurement. Injection of a current pulse (200-400 ms2) was followed by biphasic hyperpolarization of the SM stimulus electrode. A depolarization phase reached threshold for action potentials generation. HAP was unaffected by t-tubocurarine (0.1 μM) or atropine (1 μM), and thus not likely result of endogenous acetylcholine release. Removal of extracellular sodium (choline replacement), but not of Ca2+ or Cl, abolished the HAP. Na,M,K-pump blockers (3-10 μM ouabain, Na-free lithium Ringer) as well as Na-axide blocked the HAP generation; however, 2.4-DNP (0.1 μM) only depressed it. Addition of cesium (2-5 mM) caused a conc dependent increase in HAP amplitude (> 25%; 110% at ED50, 7 m Ms Cs and duration and slowing of the rate of repolarization 0.031/sec ± 0.004A, n = 4), more than could be explained by a depression of inward rectification. HAP was not accompanied by changes in membrane conductance.

These results suggest that HAP in preganglionic terminals results from activation of an electrogenic pump. (This work was supported in part by MRC and CRC)

**477.8** ALTERNATIVE SOLUTIONS OF ANIMAL IMPULSE PROPAGATION INTO A LARGER-DIAMETER REGION. R.D. Gelfinger*, Dept. of Physiology & Biophysics, Wright State University, Dayton, OH 45435. 

Impulse propagation was simulated for unmyelinated axons whose diameter changed from 1 to 2-10 μm. The 1-dimensional cable equation was solved with a finite-difference discretization (1). The spatial integration step (Ax=3 μm) was constant, hence, the electronic step Ax/A = 0.5 was geometry-dependent (2). The Hodgkin-Huxley equations (3) defined excitability, first-order differential (4) and second-order (5) Euler integrations over very small time steps (e.g., = 0.1 μs) were kept constant during each run (6). No predictor/corrector methods were used and the electrotonic circuit was not closed. The electrotonic step was 10°C. It was assumed that Na, K, and leak maximal conductances and other properties remained constant during the increase in diameter. CV(x) at the diameter expansion if the electrotonic step in the expanded region equalled that of the smaller-diameter region. Correcting the CV(x) at the diameter expansion, CV(x) changed axially: first increased, then decreased, and finally increased at the expansion to a maximum. Impulse propagation was still possible in a single living motor axon, while imposed electrical activity reshapes both metabolic and synaptic performance.

MODULATION OF LOCAL ANESTHETIC BLOCKADE IN SINGLE FIBERS BY ACTIVATION OF NEIGHBORS IN PERIPHERAL NERVE. S.A. Raymond*, S.C. Steffen, J.G. Thalhammer and C.R. Zochodne. Anesthesia Research, Brigham & Women's Hospital, Boston, MA 02115.

Single axonal units from isolated frog sciatic nerve were recorded via suction electrodes which were stimulated using a train of 5-3 times the tonic threshold for the recorded unit) during exposure of the nerve to stable concentrations of the local anesthetic lidocaine. At [lidocaine] below the threshold for a tonic "ionic" conductance failure for above-threshold stimuli at rates >0.5 Hz, units conduced impulses at a slowed velocity but with 100% fidelity. Increasing the number of neighboring units firing to each stimulation burst by increasing the stimulus current by a factor of 10 further slowed the conduction velocity, or CV, in 28 of 28 fibers studied, and led progressively to a fall in CV of conduction. The impulse slowing began after the first impulse at the tonal intensity and then progressively increased over about 30 s. Slowing or block also persisted for at least 30 s after the stimulus intensity was returned to baseline intensity or failure was observed without lidocaine. Instead, the tonal stroke intensity with [lidocaine] = 0 increased by 10% (reduced latency by 0.3-0.5 ms).

The recovery time for latency to return to the tonic latency, recorded prior to the tonal stroke intensity, depended on the number of stimuli given at the higher intensity. If the intensity was maintained at the high level, activating more neighboring fibers, then the slowing or block was likewise maintained. Repeated activation of conduction bursts of 8 impulses at tonal intensity produced conduction failure that persisted for more than 30 min. The cumulative slowing and block was observed only for fibers that had conduction failure since in cases where multiple fibers were recorded, the ones near block did not slow when the intensity was increased. Because of the 30 s accumulation and recovery times and because of a transient increase we observed in the CV after tetanic conditioning, which was known to result in post-tetanic hyperpolarization, we attribute the modulation of block to a potentiation of lidocaine blocking by a depolarization of the affected axon by its activated neighbors, possibly resulting from increased axonal potassium.

INTERLEUKIN-1β IL-1β INHIBITS SYNAPTIC TRANSMISSION IN THE BASOLATERAL AMYGDALA (BLA). E-J. Yu, D. Rainnie and P. Shimnick-Gallagher*. Dept. of Pharmacology, Univ. of Texas Medical Branch, Galveston, TX 77555

IL-1β, a cytokine, has central actions including anticonvulsant activity. We analyzed IL-1β effects on synaptic transmission using intracellular recording in the BLA, a nucleus involved in limbic epilepsy. In the BLA, stimulating the stria terminalis (ST) or lateral amygdala (LA) elicits excitatory post synaptic potentials (EPSPs) and fast- and slow-inhibitory post synaptic potentials (IPSPs) via both feed-forward and direct pathways. ST- and LA-evoked EPSPs were reversibly depressed by IL-1β (2 ng/ml). Fast- and slow-IPSPs evoked by stimulating the ST and LA were also reduced or completely blocked suggesting direct and indirect effects on GABAergic transmission. Furthermore, the reversal potential for the IPSP was not altered by IL-1β. Analysis of input-output relationships indicated that the inhibitory effect of IL-1β on synaptic transmission was not overcome by increasing the stimulus intensity. We tested whether IL-1β inhibition was due to a pre- or postsynaptic action by applying agonists exogenously. Muscimol responses were not altered by IL-1β suggesting presynaptic inhibition of the fast IPSP. Responses to AMPA were slightly decreased but the ST- and LA-evoked EPSPs were decreased to a greater extent; IL-1β effects on AMPA responses were not reversible. These data suggest that IL-1β inhibits excitatory and inhibitory transmission at a presynaptic site and provide evidence that IL-1β, a mediator of the immune response, has an inhibitory effect on synaptic transmission in CNS neurons. Furthermore, these results suggest that the BLA nucleus may be a neuronal substrate for interactions between the immune and central nervous systems.(supported by NS 29265).

EXTRACELLULAR MESSENGERS PRODUCED BY ECTOPROTEIN KINASE IN DEVELOPING NEURONS. H. Yang, M.V. Hogan and Y.1. Endlich. CUNY at Staten Island, NY 10301 and the Biology Doctoral Program of CUNY Graduate School.

Ecto-Protein kinase (ePK) utilizes extracellular ATP to phosphorylate proteins localized at the external surface of the neuronal plasma membrane. To determine the role of ePK in neuronal development, we investigate primary neurons cultured from the telencephalon of 7-day chick embryos. Phosphorylation reactions are carried out with cells attached to 48-well plates. For ePK assays we add γ-32P-ATP (0.1 μM, 15Ci/mM) and incubate for 10 min. To incubate intracellular proteins an equivalent dose (15Ci/mM) of [32P]ATP is added, with [32P]ADP at 2 min. We find that two proteins with apparent MW of 11.7K and 13K became rapidly phosphorylated upon addition of γ[32P]-ATP to the medium, but were not labeled at all even after 1-2 hrs incubation with [32P]. These proteins were identified as the substrates of ePK. The extracellular phosphorylation of these proteins was found to peak at the onset of rapid neurogenesis. In the present study, we expose the cells in three times with Krebs-Ringer buffer just prior to the ePK reaction, to remove all soluble components. Immediately after 10 min incubation with γ[32P]-ATP, the medium was separated from the attached cells by centrifugation (150,000 x g, 90 min). The 11.7K and 13K phosphorylated substrates of ePK were found in the soluble fraction. Thus, during the extracellular phosphorylation reaction these phosphorylated proteins detach from the cell surface. In developing neurons, this process may provide a unique, novel means of controlling growth and function of target neurons, and for interaction with components of the extracellular matrix.

CONVERGENT REGULATION OF BRAIN SODIUM CHANNELS BY CAMP-DEPENDENT PROTEIN KINASE AND PROTEIN KINASE C. Ming Li*, James W. West, Todd Scheuer, William A. Catterall. Dept. of Pharmacology, University of Washington, Seattle, WA 98195.

Direct application of the catalytic subunit of camp-dependent protein kinase (cAMP-PK) and ATP to the cytoplasmic surface of rat brain Na channels is excised in-out our membrane patches reduces channel activity. Protein kinase C (PKC) phosphorylation of Ser1506 in the conserved intracellular loop between domains III and IV of the alpha subunit slows inactivation and allows reduction of conductive activity by phosphorylation at another site in the loop between domains I and II (Numann et al., preceding abstract). Since phosphorylation at Ser1506 is necessary but not sufficient for reduction of Na current by PKC, we examined whether it might also control reduction of channel activity by phosphorylation of Ser1506 directly. PKC, no current recorded from Chinese hamster ova cells stably expressing Type IIa sodium channels with the mutation Ser1506Ala were unaffected by application of cAMP-PK and ATP. Application of cAMP-PK and ATP to 6 patches containing wild-type channels reduced the current by 40% in the same series of experiments. The reduction in wild-type channel activity by cAMP-PK cannot be due to phosphorylation of Ser1506 since: 1) this site is not phosphorylated by cAMP-PK in biochemical experiments and 2) phosphorylation at this site by PKC causes only slowing of inactivation of Ser1506 by PKC. No current recorded from Chinese hamster ova cells stably expressing Type IIA sodium channels with the mutation Ser1506Ala were unaffected by application of cAMP-PK and ATP. The PKC consensus site at Ser1506 was converted to a cAMP-PK consensus site by conversion of Lys1507 and Lys1508 to Glu. In contrast to wild-type Na currents are slowed and reduced by cAMP-PK and ATP. The effects of cAMP-PK are similar to PKC in wild-type and consistent with the conclusion that phosphorylation of Ser1506 by PKC slows Na channel inactivation and regulates the reduction of Na channel activity by both PKC and cAMP-PK.

MUTAGENESIS OF THE RAT BRAIN SODIUM CHANNEL PROTEIN KINASE A (PKA) PHOSPHORYLATION SITES. R.D. Smith* and A.L. Goldin, Dept. of Pharmacology & Microbiology Genetics, U. California, Irvine, CA 92717.

We have previously described that substitution of the cAMP binding protein kinase A (PKA) in Xenopus oocytes results in an increase in sodium currents expressed from the rat brain type I sodium channel clone. We have now used site-directed mutagenesis to determine the current control by phosphatase activity. Protein kinase A (PKA) phosphorylation of the sodium channel alpha-subunit, Ser1506 was the result of direct phosphorylation of the sodium channel alpha-subunit. The sodium channel has five consensus PKA phosphorylation sites located in the linker region between domains I and II. It is possible that sites were either eliminated by replacing the serine residues with alanine, or were disabled by replacing the serine residues with aspartate. All five of the serine to alanine substitutions resulted in functional changes in sodium currents, with the most significant effect being a decrease in current. The voltage-dependent properties and inactivation kinetics of all of the mutants were similar to those of the wild-type channel. All five of the mutant channels also showed some degree of the following PKA stimulation; but the magnitude of the effect was quite variable and dependent on the specific mutation. Four of the five serine to aspartic acid mutations have thus far been expressed. The current properties of these mutated channels were tested by each position is sufficient for normal sodium channel function.

CLONING AND SEQUENCE OF A PUTATIVE SQUIRREL SODIUM CHANNEL cDNA AND A PROPOSED TERTIARY Structure MODEL. C.B. Mile and P.T. Catterall. Electrotechnical Laboratory, Tsukuba, Ibaraki 305, Japan.

With polymerase chain reaction and recombinant DNA techniques, we have cloned a complementary 4.9 kbp cDNA which seems to encode a sodium channel protein of the optic lobe of squid Loligo bleekeri. The total number of amino acid residues deduced from the cDNA is 1,522, about three-fourths of that of rat brain I, II and III (each being about 2,000) and an even proportion in eel (1,820). The estimated molecular weight of the squid sodium channel protein is 174,105 dalton. The squid sodium channel is basically quite similar to that of vertebrates, and consists of four domains I, II, III and IV, each containing five hydrophilic segments (S1, S2, S3, S5 and S6), one characteristic segment with strong positive charge (S4), and short intervening sequences. Both a negative charge and a positive one in S2, and a negative charge in S3 as well, are entirely conserved at identical positions in all the domains; only the positive charges are serially repeated at every third position in I-IV. On the basis of the amino acid sequence data, we propose a tertiary structure model of the squid sodium channel.

Previous work by our laboratories has shown that SM2 is the predominant Na+ channel gene expressed by the neuronal derivatives of the RT4 cell line family. Since the RT4 family was derived by a retroviral transformation, we presented the possibility that the SM2 Na+ channel gene might be important in vivo in the rat CNS. In addition our findings suggested that the RT4 system may derive from dorsal root ganglia (DRG) since small cell neurons from rat DRG have high levels of Na+ current and the only known Na+ channel gene thought to encode a TTX-resistant channel is the SM2 gene. We are pursuing two lines of investigation: 1) to ask whether other markers of small cell DRG neurons are expressed by the RT4 neuronal cell types. We have examined the expression of SM2 from newborn rats by RNase protection assay and detected low levels of SM2 mRNA. We are currently in the process of examining DRG by in situ hybridization histochemistry to determine which DRG cell type(s) express SM2. We have also determined that the RT4 neuronal derivatives do not express the three neurofilament proteins, as is the case for small cell DRG neurons. Small cell DRG neurons express the intermediate filament protein peripherin and we are presently examining whether the RT4 neuronal derivatives express peripherin.

THE SODIUM CHANNELS OF THE CYANEID JELLYFISH Cyanea capillata. A HIGH MOLECULAR WEIGHT PROTEIN WHICH BINDS THE CALCIUM CHANNEL BLOCKER AZIDOPINE. Peter A. V. Anderson and John A. Schetz. Dept. of Neurosciences and the Whitney Laboratory, Univ. of Florida, 9505 Ocean Shore Blvd, St. Augustine, Florida 32080.

Previous electrophysiological studies of neurons from the jellyfish Cyanea capillata (Anderson 1987, J. Physiol., 396, 86P) revealed the presence of a fast Na+ current which is completely insensitive to the classic Na+ channel blocker, TTX, but it is blocked by the L-type Ca++ channel blockers known as dihydropyridines (DHP). Since Cyanea Ca++ currents are insensitive to DHPs, this unusual combination of channel pharmacology in Cyanea allowed biochemical analysis of the Cyanea Na+ channel. Isolated membranes from nerve-rich tissue in Cyanea were digitonin-solubilized, applied to an azidopine affinity column and eluted with drug. Column eluates were concentrated and size fractionated by SDS-PAGE. Silver staining revealed a distinct protein band with a molecular weight of approximately 200 KDa only in column fractions eluted with a concentrated DHP solution. This size is consistent with that deduced from a putative Na+ channel cDNA isolated from Cyanea.

Special thanks to Dr. H. Glossman for providing Azidopine. Supported by NSF Grant BNS 9109155 (PAA).

Voltage-gated sodium channels are important contributors to the intrinsic excitability properties of CNS neurons. The aim of this study was to determine whether the relative expression of human brain sodium channel (HBSC) subtypes I and II is altered in epileptic brains compared to those of normal controls. To this end, we show that the ratio of these two subtype mRNAs varies markedly between different normal brain regions along the neuroaxis, but for a given region the value is generally consistent between individuals (Lee et al., FEBS Lett., in press). Epileptic tissue was obtained at surgery from patients undergoing treatment for intractable seizures. Postmortem tissue was obtained from brain regions, age and sex were used as normal controls. Following RNA extraction, the relative amounts of type I and II sodium channel mRNA was compared in these tissues using a modification of the ligase detection reaction as described previously (Lu et al., FEBS Lett., in press). This protocol, combining high sensitivity and high specificity, proves useful for measurements of highly homologous messages such as HBSC I and II, since specificity is provided at the level of single nucleotide differences.

Compared to normal postmortem controls, the data reveal an increased ratio of the I:II ratio in epileptic tissues, with moderate relative increases in HBSC I-specific transcripts. Additionally, a 13:9 ratio of 0.43 was determined for normal temporal lobe, a region not previously characterized with respect to sodium channel mRNA expression. These results suggest a potential correlation between epileptic activity and alterations in the expression of subtypes I and II of the human brain sodium channel. Moreover, these results may lend insight into the control of neuronal excitability and its contribution to the state of hyperexcitability in epileptic tissue.

FOUR FORMING REGIONS ON VOLTAGE-SENSITIVE POTASSIUM AND SODIUM CHANNELS SHARE A COMMON SECONDARY STRUCTURAL MOTIF TARGETED BY STRUCTURALLY SIMILAR SCORPION TOXINS. John A. Schetz, Department of Neuroscience and The Whitney Laboratory of the University of Florida, Gainesville, Florida 32607.

A secondary structure within the putative SS-56 pore-forming regions of voltage-sensitive K+ and Na+ channels was compared and quantified with a statistical metric (SCH (C) version 6.10). The metric predicts that the a-scorpion toxin receptor region mapped to SS-556 on rat brain II Na+ channel and the charybotoxin receptor region mapped to SS-56 on the Shaker A K+ potassium channel are structurally similar (overall fit = 92%), even though their amino acid sequences are sparsely homologous (18%). The striking secondary structural similarity between K+ channel and Na+ channel sequences in comparable SS-56 regions demonstrates that scorpion peptide toxins target structurally similar channel receptor sites. This result, in combination with the fact that the peptide ligands, charybotoxin and a-scorpion toxin Aa II, are themselves structurally similar (Bontems et al. 1991, Science, 254, 1521-1523), invites the hypothesis that venomous peptide ligands of comparable structure bind "pore"/receptor regions of comparable structure.

BIOCHEMICAL EVIDENCE THAT THE TTX-INSSENSITIVE SODIUM CHANNEL IN THE JELLYFISH Cyanea capillata IS A HIGH MOLECULAR WEIGHT PROTEIN WHICH BINDS THE CALCIUM CHANNEL BLOCKER AZIDOPINE. Peter A. V. Anderson and John A. Schetz. Dept. of Neurosciences and the Whitney Laboratory, Univ. of Florida, 9505 Ocean Shore Blvd, St. Augustine, Florida 32080.

Although the literature on saxitoxin (STX) binding in the CNS is abundant, there is little data on the neuroanatomical distribution and STX binding properties in various brain nuclei. In the present study, we examined in detail the saturation profiles of STX binding at several CNS levels using a broad concentration range of STX (up to 64 nM) and mapped STX sites at low (2 nM) and high (15 nM) concentrations of STX. Since the density of STX binding sites (nM) may be an important factor that determines resistance to anoxia, we also compared rat to cattle CNS. We found that 1) Scatchard plots were linear with Kd values around 1 nM for a region of the brain including most cortical areas; 2) in some nuclei, especially in the brainstem, these plots showed an increase followed by a decrease in Bound/FREE Versus Bound; 3) STX binding density was heterogeneous at both binding concentrations with a much higher density in rostral areas than in the brainstem; and 4) saturation patterns in the turtle brain were similar to those of the rat, but STX binding density was much lower (several to 10 fold) than in the rat. We conclude that STX binds mainly to a high affinity site and 2) positive cooperativity occurs with STX binding in some areas. Some areas have shown that Na+ plays an important role during anoxia, we speculate that low binding density in the turtle brain may be partly at the basis of its hypoxic tolerance.

Previously, a high-affinity site for STX was mapped to a site in the rat brain similar to the binding site for benzodiazepines. Using this approach, we have shown that benzodiazepines at high concentrations bind to a single site that is distinct from the TTX-binding site in the rat brain. In the present study, STX binding was measured in several rat brain regions using a variety of concentrations of STX ranging from 0.1-50 nM, and the data were analyzed using a one-site binding model. The results showed that there are at least three distinct binding sites in the rat brain, each with a different affinity for STX. The binding of STX was also measured in several areas of the turtle brain. The binding of STX was highest in the medulla oblongata and the spinal cord, with lower binding in the brainstem and cerebrum. The binding of STX was also measured in several areas of the turtle brain. The binding of STX was highest in the medulla oblongata and the spinal cord, with lower binding in the brainstem and cerebrum. SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

Dorsal root ganglion neurons acutely dissociated from 3-12 day old rats express TTX-sensitive (TTX-S, 1 nM) and TTX-resistant (TTX-R, Kp = 100 μM) sodium channels, which have been shown to differ in their biophysical and pharmacological properties. Leiurus quinquestratus, scorpion venom and sea anemone toxin ATX-II (1-100 nM) exerted no significant effects on TTX-S and TTX-R currents. Tissue dissociation procedures (collagenase-dispase, papain, trypsin, and mechanical dissociation) were systematically examined, each generating the same results. The binding region(s) of both toxins may thus be absent in these cultures. α-Dihydrorayanotoxin (GTX) and deltamethrin, however, each exerted differential effects on TTX-S and TTX-R channels. GTX (100 nM-10 μM) shifted TTX-S channel activation voltage slightly (~2.5 ± 4.1 mV, n=6), without affecting reversal potential. TTX-R current activation was minimally affected (~3.5 ± 4.3 mV, n=8) whereas the reversal potential was dramatically shifted (~17.9 ± 9.1 mV). Deltamethrin (1-100 nM), a type II pyrethroid, shifted activation and reversal potentials of the TTX-S current, without a significant effect on tail current. TTX-R tail current, however, was greatly prolonged, with rising values of greater than 10 seconds. The differential properties of the TTX-R and TTX-S sodium channels continue to be of interest in CNS development and drug interactions. Supported by NIH grants R31 MH09389 and R01 NS14143.

SODIUM CHANNELS

478.15 DIFFERENCES IN THE NEUROEXCITATORY ACTIONS OF SODIUM CHANNEL SPECIFIC NEUROTOXINS IN RAT AND TROUT BRAIN SYMPATHEICOS. J.T. Epstein, K.A. Plejtey, J.L. Baumussen and A.R. Holman, Dept. of Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI 53226.

The effect of pyrotoxin insecticides and other sodium channel specific neurotoxins on neuronal excitability were investigated in rat and trout brain synaptosome preparations using a membrane permeant, lipophilic cation ([3H]-tetraphenylphosphonium (TPP+)). Concentration-dependent and tetraethylammonium (TEA)-sensitive decreases in TPP+ accumulation indicative of membrane depolarization were produced by acridine (Acn), veratridine (Vid), scorpion (Leiurus quinquestratus) venom (ScV) and type I and II pyrotoxins in both species. Acn, Vid and ScV were more potent and efficacious membrane depolarizing agents in rat synaptosomes than in trout synaptosomes. Type II (deltamethrin, cypermethrin and fenvalerate) pyrethroids produced similar depolarizing responses in rat and trout synaptosomes, however, the R.I., or asomer of deltamethrin which had no effect on membrane potential in rat synaptosomes depolarized trout synaptosomes. In addition, the type I pyrethroid, permethrin, exhibited significantly greater efficacy in trout synaptosomes compared to several sodium channel specific neurotoxins and suggest that some of the neurotoxin binding domains of the voltage-sensitive sodium channel in trout brain differ from those in mammalian brain. The hypersensitivity of fish to the neurotoxic actions of pyrethroid insecticides may be related to these differences. (E500006 and E5001959)

478.17 EFFECT OF SODIUM CHANNEL MODULATING DRUGS ON LOSS OF EPSFS FROM HYPOTHYPOGLYCEMIA IN RAT HIPPOCAMPAL SLICES IN VITRO. C.P. Tasson, J.L. Tatter, P.C. Hare. Dep. of Physiology and Pharmacology, Wright State University, Dayton, OH 45419.

Previous studies with phenytoin, lidocaine and tetrodotoxin in various models of ischemia have shown no protection, suggesting the involvement of voltage-sensitive sodium channels in ischemic brain damage. We investigated this hypothesis with several modulators of voltage-sensitive sodium channels using rat hippocampal slices under conditions that mimic ischemia. Hippocampal slices were incubated under control conditions and then subjected to a 15 min period of "ischemia" from depolarization produced by an increase in extracellular K+ (from 3 to 60 mM). This treatment caused a loss of synaptic potentials over 2-5 min and a sudden negative shift in extracellular voltage corresponding to loss of ion homeostasis after about 8 min. Return of normal medium failed to recover EPSFs in any of 96 control experiments.

However, treatment with phenytoin (20 or 50 μM), lidocaine (50 or 100 μM), carbamazepine (50 μM), or verapamil (10 μM) significantly delayed the onset of negative voltage shifts and increased the number of slices that recovered EPSFs. These neuroproactive effects were seen at drug concentrations that did not alter synaptic action potential amplitude, indicating that sodium channels were modulated but not blocked. Nimodipine at a concentration (1 μM) that modulates L-type voltage-sensitive calcium channels did not alter synaptic action potentials. DIDS and D-APV, modulators of voltage-dependent sodium channels by anticonvulsant or local anesthetic drugs may be beneficial for treatment of cerebral ischemia.
478.19 ANTIMYOTONIC ACTIVITY AND USE-DEPENDENT BLOCK OF SKELETAL MUSCLE Na+ CHANNELS BY ENANTIOISOMERS OF TOCAINIDE AND MEXILETINE. A. De Luca*, C. Panchal, Y. Tongiorgi, S. H. Bryan, and D. C. Cameron. Dept. of Pharmacology and Pharmacoeconomics, Fac. of Pharmacy, Univ. of Bari, Italy and Dept. of Pharmacol. and Cell Biophysics, Univ. of Cincinnati, USA.

The use dependence of class I antiarrhythmic drugs as tocainide, as racemate, and as its individual enantiomers on rat muscle sodium channels has been studied. The high affinity interaction during slow inactivation states of Na+ channels (De Luca et al., Neurosci. Lett., 344, 75-78, 1998) in mammalian muscle cells has been described to be stereospecific (Tricario et al., Pflügers Arch., 418: 500, 1991). To clarify the role of stereospecificity in the use-dependence of these drugs, the ability of enantiomers of tocainide and mexiletine to solve abnormal membrane excitability was evaluated "in vitro", by means of two intracellular microelectrodes technique, on rat extensor digitorum longus (EDL) muscle, made myotonic by previous ionization with 50µM atracurium-9-carboxylic acid (9AC), and on external intercostal muscle fibers from congestiously myotonic goats. On rat EDL, 30µM (S)-tocainide completely antagonized the 9AC-induced hyperexcitability, whereas 10µM (R)-tocainide inhibited only 25% the myotonic repetitive firing. On the other hand, 50µM of (R)- and (S)-tocainide inhibited 9AC hyperexcitability by 70% and 60%, respectively. On myotonic goats, 10µM (R)-tocainide fully restored normal membrane excitability, whereas 100µM (S)- was almost ineffective. These compounds were also tested on Na+ currents recorded from goldfish semimembranosus muscle fibers by means of triple Vaseline gap voltage clamp. External application of 500µM of either (R) (+)- and (S)-tocainide blocked Na+ currents by 25-50%. Similarly, both enantiomers of mexiteline had an EC50 of about 300µM. Either eosin or racemates of mexiteline and mexiletine were strongly use-dependent, i.e., the further cumulative reduced peak Na+ current (up to 70%) upon repetitive stimulation at 2Hz frequency. The present data suggest that the presence of a weakly stereospecific receptor (as in frog muscle), does not impair the use-dependence of Na+ channel blockers. However, it is the presence of highly stereospecific site, as in mammals, modulates use dependence of drugs with pronounced stereoselectivity, as tocainide and this might have important therapeutic implications. (Granted by CNRS 91.0026 and Telethon-Italy, 1991).

NON-NA (ACTIVATING), TTX-SENSITIVE Na⁺ CONDUCTANCE IN RAT OPTIC NERVE AXONS: POSSIBLE PHYSIOLOGICAL AND PHARMACOLOGICAL ROLES.  
Dept. Neurology, Yale School of Medicine, New Haven, CT 06510.  
Sodium channels provide the rapid depolarization underlying axonal action potentials. Classical channel kinetic models describe channels quickly and completely inactivate at depolarized potentials, contributing to rapid termination of the action potential. TTX-sensitive Na⁺ spicules (ROP) as a model to study the ionic mechanisms of anoxia in current meylitined axons. Anoxic injury in the RON is critically dependent on Na influx via a TTX-sensitive Na conductance. However, conventional Na channels should be inactive at the depolarized membrane potentials that occur in anoxic tissue. We therefore hypothesized that a non-inactivating Na conductance must exist, which mediates pathological Na fluxes during anoxia. To test this prediction, we studied RONs with a modified griseofulvin technique. The recorded DC potential is a reliable fraction of the true complex axonal resting potential (VR), behaving as a linear function of transp-  
membrane voltage (VR=4 mV at 10 mV; VR-10 mV at 10 mV) and at two levels of  
depolarization (KJ=15 and 40 mV); at [K]=40 mV, resting potential decreased to  
44% of control. A TTX-induced hyperpolarization was observed at each value of  
[K], indicating that a fast, non-inactivating Na conductance exists at rest and 
at depolarized membrane potentials in RON axons. PKP-2 PNa were estimated to be  
50 22.1 and 17.8 at [K]=15 and 40 mV, respectively. Following the 
TTX-induced hyperpolarization, VR began to depolarize. We suggest that the  
depolarization was partly due to inhibition of the Na K-ATPase secondary to  
depolarization of intracellular Na. We conclude that meylitined axons of the RON possess a TTX-sensitive, non-inactivating Na conductance. This conductance may function as a source of intracellular Na for the Na-K-ATPase under physiological conditions. Under pathological conditions such as anoxia, this conductance plays a central role in  
modulating irreversible injury by admitting Na, raising (Na) and driving the Na-Ca 
exchange to import damaging quantities of Ca. This non-inactivating Na conductance may have unique pharmacological properties and its blockade may  
protect CNS while matter from anoxia without abolishing electrogenesis (RES was supported by a Convervational Fellowship from the Medical Research Council of Canada).

SPONTANEOUS TTX-SENSITIVE Na⁺ CURRENTS IN RATTEN SENSORY NEURONS MAY INVOLVE ALL-OR-NONE Ca²⁺ TRANSIENTS.  
Lab. of Neurophsiology, NNIDS, NIH, Bethesda, MD.  
Whole-cell patch recordings in the presence of 1-3 μm tetrodotoxin (TTX) revealed spontaneous transient inward currents (STICs) in cultured (1-3 weeks) dorsal root ganglion cells dissociated from 19-20-day-old rat embryos. The frequency of STICs was below the threshold of detection before the peak amplitude. Removal of extracellular Ca²⁺ decreased their frequency to 7 to 70% of control, but did not eliminate STICs. Addition of 2.5 mM Mgs²⁺ increased their frequency to 2.5 times of control, but preserved the preferred-amplitude characteristics. Replacement of extracellular Na⁺ with N-methyl-D- 
glucamine reduced the frequency of STICs, shifted the distributions of peak amplitudes to lower levels, prolonged their time to peak, and decreased their rate of rise. Extracellular Na⁺ free reversibly eliminated STICs. When a membrane permeable Ca²⁺ chelator, BAPTA-AM, was added to the bath, the frequency of STICs decreased progressively to 6% of control. The properties of STICs suggest that these TTX-resistant Na⁺ dependent currents may be activated by all-or-none Ca²⁺ transients released from intracellular stores.  

478. 28  
Action potentials in cultured hippocampal neurons from the trisomy 16 (T16) mouse have a slower depolarization rate than control neurons. This is likely due to differences in the voltage dependent sodium current. Primary cultures of hippocampal neurons were prepared from control and T16 mouse fetuses at day E15-16. Whole cell patch clamp recordings were performed from neurons 2-4 week old neurons. The extracellular medium included 130 NaCl, the intracellular medium included 5 NaCl. Currents were evoked with a 10 ms pulse in 10 ms steps between -50 mV to 90 mV from a holding potential of -40 mV. The mean membrane resistances were approximately 500 MΩ, the capacitances approximately 30 pF and the reversal potentials approximately +80 mV. None of these values were significantly different between control and T16 neurons. The mean maximum inward current was -125 pA/pF for control neurons (n=16) and -62 pA/pF for T16 neurons (n=16) (significant at p < 0.01), and was abolished by 1μM TTX, but unaffected by 2 μM CdCl₃. This indicates that the current is a voltage-dependent sodium current, and likely explains the reduced depolarization rate of the action potential.
478.31 ELECTROPHYSILOGICAL CHARACTERIZATION OF CATHA CELLS - A NEW CATECHOLAMINERGIC CNS CELL LINE. M. Lazareno, D. A. Chakrabarty, K. Dunlap. Neuroscience Program, Tufts Univ. Sch. of Med., Boston, MA 02111. A CNS cell line (CATHA) was previously derived from a brain tumor from a transgenic mouse in which V540 T antigen was under the transcriptional control of rat tyrosine hydroxylase 5' flanking sequences. The cells synthesize catecholamines and have neurotransmitter and sympathophin proteins whereas glial fibillary acidic protein is absent suggesting that the CATHA cells are neuronal in origin. We have evidence for the presence of voltage-dependent ion channels by whole cell voltage-clamp recording. When CATHA cells are depolarized from a resting potential of -80 mV to between -40 and -20 mV, a fast-inactivating inward current is observed. Peak current is reached within 2 ms and is followed by an exponential inactivation (1.6 ms). Current-voltage relations show a maximum current near 0 mV. This current resembles that of the voltage-dependent Na+ channels in other preparations. This was further confirmed by ion substitution experiments in which external NaCl was replaced with N-methyl-D-glucamine (NMDG); this substitution eliminated the current. In addition, 250 mM tetradotoxin (TX) blocked the current in a reversible manner. These findings suggest that CATHA cells express voltage-gated Na+ channels. When depolarized to -40 mV, a longer lasting inward current is observed in approximately 40% of the CATHA cells. This current is blocked by 100 μM cadmium and is carried predominantly by cadmium. In other CATHA cells a long-lasting, more slowly activating outward "K+" like current is seen. Therefore, these transformed cells appear to possess voltage-gated sodium channels, calcium channels, and possibly potassium channels.

478.32 NA+/K+ ATPase INHIBITORS BLOCK PALTOXYL INDUCED INACTIVATION OF IONIC CURRENTS IN FROG MUSCLE MEMBRANE. M.B. Rodriguez de Salazaga, S. Ortiz-Miranda and G. Escalona de Motta*. University of Puerto Rico Dept. of Biology and Institute of Neurobiology, San Juan, Puerto Rico. Paltoxon (PTX), isolated from zoanthids of the genus Paltozon (Cnidaria) and considered one of the most potent marine toxins, has been proposed to increase Na+ permeability of cell membranes through a mechanism involving the Na+ K+ ATPase. In vivo inhibition of Na+ K+ ATPase. However, the inhibitory action of this glycoside was dependent on their chemical structure, monoglycosides being the most active inhibitors. This results confirm a relationship between the depolarizing effect of this toxin and the activity of the membrane Na+/K+ ATPase. (Work was supported by NIH grants GM168102, NS07464 and NOAA, USDC Sea Grant College Program at UPR).

CALCIUM CHANNEL MOLECULAR BIOLOGY

479.1 CLONING OF THE α1 SUBUNIT OF A VOLTAGE-DEPENDENT CALCIUM CHANNEL EXPRESSED IN THE ELECTRIC ORGANS FROM NARCINE BRIASISCUISI. M. Philip, J. Lin, C. Hastings, L. Stiib, S. Azhar, J. Forc, J. Ramachandran, and J. Bell. Neuron Corporation, 3760 Haven Avenue, Menlo Park CA 94025. The electric organ of the fish Narcine brasiliensis is a rich source of molecules such as calcium channels involved in neuronal communication. Using two oligonucleotides from motif IV and the carboxy tail of the rabbit skeletal muscle calcium channel as probes, we cloned a cDNA encoding an electromotor nucls as template, and PCR, we cloned a 570 bp fragment and subsequently used it as a probe to screen a cDNA library made from electromotor nucls. From the library, we isolated several overlapping clones covering almost the full length of the message. Upon sequencing, these clones showed a high similarity to Class D channels (Stuchl, T.P. et al., (1990) Proc. Natl. Acad. Sci. Vol 87, 3391; Williams, M.E. et al., (1992) Neuron, Vol 8, 757). Human and fish genes highly conserved with 79% identity overall at the amino acid level. There is almost complete conservation of transmembrane domains and significant divergence in the intracellular regions between motifs I and II and between motifs II and III. In preliminary results, the C-terminal region of our fish clone is relatively short and diverges completely from the human clone 177 residues from the last transmembrane domain, perhaps suggesting alternate splicing in this region. It appears that the subtypes of calcium channels arose early in vertebrate evolution and are highly conserved among different species. We also obtained a presumptive splice variant, unique from other published sodium or calcium channels, which has two in-frame deletions of 129 bases and 66 bases corresponding to the IVS3 and IVS5 transmembrane domains.

479.3 CLONING AND CHARACTERIZATION OF A NOVEL α1 SUBUNIT OF DROPSOPHILA Ca2+ CHANNEL. W. Zheng, G.P. Feng, D.F. Eberl, D.J. Trickle* and L. M. Hall. Dept. of Biochemical Pharmacology, School of Pharmacy, SUNY/Buffalo, NY 14260. The most abundant Drosophila head membrane channels have different pharmacological properties than those of vertebrate L-type Ca2+ channels. These Drosophila Ca2+ channels have high binding affinity for phyllolamines, but are insensitive to dihydropyridines and to benzothiazepines whereas the vertebrate L-type channels are sensitive to all three classes of the Ca2+ channel antagonists. We report here a complete sequence of the Ca2+ channel α1, subunit cloned from a Drosophila head cDNA library. This cDNA encodes a deduced protein estimated to contain 1964 amino acids. It exhibits 79.5, 72.2 and 71.2% sequence similarity to the α2 subunit expressed in rat brain (D), rabbit skeletal muscle and heart respectively. A comparison of the Ca2+ channel sequences from Drosophila and vertebrates will be presented which provides important insight concerning the nature of phyllolamine and dihydropyridine binding sites. Northern analysis shows that this α1 subunit mRNA is expressed as a single size class in leg (9.5kb) and body (9.6kb) but as three size classes (9.5, 10.2 and 12.5) in head. This gene has also been localized on the left arm of chromosome 4 by in situ hybridization. Mutant analysis will define the physiological developmental role of this channel in the whole organism. (Supported by NIH grants HL16003, HL39369 and GM24850-02).
479.5 MOLECULAR CLONING AND REGIONAL EXPRESSION OF A RAT BRAIN CALCIUM CHANNEL L-P Type Subunit. J.P. Szurszewski, T.H. Purves, D.J. Dubel, W.J. Tontonoz, T.Y.B. Starr, S.R. Vishteg and T.P. Szurszewski. Biotechnology Laboratory and "Division of Neurological Sciences, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3.

Voltage-gated Ca channels are heterologeric complexes that include an alpha-1 subunit that serves both as a voltage sensor and ion conduction channel. In addition, exogenous expression studies demonstrate that separate subunits (alpha-2, beta and gamma) alter the physiological properties of the alpha-1 subunit. In the nervous system, the exact subunit composition of different neuronal Ca channel types has not been described and it is not yet known whether all Ca channel alpha-1 subunits are associated with auxiliary subunits. Utilizing the skeletal muscle alpha-2 subunit as a probe we have isolated a 4.4 kb cDNA from a rat brain library. The cDNA encodes a 10% amino acid protein (123 kDa) predicted molecular mass) that shows 93% and 94% amino acid identity to rabbit skeletal muscle and human brain Ca channel alpha-1 subunits, respectively. The cellular localization of the alpha-2 subunit expression was examined in adult rat brain using a pigment hybridization with antisense oligonucleotides.

Antibody studies reveals that the alpha-2 subunit is highly expressed in a subset of neurons in the cerebellum, olfactory bulb, hippocampus and cortex. The expression of the brain alpha-2 subunit does not correlate exactly, with the expression of Ca channel alpha-1 subunits and suggests that only a subset of neuronal Ca channels are associated with an alpha-2 subunit.

479.6 cDNA CLONING OF A CALCIUM CHANNEL HIGHLY EXPRESSED IN THE HIPPOCAMPUS. L-C. Chong, L.G. Moon and T.J. Trimmer. Biotechnology Laboratory, Univ. of British Columbia, Vancouver, B.C., Canada V6T 1Z3.

Screening of a cDNA library constructed from whole rat brain RNA identified four major subtypes of Ca channel alpha-1 subunits (classes A, B, C, and D). DNA sequencing of the four Ca channel classes A and B alpha-1 subunits encode distinct L-type Ca channels while the class A and B alpha-1 subunits are likely to encode P and N type Ca channels, respectively. To identify Ca channels that may be involved in processes such as long-term potentiation, we have utilized the polymerase chain reaction (PCR) to amplify Ca channel sequences expressed in the hippocampus. Degenerate oligonucleotides were used to amplify hippocampus RNA isolated from adult rats. The PCR products were cloned and analyzed by DNA sequencing. Of 18 clones examined, 15 were identified as previously characterized Ca channel alpha-1 subunits, while 3 encode a new class of Ca channel (designated class E). The deduced primary structure of the class E protein is most closely related to the brain class A and B alpha-1 subunits. Limited amino acid identity to the brain class C and D alpha-1 subunit suggests that it is close to E channel corresponds to an L-type Ca channel. Northern blot analysis shows that the class E Ca channel is encoded by an approx. 12 kb RNA that is expressed throughout the rat CNS and is most abundant in the hippocampus. This pattern of expression is distinct from previously cloned Ca channels and may reflect a unique physiological role for the class E Ca channel in the CNS.

479.7 CHROMOSOMAL LOCALIZATION OF MURINE GENES ENCODING α1, α2, and β-SUBUNITS OF THE DHP-SENSITIVE L-TYPE CALCIUM CHANNELS. L. Qin, L. Marks, H.-L. Kim, and K. Kazazk. LMB, NINDS, TGL, NCI, and LAMM, NIADDK, Bethesda, MD 20892.

Recent molecular cloning has indicated that a heterogeneous family of voltage-sensitive Ca²⁺ channels are expressed in mammalian brain, providing structural bases for the functional diversity of neuronal Ca²⁺ channels. As a first step toward understanding genetic bases for diversity of brain Ca²⁺ channels, we have begun mapping the genes encoding the α1, α2, and β subunits of the dihydropyridine (DHP)-sensitive L-type Ca²⁺ channels. Previously, we and others localized two of the α1 subunit genes (Cchα1 and Cchα2) on mouse and human chromosomes (Powell et al., Genomics 1991; 54:68-79; 1991; Chiu et al., Genomics 1991; 11:21-91, 1991). Here, we have determined the chromosomal location of the third subunit gene, Cchα3, which encodes the isoform predominantly expressed in skinned skeletal muscle. Analysis of the progeny of an inbred strain cross positioned Cchα3 at 3.3 cM proximal to the Peps-3 locus on Chr 1. In contrast to the α1 subunit which are encoded by 3 distinct genes located on three different chromosomes, the Cchα2 and Cchβ subunits are encoded by a single gene, located on Chr 5 and 11, respectively. Analysis of 5 alleles for genes in an interspecies cross between Mus and C57 mice shows that the α2 subunit gene, termed Cchβ2, is positioned at the centromeric end of Chr 5, with gene order centromere-Cchβ1-Cchβ2-Cchβ3-Cchβ4. Similarly, the gene for the β subunit is mapped on Chr 11 with the gene order centromere - Sacr - Cchβ1-Bap3. Our mapping data indicate that the DHP-sensitive Ca²⁺ channel genes are apparently dispersed in the mouse genome, unlike the Na⁺ channel whose genes are clustered on Chr 2.

The dihydropyridine (DHP)-sensitive, L-type Ca²⁺ channel from skeletal muscle consists of 5 polypeptide subunits (α1, α2, β, γ, and δ). The α1 subunit of the Ca²⁺ channel can form the functional Ca²⁺ channels in Xenopus oocytes. However, cojection of skeletal muscle α2-6 and β subunit mRNAs with the α1 subunit mRNA drastically changed the electrophysiologic characteristics of the expressed Ca²⁺ channels. These findings suggest that α2-6 and/or β subunits may play a modulatory role in regulating Ca²⁺ channel function. Previously, we cloned and characterized the molecular properties of the DHP-sensitive α1 Ca²⁺ channel and α2 and β subunits. Here, we report the primary structure of rat brain DHP-sensitive Ca²⁺ channel β subunit and identify the distribution of its mRNA. Two cDNA clones, BT11 and BT8, encoding the β subunit were isolated and characterized. The deduced amino acid sequence of BT11 cDNA is very similar to that of the rabbit skeletal muscle β subunit, showing 96% amino acid identity. The BT8 clone is a spliced variant of BT11 with deletion of a 45-amino acid fragment. The distribution of rat DHP-sensitive Ca²⁺ channel β subunit mRNA was examined in prenatal (E16, E19), postnatal (P0, P6, P12), and adult rat brains as well as whole-body sections of E19 embryos. In adult rat brain, large amounts of β subunit mRNA were found in the hippocampus, dentate gyrus, and medial habenula. A high level of DHP-sensitive Ca²⁺ channel β subunit transcript was already expressed at E16, and transcript levels significantly changed in several areas during development.

479.9 DIFFERENTIAL EXPRESSION OF BRAIN L-TYPE AND P-TYPE CALCIUM CHANNEL mRNA IN ADULT AND DEVELOPING RAT BRAIN. H. Kim†, H.-L. Kim, and H. Chun. LMB, NINDS, NIH, Bethesda, MD 20892.

The four major types of voltage-sensitive Ca²⁺ channels present in the central nervous system (CNS) are classified as N-, L-, P-, and T-types. Earlier localization studies indicated that L-type Ca²⁺ channels are predominately expressed in those brain regions important for neurotransmitter function (Chapman et al., Trends Neurosci. 1989; 16:299-69, 1989). Several studies suggest that the P-type Ca²⁺ channels, initially identified in cerebellar Purkinje cells, are distributed more widely throughout the brain. Here, we investigated mRNA expression patterns of the α1 subunit of L- and P-type Ca²⁺ channels of adult and developing rat brains by in situ hybridization histochemistry, using the specific cRNA probes. The L-type α1 subunit transcript was abundantly expressed in the olfactory bulb, dentate gyrus, parietal and piriform cortices, superior colliculus, and facial nucleus; whereas the P-type α1 subunit was highly expressed in the hippocampus (CA3 region), geniculate bodies, inferior colliculus, and cerebellum. The cellular localization disclosed differential labeling of distinct cell types in various brain areas, suggesting that L- and P-type Ca²⁺ channels may be localized in specific subpopulations of neurons with this conclusion, relative L-type Ca²⁺ channel mRNA contents in different brain regions varied during development, whereas the P-type Ca²⁺ channel transcript gradually increased from very low levels during low levels during embryonic development (E16), peaked at the highest level at P12, and decreased thereafter in adults. The data reveal that spatial localization and temporal expression patterns of L- and P-type Ca²⁺ channel mRNA contents change developmentally, and suggest physiological role(s) for these channels in mammalian CNS ontogeny.

At least four different α1 subunit genes are expressed in the central nervous system, designated α₈ through α₄. We report the primary structure of the α₈ subunit and the functional expression of a human N-type voltage-dependent Ca²⁺ channel mediated by this α₁ subunit. Functional expression was achieved by transient coexpression of α₄ with human neuronal α₂ and β subunits [Williams et al. Neuron 87:1 (1992)] in mammalian cell culture. Whole cell recordings revealed a high-voltage activated, inactivating channel that was sensitive to blocking potential, insensitive to Bay K 8644 (1 μM) and irreversibly blocked by ω-conotoxin (0.5 μM) (see abstract by Feldman et al.) Transfected cells expressed a single class of high-affinity ω-conotoxin binding sites (Kₐ = 55 ± 18 pM; B_max = 25,000 ± 10,000 receptors per cell).

The predicted α₈ subunit structure consists of the characteristic twenty-four transmembrane topology domains characteristic of α₁ subunits. The predicted α₈ amino acid sequence is 64.1% and 43.0% identical to the rabbit Bi (α₂) dihydropyridine-sensitive and human α₁ dihydropyridine-sensitive subunits, respectively. α₈ has a characteristic large putative cytoplasmic loop between the IIßS and IIßII S transmembrane domains like the rabbit Bi subunit but is only 29.3% identical through a majority of the loop. The α₈ primary transcript is differentially processed to produce at least two isoforms, α₈a and α₈b, calculated molecular weights of 287,604 (40%) and 251,757 molecular weight (59%).
479.11

N-type Ca channels, found in neurons but not in muscle, are irreversibly blocked by omega toxin. Activation requires calcium-dependent depolarizations from negative holding potentials, and inactivation occurs over several minutes at 0 mV. We have now isolated cDNAs encoding a human omega toxin-sensitive (n-type) Ca channel and an n-type Ca channel with the properties of N-type channels.

Whole-cell recordings from transfected cells revealed Ba2+ currents up to several nA, irreversibly blocked by 0.5-10 μM omega toxin. At 0 mV, the current density was concentration dependent, consistent with rates measured in neurons. Activation began near -20 mV, and peaked near 10 mV. The current usually activated within 100 mV, and the time constant of rise of the peak was 60 ms (r0 = 1 s). Rates inward activation dominated at test pulses of 0 or 10 mV, r0 dominated at >10 mV. The currents were sensitive to holding potential, with a 20% decrease occurring at 40 to 60 mV and 90% inactivation near -40 mV. Currents were reversibly blocked by 50 μM Ca2+, and were not affected by dihydropyridines. Two observations suggest that the expressed channel is under tonic inhibition in the host cell; currents typically increased in magnitude 2 to 20-fold during the first several minutes of recording, and currents increased in magnitude when the test pulse was immediately preceded by a brief strong depolarization.

Thus, many of the properties attributed to N-type channels observed in neurons are exhibited by the recombinantly expressed channel.

CLONING OF A cDNA FOR A SYNAPTIC PLASMA MEMBRANE Na+/Ca2+ EXCHANGER: M. I. Michaelis*, J. Welch, K. Kumar, J. Foye and G. H. Davis, Depart. of Pharmacology and Toxicology, Univ. Kansas, Lawrence, KS 66045.
The Na+/Ca2+ exchanger is a plasma membrane protein which is believed to play a role in the regulation of Ca2+ fluxes, particularly in excitable cells. We have used a full-length cDNA encoding a human sodium-calcium exchanger (NCX subunit [see abstract by Ellis et al.] that, when transiently expressed in transfected mammalian cells with previously isolated cDNAs encoding human membrane Na+/K+ ATPase (Williamson et al., Neuron 8:711, 1992), expresses Ca channels with the properties of N-type channels.

The Na+/Ca2+ exchanger is a plasma membrane protein which is believed to play a role in the regulation of Ca2+ fluxes, particularly in excitable cells. We have used a full-length cDNA encoding a human sodium-calcium exchanger (NCX subunit [see abstract by Ellis et al.] that, when transiently expressed in transfected mammalian cells with previously isolated cDNAs encoding human membrane Na+/K+ ATPase (Williamson et al., Neuron 8:711, 1992), expresses Ca channels with the properties of N-type channels.

Whole-cell recordings from transfected cells revealed Ba2+ currents up to several nA, irreversibly blocked by 0.5-10 μM omega toxin. At 0 mV, the current density was concentration dependent, consistent with rates measured in neurons. Activation began near -20 mV, and peaked near 10 mV. AF64A (ETHYLCHELINE AZIDIRINUM ION) PRODUCES OXIDATIVE STRESS: RELATION TO CHLORITOXICITY AND FUNCTIONAL DEFICITS. J. Walsh, G. Weisbrod, R. W. Bacon, and E. Bondy*, Dept. Psychology, Rutgers Univ., New Brunswick, NJ 08903, and 1 Univ. of California, Irvine, CA 92717.

AF64A produces (1) a persistent decrease in pre synaptic cholinergic function, (2) a loss of cholinergic neurons in the medial septum, and (3) cognitive impairments. While AF64A inhibits high affinity choline uptake (HACHO) the mechanisms responsible for its long-term neurotoxicity are not well-characterized. The following experiments examined the potential role of oxidative stress in the cholinotoxicity and functional deficits induced by AF64A. Male Sprague-Dawley rats were bilaterally injected icv with artificial CSF or 3 mmol of AF64A. Rats were sacrificed two days following surgery and it was determined that AF64A increased the production of conjugated dienes, an index of lipid peroxidation and oxidative stress, and decreased the activity of choline CHAT in the hippocampus (HCPC).

Furthermore, there was a significant correlation between the degree of cholinergic toxicity and the extent of lipid peroxidation. In a subsequent study rats were p.o treated with saline or 50 mg/kg of the anti-oxidant Vitamin E (VE) ac 24 hrs and 15 min prior to icv injection of artificial CSF or AF64A (3 mmol/side). Vitamin E prevented the AF64A-induced (1) deficits in acquisition and retention in a Morris-water maze task and (2) the decrease in HACHO in the HPC. Thus, while the structure of AF64A leads to its accumulation in cholinergic neurons oxidative stress might significantly contribute to the cholinotoxicity and functional deficits induced by this compound. Supported by a Bush Grant to JTW.

EXCITOTOXIC LESIONS OF THE PEDUCULOPONTINE SEGMENTAL NUCLEUS IMPAIR RADIAL-ARM MAZE PERFORMANCE. Larry J. Butcher*, Justin D. Oh, and Cheryl Crase, Laboratory of Chemical Neuroanatomy and Dept. Psychology, UCLA, Los Angeles, CA 90024-1563, U.S.A.

Lesions of the pedunculopontine tegmental nucleus (PPT) lead to reduced choline acetyltransferase (ChAT) immunoreactivity in cholinergic basal forebrain nuclei (Oh et al., Soc. Neurosci. Abstr., 15, 782, 1989). In order to assess possible effects of PPT lesion on spatial memory, 10 female Sprague-Dawley rats with excitotoxic lesions were trained and tested on an 8-arm radial maze. After rats (n=5) reached a 90% error rate defined as no entries into an arm already entered, 3.8 mmol kainate (0.1 µl, total injection time = 4.5 min) was injected unilaterally into the PPT. Five additional rats served as controls and were injected with 0.1 µl of saline into the PPT. Starting on the day after surgery, and for an additional 6 days, rats were tested on the maze and the behavioral data was statistically analyzed with a 2-way mixed-design ANOVA. Lesioned rats, but not controls, showed a significantly greater impairment in spatial memory performance [F(1,12) = 12.143, Mse = 0.623, p<0.05]. These data suggest that excitotoxic lesions of the cells in the PPT nucleus have a deleterious effect on the spatial memory of rats.

480.4
RADIAL-ARM MAZE PERFORMANCE IN RATS IS IMPAIRED BY VESAMICOL (N-TRANS-1,4-PHENYLDIPERIDINO) CYCLOHEXANOL, A POTENT INHIBITOR OF CHOLINE ACTIVE TRANSPORT BY SYNAPTIC VESICLES. Justin D. Oh*, Sonia Bockenauer, Antoine Keller, Stanley M. Parsons, Gary A. Rogers and Larry J. Butcher, Laboratory of Chemical Neuroanatomy and Dept. Psychology, UCLA, Los Angeles, CA 90024-1563, U.S.A. and Dept. of Chemistry, University of California, San Diego, CA 92093.

Effects on both choline acetyl-transferase (ChAT) immunohistochemistry and 8-arm radial maze performance were found for the drug Vesamicol, a potent inhibitor of acetylcholine (ACh) active transport by synaptic vesicles. Female rats (n=20) were randomly assigned either to vesamical group or vehicle control group. Rats received bilateral injections of 1 (ng vesamicol (2.0 x 0.5 mm) dissolved in PBS (pH=7.2) containing DMSO and acetic acid intraperitoneally in the nucleus basalis of Meynert (n=5) or intraventricularly (n=5). Rats injected with vesamicol showed significantly reduced numbers of CHAT-immunopositive cells in the basal forebrain 7 days following surgery and showed significantly increased the nucleus basalis of Meynert (n=5) or intraventricularly (n=5). Rats injected with vesamicol showed significantly reduced numbers of CHAT-immunopositive cells in the basal forebrain 7 days following surgery and showed significantly increased the nucleus basalis of Meynert (n=5) or intraventricularly (n=5). The nerve growth factor receptor revealed no actual cell loss or morphologic aberration in these cholinergic neurons. As measured by entries to repeat, radial-arm maze choice accuracy was significantly impaired in the vesamicol group compared to the control group (p<0.05). Paralleling the time-course of ChAT immunoreactivity decrease, the effects of vesamical on maze performance were significantly different from control group 6 and 7 days post-surgery. [Support: USPHS grant NS 10928 to L.L.B.].

SELECTIVITY OF AN AFFINITY LIGAND, HEMICHLINOMUS MUSTARD, FOR THE HIGH AFFINITY CHOLINE TRANSPORT SYSTEM. K.H. Gylys* and D.J. Jenden Department of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024.

Hemicholinium mustard has been shown to be an irreversible inhibitor of high affinity choline uptake (HACU) in several preparations. (Smart, 1981, 1983; Gylys et al., 1990). In the present experiments the specificity of these irreversible effects was examined with respect to other cholinergic proteins and other sodium-dependent transport systems. To measure the effects of HCM on choline acetyltransferase (ChAT), synaptosomes were incubated in HCM, then washed. The synaptosomes were lysed and the ChAT activity was measured. Treatment with 50 μM HCM, a concentration that inhibits 100% of synaptosomal HACU, results in a 24% decrease in ChAT activity. In other experiments, rat brain membranes were incubated with 1 μM HCM and then washed before saturation studies with the muscarinic receptor ligand [3H]QNB were carried out. HCM pre-incubation showed no significant effect on either the affinity or number of muscarinic receptors. Dopamine (DA) transport is also relatively unaffected by HCM pre-treatment: 10 μM HCM, which inhibits HACU in synaptosomes by >90%, inhibits DA transport by 11%. These results support the use of HCM as an affinity ligand for HACU. (Supported by MH 17691)

CHOLINE BLOOD PRESSURE IN HYPOTENSIVE RATS IN Volvement of Vasopressin. V. Svec, I.I. Ulus*, S.Gürün, B.K.Kiran and L.R. Büyükuysal. Dept. of Pharmacology, Uludag Univ. Medical School., Bursa, TURKEY.

Left carotid artery of rats (280–350 g) was cannulated with PE 50 tubing to monitor blood pressure and animals were made hypotensive by bleeding (2 ml/100 g of body weight) or by treatment with histamine (10 mg/kg; ia), hekmasethionium (15 mg/kg; ip), phenylamine (5 mg/kg; ia) or 6-hydroxydopamine (50 mg/kg/iv). Intracerebroventricular (ICV) injection of choline (50–150 μg; rat) to these animals increased and restored blood pressure within 1–5 minutes after the choline treatment. Choline's effect was abolished by pretreatment of rats with necamylamine (50 μg). Pretreatment of rats with atropine (10 μg; ICV) failed to alter the effect of ICV choline. ICV choline (50 μg) also failed to increase and restore blood pressure when rats were pretreated with hemicholinium-3 (20 μg; ICV) 15 minutes before ICV choline. The increase in plasma levels of vasopressin was associated with the increase in blood pressure in ICV choline treated hypotensive rats. When animals were treated with an antagonist of vasopressin (10 μg/kg; ia) five minutes after ICV choline (150 μg) blood pressure decreased immediately to the pre-choline or to near pre-choline levels. These data indicate that ICV choline can increase and restore blood pressure in hypotensive rats by increasing the central cholinergic nicotinic neurotransmission. The increase in plasma levels of vasopressin involves in this effect of ICV choline.

EFFECTS OF APNEA ON BRAIN CHOLINE PRODUCTION IN RATS. O.U. Scremin* and D.J. Jenden. West L.A. V.A. Medical Center and UCLA School of Medicine, Dept. of Physiology and Pharmacology. Los Angeles CA 90024.

Free choline (Ch) concentration in brain tissue results from a balance between synthesis and hydrolysis of acetylcholine (ACh), synthesis and degradation of Ch containing phospholipids and exchange with plasma. Since the ability of brain tissue to synthesize Ch de novo is negligible, losses of this base through the circulation can have serious consequences for phospholipid and ACh metabolism. We tested the hypothesis that the energy deprivation associated with apnea would enhance the loss of Ch. Experiments were performed in rats, mechanically ventilated with a N2O/O2 mixture. Ch in plasma of aorta (Cha) minus that of retroglomoid vein (Ch v) multiplied by cerebral blood flow in the same vein represented the cerebral metabolic rate of Ch (CMRCh, mmol/min/kg) that reached -0.14±0.06 prior to apnea. Apnea of 1.5 min duration was followed by negative CMRCh values (-0.72±0.06 at 3 min post-apnea), returning to control after 16 min. Apnea of 3 min duration was followed by CMRCh values not different from zero during the initial 15 min followed by negative values (-0.52±0.11 at 60 min). Apnea of 6 min duration was followed by positive CMRCh initially (1.12±0.1 at 6 min) with negative values later (-0.74±0.23 at 64 min). Total Ch loss (mmol) during 1 hr was related to the duration of the apnea episode that preceded it (1.5 min= -12.05 ±3.57; 3 min= -17.09±6.13; 6 min= -27.32±4.15; Controls (no apnea)= -6.99±2.25. This enhanced Ch loss took place in spite of increased Cha. Peak Ch (mmol/ml) after apnea were: 1.5 min= 11.2±1.47; 3 min= 18.8±1.26; 6 min= 30.6± 1.07; Controls= 44.±2.1. It is concluded that apnea induces a significant loss of brain free Ch that could have metabolic consequences. Supported by the US Department of Veterans Affairs and USPHS MH 17691.
481.1  AUTORADIOGRAPHIC LOCALIZATION OF MUSCARINIC CHOLINERGIC RECEPTOR (MCR) SUBTYPES IN CAT BRAIN STEM. H.A. Baghdoyan*, M.T. Roth, R.B. Ducrow, and D.C. Magistretti. Dept. of Anesthesia, Penn State Coll. of Med., Hershey, PA, and Dept. of Neurology, Univ. of Miami Sch. of Med., Miami, FL 33136.

Brain stem cholinergic mechanisms are involved in generating REM sleep. Determination of specific MCR subtypes is not clear. The goal of the present study is to map the distribution of MCR subtypes likely to be important for sleep cycle control. Using the technique of Flynn et al. (Neurosci. Abst. 17; 586, 1991) which utilizes the kinetic properties of [3H]-methylscopolamine to differentially label MCR subtypes, we are localizing M1, M2, and M3 subtypes throughout the cat brain stem. Receptor density is quantified using CCD-camera-based image analysis. Preliminary results show that the feline medial pontine reticular formation (mPRF), a non-cholinergic, cholinergic region involved in REM sleep generation, contains very few M3 receptors (4.0 fmol/mg tissue). The pedunculopontine tegmental nucleus (PPT), which provides cholinergic input to the mPRF, also has few M3 receptors (7.4 fmol/mg). In contrast, the laterodorsal tegmental nucleus (LDT) has 18.8 fmol/mg of M3 receptors. Relatively high levels of M3 receptors were also localized to the periaqueductal gray (15.4 fmol/mg) and the substantia gelatinosa (22.0 fmol/mg). In the mPRF, LDT, and PPT, M1 and M2 receptors are being quantitated. Supported: Dept. of Anesthesia, HLA4749, MH45361 (HAB), NS24109 (RBD), NS27575 (DCM).

481.2  COMPARISON OF CHOLINERGIC PROPERTIES AND MUSCARINIC RECEPTOR SUBTYPES PRESENT IN TWO NEURAL CLONAL CELL LINES. M.A. BUCK, L.A. TAYLOR, V. REUPERT, C.E. TEDSSEND and R. McQUADE. CNS Pharmacology, Schering, Plough Research Institute, Bloomfield, NJ 07003.

Two cholinergic containing cell lines were investigated for various markers of cholinergic activity as well as characterized for muscarinic receptor subtypes. Muscarinic receptor characterization and identification in a neuronal cell line is of considerable interest to better understand cellular mechanisms responsible for the mode of interaction in the central nervous system. Cells of the homogeneous hybrid line of mouse mastocytoma X rat glioma (NG108-15) were compared with the PC12 phaeochromocytoma cell line derived from the rat adrenal medulla. PC12 and NG108-15 cells both demonstrated various levels of cholinergic activity. NG108-15 cells had the highest levels of M4 activity to choline acetyltransferase (CAT, 27.4 vs 13 nmol/mg protein) and acetylcholinesterase (AChE, 1216 vs 376 nmol/mg protein) than PC12 cells. Contrary, functional measurement of high affinity cholinergic (HACHT) indicated that PC12 cells contained almost double the activity. HACHT was sensitive to hemicholinium-3 (HC-3) and was modulated in both cell lines by muscarinic receptor agonists.

Muscarinic receptor characterization of the two cell lines was performed using saturation and competition binding studies with [3H]-acetylcholine (ACh) and characterized for the different affinity muscarinic receptor subtypes, m1-m5. Covalent labelling of the neuronal and transdifferentiated CHO cells with the muscarinic ligand, [3H]-propylenebicyclohexyl mustard (3H-PBBCM) and the mobilities of the mustard labelled species of these cells on sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) confirmed the existence of different muscarinic cholinergic receptor subtypes in these cell lines.

481.3  ALKALOIDS ISOLATED FROM TROPICAL MARINE SPONGES BOUND TO MOLECULAR TARGETS IN RAT BRAIN MEMBRANES. G.E. de Motta, R. Rosa, A.D. Rodriguez, W. Silva and C. Jiménez*. Inst. of Marine Sciences and Department of Chemistry and Biology, U. of Puerto Rico and Dept. of Pharmacology, U. Central del Caribe.

Four structurally related C11-N1 compounds isolated from sponges of the genus Agelas exhibited both stimulatory and inhibitory activities in frog skeletal and smooth muscles. Potential target sites for these compounds were evaluated for their interaction with central cholinergic receptors (mAChR) and tetrodotoxin (TX)-sensitive sodium channels using rat brain synaptosomal membranes and radioligand assays. Competition experiments utilizing tritiated quinuclidinyl benzilate ([3H]-QNB) to label mAChRs revealed the following rank order of potency: sceptor > oxotremorin > dibromoscorpine > atropine. Competition experiments using tritiated saxitoxin ([3H-STX)] as a sodium channel marker yielded the following rank order of potency: sceptor > dibromoscorpine > oxotremorin > atropine. Scatchard analyses demonstrated that sceptor, the most potent member of this group, was a competitive inhibitor of both [3H]-QNB and [3H-STX] binding. (Supported by GM08102 and NS07464, NIH, and NOAA, UPR Sea Grant Program)

Methanolic extracts prepared from clonal cultures of Ostreopsis tenuisculus, a benthic dinoflagellate, were toxic to mice by i.p. injection. Reverse phase HPLC separation using isocratic methanol as the system solvent, produced two major fractions. Fraction I, with a retention time (R) of 2.04 min, contained apparently only one component while Fraction II consisted of a major component (R = 3.69 min) and several minor components. Using radioligand assay methods we studied the effect of the crude extracts and both HPLC fractions on muscarinic acetylcholine receptors (mACHR) in rat brain synaptosomal membranes. Preincubation of membranes with crude extracts (500 µg/ml) fraction I (500 µg/ml) and II (200 µg/ml) displaced binding of tritiated quinuclidinyl benzilate by 97.9± 3.7, 64.285± 3.5% and 61 ± 1.51%, respectively. In frog gastric muscle strips, a preparation we have shown to contain mAChR, crude extracts elicited contractions similar to those induced by acetylcholine in this muscle. (Supported by GM08102 and NS07464, NIH, and NOAA, UPR Sea Grant Program)

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
481.7
HEXYLOXY-7TTP A POTENT AND SELECTIVE M1 ANTAGONIST 
INVITRO. C.H. Mich‡, F.P. Bymaster, D.O. Calligaro, S.J. Quimby, B.R. Sawyer, H.E. Shannon, J.S. Ward, P.H. Olsen, P. Sauerberg, M.J. Sheardown, P.D. Surdzik, Lilly Research Laboratories, Eli Lilly and Co., Ind., IN 46285 and Novo Nordisk, CNS Division, Mådøv, Denmark. Hexyloxy-7TTP (3-(4-hexyloxy-1,2,5-thiadiazole-3-yl)-1,2,5,6-
tetrahydro-1-methylpyridine) inhibited 3H-pirenzepine binding in rat hippocampus and 3H-oxtremorine-M binding in rat cortex with IC50 values of 7 nM and 10 nM, respectively. In 
denervated cells expressing human M1 receptors, hexyloxy-7TTP increased phosphoinositol turnover, and the potency and 
efficacy differed dependent upon the cell type in which the 
receptors were expressed (CHO-A9L>BHK). In denervated cells 
expressing m2, m3, m4 or m5 receptors, hexyloxy-7TTP was 
considerably less active. Hexyloxy-7TTP also was selective for 
M1 receptors in isolated tissues. At M1 receptors in rabbit 
vas deferens, it inhibited twitch height with an IC50 of 8 pM. 
Pirenzepine blocked the effects of hexyloxy-7TTP in rabbit 
vas deferens and had a Kb value of 10 nM. At M2 receptors in 
guinea pig atria, hexyloxy-7TTP had an IC50 of 50 nM. 
Hexyloxy-7TTP was a partial agonist in guinea pig ileum. In 
guinea pig bladder, it appeared as an agonist nor an 
antagonist. The present results demonstrate that hexyloxy-
7TTP is a potent, efficacious and selective M1 muscarinic 
agonist in-vitro.

481.8
EVIDENCE THAT M1 MUSCARINIC RECEPTOR SUBTYPE 
MEDIATE THE EFFECTS OF OXTREMORINE ON 
MUSCULOUS SEXUAL BEHAVIOR. S. Kesana and J. Velazquez-Moctezuma*, Dept. de Biologia de la 
Reproduccion, Universidad Autónoma Metropolitana Iztapalapa, 09340 Mexico D.F., Mexico. 
It has been shown that oxtremorine (Oxo), a muscarinic 
receptor agonist, has a facilitatory effect on muscular sexual behavior in rats. 
Muscarinic receptors have been divided in several subtypes. This study 
analyzes the possible participation of M1 muscarinic subtype in the 
mediation of OXO effects on muscular sexual behavior. Two 
groups of male rats received seven doses of the specific M1 antagonist 
(S)-atropine (6 mg/kg, i.p.) 30 min before assessing sexual behavior. 
Latency and frequency of mount, intromissions and ejaculations were recorded as well as 
inter-intromission interval. No changes in these parameters of 
sexual behavior were observed following TRl administration. 
In a different group of male rats, five doses of TRl were administered 
before OXO (0.4 mg/kg, i.p.). The facilitatory effect of OXO was 
completely prevented even with the smallest dose of TRl. These results 
strongly suggest the notion that cholinergic facilitation of muscular 
sexual behavior is mediated through the M1 muscarinic receptor 
subtype.

481.9
MODULATION OF ACETYLCHOLINE RELEASE 
BY MUSCARINIC RECEPTORS IS ALTERED FOLLOWING LESION 
OF CHOLINERGIC INPUTS WITH THE NEUROTOXIN AF64A. 
D. Thorne and P.E. Potter, Dept. Anesthesiology, Albert Einstein 
College of Medicine, Montefiore Medical Center, Bronx NY 10467. 
The effects of cholinergic agonists on the evoked release of 3H-
acetylcholine (ACh) were studied in male Sprague-Dawley rats in 
which hippocampal cholinergic terminals were lesioned with the 
neurotoxin AF64A (ethylcholine mustard aziridinium, 2 
rnles/ventricle). AF64A infusion, choline 
acetyltransferase activity was decreased by more than 40%. ACh 
release was evoked from superfused hippocampal slices by electrical 
stimulation (1 or 2 Hz, 2 min). The nicotine dose response curve was 
shifted to the left following treatment with AF64A. The EC50 
was shifted from 40 μM (controls) to 3.7 μM (AF64A). This change 
in response to nicotine was not due to changes in nicotinic binding sites. 
When the muscarinic receptors were blocked by atropine the nicotine 
dose response curve of control tissue, was shifted to the left (EC50=4.1 
μM). Atropine had no effect on the nicotine dose response curve of 
AF64A treated rats. In contrast, the dose response curve for 
inhibition of ACh release by the muscarinic agonist oxotremorine, 
was shifted to the right following AF64A treatment. This change in 
response to muscarinic drugs was reflected in a change in muscarinic 
M3 but not M1 binding sites.

481.10
LIGHT AND ELECTRON MICROSCOPIC LOCALIZATION OF m2 
MUSCARINIC RECEPTOR PROTEIN IN RAT SEPTUM AND 
HIPPOCAMPUS. A. Levy*, S. M. Hirsch and S. M. Edmunds, 
Dept. of Neurology, Emory University School of Medicine, Atlanta, GA 30322. 
Pharmacological studies indicate that muscarinic acetylcholine receptors 
preynaptically regulate the release of neurotransmitters. However, the 
precise identity of presynaptic genetic subtypes is unknown. 
The cellular and 
subcellular distribution of m2 receptor in medial septum and 
hippocampus was determined using subtype-specific antibodies (Levy et 
aI., 1991), avidin-biotin-peroxidase immunocytochemistry, and light 
and electron microscopic analysis. In medial septum, m2 immunoreactivity 
was present in both noncholinergic and cholinergic perikarya, and was 
more dense and punctate in the neurons. At the ultrastructural level, m2 
immunoreactivity was associated with the cytoplasmic face of the 
plasma membrane in perikarya, and in dendrites and postsynaptic densities: m2 
was also present in many terminals. In hippocampus, m2 was present 
in cell bodies and processes of large neurons in the stratum oriens and 
hilus. Neuripil immunoreactivity was abundant in the pyramidal neuron 
layer, the polymorph layer of dentate gyri. At the ultrastructural level, 
immunoreactivity primarily was in dendritic spines and rare axon 
terminals. Labeled spines contained reaction product within 
cytoplasm 
and within their postsynaptic densities. Contrary to current dogma, these 
findings indicate that in the septal region, m2 receptors are 
preynaptic (as well as postsynaptic), and that in hippocampus, m2 
muscarinic receptor immunoreactivity is postsynaptic. Supported by Alzheimer Association 
Faculty Scholar Award (AFL), NS 01387, and NS 30454.

481.11
MUSCARINIC RECEPTOR SUBTYPES INVOLVED IN CONTRACTION 
OF THE GUINEA PIG ILEUM. E.A. Thomas* and E.J. Lyle, 
Department of Pharmacology, College of Medicine, University of 
California, Irvine, CA 92717. 
Muscarinic receptor subtypes involved in smooth muscle contraction were 
investigated in the guinea pig ileum. The muscarinic agonist oxotremorine M (Oxo-M) 
caused concentration-dependent contractions of the isolated ileum (IC50=38 μM) 
with pharmacology consistent with that of an M3-mediated response. In 
order to characterize the M3 muscarinic receptors selectively, ilea were pre-treated with 
the irreversible M3 selective muscarinic agonist 4-DAMP mustard (N-(2-
chloroethyl)-4-piperidinyl diphenylacetate) (40 μM) for 1 h in the presence of the 
irreversible M1 antagontant AF64A (1 μM) and then washed extensively. 
This treatment caused a 22-fold rightward parallel shift in the concentration-effect 
curve for Oxo-M. In separate experiments, ilea were pre-treated with bistine (0.3 
μM) and then exposed (1 μM) before measuring oxotremorine-induced contractions. 
The resulting concentration-effect curve was biphasic consisting of high (50-500 μM) 
and low (>50 μM) affinity components. Similar treatment with 4-DAMP mustard and 
AF64A-116 only shifted the high affinity component, while producing a much 
egreater shift in the low affinity component of the curve. Treatment with AF64A-116 
(1 μM) abolished the high affinity component producing a monophasic 
concentration-effect curve. 4-DAMP mustard (10 μM; 1 h) also prevented 
M3- 
responsive muscarinic stimulation of phosphoinositol breakdown in the longitudinal 
muscle of the rat ileum, resulting in a 6.6-fold increase in the IC50 value with a 65% 
reduction of the maximal response. In contrast, this treatment only blocked 
M2- 
responsive mediated inhibition of adenylyl cyclase by a 2-fold increase in IC50, 
without affecting maximum inhibition. These results support the hypothesis that 
the M3 muscarinic receptors present in smooth muscle may influence contraction, 
perhaps by inhibiting relaxation induced by other receptors. Supported by N.I.H. 
Grant NS 35511.

481.12
THE (+) OPTICAL ISOMER OF (Z)-2-PCE SELECTIVELY BLOCKS 
M1, (ILEAL) BUT NOT M3, (CARDIAC) MUSCARINIC RECEPTORS. 
E.B. Thompson, M. Lu, S.M. Vogt and N.P. Ploughforth*, 
Departments of Pharmacodynamics, and Med. Chem. College of Pharmacy, 
and Pharmacology, College of Medicine, U.I. Chgo, IL 60612. 
Studies in our laboratory have utilized muscarinic antagonists as probes 
for exploring topographical areas of the muscarinic receptors. In 
these studies, direct clues as to the actual binding conformation of the 
hydrophobic portion of structurally flexible molecules (such as atropine and 
QNB) have been provided by use of synthetic analogues which are 
structurally locked into certain conformational states. (Lu et 
aI, 1991) showed that the racemic compound 2-phenyl cyclohexyl 
diethylamino ethyl ether ([Z]-2-PCE) was more potent in ileal (PA2 = 7.15) 
that in arterial (PA2 = 4.96) preparations. This suggests that the Z isomer 
is one of the most ideal selective muscarinic antagonist reported to date. In this 
study the optical isomers of the above compounds were synthesized and 
evaluated pharmacologically on isolated rat atria and ileum preparations. 
Ileal selectivity of the optical isomers was similar to that of the racemate. 
The (+) isomer was found to be a potent competitive antagonist by a factor 
>100 fold, for the ileal but not the atrial muscarinic receptors. Conversely, 
the (-) isomer appeared to be non-competitive in this ileum. The results 
indicate that the competitively antagonistic activity of the racemate is due to 
the (+) optical isomer.
481.13 PROPERTIES OF STRIATAL m4 MUSCARINIC RECEPTORS. S.L. Parkerton, H.B. Handeott, and L.T. Potter*. Molecular and Cellular Pharmacology, University of Miami School of Medicine, Miami, FL 33101. The rat striatum expresses an unusually high concentration of m4 muscarinic receptors, many m1 receptors, and a few m2 receptors (Levey et al. J. Neurosci. 11:2116). m1-Toxin quantitatively blocks the m1 receptors, and 95% of the residual receptors are m4 receptors (Parkerton et al. Neurosci. Abstrt 17:390). This approach permits the first binding studies of m4 receptors coupled to normal amounts of native G-proteins. The order of antagonist affinities was NMS, trihexyphenidyl, biperiden, oxotremorine, benzotropil, methoctramine, bethanechol, and aminopyrine, with aminopyrine, gallamine, and AF6116. Five of these ligands bound with the same affinity to rat striatal m4 receptors and human m4 receptors expressed in CHO-K1 cells. Agonist binding curves showed equal efficacies of Gpp(NH)p-sensitive high affinity (Kd) sites and Gpp(NH)p-insensitive low affinity (Kd) sites in both striatal and CHO-cell membranes. These studies suggest that m4, m2, m1 receptors (Potter et al. Mol Pharm 39:211), may be dimers. The order of Kd/Ka ratios (which often correlate with agonist efficacies) was oxo-M, oxotremorine, 4-acetylcholine, picrocarb, carbachol, methacholine and anesoline, and KA and Kd affinities were very similar in striatal and CHO cells. The order of Kd/Ka ratios, which often correlate with agonist efficacies, was oxo-M, carbachol, 4-acetylcholine, oxotremorine, anesoline and picrocarb, which would suggest that quaternary agonists work better than tertiary agonists. These data do not correlate well with the Kd values and efficacies found for agonists by McKinney et al. (Mol Pharm 40:1014) for the inhibition of cAMP levels in rat striatum. In their studies oxo-M showed high affinity and efficacy, but did so several tertiary agonists. Possible reasons for the different binding of the function data include effects of activating m1 receptors on cAMP levels, and the high activity of tertiary agonists on m2 receptors. Autoradiographic studies of m1 and m4 receptors confirm their wide distribution within the striatum, and indicate their distinct cellular locations.

481.14 ALLOSTERIC MODULATION OF MUSCARINIC RECEPTORS BY BASIC PROTEINS IN RAT CEREBRAL CORTEX AND HEART. J. He and E.E. El-Fakahany*. Division of Neuroscience Research in Psychiatry, University of Minnesota Medical School, Minneapolis, MN 55455. Allostere interactions of proteins, such as histones, myelin basic protein (MBP) and dynorphin A (1-13), with muscarinic receptors were investigated in rat cerebral cortex and heart using radioligand receptor binding assays. These basic proteins inhibited binding of the muscarinic ligand [3H]NMS at equilibrium and altered kinetics of its dissociation from the receptors. Histone VIII (rich in arginine) showed an inhibition constant value of 1.4 μM and a cooperativity value (n) of 4-5 in cerebral cortex. It also decreased the rate of dissociation of [3H]NMS with an IC50 of 0.9 μM and a maximal inhibition of 60%. No significant difference was observed between its effects in cerebral cortex and heart. MBP also inhibited [3H]NMS binding at equilibrium in a concentration-dependent manner with a lower n value (3.5 in cortex and 1.9 in heart). Maximal inhibition of specific [3H]NMS binding by MBP was reduced from 45% to 16% by increasing the concentration of [3H]NMS from 0.04 nM to 0.8 μM. The allosteric nature of MBP was also demonstrated in kinetic studies. The small basic peptide dynorphin A also exerted an allosteric effect on muscarinic receptor which was dependent on the number of basic residues. Our data suggest that positively charged amino acid residues in endogenous proteins might play a role in the regulation of the conformation of muscarinic receptors.

481.15 PHOSPHATIDYLCHOLINE-SPECIFIC PHOSPHOLIPASE D IS COUPLED TO RECEPTOR OCCUPANCY IN A9 CELLS TRANSFECTED WITH THE M3-MUSCARINIC RECEPTOR. P.G. Holbrook, J. Wendt and C.C. Felder, NIMH and NINDS, National Institute of Health, Bethesda, MD 20892. In the presence of ethanol, phospholipase D (PLD) catalyzes a transphosphatidylation reaction producing phosphatidyl-ethanol (PEI). PEI formed in A9 cells stably transfected with the rat m3 muscarinic coupled with carbachol (1mM) was isolated and analyzed by fast atom bombardment mass spectrometry. It had a molecular species profile identical to that of phosphatidylcholine (PC) from unstimulated cells. In cells labeled overnight in serum free media containing [3H]-palmitic acid and [3H]-PEI the stimulated formation of [3H]-PET required extracellular calcium (1mM) and was blocked by atropine (10 μM). TPA stimulated formation of [3H]-PET in the presence and in the absence of extracellular calcium. EC50 for carbachol stimulated [3H]-PET and [3H]-PA formation were respectively: 8.8 x 10^(-8) and 5.5 x 10^(-7) M. Experiments with receptor chimeras produced by switching the third cytoplasmic loops of the m3 and m2 receptors suggest that g-protein coupling is necessary for PLD-activation. Occupancy of muscarinic receptor subtypes that couple to PLC-specific PLC leads also to activation of a PC-specific PLC.

481.16 DIFFERENCES IN CARBACHOL BINDING AND PI TURNOVER BETWEEN THE DORSAL AND VENTRAL HIPPOCAMPUS. H. Ladinsky1, A. Garcia1, M. Zambelli1, G. Schiavi2, and S. Consolo2. Department of Biochemistry, Fondazione IRCCS Ospedale Maggiore Policlinico, Italy; Milan 20139 and Mario Negri Institute, Milan, Italy 20157. The full agonist CARB was more effective in stimulating PI turnover in the ventral (VH) than in the dorsal hippocampus (DH) while the partial agonist oxotremorine was similarly weak in both regions. No differences in density or distribution (>20% M1, 50% M3, 30% M4) of muscarinic receptor subtypes between DH and VH were found to explain the effect using several selective antagonists in competition experiments. From the affinities of pirenzepine (Kd 6.1 nM; Kd 757 nM) and DAU 6202 (4-hydroxy-3-(tropol oxycarbonyl-3,4-dihydroxy-1H quinazolin-2-one)RB 2.5 nM) to antagonize CARB-stimulated PI turnover, it appeared that about 50% of the response was activated by M1 and the other 50% by M3 receptors in either region. In binding studies against [3H]NMS, CARB recognized three agonist affinity states (SH, H, and L) in the VH and two (H and L) in the DH. Gpp(NH)p converted the SH and H to the L state in both regions. Thus, regional differences in types or concentrations of G proteins may account for the complexity with which CARB binds to muscarinic receptors and stimulates PI turnover in the areas.

481.18 COMPARISONS BETWEEN HUMAN MUSCARINIC RECEPTOR SUBTYPES COUPLED TO PHOSPHOLIPASE C AND THOSE COUPLED TO ADENYLATE CYCLASE: EFFECT OF RECEPTOR RESERVE. L.L. Lauffer, R.D. Schwarz, R.B., and C.J. Spencer. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105. Muscarinic receptors have been shown to exist as five distinct proteins which are functionally coupled to G proteins to phospholipase C (m1, m3, and m4) and adenyl cyclase (m2 and m5). Stable elevation of human receptors in CHO cells yielded cell lines with Ba2+ values ranging from 210-2450 fmoles/mg protein and Kd values of 0.1-0.8 nM (whole cell [3H]NMS binding). The use of these lines has allowed the pharmacological characterization of selectivities of various muscarinic agonists and antagonists to be determined using receptor binding and second messenger assays. Previous results obtained using PI hydrolysis, showed that both efficacy and potency of muscarinic agonists were markedly affected by receptor number, while antagonist results were not. However, it was not known whether the effects occurred in cyclase linked receptors. In the present study, activation of Hm2 and Hm4 receptors was performed in order to determine the effect of receptor number on agonist/antagonist-induced changes in cAMP formation. These results are compared to those obtained measuring PI turnover under similar conditions in Hm1, Hm3, and Hm5 cells.
842.1

Glutamate neurotoxicity is a major problem in the pathophysiology of numerous neurodegenerative diseases, including Stroke, Huntington's disease and Alzheimer's disease. Glutamate-induced neurotoxicity is mediated by the influx of calcium, however the biochemical pathways subsequent to calcium influx are poorly understood. Therefore, it would be useful to specifically alter calcium activated processes. Our laboratory has previously described a HSV-1 vector system which is capable of introducing genes into mature neurons (Science 1991;251:428-430). We are exploiting this vector system to genetically alter signal transduction pathways to elucidate intracellular mechanisms mediating glutamate neurotoxicity. Our initial studies characterized the ability of the HSV vector system to deliver genes into cortical neurons which have been previously used to assess glutamate neurotoxicity (Hartley and Choi, JPET 250:752, 1989). The prototype vector pHSVlac expresses E.coli B-galactosidase from the constitutive HSV IE 3/5 promoter. Following infection of these cortical cultures with pHSVlac, B-galactosidase expression was readily detected in 30-50% of the neurons, as well as in glia cells. Because of the importance of calcium in mediating glutamate neurotoxicity, we are expressing genes that affect calcium mediated processes and assessing their ability to alter glutamate mediated neurotoxicity.

842.2

DELAYED ADMINISTRATION OF MEMANTINE (MTE) PREVENTS NMDA RECEPTOR-MEDIATED NEURONAL DEATH. James W. Pollegrini*, M. Vincent Chen, Frances E. Jensen. Depted of Neurology, Children's Hospital and Progr. in Neurosci., Harvard Medical School, Boston, MA 02115.

Increasing evidence indicates that excitatory amino acids are responsible for neuronal cell death in a variety of neurological conditions including hypoxia-ischemia. The predominant form of neurotoxicity of the NMDA receptor-activated current may be mediated by the NMDA receptor. Recently, using rat retinal ganglion cell (RGC) cultures, we found that the anti-Parkinsonian drug MTE blocks NMDA-activated current by a mechanism of open-channel blockade ([IC50 = 1 μM]). Here, using single channel recording, we demonstrate that 12 μM MTE reduced the frequency of NMDA-elicited channel opening by 87%, shortened the mean open time by 30%, but did not change the unitary channel conductance. We had previously shown that MTE prevents NMDA receptor-mediated neurotoxicity when administered coincident with the insult in vitro or in vivo. We have now tested whether delayed administration of MTE can prevent neurotoxicity. Cultured RGCs were exposed to toxic (25 μM) glutamate levels in high Ca/low Mg medium and compared with control cells. By the next day, this insult resulted in neuronal survival of 35%. In sibling cultures, MTE (12 μM) was added at 0-7 h after glutamate exposure. Survival at 24 h was close to control levels when MTE had been administered at 0 or 1 h, and approached 80% after treatment at 4 h. Presently, we are using 7-10 day old Long-Evans rats in a bilateral carotid ligation stroke model. In 7/11 litter-matched pairs, animals treated 1 h after insult with MTE (20 mg/kg) had substantially smaller strokes by MRI and histopathology after 48 h.
482.5

A SHORT EPISODE OF SEIZURE ACTIVITY PROTECTS CA3 NEURONS FROM PROLONGED SEIZURE ACTIVITY-INDUCED DEATH.

I. Najeeb, S.S. Schreiber, A. Bruce, G. Tooco, and M. Baudry, Neurosciences Program, USC, Los Angeles, CA 90089-2520.

Systemic administration of kainic acid (KA) produces recurrent seizure activity and the loss of selectively vulnerable neuronal populations, in particular pyramidal CA3 neurons. We investigated the effects of a short episode of seizure activity on CA3 neuronal death following subsequent prolonged seizure activity. One group of adult rats was subjected to 1 hr of KA-induced seizure activity which was terminated by pentobarbital anesthesia, and treated again 16 hrs later with KA. Another group received KA twice at 16 hrs interval, while a third group received only one injection of KA at 16 hrs. No KA administration. Animals which were subjected to a short seizure episode exhibited a marked protection against delayed neuronal death in CA3 neurons resulting from a subsequent KA-induced episode of seizure activity. Histological examination of the brains of animals sacrificed 5 days after the last KA administration indicated a total absence of neuronal loss in CA3 as compared to animals which had been treated with one or two KA injections and which showed extensive neuronal loss. Immunocytochemistry of heat shock protein 72 (HSP72) performed 16 hrs after a short episode of seizure activity indicated that this period was sufficient to cause an increase of HSP72 in CA3 pyramidal cells suggesting that HSP72 could participate in the neuronal protection observed under these conditions. This phenomenon of “seizure tolerance” might therefore be viewed as an analog of the phenomenon of “ischemic tolerance” described in the brain.

482.7

SELECTIVE ANTAGONISM OF JORO SPIDER TOXIN (JSTX) AGAINST QUISQUALATE (QUIS)-INDUCED LESION IN THE HIPPOCAMPUS.

QUIS, a non-NMDA agonist, is known to provoke seizures with a selective cell loss in the hippocampus, indicating a useful neurotoxin for a specific experimental model of epilepsy. We reported that a JSTX analogue, 1-naphthylacetylspermine (1-NA-Spm), exerts a potent and selective suppression of hippocampal epileptic discharges induced by QUIS (Brain Res., in press).

The present study was conducted to evaluate whether 1-NA-Spm selectively antagonized against histological changes induced by QUIS as well. Male Wistar rats were injected icv with 1-NA-Spm followed by either QUIS or quisqualate (QUIN), a NMDA agonist. After behavioral changes were observed, the animals were subjected to histological examination. QUIS (30μg) resulted in the loss of CA3 pyramidal cells in the injection side, which was completely blocked by 1-NA-Spm (50 μg) pretreatment. Contra-lateral side remained intact irrespective of the history of repetitive seizures. JSTX analogue alone (80 μg) had virtually no effect on the cellular architecture in the hippocampus. QUIN (30 μg) induced CA1/4 lesion which was refractory to JSTX pretreatment. In several rats, JSTX appeared to exacerbate QUIN-induced changes.

482.8

LOW POTENCY OF COMPETITIVE NMDA ANTAGONISTS AGAINST GLUTAMATE NEUROTOXICITY DUE TO ASTROCYTE UPTAKE.

A puzzling feature of the pharmacology of glutamate neurotoxicity is the low potency of competitive NMDA antagonists compared to what would be expected on the basis of radioligand binding studies. These experiments were performed in order to examine the role of glutamate uptake in determining the apparent pharmacology of competitive antagonists in tissue culture models of glutamate neurotoxicity.

The potencies of APV against the transported agonist glutamate and the non-transported agonist NMDA in astrocyte-rich and astrocyte-poor cortical cultures were determined. Both antagonists were used at approximately 5 times their EC50. The IC50 of APV against glutamate (1mM) in astrocyte-rich cultures was approximately 1500 μM compared to 25 μM against NMDA (200 μM). The difference in potency disappeared in astrocyte-poor cultures in which the IC50 for APV against both glutamate (20 μM) and NMDA (200 μM) was 60-70 μM.

These results are best explained by a model in which glutamate uptake plays an important role, and in which toxicity at the dendrite and at the cell body can be differentiated.

482.9

PICOLINIC ACID MODULATES KAINIC ACID INDUCED GLUTamate RELEASE FROM RAT STRIATAL SLICES.

L.C. Vrooan, M. Pacaud, D. Desaix, and B. Bading. Department of Pharmacology and Toxicology, Queen’s University, Kingston, Ontario, Canada, K7L 3N6.

Picolinic acid (PICA), a pyridine monocarboxylic acid and metabolite of tryptophan, protects neurons from excitotoxic damage that is dependent on the presence of intact glutamergic input. It is hypothesized that PICA may produce its effect by inhibiting glutamate (Glu) release. In the present study, we examined the effect of PICA on KA-induced Glu release (1 μM) induced Glu release from rat striatal slices. Endogenous Glu release was analyzed by HPLC with fluorescence detection. A dose response relationship was observed for the inhibition of the KA-induced Glu release by PICA. PICA (100 μM) was found to significantly inhibit KA-induced Glu release by 65%, an effect similar to that produced by the selective non-NMDA receptor antagonist DRCX (500 μM). PIC inhibited the calcium dependent component of releasable Glu. Nicotinic acid and icotinic acid, two structural analogues of PIC, showed similar profiles. PICA alone was found to significantly increase basal release of Glu by 44%. These results suggest that PIC has a stimulatory as well as an inhibitory action on striatal Glu release.

AMANTADINE INHIBITS EXCITOTOXICITY IN CEREBROSPINAL FLUIDS
H.S. Lustig, K.J. von Braunschwich & J. Chen and D.A. Greeneberg,
Department of Neurology, University of California, San Francisco, CA 94110.

Excitatory amino acids (EAAs) have been implicated in the pathogenesis of acute and chronic neurodegenerative processes, and
EAAs antagonists are potent against excitotoxicity in a variety of in vivo and in vitro disease models. Certain antiparkinsonian
drugs, including amantadine, inhibit EAA responses mediated through N-
methyL-D-aspartate (NMDA)-gating EAA receptors and compete for
(P)MK-801 binding sites on NMDA receptor-gated ion channels.
Therefore, such drugs might not only reduce parkinsonian symptoms, but also modify neurodegeneration. Using neuron-enriched cultures
from embryonic rat cerebral cortex, we investigated the effect of amantadine on NMDA-induced toxicity, determined by lactate
dehydrogenase (LDH) release, and on NMDA-stimulated elevation of intracellular Ca2+ (Ca2+). Measured by fluorescence video imaging
with fura-2, LDH release from control cultures (25±2% of total LDH) was unaffected by amantadine alone at concentrations as high as
300 μM (231%). LDH release, measured 24 hr after exposure for 20 min to 100 μM NMDA, was increased to 46±3%. Pretreatment for 10 min with amantadine (10-1000 μM) inhibited the toxicity of 100 μM NMDA, with half-maximal inhibition at 30 μM and complete inhibition at 300 μM. Amantadine (100 μM) also reduced the rise in
Ca2+ produced by NMDA. These findings indicate that amantadine and other antiparkinsonian drugs with NMDA receptor antagonist
properties may protect against excitotoxic neuronal injury.

482.12

7-Chlorokyurenic acid (7-C1-KYNA), a selective antagonist of the glycine site associated with the NMDA receptor, is neuroprotective in experimental test systems. Since the compound penetrates poorly into the brain, it is difficult to explore its therapeutic potential for excitotoxic brain diseases. We have now examined if 4-chloro-
kyurenic (4-C1-KYNA), which should have easier access to the brain, can serve as a bioprecursor of 7-C1-KYNA. Cerebral cortex
extracts, incubated with [ring-13C]alanine and NADPH-diaphorase, were prepared from rat and human brain. Enzymatic production of the latter
was confirmed in all cases. In kinetic experiments with rat KAT, 4-C1-KYNA behaved like an effective competitive inhibitor, thus further
indicating its ability to serve as a substrate of KAT. Preliminary evidence suggests that conversion of 4-C1-KYNA to 7-C1-KYNA can also take place in the rat brain in vivo. Since (rat) brain KAT is predominantly localized in astrocytes which are often seen in
position to exocytotic edema, 4-C1-KYNA utilization may provide a means to produce 7-C1-KYNA in astrocytes in anatomicallly
distinct and pharmacologically relevant foci. Supported by grants NS 16102 and NS 28236 (to RS).

482.13

EXCITOTOXIC HIPPOCAMPAL DAMAGE AND NEUROPROTECTIVE AGENTS.

Glutamate agonists, such as quisqualate, kainate, N-methyl-D-aspartate (NMDA), quisqualate, and AMPA were injected intracerebroventricularly in rats to induce convulsive reactions and hippocampal damage in order to model glutamate-mediated brain injury. Animals showed typical convulsive effects and heavy lesions of hippocampal
region. In rats treated systemically with non-competitive glutamate agonists magnesium sulfate, MK 801, ketamine, or the adamanate derivative nembutal, a reduction in neuropathological signs was observed. Depen-
ding on the dose and the application schedule even complete protection was observed. Factors of the glutamate transmitter mechanism were found to be affected in lesioned areas, most prominent the activity of aspartate
aminotransferase. The vulnerability of neurons containing nitric oxide synthase (NADPH-diaphoresis stained) was observed to be related to the type of glutamate agonist used as a noxious stimulus.

482.14

REPEATED EXPOSURE TO GLUTAMATE ALTERS BOTH ITS POTENCY AND EFFICACY AS AN EXCITOTOXIN. J.M. Dubinsky.
Department of Physiology, University of Texas Health Science Center, San Antonio, Texas 78284-7756.

Transient increases in extracellular glutamate (GLU), associated with ischemic events in vivo, are thought to contribute to the eventual neuronal loss observed several days later. One hypothesis explaining this delayed excitotoxicity states that normal synaptic release of GLU becomes toxic following the initial ischemic event. To test this hypothesis, in vitro toxicity experiments were
performed on cultured hippocampal neurons experiencing two successive GLU insults. In the first toxic exposure, all cultures received 5 min of mild toxic concentrations of GLU. Dose-response curves for the percentage of surviving neurons were constructed for varying doses of GLU applied during the second 5
min exposure, 2 hr after the first. Control dose-response curves following simple solution changes as a first exposure were
characterized by an EC50 of 0.162 μM. GLU was used as the first exposure, the EC50 for the second exposure dropped slightly to 49 μM. When 100μM GLU was applied during the first exposure, the EC50 decreased to less than 5 μM. However, the amount of survival in both experiments was greater than expected from the control dose-response curve. The increase in both efficacy and potency indicate complex interactions may be involved in understanding GLU toxicity following an ischemic event. This work was supported by NIH #AG10034.

AGE DEPENDENCY OF NMDA ANTAGONIST NEUROTOXICITY
Barber, MT, Price, J, Luhovyy, TA Fuller* and JW Olney, Washington Univ., St. Louis MO 63110.

Antagonists of the NMDA subtype of glutamate receptor, including phencyclidine (PCP), MK-801 and ketamine, protect neurons against excitotoxic injury in conditions such as ischemia, hypoglycemia and status epilepticus. However, in rats these agents modulate neurotoxic side effects (pathomorphological changes in cerebrocortical neurons), and in humans, both PCP and ketamine are known to cause acute schizophrenia-like psychotic symptoms. The neurotoxic reaction associated with ketamine anesthesia, known as an "emergence" reaction, is suppressed by certain drugs (barbiturates and benzodiazepines) that also block the neurotoxic reaction in rat cortex, suggesting a relationship between the neurotoxic and psychotomimetic actions of these agents. The ketamine "emergence" reaction, like schizophrenia, is peculiarly age-dependent—typically, susceptibility is greatest in early to mid adulthood, and pediatric populations are not vulnerable. Here we report that susceptibility to the cerebrocortical neurotoxic reaction is also age-dependent with rats being non-susceptible to MK-801 neurotoxicity at 1 month of age, weakly susceptible at 2 months and not fully susceptible until 3 months.

Thus, a similar age-dependency profile characterizes: 1) the neurotoxicity of NMDA antagonists in rats, 2) the psychotomimetic effects of NMDA antagonists in humans, and 3) schizophrenia psychosis, and susceptibility to other adult-onset neurological disorders. Our findings suggest the possibility that some or all of these phenomena may be mechanistically related, and that NMDA antagonists may be safer to use as anesthetics in infancy than in adulthood. CALPAIN I INHIBITION DOES NOT BLOCK EXCITATORY AMINO ACID-INDUCED NEUROTOXICITY IN MURINE CORTICAL CULTURES. V.M. Brown and R.G. Giftard, Dept. of Anesthesia, Stanford University, Sch. of Med., Stanford, CA 94305.

Activation of the Ca2+-dependent protease calpain I has been implicated in neuronal responses to excitatory amino acids in such diverse settings as long term potentiation and ischemic brain damage. Spectrin breakdown subsequent to Calpain I activation by increased intracellular calcium has been related to neuronal death, but reports of its involvement in the development of excitatory amino acid neurotoxicity have varied in different systems. We investigated the effect of Calpain I inhibitors in cortical cultures injured by exposure to maximal and submaximal concentrations of the glutamatergic excitatory amino acids (NMDA), kainate and AMPA. Injury was assessed by release of lactate dehydrogenase. We studied both calpain inhibitor I and MDL 28170 which has high specificity for calpain II, both up to 100μM. Neither inhibitor protected neurons from brief exposure to NMDA (100μM-500μM) or 24 hr exposure to NMDA (12.5μM-500μM), kainate (20μM-300μM) or AMPA (10μM-100μM). MDL 28170 has been shown to inhibit Ca2+ ionophore A23187-induced proteolysis of spectrin in erythrocyte ghosts. We then investigated the effect of the drug on A23187-induced toxicity in our cultures. Cells exposed to the ionophore for 20 minutes were moderately injured when assessed at 24 hr. MDL 28170 reduced the neuronal damage by about 30%. Activation of calpain I does not appear to be a major source of injury in excitatory amino acid-induced neurotoxicity in neocortical cultures. Sponsored in part by NS 01425.

L-trans-2,4-pyrrolidine dicarboxylic acid (L-PDC), an Inhibitor of High Affinity Glutamate Uptake (HAGU), is Neuotopic in Neonatal Rat Brain. John E. Barber* and Faye S. Silverstein, University of Michigan, Departments of Pediatrics and Neurology, Ann Arbor, MI 48109.

Strong evidence of the neurototoxicity of endogenous glutamate (GLU) in mammalian brain was provided by the observation that DL-threo-3-hydroxyaspartate (THA), an HAGU inhibitor, was neurotoxic in the dorsal rhomboid striatum ([Neurochem 44:247]), however, THA did not elicit neuropathologic changes in the developing brain. The absence of injury was interpreted as evidence that immaturity of gluatamatergic innervation limited the potential toxicity of endogenous GLU at this developmental stage. Yet, the specific mechanism for the hypothesis that endogenous GLU can be neurotoxic in the developing brain. To address this issue, we assessed the neurotoxicity of the selective HAGU inhibitor L-PDC ([Med Chem 34:717]) in 7 day old rats. L-PDC (75 μM) was injected into right anterior striatum (STR) (568 nmol, n=2) or through dorsal hippocampus into posterior STR (568 nmol, n=4, 150 nmol, n=2). Neuropathology was assessed in animals killed 5 days later. After anterior injections, focal neuronal necrosis was evident in dorsal STR. High-dose posterior injections caused prominent hippocampal lesions with CA1.3 pyramidal layer thinning and focal necroses in dorsal thalamus. Small foci of pyramidal cell loss. Focal cortical necroses and caudal cysts were apparent adjacent to the injection track. Preliminary autoradiographic 3H-GLU binding assays were also done; L-PDC (10 μM or 50 μM) did not displace 3H-GLU, suggesting that L-PDC lacked intrinsic agonist properties. Thus, L-PDC-induced brain injury provides direct support for the hypothesis that endogenous GLU may be neurotoxic in the developing brain.

DISCOVERY OF A HIGH AFFINITY, SODIUM-DEPENDENT L-PROLINE TRANSPORTER EXPRESSED IN SUBPOPULATIONS OF PUTATIVE GLUTAMERGIC NEURONS.

We have used PGP with degenerate oligonucleotides derived from two conserved regions of the norepinephrine and GABA transporters to identify novel sodium-dependent carrier in brain. One PCR product hybridized to a 4 kb RNA concentrated in subpopulations of putative glutamatergic neurons. Prominent in this localization signals were observed over cortical cells of the olfactory bulb, pyramidal cells of layer V of the cerebral cortex, pyramidal cells of the piriform cortex, and pyramidal cells of field CA3 of the hippocampus. In contrast, background labeling was observed over granule cells of the dentate gyrus, caudate-putamen, white matter tracts, facial plexus, and ependymal cells of the cerebral ventricles. Transient expression of the gluta-1 cDNA constructs in sodium-dependent, high affinity (Km=9.7 μM) L-proline uptake in Hela cells which exhibited a pharmacological profile similar to that for high affinity L-proline transport in rat hypothalamus. The cloned transporter CTPD predicts a 637 amino acid protein with 12 putative transmembrane domains and exhibits 44-45% amino acid sequence identity with other members of the emerging family of neurotransmitter-sodiumdependent syperactive findings to high affinity L-proline in specific excitatory pathways in the CNS and provide the basis for a direct molecular analysis of the presynaptic components of these excitatory projections.

CHANGES OF pH DURING GLUTAMATE UPTAKE. M. Bonier*, M. Szatkowska, A. Amato and D. Archbishop, Dept of Physiology, University College London, Gower St, London WC1H 0BT, UK.

Uptake of glutamate into glial cells and neurons ultimately terminates the post-synaptic action of the neurotransmitter. The glutamate uptake carrier is known to be powered by the co-transport of an excess of Na+ ions (at least 2) and it also counter-transportes one K+ ion.

When L-glutamate or D-aspartate uptake was activated in whole-cell clamped Müller cells from the salamander, a pH sensitive electrode outside the cell detected an alkalization of the extracellular medium, and intracellular BCECF detected an internal acidification. Intracellular pH was not perturbed when cells were perfused with CI−, outside when stimulated with CI− inside the cell. These data suggest that a pH changing anion such as OH− or HCO3− is transported out of the cell by the uptake carrier and that CI− can be transported in place of this anion. Inhibition of carbonic anhydrase by acetazolamide had no effect on the intracellular acidification or the extracellular alkalization, suggesting that HCO3− is not counter-transported on the carrier.

We therefore propose an uptake stoichiometry in which one glutamate ion is transported into the cell together with 2 Na+ ions, and one K+ ion and one OH− are counter-transported, per cycle of the anion (Supported by the Wellcome Trust, M.R.C., and Science Plan of the European Community)

The glutamate-gated, linked mGluR1 and the ion-channel-complex of the NMDA receptor mediate slow and fast responses of neurons to glutamate, respectively. We find that both mGluR1 and NMDA receptors are widely distributed. However, in a number of brain regions, they occur in distinctly different neuronal populations.

For instance, mGluR1 predominates in the non-pyramidal neurons of the cerebral cortex, stratum oriens of CA1 and CA3 of the hippocampus, islands of Calleja, subthalamic nucleus, lateral hypothalamic area, and the ventricular layer of the cerebellum. In contrast, the NMDA receptor predominates in the pyramidal neurons of the cerebral cortex and the hippocampus, medium spiny neurons of the striatum, paraventricular nucleus of hypothalamus, and the granule cell layer of the cerebellum.

These findings, in combination with reports of the distribution of other glutamate receptors, suggest that while many neurons are equipped to mediate both slow and fast responses to glutamate, many others are specialized to have either a slow or fast response.

483.4 DISTRIBUTION AND MORPHOLOGY OF NEURONS EXPRESSING THE GLUR 2/3 SUBUNIT IN FOUR NEOCORTICAL AREAS OF MONKEYS. Francesco Conti* and Andrea Minelli. Institute of Human Physiology, University of Padua, Via Ranieri, 160031 Ascona (Italy).

In the last few years, several non-NMDA ionotropic glutamate (Glu) receptor subunits (Glur) have been cloned. Four of these, Glur 1-4 (or Glu A-D), have pharmacological properties of AMPA receptors and appear to form heterometamer receptor complexes. Recent data show that the Glur 2 subunit appears to be dominant in determining the properties of the receptor complex, since its presence is required for the "C"-type activity. Here we report the distribution and morphology of neurons expressing the Glur 2/3 subunit in four neocortical areas of the monkey brain as studied using a subunit-specific antibody produced and characterized in Dr. Wentholt's lab (Wentholt et al., J. Biol. Chem., 267: 501-507, 1992). Under deep barbiturate anaesthesia, animals were perfused transcardially with phosphate buffer followed by 4% paraformaldehyde, the brain was removed, and postfixed. Small blocks from the primary somatic sensory (areas 3a, 3b, 1, and 2), the primary visual (area 17), the primary motor (area 4) and the posterior parietal (area 5) cortices were cut on a Vibratome in 15-µm thick sections, and processed for Glur-ICC (Ab 25) using the ABC method. Immunostaining was present both on cell bodies (excluding the nucleus) and on the major dendrites, and in the neuropil (mostly on dendritic processes).The pattern of Glur 2/3-positive neurons was basically similar in the four areas studied and was characterized by the presence of numerous small and medium sized pyramidal neurons in layer II and upper layer III, sparse non-pyramidal neurons in layer lower III and in layer IV, and some pyramidal and non-pyramidal neurons in layers V-VI. Some differences were, however, present when comparing the four areas: the number of positive neurons in layer IV was highest in areas 17 and 5, whereas the number of pyramidal neurons in layers V-VI was highest in area 4. The identity of immunoneactive non-pyramidal neurons could not be determined at the light microscope, and experiments are in progress to define the ultrastructural features of these neurons.

483.5 EVIDENCE FOR GLUTAMATERGIC NONPYRAMIDAL NEURONS IN THE RAT HIPPOCAMPUS: GOLGI STAINING COMBINED WITH POSTEMBEDDING IMMUNOCYTOCHEMISTRY. E. Soriguera*, H.-D. Hoffmann* and M. Frotscher*, †-Unit of Cell Biology, Faculty of Biology, Univ. Barcelona, Spain 08028; †-Inst. Anat., Univ. Freiburg, D-7800 Freiburg, FRG.

Nonpyramidal neurons of the hippocampus are known to be inhibitory using GABA as a neurotransmitter. They control the principal cells, granule cells and pyramidal neurons, which are excitatory. By using postembedding immunocytochemistry in combination with Golgi staining, we provide evidence here that at least two types of nonpyramidal neurons in the rat hippocampus use glutamate as transmitter.

Many cells in the hilus and a novel type of spiny nonpyramidal cell in the mossy fiber projection zone of CA3 were Golgi-stained, gold-toned, and processed for postembedding immunocytochemistry using glutamate and GABA antibodies. At the electron microscopic level, both cell types were seen to receive many inputs from the mossy fibers. When adjacent sections through the cell body region of Golgi-stained neurons were immunostained, both cell types reacted for glutamate, like the pyramidal and granule cells, but did not stain for GABA. In contrast, many other local circuit neurons were GABA-positive but could not be immunostained with the glutamate antibody. Exclusory glutamatergic nonpyramidal cells that are integrated in the main excitatory pathway of the hippocampal circuit may play a hitherto underestimated role in hippocampal circuitry. (Supported by the DFG: Fr 620/1-5 and FIS 991262-2)

483.6 PHOSPHATE-ACTIVATED GLUTAMINASE mRNA EXPRESSION IN RAT SPINAL CORD. B. Styrivasaas* and K.E. Miller. Dept. Anatomical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

Phosphate-activated glutaminase (PAG) is the enzyme responsible for converting glutamine to glutamate in glutaamatergic and GABAergic neurons. We have examined PAG mRNA in rat spinal cord using RNA blots and in situ hybridization. Spinal cords, kidneys, and brains from normal rats and total RNA was extracted, and slot blots were prepared. 32P-labelled PAG cDNA (ATCC: BamH I, EcoRI) was used to probe RNA blots. PAG mRNA was expressed in spinal cord similar to brain and kidney. To localize PAG mRNA to neurons, in situ hybridization was performed on sections from cervical, thoracic, and lumbar spinal cord and dorsal root ganglia (DRG). 32P-labelled PAG cDNA was used for autoradiographic localization and digoxigenin-labelled PAG cDNA or 20mer PAG oligoprobes were used for nonradioactive localization. In the DRG, most neurons were labelled. In addition to intensely labelled motor neurons, other labelled spinal neurons were found in the intermediolateral cell column, lateral spinal and cervical nuclei, marginal zone, substantia gelatinosa, and central gray region (lamina X). The results from this study indicate that PAG mRNA is expressed in specific neurons of rat DRG and spinal cord, including some neurons not previously considered glutamatergic or GABAergic. Supported by NS27213 (KEM).

483.7 THREE SUBPOPULATIONS OF CORTICAL GABAERGIC INTRINSIC NEURONS IN THE RAT. Y. Kubota* and P.G. Jones Laboratory for Neural Systems, Frontier Research Program, RIKEN, Wako, Saitama 351-01, Japan and Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Recent studies have revealed that the cortical GABAergic neurons contain a wide variety of other neuroactive substances and specific calcium binding proteins. In this study we demonstrated the subpopulations of GABAergic neurons in different cortical area of the rat with double immunohistochemical methods. In all areas of the seocortex, intrinsic GABAergic neurons are subdivided into at least three types based on the selective colocalization of parvalbumin, cabindin D 28kd or choline acetyltransferase (ChAT). All cabindin D 28 kd/GABA immunoreactive cells show somatostatin immunoreactivity and a small number of cabindin D 28kd containing cells also show neuropeptide Y immunoreactivity and NADPH-diaphorase staining. All ChAT/GABA immunoreactive cells also show VIP immunoreactivity. In the piriform cortex and entorhinal cortex, these three subpopulations of neurons have slightly different characteristics. GABAergic parvalbumin containing neurons always contain cabindin D 28kd but about half the cabindin D 28kd containing neurons do not show parvalbumin immunoreactivity.

483.8 GLUTAMATE, GABA AND SUBSTANCE P IN THE PARAVENTRICULAR NUCLEUS OF THE THALAMUS (PV): AN IMMUNOELECTRON MICROSCOPIC STUDY IN THE RAT. G. Balercia, S. De Biasi*, A. Ambrosi* and M. Benussi. University of Verona. Italy and Department of General Physiology and Biochemistry, University of Milan, Italy.

PV is part of the midline group of thalamic nuclei and its synaptic organization and neurochemical features are still largely unknown. Immunopositivity for GABA and glutamate (Glu) in the rat PV was here revealed by a post-embedding immunogold procedure, and that for substance P(SP) by a pre-embedding method, using polyclonal antiser. Glu, GABA, SP-immunopositive (IR) terminals were observed whereas only Glu-immunopositivity was also detected in neuronal perikarya, thus confirming the extrinsic origin of the GABAergic and Spergic innervation of the rat PV. Glu-IR terminals contain round clear vesicles and occasionally large granular ones; they make asymmetric synaptic contacts with proximal and distal dendritic arborizations. GABA-immunolabeling is in small to medium-sized terminals that contain clear pleomorphic vesicles and make symmetric synapses on dendrites of different caliber and frequently on cell bodies; some of them also contain several large granular ones. Sp-IR arborizations are present in small, dome-shaped terminals contacting distal dendrites, and in medium- to large-sized terminals contacting proximal dendrites and their spines. SP-IR axon terminals containing clear and contain round clear vesicles and a variable number of large granular vesicles. Supported by NIH NS27872 and Italian CNR and MURST.
483.9

GLUTAMATE-IMMUNOREACTIVE CLIMBING FIBERS IN THE RAT CEREBELLAR GLAIR CORTEX. P. G. Glende, F. C. Oertig, L. Hennequet, J. Gondra and P. Stress. Dept. of Neuroscience, Basque Country University, E-48080 Bilbao; 1Insttitut für Hirnforschung, University of Zürich, CH-8029 Zürich.

The nature of the climbing fiber transmitter is still a matter of debate. To determine whether glutamate-immunoreactive profiles with neurobiological characteristics of climbing fibers could be found in the rat cerebellar cortex, an immunocytochemical study was performed at the levels of light (LM) and electron microscopy (EM). A monoclonal 'anti-glutamate' antibody was used in combination with postembbeding staining. At the LM level, strongly labeled fibrous profiles and chains of interconnected varicosities appeared, often in close apposition to principal Purkinje cell dendrites. In EM preparations, some immunoreactive presynaptic elements were varicosities and elongated profiles that were 3-4 times more heavily labeled than their post-synaptic partners. These results show that a subset of climbing fibers and their terminals contain relatively high levels of glutamate-like immunoreactivity and provide additional evidence for a role of glutamate as transmitter in these cerebellar afferents. Supported by Proyecto del Gobierno Vasco grant 9108, DGICYT grant PB91-0087 and Swiss National Foundation grant 31-27822-89.

483.11

As part of a broader investigation we tested whether terminals of large fibers mediating low-threshold cutaneous input are enriched in glutamate or aspartate. Four to 7 days after injection of HRP conjugated to B subunit of cholera toxin in the sciatic a., rats were perfused with 2.5% glutaraldehyde/0.5% paraformaldehyde/0.1% picric acid. Vibration sections of lumbar spinal segments were cut, reacted for TMB and embedded in plastic. Blocks from lamina I were cut out; thin sections were stained with glutamate and aspartate antisera separately or in combination using different sizes of gold particles. Quantitative EM methods were employed to compare the density of gold particles coding for either antiserum in labeled terminals. To help define background, sections were also stained for GABA.

Mean staining level for glutamate was above background in primary afferent terminals in lamina IV compared with staining in dendrites, glia and GABA-positive terminals. Staining for aspartate was only marginally higher than background in afferent terminals and was elevated in dendrites as well. Density of staining for both amino acids in primary afferent terminals in lamina IV was lower than that in terminals of primary (unmyelinated and small myelinated) fibers in lamina II (Phenax et al., Neurosci. Abst.1991).

483.12

We have previously observed GLU neurons and processes in the ventrolateral subnucleus of the tractus solitarius (VNTS) using light microscopy. In this study, we have attempted to define the types of immunoreactive profiles which are found in the VNTS. Adult mongrel cats were anesthetized and perfused through the descending aorta with a combination of 4% paraformaldehyde and 0.2% glutaraldehyde. Vibratome sections were processed by an avidin-biotin based immunoperoxidase method utilizing a mouse anti-glutamate antisera (IMSTAR). We have observed several small GLU perikarya with a large invaginated nucleus and a thin rim of immunoreactive cytoplasm. In addition, we have seen a few large GLU neurons with similar characteristics. Numerous large GLU dendrites receiving primarily asymmetric synapses from unlabelled nerve terminals were also seen. GLU axons were observed and unmyelinated. As yet, we have not observed any GLU nerve terminals in the VNTS. These data suggest that some of the inspiratory neurons which predominate in the DRG utilize glutamate as an excitatory neurotransmitter, however, as yet the data do not indicate a role for glutamatergic nerve terminals in the regulation of the activity of DRG neurons. Supported by NIH HL 1RO1-44822 and the American Heart Association.

483.13

GLUTAMATE AND ASPARTEATE IMMUNOREACTIVITY IN CORtical STROTRAL NEURONS OF THE RAT - B. Glutamata* - Ist. Fisiologia umana, University of Catania, I-95125, Catania ITALY.

The aim of the present work was to test whether cortical neurons are immunostained by antisera raised in rabbits against glutamate and aspartate conjugated to hemocyanin by glutaraldehyde (Hepler et al., J. Histochem. Cytochem., 1988, 36: 13-22). Corticostriatal neurons were identified by the retrograde transport of a tracer (colloidal gold-labeled WGA-apoHRP; Basbaum and Menétrey, J. Comp. Neurol., 1987, 261: 306-318) pressure-injected in the caudate-putamen; antisera were visualized by peroxidase immunocytochemistry using the ABC method. The bulk of corticostriatal neurons was observed in layer V of frontal and parietal areas, mainly in the ipsilateral hemisphere. In a sample of 1019 corticostriatal neurons in sections processed for Glu-antiserum, 595 (or 59%) were immunostained; in a sample of 1470 corticostriatal neurons in sections processed for Asp-antiserum, 837 (or 57%) were immunostained. Since it has been previously demonstrated that the two antisera largely reveal distinct populations of cortical neurons, results obtained combining Glu- and Asp-immunocytochemistry indicate that the entire population of corticostriatal neurons contains elevated concentrations of Glu or Asp in their cell body.

483.14

The nucleus raphe pallidus (NRP) has been described to evoke, upon electrical stimulation, a rapid depolarization and action potential discharges in cat hindlimb motoneurons of both flexor and extensor origins (Fung and Barnes, 1989, Neuroscience, 20: 183-190). We sought to uncover two fundamental questions pertaining to such findings: (1) whether the motor excitation is caused by rapheospinal neurons or other descending systems traversing through or adjacent to the medullary sites of stimulation; (2) is the fast, excitatory glutamatergic (Glu) neurotransmitter involved in the bulbospinal excitation of hindlimb motoneurons?

Using the simultaneous, dual (Glu and serotonin) immunofluorescence method in combination with retrogradetract-tracing technique (by unilaterally injecting FITC- labeled microspheres to L7 ventral horn), spatially projecting neurons arising from NRP and nucleus raphe obscurus (NRO) were frequently found to be found in L7 of either or both anterograde, with more triple-labeled compared to double-labeled cells. Electrical stimuli (4 pulses of 50 μA duration, 50 10-15 μA stimulation, 90-190 μs) applied to these medullary sites, in decerebrate cats, potentiated the L7 monosynaptic reflex (MSR). That the NRO or NRP neurons (instead of adjacent fiber systems) were the main source of the MSR enhancement was confirmed by a simultaneous recordings of the MSR upon chemically stimulating these rapheospinal neurons with 0.2-0.5 μl of 5.0 M glutamate. Microinjections of the vehicle to the same sites with glutamate showed no changes on the ventral root responses. These data support a role of glutamate in rapheospinally induced excitation of lumbar cord somatomotor outflow in cats.

483.15

Glutamate (Glu) is considered to be a major excitatory neurotransmit-
ter in the central nervous system. Previously reported presence of Glu-like immunoreactivity (Glu-IR) is not observed in the rodent catalcholaminergic nocu-
locus coeruleus (LC) raises two questions: (1) Are there any Glu-IR neurons in the catalcholaminergic/clopisynetic system of the cat? (2) What is the physiologi-
ical role, if any, of Glu in LC control of spinal motoneurons?

In this study we used simultaneous immunofluorescence technique to iden-
tify tyrosine hydroxylase (TH) and Glu immunoreactivities in neurons that were retrogradely labeled by viral (L7 ventral horn) injections of
flourescent microspheres (Zhou et al., 1992, J. Chem. Neuroanat. 5:1-10). We found a widespread association between Glu and TH in most (>80%) de-
sorbing neurons and they were distributed randomly throughout the
nocrocardial extent of the LC complex. Electrical stimulation (4 pulses of 50
an d d t 1 00 Hz, intensity = 50-200 uA) of the LC complex, in
decerebrate cats, consistently induced L7 motoneuron discharges recordable
(isually as ventrol root responses. The LC evoked ventral root re-
sponses were reversely reduced (>50%) upon intraperitoneal injections of
the non-NMDA antagonist CNQX (in a total of 4 pere trial along the vent-
ral cone, each penetration consisted of 2 injections of 5 ng/0.2 uL).

Vehicle injections were without any significant effect on the LC evoked
ventral root responses. These results suggest that Glu has a pivotal role in
mediating coeruleosympathetic excitation of lumbar motoneurons in cats.

484.1 DISTRIBUTION OF THE NMDA RECEPTOR ANTAGONISTS [3H]C-
GCS 19755 AND [3H]MK-801 AFTER INTRACRANIAL INJECTION

The tissue distribution of [3H]C-GCS 19755 and [3H]MK-801 was in-
vestigated for up to 6 h after single lumbar spinal i.t. injection. [3H]C-
GCS 19755 distributed slowly from its injection site towards
brainstem and cortex. In the cortex, the radioactivity peaking 3-4 h after
injection. At no time did the level in frontal cortex exceed 10
% of the level in lumbar spinal cord. The highest peripheral level of
[3H]C-GCS 19755 was found in kidneys. [3H]MK-801 redistributed
rapidly from the spinal cord injection site to peripheral organs. The
highest peripheral levels of [3H]MK-801 were found in lungs and liver,
where the radioactivity peaked between 10 and 30 min after the
injection. The levels of [3H]C-GCS 19755 were consistently higher in
CNS tissues (except for the first 15 min in frontal cortex) and bleed
the corresponding levels of [3H]MK-801. The opposite relationship was
true in liver, lungs, kidneys, stomach, intestine, spleen and heart.

The effect of the latency in the hot plate test was quantified in the same animals immediately prior to sacrifice for
the distribution study. For the first hour after the injection, the
effect of CGS 19755 in the hot plate followed the temporal
distribution of this antagonist to the lumbar region of spinal cord.
MK-801 was substantially less effective in the hot plate test even at 100
times the effective equimolar dose of [3H]C-GCS 19755. The masked
difference in the distribution profile of [3H]MK-801 and [3H]C-GCS
19755 in the spinal cord does not appear to explain the lack of effect of
MK-801 in the hot plate test.

484.2 EFFECTS OF GLYCINE ON DIZOCYLIDINE-INDUCED CHANGES IN
ACOUSTIC STARTLE. R.S. Mambach. Dept. of Pharmacology &
Toxicology, Medical College of Virginia, Richmond, VA 23298-0619.

Dizocilpine significantly elevated startle magnitude and eliminated
prepulse inhibition, but glycine (17 and 56 mg/kg) and milcarnine (10-100 mg/kg)
had no effect. Moreover, administration of these compounds did not affect
changes in response magnitude and pre-pulse inhibition produced by
dizocilpine. A higher dose of glycine, 170 mg/kg, had no effect on startle
magnitude but in combination with dizocilpine killed 42% of the subjects
tested. Except for the lethal effects of glycine-dizocilpine combinations,
these preliminary results do not indicate that behavioral effects of NMDA
antagonists acting at the PCP receptor are modified by exogenous glycine.
Further work with glycine antagonists and selective agonists at the
strypnine-insensitive glycine binding site will explore other possible
interactions with PCP-like drugs. Supported by PHS grant MH-46631.

484.3 NOVEL ANALOGS OF DEXTROMETHORPHAN ANTAGONIZE NMDA

Dextromethorphan (DM) and its major metabolite
dextrorphan (DX) possess significant
anticonvulsant activity. We have previously reported on the anticonvulsant effects of a novel series of 3-substituted DM analogs to protect rats
against maximal electroshock-induced convulsions. To date, three analogs have been synthesized which are more potent anticonvulsants than DM. In
this study we explored the potential anticonvulsant nature of these DM analogs in a rat model of NMDA
(15 nM, i.c.v.) convulsions. Pretreatment with DM (20-80 μg, i.c.v.) delayed the onset to NMDA-
induced "popcorn" convulsions, whereas having little
or no effect on the incidence of convulsions. DX (2.5-
20 μg, i.c.v.) attenuated both latency and
incidence. Of the three analogs tested, the
ethyether derivative of DM, AHN0136 (20-80 μg,
mc), was the most potent anticonvulsant
exhibiting complete protection against NMDA
cconvulsions. The isopropyl ether and primary amine derivative were at least as potent as DM. These
results will be discussed relative to
receptor mechanism of action, behavioral
side effects and possible clinical usefulness.

484.4 CONANTOKIN PEPTIDE FROM CONUS GEOGRAPHUS
MODULATES [3H]NMDA-PERIDINE (TCP) BINDING TO THE
NMDA CHANNEL AND REDUCES NMDA RECEPTOR CURRENT.
L. L. Couplingour, D. M. Rock, C. Harchin, J. Hawley and G. W.
Campbell*, Parke-Davis Pharmaceutical Res. Div., Warner-Lambert
Co., Ann Arbor, Ml 48106-1047.

C. conatus (CT-G) is a seventeen amino-acid peptide extracted from the venom of the marine snail Conus geographicus. It previously
has been shown to interact with the NMDA subtype of glutamate
receptor. In well washed Triton-treated rat brain membranes the
binding of [3H]TCP was markedly enhanced upon the addition of
the NMDA channel agonist, glutamate and glycine. The maximal
enhancement caused by glycine (no added glutamate) was reduced in the presence of CT-G (2 εM). The maximal enhancement by glutamate
(no added glycine) was unaffected, but the concentration-response curve for glutamate enhancement was shifted to the right by CT-G. In
addition, CT-G did not affect the binding of [3H]AMPA or [3H]kainate
to non-NMDA receptors. This data suggests a selective effect on the
glycine site of the NMDA channel.

In cultured rat cortical neurons CT-G (2-20 εM) reduced the
amplitude of whole-cell NMDA receptor currents and the frequency of
NMDA-evoked single-channel openings in excited outside-out patch
clamp recordings. Inset of the reduction of whole-cell single-channel current by CT-G was slow, and the reductions were not readily
reversible.

EXCITATORY AMINO ACIDS: PHARMACOLOGY V

THURSDAY AM
484.5 KINETIC ANALYSIS OF NMDA MODULATORS ON [H]MK-801 BINDING. D.P. Carrozzi*, K. Williams and P.B. Molinoff, Dept. of Pharmacol., Univ. of Penn., Phila., PA 19104.

The NMDA receptor complex contains a distinct binding site for polyamines, including spermine, which enhance the binding of [H]MK-801, at a site within the ion channel. In the present studies, analysis of the kinetics of association of [H]MK-801 was used to investigate potential mechanisms of action of polyamines. Experiments were performed to determine whether specific modulators alter the conformation or dynamics of the receptor, which might be detected as an increase in the observed association rate (K_a). The observed association rates were biphasic in the presence of glutamate and spermine (g) or g plus spermine and were not altered by preincubation of membranes with these modulators before addition of [H]MK-801. This suggests a mechanism that involves a change in the duration of the open and closed states rather than a persistent change in the conformation of the receptor. In other experiments, the rates of association (fast and slow) were independent of the concentration of g plus spermine (30 μM), a condition which results in maximal changes in equilibrium binding. These results, which were an unexpected finding, suggest that the limiting factor of [H]MK-801 binding even under these conditions, involves access of ligand to its binding site. This phenomenon may involve changes in the dynamics of channel opening initiated by activation of the polyamine site (supported by USPHS grant GM47481 and NS30000).

484.6 DIAMINES INHIBIT NMDA RECEPTOR RESPONSES THROUGH A CHANNEL-BLOCKING MECHANISM. S. Subramaniam*, S.D. Donevan and M.A. Rogawski, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

It has been proposed that the inhibitory actions of the diamines diaminodiacetate (DA-10) and diaminodiacetate (DA-12) on NMDA-receptor responses is due to their actions as inverse agonists at the polyamine site. Recently, we and others have observed that the polyamines spermine and spermidine can block the NMDA receptor through an open channel mechanism. In this study we examined whether diamines could affect NMDA channels through a similar mechanism. In whole-cell recordings from cultured rat hippocampal neurons (V_m = -60 mV), the diamines inhibited NMDA currents in a concentration-dependent fashion. The efficacies of the diamines increased with increasing length of the carbon chain. Thus, DA-12, the longest diamine tested, was the most potent (IC_50 = 7 μM), whereas diaminopropene (DA-3), the shortest diamine tested, produced only partial inhibition (~70% at 10 mM). The blocking action of the polycationic diamines decreased at positive holding potentials supporting a channel blocking mechanism. In outside-out patches, DA-12 produced a flicker block of NMDA-induced single-channel currents whereas the shorter diamine putrescine (DA-4) produced an apparent reduction in channel amplitude. The ability to resolve flickering with DA-12 but not with the less potent shorter chain diamine DA-4 may reflect differences in binding kinetics but we cannot rule out the possibility of a distinct mechanism of block for the shorter diamines. These observations highlight the potential for using diamines as blockers of NMDA currents through an open channel mechanism, and therefore it may not be necessary to invoke inverse-agonist properties of these compounds to explain their inhibitory actions on NMDA receptor responses.

484.7 NEUROCHEMICAL TOLERANCE TO MK-801 (DIZOCILPINE) IN THE MOUSE. P.H. Hutson, I.J. Bristow, K. Flaitman, L. Thorn and M.D. Trickelburg, Merck Sharp and Dohme Research Laboratories, Neurosciences Research Centre, Terlings Park, Harlow, Essex CM3 2QQ, U.K.

In addition to anticonvulsant and neuroprotective effects, acute administration of the non-competitive NMDA receptor antagonist, MK-801 (dizocilpine) stimulates the turnover of dopamine in corticostriatal brain. We now show that chronic treatment with MK-801 decreases the neurochemical response to the compound in the nucleus accumbens, but not in the medial prefrontal cortex (mPFC).

Dihydroxyphenylacetic acid (DOPAC) was determined in mouse brain regions by HPLC and electrochemical detection. In mice killed 60 min after drug administration (15 mg/kg, s.c.) to minimize the concentration of DOPAC (mg/g tissue) by 60 and 85% in mouse nucleus accumbens and medial prefrontal cortex respectively (Table 1). Fatty eight hours after i.p. injection of 10 mg/kg MK-801, this same dose given 60 min before death again markedly increased DOPAC concentration in our medial prefrontal cortex (89%), but to a much reduced response in the nucleus accumbens (18%). Neither acute nor chronic drug treatment altered striatal DOPAC concentration.

Thus, mesolimbic and mesocortical dopaminergic neurons appear to be differentially affected by chronic treatment with MK-801.

484.8 IFENPRODIL SELECTIVELY POTENTIATES NMDA-INDUCED DEPOLARIZATIONS IN THE RAT CORTICAL WEDGE IN VITRO. P.L. Herring* and D.A. Lowe, Sandox Research Institute, P.O. Box,CH 3006 Bern, Switzerland.

Ifenprodil, an agent thought to interact with the polyamine site of the NMDA receptor (Cartier et al. Europ. J. Pharmacol. 164:611, 1989), was studied in cortical wedges as described by Lowe et al.(Neuro.Letters 113:315, 1990). Excitatory amino acids (EAAs) were added to ACSF perfused into the chamber containing the cortical layers. Effects were quantified by determining the area under the curve of EAA-induced depolarizations. In Mg2+-free ACSF Ifenprodil (10 to 1000μM) potentiated NMDA-induced depolarizations by 50 to 187% over controls (mean±SD: 97±52). This potentiating effect was not observed in ACSF containing 1mM [Mg2+] and was attenuated at 0.2 mM [Mg2+]. The potentiation was fully reversed by 5μM 7-chloro-kynurenic acid (7CI-KYAC). If the potentiation was established before 7CI-KYAC application it reapplied after washout of the antagonist. Depolarizations elicited by non-NMDA EAA agonists such as AMPA and quisqualate were not affected by Ifenprodil. The potentiating effect of Ifenprodil is therefore NMDA specific and the experiments with Mg2+ and 7CI-KYAC suggest a site of action deep within the NMDA operated channel.

Polyamines are known to modulate excitatory synaptic transmission mediated by N-methyl-D-aspartate (NMDA) receptor. We tested the effect of increased putrescine levels in transgenic mice line that overexpresses human ornithine decarboxylase on the spatial learning/memory and the epileptic seizure threshold. Concentrations of putrescine in the different brain areas of transgenic mice increased from undetectable (limit 5 μmol/g) to more than 60 μmol/g compared with their nontransgenic littermates. Contents of spermidine and spermine remained unchanged. Transgenic mice had impaired appetitive water maze learning test (expressed using task latency). Transgenic mice also increased seizure threshold to clonic phase of pentyleneetetrazol-induced seizures and to tonic phase of corneal electroshock convulsions. The effect against electroshock convulsions was potentiated when putrescine content was further increased in the levels of 5 μmol/g. These results suggest that putrescine may play an important role in the excitatory neurotransmission.

484.10 EFFICACY OF SYNTHETIC POLYAMINES IN MODULATING NMDA-MEDIATED INCREASES IN INTRACELLULAR CALCIUM. J.M. Fahy*, G.L. Pitchard, L.G. Miller. Dept. of Pharmacology and Experimental Therapeutics and Neuroscience Program, Tufts Univ. School of Medicine Boston, MA 02111.

The endogenous polyamines spermine and spermidine potentiates N-methyl-D-aspartate (NMDA) receptor ionophore-mediated events. We have previously shown that both spermine and spermidine are able to potentiate NMDA-mediated increases in intracellular calcium ([Ca2+]i) of cultured chick cortical neurons using the calcium sensitive fluorescent dye Fura2. The present study characteristics structurally related synthetic polyamines. IBPA (3,3’ imino-bis-propylene) and AEPD (N-(2-aminoethyl)-1,3 propanediamine) are triamines which differ from spermidine in the length of one aliphatic chain between central terminal amines. IBPA potentiated NMDA-mediated increases of [Ca2+]i at concentrations of 100 , 250, 500 and 1000 μM. Its effects at these concentrations were also approximately 40% greater than effects of spermine. AEPD produced an increase of [Ca2+]i only at1 mM. Diaminodiacetate(DA10) is a putative inverse agonist at the NMDA receptor ionophore and in this system decreases NMDA-mediated increases of [Ca2+]i. No other diamine tested(DAS-DAE) had a similar effect. Only DAS(cadaverine) at 1 mM significantly altered NMDA-mediated responses by increasing, not decreasing, [Ca2+]i. As previously reported, the effect of putrescine may predict the functional efficacy of a synthetic polyamine but it is strongly influenced by the properties of other sidechains.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

NMDA antagonists, such as MK-801, block induction of hippocampal long term potentiation (LTP) and impair the performance of rats on various behavioral tasks, especially acquisition of spatial learning/memory tasks. NMDA antagonists also produce neurotoxic side effects. Two hours after subcutaneous injection of a single low dose of MK-801, pathomorphological changes appeared in the hippocampal cortices. A neurochemical definitional receptor is implicated in this neuropathic reaction in that the reaction is blocked by certain antimuscarinic drugs, including scopolamine. Since this neurotoxic reaction occurs in the hippocampal cortices and not hippocampal neurons, the question arises whether the memory impairing effects of MK-801 might reflect a functional disruption by high sinapical neurons. In this case, scopolamine might block the memory-impairing action just as it blocks the neurotoxic action of MK-801 on cortical neurons. Using a hole board test and cross-over design, we found that MK-801 (0.05 mg/kg, i.p.) compared to scopolamine (0.025 mg/kg ip) or saline, significantly impaired the ability of male rats to learn a novel location after 4 hours a food reward. However, when scopolamine (0.025 mg/kg ip) was coadministered with MK-801 (0.05 mg/kg ip), rats performed like saline controls and better (marginally nonsignificant, p = .077) than MK-801-treated rats. Moreover, significantly more animals were unable to learn the task under the influence of MK-801 alone (7/23) compared to MK-801 + scopolamine (0/23). These findings suggest, contrary to popular assumption, that the locus of action of NMDA antagonists in causing a performance deficit in learning tasks may be the cortical rather than the hippocampal. If so, it may be necessary to reinterpret prior behavioral studies in which performance deficits in learning tests have been attributed either explicitly or implicitly to an action of the drug on LTP-like mechanisms. Supported by R01 MH 38894 (JWO), DA 05072, DA 06454 and AG 10561.

484.12 INTRACRANIAL INJECTION OF Dopamine IN A DENERVATED STRIATUM REVERSES CIRCLING INDUCED BY THE NMDA ANTAGONIST MK-801. J.A.St-Pierre, L.Giguere and P.J.Bédard, Centre de Recherche en Neurobiologie, Hôpital Ste-Justine, Laval University, Quebec City, Canada.

Cats were treated with 6-OHDA in the left medial forebrain bundle. Fifteen days later, they were tested with amphetamine (0.25mg/kg s.c.). Microinjections of different doses of dopamine (1, 25 or 50µg/µl) were performed by guide-cannula stereotactically into the striatum. Dopamine induced a contralateral circling response, in a dose-dependent manner, which was projected into the lesioned side. Similarly, microinjection of dopamine into the lesioned side followed by stereotactic injection of MK-801 (100 µg/µl) 20 minutes later, produced a contralateral circling response. However, this circling response persisted with 4 fold that of the circling induced by dopamine alone. As previously reported in unilateral lesioned rats, MK-801 alone, produce an ipsilateral circling response (Co-Pierre et al., Soc for Neurosci, 1991) whereas microinjection of dopamine combined with MK-801 reverses the circling elicited. Taken together, our results suggest that the potentiation seen in the present experiment cannot be explained by increased release of dopamine. In addition, the circling response induced by the suppression of the glutamatergic neurotransmission seems to be facilitated by dopamine receptor activation. Supported by MRC of Canada.

Three ionotropic receptors (NMDA, KA and AMPA) which bind L-glutamate are present in various CNS structures. However, their existence on mesocorticlimbic dopamine (DA) neurons is less clear. Information about the factors controlling the excitability of these neurons may provide some insight into the neurobiology of schizophrenia, and the reinforcing properties of drugs of abuse. In midbrain slices extracellular recordings were made from VTA DA neurons identified by location, pacemaker-like firing, a rate of < 5 spikes/s, and action potential durations > 2 ms. Superfusion with NMDA, KA and AMPA produced dose-dependent reversible excitations at all 52 neurons tested. The threshold for NMDA (N=17) activation was 1.3 µM, with 10 and 30 µM increasing rates by 1.7 and 3.0 spikes/s. The threshold for KA (N=25) was 300 nM-1 µM, with increases of 1.5 and 2.4 spikes/s occurring at 10 and 100 µM. AMPA (N=10) was the most potent excitant, with a threshold at 100 nM and increases of 3.4 spikes/s at 1 µM. Also, none of the agonists changed the firing pattern from regular to bunting activity. The effects of NMDA were antagonized by 30 µM CGS 19755, while KA and AMPA were selectively blocked by 10 and 1 µM NBQX. The antagonists did not affect spontaneous firing. These data indicate that the excitability of VTA neurons is under the influence of the three glutamate receptor subtypes with a rank order of potency of AMPA > kainate > NMDA.

Intracellular and extracellular recordings were obtained from SPN in neonate rat spinal cord slices. Focal electrical stimulation of the dorsal horn or lateral funiculus evoked an EPSP which was both voltage-dependent and potential-sustained over several action potentials. The EPSP was partly reduced by the selective NMDA receptor antagonists APV, CPP and MK801 and was completely abolished by the non-NMDA receptor antagonist CNQX. Superfusion of the selective EAA receptor agonists AMPA, kainate, quisqualate, NMDA and ACDF induced concentration-dependent depolarisations in all neurons tested. AMPA, kainate and NMDA-induced responses were blocked by a cocktail of both NMDA (APV, CPP or MK801) and non-NMDA (CNQX or DOPQ) antagonists, whereas responses to quisqualate and ACDF persisted. Depolarising responses to quisqualate and ACDF were associated with an increase in neuronal input resistance and decreased in amplitude with increased membrane hyperpolarisation. In a subpopulation of cells, quisqualate and ACDF induced oscillations in membrane potential which gave rise to rhythmic burst firing at higher agonist doses.

We conclude that both AMPA and NMDA subtypes of receptors mediate synaptic transmission in SPN. Glutamate can also act via a metabotropic receptor to excite SPN by reducing a potassium conductance, and in some SPN to induce rhythmic activity.

This work is supported by the British Heart Foundation, the Wellcome Trust and the MRC.

484.16 KYNURENIC ACID MODULATES EXCITATORY AMINO ACID-INDUCED EXCITATION OF DOPAMINE-CONTAINING NEURONS IN RAT SUBSTANTIA NIGRA. H.-Q. Wu, R. Schewe and P.D. Shepherd, Maryland Psychiatric Research Center, Baltimore, MD 21228.

Kyurenic acid (KYNA), an endogenous antagonist of ionotropic excitatory amino acid (EAA) receptors, was tested for its ability to modulate NMDA and AMPA-induced excitation of dopamine (DA)-containing neurons in the rat substantia nigra (SNc). Experiments were conducted using conventional extracellular recording techniques in conjunction with a simple data preparation. Bath application of NMDA (1-20 µM) or AMPA (1-10 µM) produced a concentration-dependent increase in the firing rate of SNc DA neurons. The highest concentration of both agonists produced a rapid and reversible cessation of activity that was attributed to acute induction of depolarization block. KYNA (10 µM - 1 mM) inhibited the excitatory effects of NMDA in a concentration-dependent fashion (DC50 = 100 µM) without affecting basal firing rate. KYNA (100 µM) proved slightly more potent in inhibiting the effects of AMPA. Perfusion of tissue slices with low Mg2+ Ringer's (0.12mM) increased the NMDA-induced excitation of DA neurons but failed to affect the ability of KYNA to antagonize the effects of NMDA. Addition of glucose (up to 100 µM) or kynurenic acid (1 mM) to the perfusion medium of KYNA, to the bathing solution had no effect on either basal firing rate or the increase in firing produced by concomitant application of NMDA. Co-application of D-serine (100 µM) partially attenuated the ability of KYNA to block the excitatory effects of NMDA. Thus, the ability of KYNA to block NMDA-induced excitation of mesolimbic DA neurons may involve an interaction with the glycine allosteric site on the NMDA receptor. Taken together, these data suggest that endogenous KYNA may play an important role in regulating DA cell excitability by modulating EAA neurotransmission.
EXCITATORY AMINO ACIDS: RECPTORS VI

485.1
GLUTAMATE AND GLYCINE ACT SYNERGISTICALLY TO STIMULATE "[H]MK-801 BUNDING TO NMDA RECEPTORS." J. S. Maruyama* and K. Batchley. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

In well-washed membranes, glutamate increased each other's efficacies to stimulate [H]MK-801 binding to NMDA receptors, with no detectable effects in their potencies. Glutamate was virtually unable to enhance [H]MK-801 binding in the absence of glycine or in the presence of glycine antagonists, confirming the idea that occupancy of the glycine site is an absolute requirement for NMDA receptor activation. Conversely, the efficacy of glycine to stimulate [H]MK-801 binding was greatly reduced in the absence of glutamate and in the presence of glutamate antagonists. However, [H]MK-801 binding was stimulated to high concentrations (1 mM) of glutamate or glycine acting independently of each other. These low affinity components for glutamate and glycine are probably due to an agonist action of glutamate at the glycine site and of glycine at the glutamate site, respectively. In agreement with this idea, glutamate inhibited [H]glutamate binding, and glycine inhibited [H]glutamate binding, each at millimolar concentrations. Moreover, the potency and the low affinity component for glycine was reduced by glutamate but not by glycine antagonists, but not by glycine antagonists. These results indicate that 1) simultaneous occupancy of the glutamate and glycine sites is necessary to activate NMDA receptors, and 2) glutamate and glycine at millimolar concentrations can act as agonists at the high affinity site for the other compound in the NMDA receptor.

485.2

Depending upon concentration, magnesium can either inhibit or potentiate the binding of the NMDA channel blockers [H]MK-801 or [H]TCP. To determine how magnesium produces these effects, we examined the action of magnesium binding at synaptic sites and at sites of rat hippocampal NMDA receptor: glycine, glutamate, and the [H]TCP binding sites (i.e., phencyclidine receptor). At previously reported by others, magnesium produced basic effects on [H]TCP binding: magnesium exerted potentiating effects at lower concentrations and inhibitory effects at higher concentrations. Both effects required association of the glutamate and glycine binding sites. The inhibition of magnesium on [H]TCP binding was paralleled by an inhibitory effect on the apparent affinity of the [H]TCP binding site. The potentiating effects of lower concentrations of magnesium were associated with a concentration-dependent increase of both the association and dissociation rate of [H]TCP without change in either the Kd or Bmax of [H]TCP binding. Magnesium also increased the affinity of [H]TCP at concentrations comparable to those that increased [H]TCP binding. Magnesium did not modify NMDA-displaceable [H]glutamate binding. These findings support the idea that magnesium has two distinct effects on the NMDA receptor: 1) the apparently competitive interaction between magnesium and [H]TCP binding which likely corresponds to the well characterized channel blocking action; 2) a potentiation of NMDA channel activation likely mediated by the increased affinity of glycine binding.

485.3

NMDA receptor mediated neurotransmission is regulated by polyamines. To examine the direct interaction of polyamines with the NMDA receptor we determined the effects of the polyamines spermine (SPM) and spermidine (SD) on the binding of the NMDA channel blocker, [H]TCP. Both SPM and SD produced biphasic effects on non-equilibrium binding of [H]TCP. Both the potentiating and inhibitory effects of polyamines required agonist binding at both the glutamate and glycine binding sites. The potentiating effect, detected at concentrations of polyamines less than 30 mM, was associated with increases of both the association and dissociation rates of [H]TCP binding. The inhibitory effect of polyamines, detected at concentrations of polyamines greater than 100 mM, was associated with a decrease of the apparent affinity of [H]TCP binding. This study suggests that SPM and SD both have two distinct actions on the NMDA receptor: 1) the apparently competitive interaction between polyamines and [H]TCP binding which likely corresponds to the voltage-dependent block of NMDA channels described by MacDonald et al (1992); 2) a potentiation of the inhibitory effect due to an increase in the duration of which may correspond to the increased channel open frequency described by MacDonald et al.

THE NMDA ANTAGONIST [H]EPINIPRODIL BINDS TO HETEROGENOUS POLYAMINE-SENSITIVE SITES IN RAT BRAIN. H. Schoenaerken, S. Pignone and B. Ehrlich. Department of Biology, Synthetica Research Inc., P.O. Box 1601, Suite 500, 2000 Bayshore Drive, Durham, NC 27710.

The noncompetitive NMDA antagonist and cerebral anti-inhematic properties of ifenprodil have been described to binding to NMDA-like receptors in the hippocampus and NMDA receptor blocker, [H]TCP. Both SPM and SD produced biphasic effects on non-equilibrium binding of [H]TCP. Both the potentiating and inhibitory effects of polyamines required agonist binding at both the glutamate and glycine binding sites. The potentiating effect, detected at concentrations of polyamines less than 30 mM, was associated with increases of both the association and dissociation rates of [H]TCP binding. The inhibitory effect of polyamines, detected at concentrations of polyamines greater than 100 mM, was associated with a decrease of the apparent affinity of [H]TCP binding. This study suggests that SPM and SD both have two distinct actions on the NMDA receptor: 1) the apparently competitive interaction between polyamines and [H]TCP binding which likely corresponds to the voltage-dependent block of NMDA channels described by MacDonald et al (1992); 2) a potentiation of the inhibitory effect due to an increase in the duration of which may correspond to the increased channel open frequency described by MacDonald et al.

7-CX-DEPENDENT AND INDEPENDENT EFFECTS OF POLYMANNOSIDIC ACIDS ON NMDA RECEPTOR INACTIVATION. L.S. Zukin, D.C. Javitt, R. Sirinar, M. Frisplante, Dept. of Psychiatry and Neurosciences, Albert Einstein College of Medicine and Bronx Psychiatric Center, Bronx, NY 10461.
Activation of N-methyl-D-aspartate (NMDA) receptors is regulated at distinct sites by molecules and processes in order to determine the differential effects of polymannosides and glycine on NMDA receptor activation, kinetics of [3H]MK-801 binding were measured in the absence and presence of L-glutamate, the non-competitive antagonist spermine and the putative competitive antagonist 7-CX. Two components of association were found: a fast component (not observed under control conditions) reflecting binding to the activated conformer complex and a slow component reflecting binding to agonist-associated closed conformations. Addition of L-glutamate (0.3-100mM) alone led to a dose-dependent 3-fold increase in total binding that significantly increase binding manifesting fast kinetics. Spermine significantly potentiated the degree to which L-glutamate stimulated total steady-state binding and also led to a large increase in the percentage of total steady-state binding that was attributable to the fast component of association. 7-CX attenuated the degree to which spermine increased the percentage of binding attributable to the fast component without affecting the spermine-induced increase in total binding. These findings suggest that the glycyne site primarily regulates the interconversion between open and closed conformations of the NMDA receptor complex whereas the spermine site regulates both the total number of non-desensitized complexes and the interconversion between open closed conformations.

Previously, we showed a dual effect of spermine (SPM) on the N- methion-D-aspartate (NMDA)-evoked [3H]NMDA release in hippocampal slices (Fachetti et al., Soc. Neurosci. 17:108-13). This was possible by distinct evaluation of the release burst directly by NMDA, in fractions with the agonist (NMDA fractions), and indirectly, in later fractions in the absence of the agonist (tail fractions), collected up to 25 min. We now demonstrate that MK-801, a blocker of synaptic transmission, discloses the enhanced SPM effect on the NMDA fractions, while the tail fractions-related effect is insensitive to TTX. In all experiments sliced hippocampi from Wistar rats (200-225 g) were used. Fractions (5 min each) were collected and fractional release (FR) expressed as percent of the [3H]NMDA present in the tissue at the corresponding times. 500 μM NMDA evoked 7.08±0.86% FR. TTX (2 μM) inhibited NMDA fractions of approximately 90% (P<0.01). 1 mM SPM, added inactive, restored FR to 3.71±0.37% (P<0.01). Moreover, the increasing effect of SPM on the tail fractions was not modified by TTX. 400 μM D(−)-2-amino-7-phosphonoheptanoic acid significantly prevented SPM effect (1.62±0.26% FR, P<0.01), in the presence of TTX. Our data suggest that SPM may modulate the NMDA-induced [3H]NMDA hippocampal release by acting on presynaptic NMDA receptors.

485.8
Concentration-jump experiments on voltage-clamped rat cortical neurones in culture have previously indicated an allosteric interaction between the glycyne- and glutamate-recognition sites on the NMDA receptor complex (Kemp & Priestley, Mol. Pharmacol., 39, 1991, 666-670) Thus, glutamate dissociates more slowly from its recognition site on the NMDA-receptor complex when glycyne is bound to the glycyne recognition site than when the low efficacy partial agonist, (−)-HA 966, is bound. We have extended these observations of interactions between these two co-agonist recognition sites by evaluating the effect of a range of agonists with differing levels of efficacy and affinity binding at one of the sites on the kinetics of agonists acting at the other.
The dissociation rate for glycyne in the presence of (−)-HA 966 is significantly faster than that seen in the presence of glycyne. Similar, but progressively smaller effects were seen with D-cycloserine, APDC (Aminoacyclopentaneacetic acid) and L-alanine. A reciprocal effect on glycyne kinetics was found to occur with several NMDA receptor agonists. Thus, the dissociation rate for glycyne was lowest in the presence of glutamate and became progressively faster in the presence of NMDA, quinolinic acid and cis-2,3-PDA (piperidinedicarboxylic acid).
These results suggest that co-agonists acting at the NMDA and glycine recognition sites on the NMDA receptor complex influence each other's affinity by an allosteric interaction the extent of which appears to correlate with the level of efficacy of the agonist rather than its affinity.

485.10
It is well established that glycyne potentiates responses mediated by the N-methyl-D-aspartate (NMDA) subtype of the glutamate receptor. We have characterized with [3H]glycyne these strychnine-insensitive binding sites in cerebral cortical membranes isolated from adult and 7-day-old mice. The binding was saturable, consisting of only one component in both age groups studied. The maximal binding capacity Bmax was significantly higher in immature mice than in adults. The binding constant KB was greater in immature mice, indicating lower affinity of the binding sites for glycyne. The binding was most strongly inhibited by glycyne itself, followed by zinc and β-alanine in both immature and mature cerebral cortex. β-Alanine was found to cause a mixed type of inhibition in glycyne binding. The binding of β-[3H]glycyne to cerebral cortical membranes was also saturable, consisting of one component. The binding constant KB for β-alanine was of the same order of magnitude as KB for glycyne, whereas the binding capacity Bmax was smaller. The binding of β-alanine was inhibited by glycyne, NMDA and glutamate but not by strychnine. The results point to the possibility that β-alanine could act at the glycyne modulatory site in the NMDA receptor complex of adult cerebral cortex. (Supported by the Emil Aallon Foundation, Finland.)
Differential Effects of L-Glutamate on [3H]-MK-801 Binding in PCP-Treated Weaning Rats Compared to Saline-Treated Controls. R. Sirota, Dept. of Psychiatry and Neurology, SUNY Buffalo, Buffalo, NY.

The developing rat brain is more susceptible to N-methyl-D-aspartate (NMDA) receptor-mediated neurotoxicity compared to adults. We have shown that in vivo microdialysis analyses of [3H]-MK-801 binding indicate lower density of binding sites in weaning rats treated postnatally with phencyclidine (PCP) compared to saline-treated rats; [3H]-MK-801 binding was used as a probe for NMDA channel activation. Here we report characterization of L-glutamate-induced NMDA receptor activation on [3H]-MK-801 binding in postnatal PCP-treated rats. Rats were treated with PCP (6 mg/kg) for 11 days. Controls received saline injections. [3H]-MK-801 bindings were measured in forebrain synaptosomal membranes prepared from PCP- and saline-treated animals, both in the absence and presence of 100 µM of L-glutamate (0-100 µM) with or without added glycine (10 µM). In the absence of added glycine, incubation in the presence of L-glutamate lead to a dose-dependent increase in specific [3H]-MK-801 binding both in the PCP- and saline-treated rats but neither mean EC50 values nor maximum [3H]-MK-801 bindings were different between the two groups. When binding was carried out in the added presence of glycine, maximal binding in the PCP-treated rats were lower than in the saline-treated controls. The mean EC50 value for L-glutamate-stimulated [3H]-MK-801 binding was reduced in both experimental and control rats but there was no apparent difference in the mean EC50 values between the two groups. These findings suggest PCP-treated rats in early postnatal period in rat alters the agonist-induced regulation of the NMDA channel activation.

Glutamate Sensitive Binding of [3H]-MK-801 to Intact Cerebellar Granule Cells. T.E. Murray* and V.J. Caldwell, Oregon State Univ., College of Pharmacy, Corvallis, OR 97331.

Efforts to label NMDA receptors in membrane preparations derived from rat cerebellum have yielded conflicting results. Although unsuccessful attempts to detect specific binding of [3H]TCP and [3H]-MK-801 in rat cerebellar membranes have been reported, a demonstration of binding of [3H]-TCP and [3H]-MK-801 labeling of cerebellar membranes has recently appeared (Ebert et al., Europ. J. Pharmacol.-Mol. Pharmacol. Sect. 208, 49, 1991). These cerebellar studding sites are distinct inasmuch as the affinity for [3H]-MK-801 is substantially lower than that of NMDA receptors in forebrain structures. To further explore the characteristics of cerebellar NMDA receptors, we have investigated the binding of [3H]-MK-801 in intact cultured cerebellar granule cells. The binding of [3H]-MK-801 was inhibited in a concentration-dependent manner by glutamate (1-300 µM). The glutamate inhibition of [3H]-MK-801 binding to intact granule cells was reversed by Mg2+ in concentrations ranging from 1 to 10,000 µM. Similarly, the glutamate-induced inhibition of binding was antagonized by the competitive NMDA receptor antagonist AP-5. Noncompetitive NMDA receptor antagonists such as MK-801, phencyclidine, and dextrophan produced biphasic effects on [3H]-MK-801 binding with low concentrations stimulating and high concentrations inhibiting binding. Equilibrium saturation analysis of the [3H]-MK-801 binding resulted in a Kd value of 77 µM and a Bmax value of 1.1 pmol/mg. Competition experiments indicated that glutamate exerted similar negative modulation of cerebellar NMDA receptors labeled with [3H]dextrophan. These results suggest intact cerebellar granule cells in culture express functional NMDA receptors.

Glutamate Sensitive Binding of [3H]-MK-801 to Intact Cerebellar Granule Cells. T.E. Murray* and V.J. Caldwell, Oregon State Univ., College of Pharmacy, Corvallis, OR 97331.

Glutamate Sensitive Binding of [3H]-MK-801 to Intact Cerebellar Granule Cells. T.E. Murray* and V.J. Caldwell, Oregon State Univ., College of Pharmacy, Corvallis, OR 97331.

Glutamate Sensitive Binding of [3H]-MK-801 to Intact Cerebellar Granule Cells. T.E. Murray* and V.J. Caldwell, Oregon State Univ., College of Pharmacy, Corvallis, OR 97331.

Evidence that high and low affinity AMPA binding sites reflect membrane-dependent stages of a single receptor. R. Hall, M. Kessler* and L. Jones, Center for Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

AMPA-type glutamate receptors are the primary mediators of excitatory neurotransmission in mammalian forebrain and are also thought to be central to the form of synaptic plasticity known as long-term potentiation (Staubli et al., Psychobiol. 18:377, 1990). Binding of [3H]-AMPA (DL-α-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid) to membranes of cortical synaptosomes is dependent on the presence of potassium thiocyanate resulting in curvilinear Scatchard plots which could be resolved by regression analysis into two large affinity components (Kd<sub>1</sub> = 200-1000 nM approx. 50% of the total binding and Kd<sub>2</sub> = 10 µM approx. 10% of the sites). Treatment with 0.4% Triton X-100 resulted in a solubilized fraction which contained 74% of the sites recovered after solubilization. These sites were uniformly of the high affinity type with a Kd of 29 ± 5 nM. The total number of these sites was three to five times higher than the number of high affinity sites which was present in the starting membranes. Due to the solubilization of the high affinity receptor it was not possible to convert low affinity into high affinity receptors; it follows from this that the two affinity states represent interconvertible forms of the same receptor rather than separate receptors. The only mechanism for the presence of two affinity states appears to be greatly reduced in number in lysed synaptic plasma membranes; they accounted for only 1% of total binding in BPA. The evidence suggests that the high affinity receptor binds to a synaptic environment which keeps receptors in a low affinity state and that it is the lack of this factor during solubilization which allows receptors to revert to a high affinity state. RARE VISUALIZATION OF NMDA RECEPTORS: CHARACTERIZATION OF (+)-[3H]MK-801 BINDING TO THIN SECTIONS OF RAT BRAIN. W. Jacobson and G.A. Cotrell Department of Obstetrics and Gynecology, Uniformed Services University of the Health Sciences, Bethesda, Maryland 20814.
We have developed and characterized a method for the rapid autoradiographic identification of a competitive NMDA receptor antagonist. The compound (+)-[3H]MK-801 was one of the first NMDA receptor antagonists to be characterized. In the present study, we have developed a method for the rapid identification of NMDA receptor binding sites in thin sections of rat brain. The method involves the use of a high-speed tissue processor and the incorporation of (+)-[3H]MK-801 into the tissue sections. The method is rapid, sensitive, and specific for the identification of NMDA receptor binding sites in thin sections of rat brain.

MATERNAL VITAMIN B-6 DEFICIENCY ALTERS POSTNATAL DEVELOPMENT AND ZINC REGULATION OF HIPPOCAMPSAL NMDA RECEPTOR-ION CHANNELS. T.R. Guillemin and R.C. McGeer, Department of Environmental Health Sciences, The Johns Hopkins University School of Hygiene and Public Health, Baltimore, MD.
Vitamin B-6 (pyridoxine) deficiency during development results in reduced function of NMDA receptor-ion channels in the cerebral cortex (CTX) of 14 day old rats (Guillemin TR, Neuroscience. Lett. 121:207-210, 1991). The present investigation examines the effects of vitamin B-6 deficiency during development on the number of NMDA receptor-ion channels and zinc (Zn) uptake by the CTX. Long Evans rats (125-150 g) were fed either a normal (7.0 mg/kg pyridoxine, HCL-PH7) or marginally deficient B6 diet (0.7 mg/kg pyridoxine) for 2 weeks prior to mating. pups and progeny (weaned at 21 days of age) were fed the same diet through 14 days of age. NMDA receptor-ion channel binding was assessed at postnatal day (PND) 7, 14, 21, 28, and 36 as described (Guillemin TR, Fbd). The effect of the NMDA receptor agonist (10 μM) and zinc (Zn) on NMDA receptor-ion channel binding was also measured as a function of age. Cortical membranes from PND 7 rats were significantly more sensitive (IC50 = 0.9 nM) to the inhibitory effects of Mg than any other age tested (IC50 = 2.53 μM). There were no significant effects of diet. In normal rats, Zn showed a decrease in the IC50 (112 μM) at PND 7 to PND 21, and 25, and 36 (IC50 = 7.3, 3.0, and 4.5 μM, respectively). However, B6 deficient membranes at PND 7 required greater amounts of Zn to produce the same inhibitory effect as NMDA receptor-ion channel binding relative to age matched controls. These results suggest that vitamin B-6 deficiency may influence the postnatal development and regulation of NMDA receptor-ion channels in the rat cerebral cortex (Grass M # HD2093).

NMDA-RECEPTOR mRNA EXPRESSION IN THE CORTEX AND HIPPOCAMPUS OF CYCLING AND LACTATING RATS. R. Abrav, B. Atteni, G. E. Hoffman, and N. S. Smith, Department of Physiology, University of Pittsburgh, Pittsburgh, PA 15261.
Using cFos mRNA as a marker of neuronal activation, we observed an inhibition of cortical and hippocampal activation in response to NMDA, but not kainate, in lactating rats. This lack of responsiveness to kainate in lactating rats could be due to a decrease in the number of NMDA receptors in these areas. To examine this possibility, we measured the expression of NMDA-R mRNA in cycling and lactating rats. In situ hybridization was performed using a 14-nt labeled riboprobe recognizing 1.4 kb of the NMDAR1 mRNA. Areas of silver grains were analyzed in the parietal cortex, the piriform cortex, the CA1 region of the hippocampus, and the dentate gyrus, using the Optimas Image Analysis System. NMDA-R mRNA was abundant in all areas of the brain examined. Differences in NMDA-R mRNA expression between cycling and lactating rats were observed only in the CA1 region of the hippocampus (18% decrease in the lactating rats). Differences in NMDA receptor expression were not detected by Northern Blot analysis of tissue isolated from the cortex or hippocampus. These data suggest that the changes in NMDA-R mRNA expression in the lactating rat are very small, and that alterations in NMDA receptors in the regions examined might not explain the functional deficits in cortical activation in response to NMDA. Other possible explanations are that a small but key subpopulation of neurons is altered in the cortex, or that changes in NMDA receptors occur within the brainstem or spinal cord rather than in the cortex. It is also possible that suckling may inhibit activation of brainstem pathways necessary for cortical activation. Supported by NIH Grant HD14643.

BACLOFEN INHIBITS THE INCREASE IN CYCLIC AMP INDUCED BY HIGH FREQUENCY ELECTRICAL STIMULATION IN THE DENTATE GYRUS OF RAT HIPPOCAMPAL SLICE. M.J. Bonnarme and J.M. Savarey, Department of Pharmacy, Uniformed Services University of the Health Sciences, Bethesda, Maryland 20814.
Activation of second messenger systems is implicated in the induction and maintenance of long term potentiation (LTP) and of synaptic plasticity. A high-frequency train (HFT; 100 Hz, 2 sec) of electrical stimuli was applied to the medial perforant path in the dentate gyrus of rat hippocampal slices. After HFT the dentate gyrus was cut from the rest of the slice and CA3 and CA1 levels of cAMP were determined by a protein binding assay. Each treatment group consisted of 3 slices from each of 6 rats. One min after HHT, CA3 levels increased to 240% of levels in slices that did not receive an HFT. Immediate post-treatment exposure of slices to baclofen (10, 100, 1000 μM) for 1 min resulted in concentration-dependent inhibition of HFT-stimulated CA3 levels. Levels of cAMP were reduced by 50% by 10 μM baclofen compared to levels produced post-HFT without baclofen. A high concentration (1000 μM) of baclofen post-HFT suppressed cAMP to basal levels. Pre-treatment of slices with 100 μM baclofen for 20 min before HFT also inhibited the baclofen-induced increase in cAMP to a similar degree as post-HFT baclofen. However, pre-HFT treatment with 10 μM baclofen did not produce any significant suppression of HFT-stimulated cAMP. These results suggest that the baclofen-sensitive GABA-B receptor can regulate stimulated cAMP levels in the dentate gyrus.

IN VITRO AND IN VIVO EFFECTS OF BACLOFEN ON CAMP OVERFLOW IN RAT CEREBRAL CORTEX. A.K. Knight, A.P. Whitton, and N.G. Brew, Dept of Pharmacology, School of Pharmacy, 29-39 Brunswick Square, London, UK.
The dual effect of baclofen upon cAMP production in brain tissue in vitro is well documented. The purpose of the present study is to elucidate and compare its effects in vivo.
In vivo experiments were performed by incubating aliquots of rat cortex chopped cortical slices for 10 min with either 10 μM forskolin or 100 μM noradrenaline to stimulate adenyl cyclase (AC) activity. In vivo experiments were performed by implanting a concentration dialysis probe into the frontal cortex, 100 μM forskolin was delivered at a flow rate of 2 μl/h, the dialysate was collected over two pulses, the first (31) to standardize the preparation, the second (32) for experimental manipulation. Radioimmunoassay was used to quantify the cAMP accumulated in the superfuse dialysis as a measure of AC activity. In vivo baclofen (0.01 to 100 μM) had no effect on baseline cAMP production but was found to dose dependently inhibit forskolin stimulated AC activity (pEC50 = 6.07 ± 0.29) and to augment the maximum stimulation obtained with noradrenaline (pEC50 = 5.94 ± 0.17). In vivo, 10 μM baclofen also failed to alter base line cAMP. However, when baclofen (10 μM) was administered simultaneously with forskolin during 30 min infusion, cAMP overflow was not reduced when compared to control 2B, but instead appeared to increase the stimulation produced by forskolin (S2/S1 ratio = 1.59 ± 0.57, control = 0.57 ± 0.07). The reasons for this are currently under investigation.
486.3 EFFECT OF (+)-BACLOFEN ON cAMP FORMATION AND SUBSTANCE P RELEASE FROM RAT SPINAL CORD. N.G. Bowery and M. Malcangio. Dept. of Pharmacology, School of Pharmacy, Univ. of London, London WC1N 1AX.

It has been proposed that baclofen may induce antinociception in rodents through activation on GABA_A receptors localized on the spinal cord. In this study we have investigated the effect(s) of (+)-baclofen on stimulated cAMP formation in rat spinal cord slices (350x350 μm) and on substance P release evoked by electrical stimulation (15 V, 10Hz, 1ms) of dorsal roots attached to spinal cord slices. (+)- Baclofen, dose dependent (10-100 μM), inhibited forskolin (10 μM)-induced formation of cAMP (maximal inhibition 56±5% at 100 μM) but this was not prevented by CGP 33548 (concentrations up to 1.5 mM). By contrast with cerebral cortical slices (+)-baclofen (1-100 μM) failed to enhance noradrenaline (100 μM)-induced formation of cAMP. Evoked release of substance P-LI was completely inhibited by (+)-baclofen (IC50 ~ 4.5 μM). Whilst GABA_A mediating analgesia may stem from a reduction in primary afferent neurotransmitter release it seems unlikely that an alteration in cAMP production is implicated.

486.5 ALTERATIONS IN TBPS BINDING IN THE LICODAINE-KINDLED RAT MODEL OF EPILEPSY. Marc S. Abel and Daniel E. Cashey. Department of Cell Biology and Anatomy, UHS/The Chicago Medical School, North Chicago, IL.

This autoradiographic study examined regional GABA_A receptors in chemically kindled rats. [3H]-Beryl bicyclophosphorothionate (TBPS), which binds to the GABA_A receptor chloride channel, was used as a ligand to identify GABA_A receptor complexes. Male Sprague-Dawley rats were injected daily with lidocaine (65 mg/kg, i.p.). Control rats received an equal volume of saline vehicle. Seizure activity was evaluated using the Racine Scale of 5 behavioral stages. The animals displayed a gradual increase in the severity of behavioral indices and by day 20 greater than 50% were in Stage 4 or 5. Midway through the injection regime some animals exhibited a gradual regression toward less severe behavioral stages; these animals were considered 'compensated'. After 25 injections the animals were killed, the brains removed and 30 μm sections incubated with 2 nM [3H]TBPS. Brain paste standards were prepared and included in the autoradiographic process. After appropriate exposure, the developed films were analyzed using a computer based imaging system. Binding was decreased in the subiculum, posterior lateral thalamic nuclei, hippocampal regions CA1 and CA3, and cerebellar nuclei in sections from kindled animals as compared to controls. Sections from rats that 'compensated' during the kindling process had normal or slightly elevated [3H]TBPS binding in those regions. These data support the hypothesis that alterations in the GABA_A receptor occur during the kindling process.

Under two-lever drug vs. no-drug discrimination procedures, the LDP training condition previously shown to be unique among benzodiazepines (BD) training conditions studied to date in that rats did not acquire the BD to pentobarbital reliably, even when training dose and tolerance to its rate-decreasing action were manipulated (Ablow and Griffiths, Environ. Pharmacol., 1989, 28, 20). Subsequently, generalization profiles for LDP, DP, and PB training conditions have been directly compared in Long-Evans rats in tests with a range of BD agonists and partial agonists, barbiturates, and other anxiolytics or sedatives. Rats in all three training groups generalized to BD, but greater selectivity in generalization to barbiturates and other sedative/anxiolytic compounds occurred in rats trained to discriminate LDP than DP. Rats trained to discriminate LDP failed to generalize reliably to any barbiturate or other non-BD sedative/anxiolytic, but the profiles for rats trained to discriminate DZP and DP were comparable. Among novel BD-receptor ligands, abacavir occluded drug lever responding under all conditions; zolpidem did so in the PB and DP conditions but not as reliably in the LDP condition. (Supported by NIH Grant DA 01431)

A depolarizing bicuculline sensitive response can be elicited in slices of hippocampus under conditions that induce a slow wave. This response is not evoked by the antagonism of excitatory amino acid receptor and seems to occur throughout the tissue. This response also occurs spontaneously in the presence of ABA, and does not appear to occur simultaneously throughout the tissue. It has been shown that there is some delay in the occurrence of the response between the distal CA3 dendrites and the subiculum. The delay across 2mm of tissue is approximately 150 msec suggesting there may be a synaptic component to the response and/or that there may be a loci where the response originates. The ability of GABAergic cells to produce depolarizing responses may be important in stabilizing GABAergic networks as well as limiting seizure-like activity. Whether activation of the postsynaptic cell through this mechanism may change the efficacy of synaptic contacts is a possibility, since calcium can enter the cell through these channels. When this occurs intracellular calcium increases, even when not paired with synaptic activation which produces synaptic modifications. As this response is most prominent in neonates, this would be a good mechanism for laying down a framework of GABAergic connections.

Baclofen application has resulted in facilitation of depression, and no effect in various thalamic nuclei. These separate results have led to the speculation that baclofen effects on GABA_A receptors demonstrate regional and laminar differences. We utilized a 16 channel rake electrode with subsequent SDT analysis and intracellular recordings to examine the laminar effects of baclofen following white matter stimulation in 16-22 day old rat visual cortex. Monosynaptic EPSPs in both layer II/III and V were unaffected by low doses (0.5-2.0 μM) of baclofen and equally attenuated by high doses (10-40 μM). Polykynetic EPSPs were selectively attenuated in layer II/III at low doses while layer V EPSPs were facilitated. Low dose baclofen selectively attenuated EPSPs in both layers. We conclude that baclofen, acting at presynaptic terminals, demonstrates differential laminar effects in immature rat visual cortex.

DECREASED NEURAL INHIBITION IN IN VITRO HIPPOCAMPUS AFTER 1 WEEK FLURAZEPAM (FZP) TREATMENT: AN INTRACLASSICAL STUDY. K.J. Stieglitz and E.L. Tietz. Department of Pharmacology, Medical College of Ohio, Toledo, OH 43699

FZP treatment significantly reduces GABA-mediated hippocampal paired-pulse inhibition (Xie and Tietz, 1991). Orthodromic EPSP-IPSP sequence and action potential (AP) burst frequency and duration, elicited by a 1 sec depolarizing current, was examined in vitro superfused slices 48 hr after 1 week FZP treatment. Male rats (175-200 gm) were offered FZP in the drinking water (100 mg/kg X 3 X 4 dy); selected 1 day after withdrawal of FZP. Control slices were treated (6 cells/5 rats) and control (7 cells/4 rats) slices had stable resting membrane potentials (RMP) -44.5±0.8 mV. Resting potentials > 30 mV (78.3±0.6 vs 93.9±1.6) and antidromic APs > 70 mV (82±2.9 vs 81±1.5) were held at <60 mV throughout the experiment. EPSP-IPSPs elicited by just subthreshold Schaffer-collateral stimulation were recorded (3 M KCl filled glass pipettes, 100-170 MΩ) from CA1 pyramidal cells (24°C). There was a significant (p<0.01) reduction in the amplitude of the FIPSP (1.4±0.6 vs 6.3±0.7 mV) and sIPSP (1.5±0.4 vs 6.5±0.7 mV) and an increase in EPSP amplitude (16.5±1.3 vs 5.4±0.8 mV). The small increase in burst duration and frequency (265±46.6 mS, 34±0.2£4 Hz vs 245±24.6 mS, 29±4.2 Hz) was significant (p<0.10). These data provide additional evidence regarding the nature of the impairment in GABA-mediated hippocampal function in chronic benzodiazepine treated rats. Supported by NIDA grant R01-DA04075.

469.11
GABA RECEPTOR ACTIVATION INDUCES GABA AND GLUTAMATE RELEASE FROM PROPERIC AREA. 1.0. Nakhabina, 1.0. Sokolov, 1.0. Blakaya, 1.0. K. Okajima, 1.0. K. Nishiyama, 1.0. Dept. of Psychiatry, 1.0. Biochemistry, 1.0. Molecular Pharmacology, 1.0. and Neuroscience, 1.0. Albert Einstein College of Medicine, Bronx, New York 10461.

The effect of y-aminobutyric acid (GABA) receptor agonists on release in vitro of radiolabeled GABA and glutamate was studied using a crude preparation of isolated nerve terminals (neurosecretory). GABA agonists were incubated (2 min., 37°C) with neurons prepared from hypothalamic (HYP), preoptic area (POA) and cortex (COR) tissues. GABA and the GABA receptor agonist muscimol, but not the GABA receptor agonist (-)-baclofen, stimulated [3H]-GABA and [3H]-glutamate release from POA but not HYP or COR neurons of male rats. These effects were partially inhibited by the GABA receptor antagonist picrotoxin and bicuculline. Muscimol-induced release of H-glutamate and [3H]-GABA was dependent on extracellular Ca2+. Muscimol failed to release N-H-GABA and N-glutamate from POA neurons of ovariectomized female rats. However, administration of estradiol and progestrone to ovariectomized female rats caused the appearance of muscimol-induced release of amino acids comparable to that obtained in male rats. Therefore, GABA receptor-induced release of amino acids is brain region-specific and modified by hormonal status.

GABA MODULATES CALCIUM AND MEMBRANE POTENTIAL OSCILLATIONS IN IMMORTALIZED HYPOTHALAMIC NEURONS. A.C. Dong, 1.0. Dept. of Neurology and Anesthesiology, UCLA School of Medicine, Los Angeles CA 90024

Cloned GHRH-secreting hypothalamic neurons (GT-1-7) in culture showed spontaneous oscillations in [Ca2+]i, as measured with fluorescence videomicroscopy. [Ca2+]i oscillations had a periodicity of approximately 160-260 seconds and the peak [Ca2+]i of each oscillation ranged from 100-500 nm. Ca2+ oscillations of individual cells were generally asynchronous, although some groups of cells showed synchronized oscillations. Spontaneous Ca2+ oscillations were reversibly abolished by 1µm TTX. Bath application of 1µM GABA evoked an increase in [Ca2+]i, in most cells (100-200 mV), and increased the frequency of Ca2+ oscillations; 10µM GABA evoked a greater increase in [Ca2+]i (100-500 mV) in some cells. Further increasing the frequency of Ca2+ oscillations was possible by increasing the frequency of Ca2+ oscillations. These responses to GABA were inhibited by 10µM bicuculline. Using the patch-clamp technique under current-clamp conditions, GT-1-7 cells showed oscillations of membrane potential between -60 and +20 mV, with a periodicity of 0.3-0.6 sec. These responses to GABA were inhibited by 10µM bicuculline. Under voltage-clamp conditions, GABA activated chloride currents which were blocked by bicuculline (1µM) and Zn2+ (100 µM). These results suggest that GABA mediated GABA receptors on GT-1-7 cells and that these responses inhibit GT-1-7 cell activity. Supported in part by a grant from the National Institutes of Health and by a grant from the Northern California Research Institute.

FEEDFORWARD INHIBITION IS REDUCED IN HIPPOCAMPUS AFTER CHRONIC BENZODIAZEPINE TREATMENT. X. Zeng and L. Tietz* Dept. of Pharmacology, Med. Coll. Ohio, Toledo, OH 43699

Recent studies alluded to the role of feedforward inhibition in mediating the effect of GABA agonists in CA1 region of hippocampus (Tietz, 1991). In this study, we investigated the role of feedforward inhibition in slices from 1 week chronic flurazepam (FZP) treated rats was examined in slices according to Lujic and Dunwiddie (1992). Slices (400 µm) were cut, 48 hr after treatment, from male rats (175-200 gm) offered FZP (100 mg/kg X 3 X 4 dy) in the drinking water. Control rats received saccharin water. Control and test population evoked by stratum radiatum stimulation (S2) on the subicular side of an extracellular recording electrode (2 µM NaCl filled glass pipette, 2-5 Mohm) were compared. The test pulse followed an orthodromic condition pulse (S1), subthreshold for a population spike, with interpulse intervals (IPI) of 10-100 ms. A knife cut was made through the alveus between SI and the recording electrode to block recurrent inhibition. Feedforward inhibition in control slices ranged from 100-555. Treated slices showed a significant (20-40%, p<0.01) reduction in feedforward inhibition and all levels of GABA-mediated inhibition are impaired in CA1 region of hippocampus of chronic benzodiazepine treated rats. Supported by NIDA grant R01-DA04075.

469.14

Neuronal cell lines provide a source of pure populations of neurons and allow the properties of many neurotransmitter receptors to be studied. None of the neuronal cell lines have been reported to express functional GABA receptors. In this study, there have been no reports of cell lines expressing functional GABA receptors. Using biochemical and electrophysiological techniques, we have identified neuronal GABA cell lines expressing functional GABA receptors. Membranes from immortalized hypothalamic (GT-1-7) neurons bound [3H]-GABA (IC50 0.5±0.2 µM) with high affinity and selectivity for GABA. This binding was displaced by GABA and related compounds, including (R,R)-baclofen, (S,S)-baclofen, muscimol, GABA-A agonist. The binding of [3H]-GABA was selective for GABA-A receptors. In addition, [3H]-GABA binding was blocked by bicuculline (1µM) and Zn2+ (100 µM). These results suggest that GABA receptor agonists on GT-1-7 cells lack y.subscripts. The neuronal cell line GT-1-7 contains GABA receptors. In this study, the presence of mRNA encoding GABA receptors was confirmed. PCR analysis of the cells revealed the presence of mRNAs encoding α1, β3 and β5 subunits but not α2, α4, α6, β2 or β3 subunits. These cells may provide a useful model system for the regulation of GABA receptor subunit expression.

486.15 PERIPHERAL BENZODIAZEPINE RECEPTOR BINDING IN HYPOTHYROID RAT VENTRICLES I. KRAGI* & R. SMIEHOROWSKI Dept. Biological Sciences, State University of New York at Buffalo, Buffalo, NY 14260

Previously we showed that the binding of tritiated benzodiazepine (3H) diazepam to brain membranes from hypothyroid rats was significantly increased compared to that of euthyroid controls (Krakowiak et al., 1987). The present study was undertaken to determine if a similar increase in 3H diazepam binding is observed in the peripheral benzodiazepine receptor of hypothyroid rats.

486.16 ANXIOLYTIC COMPOUNDS HAVE DIFFERENTIAL EFFECTS ON RAT EEG. K.L. Skirik and C.M. Brown*. Neurogen Corp., Brantford, ON T9L 0A7. Although currently available antianxiety agents are sedative, it is unlikely that sedation is a necessary property of this class of compound. Here, different anxiolytics were examined with a view to quantifying their effects on central arousal: as an example of a sedating compound, benzodiazepine; and a barbiturate, Sodium Pentobarbital, was compared with a recently developed Type I non-sedative, Zolpimid, a non-selective benzodiazepine, and a serotonin (5-HT1a) ligand, ipsipronine, which has been shown to exhibit sedative profile, was also examined. Anxiolytics were selected and the compounds were administered via a cannulated tail vein. Vigilance was maintained by using a randomized disturbing noise source. The EEGs were analyzed, demonstrated that all compounds except ipsipronine significantly increased power in the frequency band above 1 Hz. Ipsipronine, in contrast, decreased power at these frequencies. The lowest frequency range (1-4 Hz) was also affected differentially: the barbiturate and Zolpimid increased, but ipsipronine decreased, power at these frequencies; Zolpimid had no effect. These data show that all compounds affected central arousal but there was no common action which might reflect an anxiolytic action. The EEG change produced by the two most sedating drugs indicated that there was increased recruitment of thalamocortical circuits. Such recruitment occurs with reduced vigilance. Zolpimid acted similarly but more sedating, under circumstances in which the compound reduces anxiety, increased vigilance. In conclusion these results indicate, firstly, that there is no preclinical EEG signature for anxiolytics because the EEG is a measure of the effect of these compounds on central arousal. And, secondly, that sedation is another requirement for an anxiolytic action.

487.1 PROGESTERONE-INDUCED ELEVATION IN BRAIN 3a-HYDROXY-5a-PREGNAN-20-ONE IS ASSOCIATED WITH ANXIOLYTIC BEHAVIOR AND AN INCREASE IN GABA_A RECEPTOR FUNCTION. I. Bishop*, R. Klann†, and C.K. Kellough‡. Dept. of Psychology, College of the Holy Cross, Worcester, MA. The Department of Chemistry, Southwest Foundation for Biochemical Research, San Antonio, TX, and the Department of Psychology, University of Rochester, Rochester, NY.

We have previously reported that intracerebroventricular administration of the progesterone metabolite, 3a-hydroxy-5a-pregnan-20-one (allopregnanolone), elicited significant anxiolytic behavior in a dose-dependent and stereospecific manner (Brain Res, 513: 337-343, 1990). We have also found that the anxiolytic effect of diazepam was enhanced in progesterone female rats, relative to ovarianized (OVX) rats, as was the efficacy of a GABA-A-stimulated chloride (Cl-)-influx in cortical synaptosomes (Behav Neurosci, 105: 663, 1991). These results are consistent with the well-documented role of progesterone in the control of anxiolytic behavior, since the potent i.e. "positive modulators of the GABA_A receptor.

In the following experiments, the effect of a subcutaneous injection of progesterone (P), 0.6 mg/kg or 4 mg/kg in OvX rats on exploration of an elevated plus maze was examined. Blood serum and cortical concentrations of allopregnanolone were assessed. GABA-A-stimulated Cl- influx was determined in cortical synaptosomes from a subgroup of OvX females treated with vehicle or 4 mg of P. Significant anxiolytic activity was detected 4 hours after the administration of 1 or 4 mg of P, behavioral measures of anxiolytic efficacy were significantly correlated with blood and cortical levels of allopregnanolone. Treatment also increased the sensitivity of cortical synaptosomes to GABA (GABA_A), increased the EC50 and increased the maximal efficacy with which GABA stimulated Cl- uptake. Together, these data support the hypothesis that the psychoactive effects of P are mediated by the biosynthesis of 3a-hydroxy-5a-pregnan-20-one, and that allopregnanolone subsequently augments GABA_A receptor-mediated function.

487.2 DEHYDROANDROSTROSTERONE (DHEA) IMPROVES MEMORY IN NORMAL MICE AND MICE WITH AGE-INDUCED MEMORY DEFICITS. C.L. Blackwell*, D. Davy, and R.J. Barkham. Labs View Medical Center, Sylmar, CA 91342.

DHEA is a steroid formed in the brain where it is active at the GABA_A receptor complex. DHEA has been shown to enhance memory in avoidance paradigms. The purpose of these studies was to assess the effect of DHEA on working memory in the win-stay foraging paradigm. Briefly, a food deprived mouse is placed in a T-maze with a milk reward in both goal boxes. The mouse travels the maze and is allowed to choose the milk in one of the goal boxes. On the next trial, if the mouse remembers which way it went on the previous trial, it will go the opposite way. By increasing the delay between trials the length of time a mouse can remember can be reduced. DHEA improved performance and extended the time that mice could remember by up to 120 seconds up to 100 seconds. Young adult Swiss Webster mice are able to perform with delays up to 60 seconds. In 12 month old Swiss Webster mice, 70% had a memory deficit such that they could only remember at delays of 120 seconds. DHEA (0.005 mg/kg I.P.) increased the delay that they could remember to 180 seconds. Young adult Swiss Webster mice are able to perform with delays up to 60 seconds. In 12 month old Swiss Webster mice, 70% had a memory deficit such that they could only remember at delays of 120 seconds. DHEA (0.005 mg/kg I.P.) increased the delay that they could remember to 180 seconds. Young adult Swiss Webster mice are able to perform with delays up to 60 seconds.

PHYSIOLOGICAL VARIATIONS OF GONADAL STEROIDS MAY REGULATE GABA SYNAPTIC TRANSMISSION IN THE CEREBRAL CORTEX. M.J. Al-Dahan, M.H. Jalilian-Teherani and RH Thalman. Baylor College of Medicine, Houston, TX 77030

These results show that GABA, agonist binding in the cerebral cortex is significantly affected during normal variations in gonadal steroids that occur during the estrus cycle of the rat. Well-washed synaptic plasma membranes were prepared for filtration assays of the binding of the GABA, agonist (°)-baclofen. In addition, we examined the binding of the GABA, agonist (°)-8-OH-DPAT, a 5-HT, agonist that depends upon the same G-proteins as do GABA, receptors. (°)-Baclofen binding was lowest during estrus (72±10 fmol/mg protein) and then increased over metestrus (145±2) to reach a plateau by diestrus (215±30) and proestrus (237±31). In contrast, (°)-muscimol binding was at or near its maximum during estrus, and (°)-8-OH-DPAT binding declined slightly from proestrus to estrus, but then remained constant until the next proestrus. Saturation binding experiments showed that GABA, receptor density (Bmax) approximately tracked effects upon total specific binding in that Bmax was lowest during estrus. Intracellular recording methods will be used to assess the effects of this variation in GABA, binding upon receptor-channel coupling in slices harvested from animals in different stages of the estrus cycle. Supported by NIH grant NS-21713.

CHRONIC GABA TREATMENT DOWNREGULATES GABA, RECEPTOR COMPLEX AND α mRNA SUBUNITs IN MAMMALIAN CORTICAL NEURONS. M.K. Ticku, M.C. Mhatre and A.K. Mehta. Univ. of Texas, SC, Dept. of Pharmacology, San Antonio, TX 78284-7764

Chronic exposure of GABA was investigated on the binding of ligands to GABA receptor complex, GABA-induced [3H]flunitrazepam, [3H]Ro15-1788, [3H]Ro15-4513 (°)GABA and [3H]TSBPS by 35-45%. Chronic GABA treatment also decreased the GABA induced °-influx by 45% and GABA enhancement of [3H]flunitrazepam binding by 31%. All these effects were blocked by concomitant exposure of the neurons to GABA, receptor antagonist, 6-(1H)-benzothiazine and 5-(1H)-indole. The reduction in α,°1 mRNA may underlie alteration in GABA, receptor function, downregulation and/or uncoupling, observed following chronic GABA exposure of these neurons. Finally, GABA, induces downregulation, uncoupling and a decrease in αμ mRNA subunit are a GABA, receptor mediated event. Supported by NINDS grant NS35339.

Effect of Phosphorylation-dependent Rundown on GABA Receptor Pharmacology. M. Guenels, T.T. Gibbons, & D.H. Farb. Dept. of Pharmacology & Experimental Therapeutics, Boston Univ. School of Medicine, Boston, MA 02118

Repeated application of 30 μM GABA to cultured chick spinal cord neur- um in the whole-cell voltage-clamp configuration resulted in a progressive define, or "rundown" of currents induced by 30 μM GABA. Repeated apnon of 3 μM GABA did not decrease even after induction of rundown by repeated application of 30 μM GABA. Although 3 μM GABA did not normaltically elicit rundown, rundown of the 3 μM GABA response was observed when the response was potentiated by 50-ppm-30-μM-20-μM (5nS), or when a decrease was observed at the intracellular buffer. This result is consistent with a model in which GABA, activation induces rundown by promoting GABA, receptor (GABA,RI) depol Time. After rundown, there was a decrease in the maximum response to GABA, coupled with a leftward shift of the GABA EC50 from 167 μM to 6.4 μM. When APTP was present in the intracellular buffer, the decrease in the maximum GABA, induced current was prevented and the shift in the EC50 was decreased (253 μM). Rundown was also associated with a decrease in the maximum pretransmission enhancement of the GABA response by positive modulators such as 50 μM progesterone, pentobarbital, and chlorodazoxide suggesting a decrease in the allosteric coupling of GABA and steroid recognition sites of the GABA, receptor. In contrast, there was no change in the effects of negative modulators such as pregnenolone sulfate and zinc.

487.8

The GABA, receptor/chloride channel is an oligomeric polypeptide composed of homologous subunits (α,β,γ,δ,ε), each containing four transmembrane segments (M1-M4) and a ryosim loop between M3 and M4. The bovine GABA, receptor includes in this loop a consensus sequence for phosphorylation by protein kinase C (PKC) and is phosphorylated by PKC in vitro. Phosphorylation by PKC may regulate GABA, receptor desensitization. During "whole cell patch" intracellular recording, GABA, induced currents gradually decrease in amplitude. This "rundown" is slowed by ATP and enhanced by alkaline phosphatase in the pipette medium, and may result from GABA, receptor dephosphorylation (Chen et al., J. Physiol, 420:207). We now report that intracellular PKC slows rundown of GABA currents in cultured mouse cortical neurons and L02 cells transfected with cDNAs encoding the bovine α, β, γ, and δ subunits. In cortical neurons, peak responses decreased from 20 to 50% over 20-30 min. For transfected L02 cells, the normalized peak current in cells transfected with δ, in controls decreased to 52 ± 15% (n = 7) at 12 minutes, while cells with PKC showed little decrease (97 ± 23%, n = 5). These results suggest that the rate of GABA, current rundown is regulated by PKC, presumably by phosphorylation of the δ subunit.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
487.7

Rapid desensitization of the GABA<sub>A</sub> receptor has been observed in rat cortical (t<sub>1/2</sub>=2 and 533 ms) and mouse (155 and 235 ms) neurons. The Na<sup>+</sup> current decay is not due to Na<sup>+</sup> channel inactivation, and the receptor is rapidly desensitized. The rapid desensitization of the GABA<sub>A</sub> receptor is consistent with a high affinity (K<sub>3</sub>=4 nM) and a low affinity (K<sub>4</sub>=100 nM) ligand binding sites. The high affinity site is further characterized by a rapid (<t<sub>1/2</sub>=5 ms) and a slow (<t<sub>1/2</sub>=300 ms) component, which may be due to the presence of a high and low affinity receptor subtypes. The low affinity site is characterized by a single component with a <t<sub>1/2</sub>=300 ms. The rapid desensitization of the GABA<sub>A</sub> receptor is consistent with a high affinity (K<sub>3</sub>=4 nM) and a low affinity (K<sub>4</sub>=100 nM) ligand binding sites. The high affinity site is further characterized by a rapid (<t<sub>1/2</sub>=5 ms) and a slow (<t<sub>1/2</sub>=300 ms) component, which may be due to the presence of a high and low affinity receptor subtypes. The low affinity site is characterized by a single component with a <t<sub>1/2</sub>=300 ms.

487.10

The GABA<sub>A</sub> receptor is subject to multiple subunits which have distinct functions for phosphorylation by various kinases, including PKA, PKC, and tyrosine kinases. The GABA<sub>A</sub> receptor is a member of the gamma-aminobutyric acid (GABA) receptor family, which is involved in the control of inhibitory neurotransmission. The GABA<sub>A</sub> receptor is modulated by several mechanisms, including changes in the expression of different subunit isoforms, which can alter the pharmacological properties of the receptor. The GABA<sub>A</sub> receptor is modulated by the activity of protein kinases and phosphatases, which can be regulated by various signaling pathways. The GABA<sub>A</sub> receptor is modulated by the activity of protein kinases and phosphatases, which can be regulated by various signaling pathways.
488.5 

Angiotensin (Ang II) is a peptide hormone that regulates many physiological effects on cholinergic and related indices in rat brain. PD (1-60 mg/kg, l.p.) decreased Ach levels by 50% in vivo PD may alter cholinergic function and NMDA receptor complex mediated responses.

488.6 

In many of its target cells, angiotensin II (Ang II) is known to regulate the density of its receptor in vivo. Recently, we have demonstrated that AngII produces a rapid decrease in AT1 receptors and a more delayed decline in the AT2 subtype in murine NIE-115 cells. In the present series of experiments we have examined the relative contribution of each AngII receptor subtype during agonist-induced downregulation. When AngII cells were exposed to AngII (10 nM for 20 min) there was a significant decrease in the density of both AT1 and AT2 receptors. Similarly, when cells were concurrently treated with AngII and CGP42112A (0.5 µM), a selective AT2 receptor antagonist, comparable downregulation of both receptor subtypes was observed. In contrast, when NIE-115 cells were treated with AngII in the presence of the AT1 receptor antagonist, DuP733 (2 µM), there was no decline in either receptor subtype. In fact, both AT1 and AT2 receptors significantly increased after this combination of agonist and selective antagonist exposure. These results demonstrate that AngII interaction with AT1 receptors is necessary for downregulation of both subtypes, and that selective stimulation of AT2 receptors appears to result in an upregulation of AngII receptors. As much, these data suggest that reciprocal interactions between AT1 and AT2 receptor subtypes may occur during agonist-induced downregulation in neuro-like cells. Supported by NS23986 and MH43787.

488.7 

Differentiated murine neuroblastoma NIE-115 cells possess both subtypes (AT1 and AT2) of membrane associated angiotensin II (AngII) receptors, which are similar in specificity, affinity, and molecular weight to those in rat brain. Functional slabodipilisation of NIE-115 cell membranes with the detergent CHAPS exclusively solubilizes AT1 receptors while AT2 receptors remain in the 105,000 x g pellet. Covalent cross-linking of [3H]-Angll to solubilized AngII receptors with the monofunctional cross-linker DSS specifically labeled two proteins, one minor protein of 102 kDa and one major protein of 69 kDa molecular weight. Affinity purification of solubilized AngII receptors with AngII affinity column resulted in elution of one high molecular weight band (110 kDa) and one low molecular weight band (66 kDa) when excess amounts of agonist were used to elute the proteins from the column. In contrast, when proteins were eluted with an excess amount of an agonist only one protein band eluted from the column with a molecular weight of 66 kDa. Covalent cross-linking of [3H]-AngII to affinity purified proteins derived from both sets of experiments resulted in specific labeling of one high (102 kDa) and one low molecular weight band (66 kDa) when chemical properties of the AngII receptor are similar in sequence of this protein corresponded to the sequence of PLC-a purified from guinea pig uterus. Rats were injected either with aldosterone (ALDO - 250 ug/day) or corticosterone (CORT - 50 ug/day). Control animals were injected with a propylene glycol vehicle. After 3 days, cerebellum, cerebral cortex, hippocampus, amygdala, anteromedian third ventricle (AV3V), and pituitary were dissected and proteins were analyzed by 2-D gel electrophoresis followed by immunoblotting with PLC-c antibodies. The results indicated that PLC-c was present in each of the brain regions examined. Moreover, in the brain the antigen detected two proteins of 60 and 70 kDa with different pl values, whereas in NIE-115 cells only the 60 kDa species was detected by the antisera. In AV3V, medial amygdala or pinnute, or not other brain regions, ALIDO or CORT altered the pl value of both the 60 and 70 kDa protein, and the relative amount of immunoactivity appeared to change in cultured cells as well. The physiological relevance of steroid regulation of neuronal PLC-c remains to be determined. Supported by NS23986, HD52857 and MH43787.

488.8 

Many of the cellular actions of angiotensin II are mediated by phosphoinositol (PI) hydrolysis and the attendant mobilization of intracellular Ca2+. Recently, we have reported that AngII receptors are coupled to a 60 kDa PLC-c in photo-stimulated PLC-c in cultured neuronal cells. In the present study, we have used two-dimensional (2-D) gel electrophoresis to examine the distribution of immunoreactive PLC-c in rat brain, as well as its regulation by corticosteroids. The PLC-c antibody was raised against a 60 kDa protein purified from rat liver. The N-terminal amino acid sequence of this protein corresponded to the sequence of PLC-c purified from guinea pig uterus. Rats were injected either with aldosterone (ALDO - 250 ug/day) or corticosterone (CORT - 50 ug/day). Control animals were injected with a propylene glycol vehicle. After 3 days, cerebellum, cerebral cortex, hippocampus, amygdala, anteromedian third ventricle (AV3V), and pituitary were dissected and proteins were analyzed by 2-D gel electrophoresis followed by immunoblotting with PLC-c antibodies. The results indicated that PLC-c was present in each of the brain regions examined. Moreover, in the brain the antigen detected two proteins of 60 and 70 kDa with different pl values, whereas in NIE-115 cells only the 60 kDa species was detected by the antisera. In AV3V, medial amygdala or pinnute, or not other brain regions, ALIDO or CORT altered the pl value of both the 60 and 70 kDa protein, and the relative amount of immunoactivity appeared to change in cultured cells as well. The physiological relevance of steroid regulation of neuronal PLC-c remains to be determined. Supported by NS23986, HD52857 and MH43787.

488.9 

Angiotensin (Ang II) is a peptide hormone that regulates many physiological functions including blood pressure, fluid and electrolyte homeostasis and neuronal activities of various target cells. Two types of ligands for Ang II have been described, AT1 and AT2. While both subtypes bind Ang II and its analog with comparable affinity, AT1 receptors have high affinity for Dup 753 and AT2 receptors have high affinity for PD 123195, PD 123319 (PD) and CGP 42112A. Ang II has been reported to interact with cholinergic and dopaminergic neurotransmitter systems. We investigated the AT1 ligand PD for its effects on cholinergic and related indices in rat brain. PD (100 mg/kg i.p.) given 30 min prior to sacrifice caused a dose dependent decrease of acetylcholine (Ach) content in rat striatum. The effect lasted for up to 6 h after a 30 mg/kg dose of the agent. PD in vitro did not alter the basal PD or choline uptake; thus it is unlikely to be causing the decrease in Ach levels by blocking choline uptake, suggesting that it may be releasing Ach. Basal cerebellar cGMP levels (a well characterized second messenger response modulated by the N-methyl D-aspartate (NMDA) receptor complex) were decreased by PD at 30, but not at 3 and 10 mg/kg. These results suggest that in vivo PD may alter cholinergic function and NMDA receptor complex mediated responses.

We characterized the binding of 125I-Endothelin (ET-1) to purified plasma membranes from whole rat brain and heart. Binding reactions were done in 0.5 ml of 137 mM NaCl, 10 mM HEPES (pH 7.4), 0.1% BSA, and the following protease inhibitors: soybean trypsin inhibitor (50 μg/ml), leupeptin (0.5 μg/ml) and pepstatin (0.7 μg/ml). To distinguish ET receptor subtypes we performed displacement curves using 0.2 nM 125I-ET-1 and increasing concentrations of either ET-1 or ET-3 (IC50 = 0.2 nM). Alamethicin (50 μg/tube) was shown to increase H-ouabain binding to rat brain (40%), but had no effect on 125I-ET-1 binding. Alamethicin was included in assays to characterize the effects of added MgCl₂ and guanine nucleotides. Scatchard analysis showed no effect of 10 μM MgCl₂ or 10 μM ET-1 binding Kd and Bmax (0.17 nM, 0.14 nM; 0.19 pmol/mg, 0.18 pmol/mg with or without MgCl₂, respectively). Increasing concentrations of either GTPγS or GDPβS had no effect on 125I-ET-1 binding to rat brain. Similarly, GDPβS (100 μM) had no effect on 125I-ET-1 binding to rat brain. In conclusion, both ET-A (heart) and ET-B (brain) receptors exist in a high affinity state in purified plasma membranes, which is not affected by the presence of MgCl₂ or guanine nucleotides such as GTPγS or GDPβS.

488.12 USE OF SELECTIVE ANTAGONISTS TO SUBSTANTIATE THE EXISTENCE OF A B₃-KININ RECEPTOR SUBTYPE IN SPINAL CARDIOVASCULAR CONTROL. P. Lopez, D. Rengo, M. Thakur and R. Couture. Dept. Physiology, Faculty of Medicine, Université de Montréal, Montréal, Canada H3C 3J7 and Dept. Pharmacology, Faculty of Medicine, Sherbrooke University, Sherbrooke, Canada J1H 5N4.

A role for kinins has been suggested in spinal cardiovascular regulation and autonomic control studies. We have demonstrated the presence of B₃-Kinin receptors in the rat spinal cord. In this study, selective antagonists were used to further characterize the receptor subtype involved in the intrathecal (i.t.) action of bradykinin (BK) on mean arterial pressure (MAP) and heart rate (HR) of the conscious rat. The i.t. injection of BK (81 pmol at T-9) elicited a transient increase of MAP and a longer lasting decrease of HR. The cardiovascular response to BK was significantly and dose-dependently inhibited by the prior i.t. injection (717-800 pmol, 3-5 min earlier) of three B₃ receptor antagonists (D-Arg[9Hyp,D-Phe₇]Leu²)-BK, D-Arg[Tyr,D-Phe₇]Leu²)-BK, D-Arg[Hyp,D-Phe₇]Leu²)-BK, but remained unaffected by pretreatment with similar doses of antagonists for the B₆ receptor (D-Arg[9Hyp,D-Phe₇]Leu²)-BK, D-Arg[9Hyp,Gly₇]Leu²)-BK) or the B₁ receptor (D-Arg[9Hyp,Glu₇]Leu²)-BK). Similarly, D-Arg[9Hyp,Glu₇]D-Phe₇]Leu²)-BK, D-Arg[9Hyp,Glu₇]D-Phe₇]Leu²)-BK, two non-selective antagonists for B₃ and B₁ receptors, failed to antagonize the cardiovascular responses to BK and displayed agonic activities at higher doses. Doses 10-fold higher (7.7 nmol) of Hoe 140, a potent antagonist for peripheral B₁ receptors, were required to inhibit the response to BK. These results suggest that BK may affect the cardiovascular system by acting on a B₃ receptor subtype in the rat spinal cord. [Supported by the MRC of Canada].

488.13 CHARACTERIZATION OF NON-OPIOID [3H]-DYN A-(1-13) BINDING SITES IN RAT HEART MEMBRANE PREPARATIONS. M. Dumont* and S. Lemarie. Department of Pharmacology, University of Ottawa, Ontario Canada K1H 8M5.

In the brain, Dynorphin A (DYN A) interacts with both opioid and non-opioid receptors, the stimulation of the non-opioid receptor resulting in a loss of tail flick reflex and hindlimb paralysis. In the heart, DYN A also includes non-opioid effects such as a passive inotropic effect and cardiac arrhythmia. Using membrane binding techniques, we have characterized the cardiac non-opioid DYN A receptor using [3H]-DYN A-(1-13). Binding assays were performed in two milligrams of membrane (0.8 mg protein) in 5 mM Tris-HCl (pH 7.4); 0.2% BSA at 4°C for 120 min followed by filtration through polyethyleneimine treated glass microfiber filters. [3H]-DYN A-(1-13) binding sites were sensitive to tryptic and scatchard analysis yielded linear plots with a Kd of 56.5 nM and a Bmax of 1.91 pmol/mg protein. In competition experiments, [3H]-DYN A-(1-13) binding was displaced by DYN A-(1-13), DYN A-(2-13) but not by DYN A-(1-8) and levorphanol. [3H]-DYN A-(1-13) binding was insensitive to e (DTG, (+)-3 PPP, (+)-SKF-10047) and PCP (TCP, MK-801) ligands. These results suggest that [3H]-DYN A-(1-13) labels a non-opioid DYN A receptor in the heart which upon stimulation may lead to cellular damage as seen in myocardial ischemia. Supported by HSFO.

488.14 PRESENSE OF FUNCTIONAL CORTICOTROPIN-RELEASE HORMONE RECEPTORS IN HUMAN Y-79 RETINOBlastoma CELLS. Maia C. Olimas* and Pierluigi Ovalli. Department of Neurosciences, University of Cagliari, Cagliari, Italy.

In human Y-79 retinoblastoma cells corticotropin-releasing hormone (CRH) produces a marked (60-fold) and rapid increase of adenyl cyclase activity. The concentrations of the peptide producing half-maximal (EC50) and maximal stimulations were 60 nM and 1.5-5 μM, respectively. The effect of CRH is GTP dependent, being minimal in the absence of added nucleotide and maximal at 10 μM GTP. The specific CRH receptor antagonist α-helical CRH 9-41 competively counteracts the CRH stimulation with a Ki value of 80 nM. Somatostatin and vasoactive intestinal peptide display sequence homology with CRH and high affinity for CRH receptors, mimick the effect of CRH with EC50 values of 10 and 11 μM, respectively. These results demonstrate the presence of functional CRH receptors in human Y-79 retinoblastoma cells and suggest that this cell line may be a suitable model in which to study the action of CRH on human retinal cell function.

CRH systems are involved in mediating various aspects of the stress response. CRH receptors in the pituitary mediate stress-induced ACTH release, whereas receptors in other brain regions likely mediate fear-related behavioral and physiological responses. The distribution and density of CRH receptors has been studied extensively in rats, but little work has been done in primates. We examined the regional distribution of CRH receptors in adult rhesus monkeys (Macaca mulata). Pituitary had the highest receptor density (302 fmol/mg protein). In brain, amygdala and cerebellum had significantly more CRH receptors than cortex, caudate, hippocampus, and hypothalamus. Scatchard analysis shows a linear binding affinity in pituitary, amygdala, and cortex (0.169-0.347 nM). The high density of receptors in pituitary and amygdala is interesting because these sites are major mediators of endocrine and behavioral changes associated with fear. Previously we showed that the pituitary-adrenal response in rhesus monkeys is not mature until animals are 12 weeks old. Quantitative autoradiographic studies were performed in pituitary and discrete regions from 0-10-week-old monkeys. In pituitary, no significant age-related differences were found. CRH receptors were evident in anterior and intermediate but not posterior lobes, and their density in the intermediate lobe was greater than in the anterior lobe. Binding sites in the anterior lobe had a “cluster-like’ distribution similar to that of corticotropes. CRH receptors in the intermediate lobe were more uniformly distributed, reflecting the distribution of corticotropin-releasing-producing cells in this region. Data from other brain regions will be presented.

Studies on several avian species have demonstrated that prolactin (PRL) and opioids (OP) regulate feeding, but neither the mechanisms nor the sites involved are identified. To address this question, we measured the density of specific [(125)I]-opiod ([125]I}-DOPPE (a deltamorphin ligand) binding sites in brain regions of adult male dark-eyed juncos (Junco hyperbola) by in vitro autoradiography. We found that specific PRL and OP binding sites are present in several hypothalamic regions (PRL: influndibulum (INF) > ventromedial hypothalamus (VMH) > paraventricular nucleus (PVN) > lateral hypothalamus (LH); OP: PVN > INF > VMH > LH). Some regions (VMH, LH) of the avian brain that contain a high density of PRL and OP binding sites control feeding behavior. Thus, these regions may constitute sites of action on this behavior of PRL or of a PRL-like molecule, and also of endogenous OP.

Several modulatory actions of the insect hormones FMRF-NH2 and related peptides on tension generated in the extensor tibiae muscle of the locust hindwing by stimulation of the slow excitatory motor neurons (SE) are now well established. Here we demonstrate modulatory effects of four newly sequenced neuropeptides isolated from the locust which are unrelated to FMRF-NH2. The following were examined: Tension, contraction rate, relaxation rate, E, and eip amplitude. The preparations were constantly perfused at 1.4ml/min and kept at 20°C. Peptides were applied as 100 μl aliquots into the superfusion line were they were diluted to a final concentration of 5μM. All peptides were isolated from extracts of brain complexes of Locusta migratoria. The following observations were made: 1) Locustatachychlin II (APF(9)FF-NH2) increased tension, the relaxation rate, eip amplitude and could induce a contraction at a stimulation frequency of 0.3 Hz. Effects lasted the presence of the peptide in the superfuse for several minutes. 2) Locustatachychlin III (APF(4)FYY-NH2) had identical effects. 3) Locustatrocnin III, a peptide belonging to a separate family of locust peptides which is supposed to stimulate locust oviducts in vitro, had short-lasting, but dramatic inhibiting effects on tension in this preparation, accompanied by a reduction in eip amplitude and a small depolarisation. 4) Locustaryminhibiting hormone (AWQDNLACW-NH2) which suppresses contractions of the hindgut and oviduct of locusts also had inhibiting effects on muscle, similar to Locustatrocnin III but at a higher dose (10μM). The results of these experiments suggest, that the hindgut of the locust may be subject to complex modulatory actions of different families of peptides. It is as such and as a experimental model particularly useful.

489.2 PEPTIDE IMMUNOREACTIVITY IN THE GENITAL GANGLION OF APLYSIA. S. B. Moffett* Dept. of Zoology, Washington State University, Pullman, WA 99164.

Cells and some other CNS neurons in Aplysia californica reproduction are well established, but neurons of the genital ganglion, located at the junction of the genital nerve with the sperm-oviduct, may also play a role. Indirect Immunofluorescence in wholemounts of the ganglia of young animals (30-50g) revealed intense immunoreactivity to Mytilus inhibitory peptide (MIP) in a quarter of the cells and SCP-1-like immunoreactivity in a non-overlapping population. MIP varicosities are densely distributed on the sperm-oviduct and ovotestis as well as in baskets of endings surrounding some non-immunoreactive cells. Antibodies generated against both catch relaxing peptide (CRP) and buccalin reveal several axons which enter the ganglion and project toward the ovotestis. The strategic position of the genital ganglion neurons and the inhibitory role that some of the peptides associated with the ganglion play in muscle contraction in other systems (Kobayashi and Munoka, 1990. Zool. Sci. 7:801; Kiss, 1991, Comp. Biochem. Physiol. 95C:207) suggest that genital ganglion neurons and bag cells may interact in coordinating egg-laying behavior.

Conantokin GV (CGV) is a neuropeptide isolated from the marine anemone Aiptasia vulgaris. CGV was originally isolated on the basis of its ability to induce a sleep-like state in young mice following ICV injection (Oliveira et al., Toxicon 23: 277, 1985). In older mice, CGV produced hyperactivity or "sleepy climber" activity, in which the hyperactivity alternated with periods of behavioral inactivity. We examined the effects of ICV injection of CGV in adult rats implanted with EEG and EMG electrodes. Animals were placed in an isolation chamber II with a red light and connected to a wheel to show free movement. Behavioral effects were visually assessed. CGV 0.11 nmol/rat had no effect on sleep or behavior. CGV 1.1 nmol/rat induced hyperactivity as well as ataxia. The EEG during this time appeared to be of greater amplitude than normal awake EEG, with overriding high amplitude waves, and could not be scored for sleep-wake stages. 5 of the 8 rats exhibited seizure-like EEG. The behavioral effects of the high dose appear similar to those seen in adult mice.

Vasoactive intestinal peptide (VIP) and related peptides are distributed in the CNS and peripheral nervous systems, and are found in high concentrations in the intestines. We previously showed (Arch. Int. Pharmacodyn. 305:14, 1990) that two VIP analogs induced a concentration-dependent contraction of guinea pig ileum, and that these analogs also induced a concentration-dependent secretion of endogenous acetylcholine (ACh). We now demonstrate that one peptide component of the venom of the Gila monster lizard Heloderma suspectum, which has a high homology to VIP, induced the release of [3H]ACh from a LM-MP preparation of guinea pig ileum. The helodermin toxin was approximately equal in potency to the most effective VIP, and the maximum evoked release of [3H]ACh was at 10 μM of each peptide. The evoked [3H]ACh released was ~ 0.3% of the total content of tritium in the tissue, which contrasts with 20 μM nicotine inducing ~ 0.4%, and 25 mM KCl inducing ~ 5%. These results show that helodermin toxin resembles VIP in specificity and ability to bind to receptors in LM-MP preparations which cause the secretion of endogenous ACh.

ATRIAL NATRIURETIC FACTOR INJECTED INTO RAT SUBFORNICAL ORGAN BLUNTS VASOPRESSIN RELEASE INDUCED BY ANGIOTENSIN II. L. Steardo*, M. Iovine, J. Perez, N. Brunello and G. Raczynski, Center of Neuropharmacology, Institute of Pharmacological Sciences, University of Milan and Department of Neurology, 2nd Medical School, University of Naples, Italy.

The recently discovered atrial peptides are thought to be importantly involved in controlling body fluid homeostasis, both in animals and in humans. The proposed mechanism by which these peptides, collectively indicated as Atrial Natriuretic Factor (ANF), regulate salt–water balance have been the subjects of intensive research over the last few years. ANF has been recognized as a hormone of the brain, its receptors have been identified in close vicinity to those of angiotensin II in circumventricular organs, such as subfornical organs (SFO) and the organum vasculosum laminae terminalis. Via Purini 5, 8005 Freiburg, Germany.

We have recently shown that intraventricular infusion of ANF into rats has been investigated. ANF in doses dependent manner has been able to attenuate the enhancing effect of peripherally injected Ang II (192 μg/Kg/min) on plasma vasopressin levels. These findings support the hypothesis that ANF influences the Ang II effect on fluid balance and they indicate SFO as one of the main sites at which this interaction occurs.

489.7  

The central nucleus of the amygdala (CEA) is known to be involved in the regulation of the parasympathetic and passive coping response to conditioned and acute stresses. Neuroanatomical studies revealed that the majority of the corticotropin-releasing hormone (CRH) containing neurons in the CEA have direct connections with autonomic regulatory nuclei in the brainstem. A 7 min infusion of 30 ng CRH (in 1 μl CSF) into the CEA of freely moving male Wistar rats under stress-free conditions, led to an increase in heart rate, without changes in plasma noradrenaline (NA), adrenaline (A), and corticosterone. The CRH-induced tachycardia was effectively blocked by pretreatment with 1 μg α-\text{CRH}, a receptor antagonist of CRH. Both CRH infusion and pretreatment with α-CRH caused a slight behavioural activation. However, administration of α-CRH alone did not induce a behavioural activation. The shock-probe defensive burying test was used to examine the conditioned stress response. The results show that CRH infusion in the CEA failed to affect heart rate in a conditioned stress test. The behavioural activity showed a remarkable response towards a more active (sympathetic) response after CRH infusion, which was blocked by pretreatment with α-CRH.

The present results suggest that CRH induces a reduction of the parasympathetic output system and passive coping strategies. As CRH is given at the level of the cell body of the CRH neurons in the CEA, the results can be explained as an autoreceptor mediated inhibition of CRH release from the CEA with parasympathetic brainstem nuclei.

489.8  

Both bombesin, a putative peptide neurotransmitter, and its receptors have a wide and extensive distribution in the hypothalamic areas, including the arcuate (ARC) and the suprachiasmatic (SCN) nuclei. A total of 100 ARC and 174 SCN neurons were recorded and tested for bombesin in brain slices. Over 75% of ARC neurons were excited by application of 0.5 nmol of bombesin into the slice chamber. The effects of bombesin on SCN neurons, however, can be differentiated between neurons with different firing patterns, viz. it excited 75% of irregular firing neurons (n=113), while it only excited 17% and inhibited 34% of regular firing neurons (n=61). A dose-dependent effect of bombesin (from 0.005 to 5 nmol) on SCN neurons was also demonstrated. In 25 SCN neurons tested for both bombesin and gastrin-releasing peptide, 24 showed similar responses (67% were excited by both peptides). Pretreatment with Leu\text{1}-cyclic\text{[CH(NH)\text{2}]}-leucine\text{10}-bombesin, a bombesin receptor antagonist, blocked 67% of the bombesin effect in SCN neurons. The data implicate that bombesin may play a significant role in the regulation of selective SCN and ARC neurons.

CRF STIMULATES CATECHOLAMINE RELEASE IN RAT MEDIAL PREFRONTAL CORTEX AND MEDIAL HYPOTHALAMUS, ASSESSED BY MICRODIALYSIS. Jan Lavicky, R. Don Brown*, and Adrian J. Dunn, Department of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130-8936.

In vivo microdialysis was used to measure changes of extracellular concentrations of catecholamines in freely moving rats in response to administration of corticotropin-releasing factor (CRF). With dialysis probes in the medial hypothalamus, intracerebroventricular (icv) administration of CRF (17 or 330 pmol) dose-dependently increased dialysate concentrations of noradrenaline (NAd) and dopamine (DA) and all their measurable metabolites except normetanephrine (NM). Dialysate concentrations of serotonin could not be measured reliably, but those of its catabolites 5-hydroxyindoleacetic acid (5-HIAA) and indicanone (SK) were also elevated. DA and NE increased within the first two 20 min collection periods, and returned to baseline within 3 h. Similar data were obtained with dialysis probes in the medial prefrontal cortex after 17 or 167 pmol of CRF icv. IP administration of CRF (1 nmol) similarly elevated dialysate concentrations of NE, DA, 5-HIAA, and catecholamines catabolites except NM in both the medial hypothalamus and the medial prefrontal cortex. These results support earlier neurochemical data suggesting that CRF administered centrally or peripherally stimulates the release of both DA and NE in the brain.

EFFECT OF GALANIN ON TUBEROINFUNDIBULAR DOPAMINERGIC NEURONAL ACTIVITY AND PROLACTIN SECRETION IN MALE AND FEMALE RATS: C. Gopalakrishnan, K.A. McInerney, K.E. Moore, and R. Lookingland, Dept. of Pharmacol./Tox., Michigan State Univ., E.Lansing, MI 48824.

Tuberoinfundibular dopaminergic (TIDA) neurons terminating in the median eminence tonically inhibit the secretion of prolactin from the anterior pituitary. Prolactin, in turn, stimulates the release of dopamine from TIDA neurons and thereby regulates its own secretion. Central administration of the neuropeptide galanin is reported to increase prolactin secretion, but it is not clear if this effect is mediated by changes in the activity of TIDA neurons. In the present study, the effects of galanin on the basal and prolactin-stimulated activity of TIDA neurons were examined by measuring the ratio of 3,4-dihydroxyphenylacetic acid (DOPAC) to dopamine in the median eminence of both male and female rats. Intracerebroventricular (icv) administration of galanin or dopamine at a rate of 5 nmol (by 15 min) increase in plasma prolactin concentrations, but failed to alter the ratio of DOPAC to dopamine in the median eminence of either male or female rats. These results indicate that galanin-induced activation of prolactin release is not mediated by changes in the activity of TIDA neurons. On the other hand, galanin decreased the ratio of DOPAC to dopamine in the median eminence of both male and female rats whose TIDA neuronal activity was stimulated following experimental procedures that increase circulating prolactin concentrations (i.e., administration of prolactin, oestradiol, or bilateral ovariectomy). Taken together, these results indicate that the inhibitory effects of galanin on the activity of TIDA neurons is dependent upon the level of activity of these neurons in both male and female rats (supported by ADAHMA grant MH 42803).

VAPORPRESSIN RELEASE FROM AMYGDALA IN VITRO. J. Baber, S. Marlo Pich, G.F. Koob and F.E. Bloom*. Department of Neuropharmacology, Scripps Research Institute, 1006 N. Torey Pines Rd., La Jolla, CA 92037.

Arginine vaporpressin (AVP) containing neurons have been shown to occur in limbic structures, including the hippocampus and amygdala, as well as in the classic magnocellular hypothalamic nuclei. We have investigated the release mechanism of AVP in vitro from dissociated rat brain regions. Micropipet amygdala, hypothalamus and somatohypophysis were each incubated in balanced Earle's salt solution for a total of 180 minutes at 37°C. After three 20-minute intervals for conditioning the cultures, perfusion with NMDA (60 mM) caused a marked stimulation of AVP release (amygdala; basal level 58 +/- 18 pg/ml, stimulated 90 +/- 23 pg/ml; hypothalamus; basal level 392 +/- 36 pg/ml, stimulated 831 +/- 91 pg/ml). No release was found with slices from the somatohypophysis. This stimulation effect is calcium dependent and was blocked in the presence of EGTA (10 mM). These results indicate that depolarizing agents induce the release of AVP-like immunoreactivity not only from the hypothalamus but also from limbic structures, such as the amygdala. This system may be suitable for evaluating the effects of other regulatory signals, such as the cytokines, on neuronal neuronepair release.

CHRONIC PEPTIDE T ADMINISTRATION PREVENTS NECROTICAL ATROPY RESULTING FROM NUCLEUS BASILIS LESIONS IN AGED RATS. D.J. Scoed1, J.M. Hug2, C.B. Phippot1, M.R. Ruff2 and G.W. Arandelus3. 1Dept. of Biology, Univ. of S Florida, Tampa, FL 33620, NICH, NIH, Bethesda, MD 20892, 2Center for Molecular & Behavioral Neuropsych, 1 Rutgers Univ., Newar, NJ 07102.

Vasoactive intestinal peptide (VIP) is co-localized in cholinergic terminals within neocortex. Since VIP has neurotransactive actions in vitro, it may be involved with, and/or be a precipitant of blood pressure changes in neocortex resulting long-term after cortical cholinergic denervation induced by nucleus basalis (NB) lesioning (Science 238:592, 1987). The two-fold purpose of the present study was: 1) to determine the long-term degenerative effects of NB lesions in the neocortex of aged rats, and 2) to test the ability of "peptide T" (PT), which has a potent peptide hormone, with VIP (7-11), to prevent any observed degenerative changes. Aged (20-21 month) male Sprague-Dawley rats received NB injections of isotonic acid (5 pg/ml in PBS) bilaterally. Immediately after lesioning, animals began receiving daily i.p. injections of either PT (1 mg) or vehicle solution. After sacrifice 5 months later, brain sections were stained with thionine for analysis of neocortical thickness (Layers II-IV) at the mid-prefrontal level. Compared to measurements from unoperated controls, NB lesioned animals given vehicle alone exhibited a significant 17.6% decrease in overall cortical thickness (p<0.002); there was a 13.2% decrease in Layer II (p<0.02), a 28.6% decrease in Layers III-V (p<0.001), and a 15.1% decrease in Layer VI (p<0.02). Chronic PT treatment completely eliminated the lesion-induced decrease in overall cortical thickness, as well as that within Layers II and VI. Also, the lesion-induced decrease in Layers III-V was significantly attenuated by PT (p<0.05). PT's action in preventing NB lesion-induced neocortical atrophy may involve a direct or indirect (glial-mediated) neuroprotective mechanism, presumably through VIP receptor activation.

OPIOID RECEPTORS: COUPLING AND BIOCHEMISTRY

490.1
SELECTIVITY PROFILES AND REGULATION BY GUANYL NUCLEOTIDES OF LIGAND BINDING TO μ, δ AND η OPIOID RECEPTORS IN BRAIN MEMBRANES. M. Williamson and J.M. Herry*. Biochemical Pharmacology Group, Paulus, Inc., Bothell, WA 98011

We have used specific radioligand binding assays for the μ, δ and η opioid receptors in whole brain membranes from guinea pig to establish selectivity profiles for various opioids and investigate effects of guanylyl nucleotide regulation of agonist binding. [3H]D-Ala2-D-Leu5-MePhe7-Gly8-val (DAMGO), [3H]D-Phe2-D-Trp6-D-Pen7-D-Leu8-Tyr9-Phe10-NH2 and [3H]ET-1 (100 nM) were used as specific radioligands for the μ, δ and η receptors, respectively. Assays were carried out in modified Krebs-Hense buffer containing protein inhibitors. Saturation isotherms revealed a single class of high affinity sites for [3H]DAMGO. Inhibition of [3H]DAMGO binding yielded the following Ki's: fentanyl (1.2 nM), nalorphine (0.76 nM), DPDPE (30 nM), naltrindole (3.2 nM), and noranolterenol (26 nM). Indirect Hill coefficients for converting ligands were near 1.0. High K(1) receptors were observed when the ratio of the Ki for s and a were 926 and 3.70, respectively. GTP-γ-S completely inhibited [3H]DAMGO binding with an IC50 of 0.35 mM. This receptor sensitivity for differentiation of μ receptors was observed when the ratio of the Ki for K(1) and a were 926 and 3.70. The Ki for DDPPE was found to be 2.2 nM for a single class of sites. USO488 was found to be highly selective for δ receptors since μ/κ=211 and δ/κ≈11,430. Norbinaltorphimine exhibited a K(1) of 0.35 mM and a K(2) of 0.39, indicating ligand heterogeneity in labeled sites. [3H]DDPPE was found to be highly selective for δ receptors, with μ/δ=168 and a/δ=500. Saturation concentrations of GTPγS or GDPβS reduced [3H]DDPPE binding. The inhibition of [3H]DDPPE at concentrations of 0.70 and 2.0 mM, and reduced the binding of [3H]DDPPE to 12% and 5% of control with IC50 of 0.15 and 0.92 μM. These results establish that guanylyl nucleotide regulation offers a new opportunity to convert μ to δ receptors to states of mixed affinity for agoists in guinea pig brain membranes.

490.2

PC12 rat pheochromocytoma cells are useful as a model system for neuronal development. In one subline of PC12 cells, PC12h, low levels of type-opioid receptors markedly increase in response to nerve growth factor (NGF). (Inoue, N. and Hatahaka, H. J. Biol. Chem. 252: 9238, 1977). However, we have been investigating the consequences of the appearance of opioid receptors in PC12h cells and examining concurrent changes in the expression of opioid-regulated genes. After 10 days of treatment with NGF, the number of opioid receptors (as measured by [3H]-diprenorphine binding), increases from a Bmax of 40 to 220 fmol/mg protein. We have previously demonstrated that the opioid receptors in this cell line can be down-regulated by etorphine, indicating that they are capable of responding to opioid agonists. In the current study, we examine the influence of whether opioid receptors in PC12h cells couple to inhibition of adenyl cyclase was addressed. Etorphine caused a dose-dependent inhibition of cAMP accumulation. This effect was reversed by naloxone. Furthermore, etorphine inhibition of cAMP accumulation was found to be non-NGF as well as NGF-treated PC12h cells. These data indicate that the opioid receptors on PC12h cells are coupled to adenyl cyclase, similar to δ receptors in other cell lines. (Supported by DA-06867)

Considerable evidence suggests that opioid receptors are members of the G-protein linked receptor family. For several G-protein coupled receptors, biochemical and immunological analyses have implicated transmembrane segments of the receptor as the sites of ligand binding. The relative potencies of the enantiomers of 2m-aminoethyl-6,14-e-n-d-ethenothetadrylporpine (I; close structural relative of etorphine) and a series of N-acetyl derivatives were assessed using a N-acetion/laxone/rat brain membrane binding assay. N-acetylation(I) had no effect on potency whereas the introduction of a hydrophobic N-phenylactyl(III), N-phenylpropionyl (IV), or N-phenylpropionate(VI) substantially increased binding potency 40-fold, and made these compounds as potent as etorphine (pK < 0.3 nm). The effect of these compounds on an electrochemically evolved potential from isolated neonatal rat spinal cord showed them to be potent agonists, with III as potent as etorphine, I, II, IV and V being less effective. The electrophysiological effects were reversed by naloxone, but upon naloxone wash-out, effects of the more hydrophobic compounds (III, IV, V) persistently returned. These results suggest that partitioning of these compounds into the hydrophobic core of the neuronal plasma membrane may play a vital role in their duration of action because the µ opioid binding site is located in the transmembrane region of opioid receptors. However, because III is a more potent agonist than IV or V, small structural changes must affect the ligand/receptor complex conformation that transmits binding information to the G-protein involved in the transmembrane signaling process.

Pretreatment of rat brain membranes with 15 mM HCl at pH 4.5 prior to assay at pH 7.4 produces the following modifications in signal transduction pathways that regulate adenyl cyclase (AC): 1) decreases stimulation of AC by Gp, 2) increases receptor-mediated inhibition of AC, and 3) increases inhibition by Na* and GTP of agonist binding to opioid receptors, with no effect on binding in the absence of Na* and GTP. In NG108-15 membranes, low pH pretreatment did not increase opioid stimulation of low KCl with or without GTP, or (U96,593) opiod of AC, in the presence of 120 mM NaCl. However, studies of the effect of Na* concentration on AC and GTPase activity in NG108-15 membranes have revealed that low pH pretreatment: 1) decreased basal AC activity in a manner that was inversely related to Na*, 2) increased opioid inhibition of AC at Na* concentrations below that required to support opioid inhibition of the enzyme in control membranes, and 3) decreased basal low KCl GTPase activity and increased opioid agonist stimulation of low KCl GTPase in a manner that was dependent on Na*. The common effect of low pH pretreatment on both AC and GTPase was to increase agonist effects at low Na* concentrations. These data suggest that a complex interaction between Gp, Gi, and inhibitory receptors is altered by low pH pretreatment.

490.5 OPIATE RECEPTOR AGONISTS REGULATE PHOSPHORYLATION OF SYNAPSIN I IN SPINAL CORD-DORSAL ROOT GANGLION COCULTURES. L. Vogel, D. Saya, S.Y. Nah, LMH, NINDS, NIH, Bethesda, MD 20892; Dept. Neurobiology, Tel-Aviv University, Tel-Aviv, 69106 Israel

κ-Opiate receptor agonists were shown to inhibit adenylate cyclase activity as well as the voltage-dependent Ca2+ channels in spinal cord-dorsal root ganglion SC-DG cocultured neurons. (Neurochem J 25: 186, 1989; J Biochem. 264:347, 1989). We have, therefore, investigated the effect of κ receptor agonists on the phosphorylation of synapsin I, a synaptic vesicle-associated protein whose phosphorylation was shown to be regulated by cAMP, depolarization, and intracellular Ca2+ concentration. Depolarization of SC-DG cocultures (by high K+ or veratridine) as well as the addition of forskolin (which activates adenylate cyclase) leads to increased phosphorylation of synapsin I. The addition of κ-opiate agonists (such as U50488 and EKX) attenuated both the K+ depolarization- and forskolin-induced phosphorylation of synapsin I. The E50 obtained for U50488 was 5 and 1 μM, respectively. This attenuation by κ agonists was blocked by the opiate antagonist naloxone and 6-κ-opiate receptor agonist had a much weaker effect compared with κ. Similarly, κ-opiate agonists attenuated (by 30-50%) the high K+ or veratridine-induced phosphorylation of synapsin I in synapsosomes prepared from spinal cord. These results show that opiate ligands modulate synapsin I phosphorylation. Moreover, the data could explain the alterations in synaptic efficacy and reduction in neurotransmitter release observed following opiate treatment. (Supported by the Minerva and Schilling Foundations, the National Institute of Drug Abuse, and the German-tranche Foundation for Scientific Research and Development.)

Nuclear opioid binding sites have been discovered in NG108-15 cells. Marker enzyme analyses, electron and fluorescence light microscopy studies at attests to the purity of nuclear preparations. Immunohistochemical staining of cryostat sections of NG108-15 cells with an anti-opioid receptor antibody corroborated a nuclear localization. Nal-D-Leu-Phe, H-D-Ala2-NMe-Phe and H-D-Phe-Cys-Thr-Phe homologous binding (Kd and Bmax), H-D-Ser-D-Phe homologous competition curves, stereospecificity and kinetic data, satisfied criteria for the presence of δ opioid sites in purified nuclear preparations; neither μ- nor κ-specific binding were detectable. Agonists, Nal-D-Leu-Phe and Nal-D-Phe, bind with high affinity to nuclear membranes and with lower affinity to chromatin. In contrast, partial agonist H-D-Phe-Cys-Thr-Phe binding sites are in nuclear membranes, while low affinity binding was found in nuclear membranes. Gp(NH)2 sensitivity of H-D Pakle binding was detected in nuclear membranes but not chromatin. Opioid binding to nuclear membranes and chromatin was abolished upon cycloheximide treatment of cells. The results suggest that NG108-15 cells contain newly synthesized G protein-coupled δ receptors in nuclear membranes and uncoupled, internalized opioid sites in chromatin.

Previous studies from this laboratory have demonstrated the presence of κ opioid receptors on membranes from the mouse thymoma cell line, R1. Chronic exposure of these cells to the κ agonist USO, 488 produced changes in the receptor population, as indicated in ligand binding assays using the κ-selective agonist [3H]U69,593. The binding of 1 nM [3H]U69,593 to membranes from USO, 488-treated cells was reduced by as much as 55% in comparison to controls, which were treated with an equivalent concentration of USO, 488 for 15 min. The effect of USO, 488 was both concentration- and time-dependent, with the maximum decrease in binding observed after 24 hr of exposure. The decrease in [3H]U69,593 binding was due to changes in the Bmax value and a 2.3 fold increase in the Kd value. The effect of chronic exposure to membranes prepared from these cells, suggesting that κ and δ opioids did not produce a change in the number or affinity of κ opioid receptors. The R1.1 cell line will provide a model for characterizing the mechanisms of receptor downregulation in cells of the immune system. (Supported by USPHS DA04355 and DA07232.)

490.8 THE PRESENCE OF 3 OPIOID RECEPTORS ON COS-7 CELL MEMBRANES. T. Zalewska, E. Malatyńska, H.1. Yamamura. Department of Pharmacology, College of Medicine, The University of Arizona, Tucson AZ, 85704.

COS-7 cells are very often used in transient gene expression. They might be considered as part of an expression system for opioid receptor cloning. We report the presence on COS-7 cell membranes of high affinity binding sites for [3H]naltrindole (an antagonist of 5 opioid receptors). Equilibrium binding studies show that [3H]naltrindole labels a homogenous population of binding sites with a dissociation constant (Kd) of 72.6 pM and Hill value not different from unity. The measured receptor density (Bmax) is 17 fmol/mg protein. Naltrindole and U69,593 selective for δ opioid receptor, p-CI-DPDE, displaced [3H]naltrindole from its binding site with high affinity. The Kd value for naltrindole is 200 pM, and for p-CI-DPDE is 315 pM. The ligands p-DL- and p-Chloro-2-Indoleacetic acid were not only inhibited [3H]naltrindole binding at micromolar concentrations. This study demonstrates the presence of 3 opioid receptor sites on COS-7 cell membranes. It is concluded that these cells should be avoided for the expression of putative δ opioid receptor genes. Supported in part by NIDA grants.
490.9

KAPP-A-LIKE RECEPTORS ON ASTROCYTES STIMULATE L-TYPE Ca2+ CHANNELS. Peter S. Eriksson, Michael Nilsson, Maria Wågberg, Elisabeth Hansson and Lars Rönnbäck*1,2. Institute of Neurobiology 1 and Department of Neurology 2 University of Göteborg, Göteborg, Sweden. Cultured astrocytes from the cerebral cortex respond to κ-receptor stimulation with a substantial elevation of the cytoplasmic free calcium, visualized through the use of the fluorescent calcium indicator fura-2. The stimulation of κ-receptors using the agonist U-50,488H increased the level of calcium through a stimulatory effect on the transmembrane calcium influx. The transmembrane influx was dose dependent. Furthermore, it was completely blocked by the selective κ-receptor antagonist nor-binaltorphimine. The presence of L-type channels was verified by the use of Bay K8644. The effect of Bay K8644 was completely blocked by nifedipine, indicating the involvement of L-type channels. L-type channel coupled κ-receptors on astrocytes might represent a novel mechanism contributing to the depressant action of opioids on synaptic transmission via decreasing the availability of extracellular calcium necessary for presynaptic transmitter release.

490.11

To identify animal models differing in opioid receptor binding parameters and in heritable behaviors, we have examined the number of Bmax (nM) and affinity (Kd) of μ and δ receptor in whole brain preparations from 8 inbred strains of mice. TH-DAMGO (0.5-21 nM) and H-D-β-endorphin (0.04-4 nM) were used to characterize μ and δ receptors, respectively. Scatchard analyses revealed that the Bmax values for μ receptors ranged from 75 to 115 fmol/mg, with a rank order among the strains of BALB C, C3H/SHJ, C57/BL10, DBA, SJL, AKR. No differences in μ receptor affinity were observed among the strains (Kd = 3-4 nM). The number of δ receptors among the strains ranged from 55-83 fmol/mg, with a rank order (BALB C < C3H, C57/Bl6J, C57/Bl6D2, CBA < DBA, SJL < AKR) very similar to that observed for μ receptors. There were no differences among the strains in δ receptor affinity (Kd = 0.4-0.5 nM).

Statistical analyses revealed a significant genetic correlation between the number of μ and δ receptors in whole brain preparations from the 8 inbred strains (r = 0.88, p < 0.01). The strong genetic correlation between the number of μ and δ opioid receptors suggests that there may be common mechanisms involved in the regulation of the expression of these receptor subtypes.

490.14

Voltage-clamp recording was used to detect functional expression of opioid receptors in the Xenopus oocyte translation system. By injecting poly(A)+RNA isolated from 3 week-old rat striatum or whole brain, the oocytes often acquired intracellular Ca2+-related oscillatory responsiveness to DAMGO (μ agonist), DAOPH (μ agonist), DPDE (δ agonist) and U-50488H (δ agonist) at a concentration of 1 μM. These responses were very potent and observed after injection of mRNA, however, water-injected oocytes never responded to any of the agonists. After sucrose-density fractionation, RNA size class of about 8 kbase encoded these opioid receptors. In the oocytes injected with striatal mRNA, DAMGO and DPDE evoked the fluctuating current with higher probability and in larger amplitude than other agonists, whereas whole brain mRNA produced more DAMGO and U-50488H responses predominantly. The DPDE response of striatal mRNA-injected oocytes was antagonized by naloxone as well as the δ-specific agonists ICI 154192 and ICI 174864. DAMGO and U-50488H responses have not been characterized yet because of strong desensitizing property. These observations suggest that putative μ, δ and subtypes of opioid receptors mobilizing intracellular Ca2+ are expressed in Xenopus oocytes by rat brain mRNA.

CHARACTERIZATION OF A POTENTIVE OPIOID RECEPTOR IN THE PROTOZOAN STENTOR. T.G. Brabin*, S. Mora*. Department of Cellular and Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260

An understanding of the biochemical events underlying opioid-mediated processes has been hindered by the lack of selective agonists or antagonists active in mammalian systems. Therefore, a simple systems approach may prove beneficial in understanding the biochemistry of opioid-mediated events. The protozoan Stentor, an invertebrate with an opioid receptor and this simple organism could provide a useful system for the biochemical study of such receptors. We have previously shown that β-endorphin (β-ends) modulates a mechano-sensory conductance in Stentor with an EC50 of 3.0 μM. The result of this modulation is behaviorally apparent as a marked decrement in the probability that a cell will contract when mechanically stimulated. The effect of β-ends appears to be receptor mediated for several reasons. First, the β-end effect is mimicked by morphine and DAGO, but not by dynorphins or the enkephalins indicating a putative μ-like receptor. Second, the actions of β-ends, DAGO, and morphine are sensitive to equimolar concentrations of the opiate antagonist naloxone. Third, the effect of β-ends is pertussin toxin (PTX) sensitive. Stentor incubated for 24 hours in 200 μg/ml of PTX do not exhibit a depression in mechanical stimulus response probability when exposed to 1 μM β-ends or 20 μM DADO. This PTX treatment has no effect on control cells’ response probability and does not affect the cells’ electrical threshold. This suggests that these opioids act through a G-protein linked opioid receptor. Finally, Stentor exhibit tolerance with the continued exposure to β-ends, which work is aimed at identifying any endogenous opioid ligands as well as characterizing this receptor utilizing pharmacological and molecular techniques.

**IN VIVO IMAGING OF OPIOID RECEPTORS WITH [125I]JOXY, A NEW IODINATED NALTREXONE DERIVATIVE.**
M.J. Iadarola, L.S. Brady, M.V. Green, K.F. Bernard, B.R. de Costa and K.C. Rice. NAB, NIDR, 2CNE, NIMH, 2DNM, CC, 2CDBB, NIMH and 2LMC, NIDDK, NIH, Bethesda, MD.

We have synthesized and radiolabeled JOXY (de Costa et al., J. Med. Chem. in press) for use in single photon emission computed tomography (SPECT) imaging of endogenous opioid receptors in humans. JOXY, an iodo-derivative of naltrexone, functions as an antagonist and is an analog of cycloFoxy, a [125I]-labeled compound used in positron emission tomography (PET). Intravenous injection of 20 uCi to rats yielded highest levels of binding in striatum and thalamus, lesser binding in other areas, and the fewest counts in cerebellum. Counts were displaced to levels in cerebellum by pretreatment with (-) but not (+) naloxone. Autoradiography of brain sections after i.v. administration showed dense binding to striatal patches, laminae I-II of spinal cord, medial habenula and interpeduncular nucleus. We used an experimental gamma camera to obtain a brain scan of a distribution of [125I]JOXY in a living animal. A planar scan in the vertex projection revealed dense accumulation of radioactivity in the thalamus, midbrain and bilaterally in the caudate nucleus. This is one of a new method for imaging receptors in small animals in vivo and suggest that JOXY will be an effective agent for use as a ligand in SPECT studies of human opioid receptors.

**GLUCOSE METABOLISM AND OPIATE RECEPTOR BINDING IN THE DEAFFERENTED CORTEX IN MONKEY BY PET.**
D.J. Doubet, R.E. Carson, M.A. Changning, R. Saunders, NAB and R.E. C. Brain Imaging Center, NIMH; Nuclear Medicine Dept, NIH, Bethesda, MD.

To examine the role of the cortical opiate system, we studied glucose metabolism and P-18 cycloxy (CF) binding in the visual system of rhesus monkeys (N=4). The forebrain commissures and one optic tract were sectioned. CF distribution volume (DV) and glucose metabolic rates (CMRG) were determined in left and right hemispheres. The deafferented occipital and parietal and temporal areas had a significantly increased DV of CF in 18 and 20.6 and a significant decrease in CMRG (12, 8 and 6) compared to the contralateral side (p<0.05). Compared to normal rhesus, CF binding was significantly increased (25%) in the contralateral occipital, parietal and temporal areas and the ipsi and contralateral central and frontal areas, but glucose metabolism was normal. CF binding and CMRG were normal in subcortical areas.

This increase in DV of CF, likely due to an increase in unoccupied opiate receptors, in areas with decreased functional activity suggests that sensory deafferentation may play a role in the modulation of opiate function and that cortico-cortical connections are important in its regulation.

**ACTIVATION OF POSTSYNAPTIC BUT NOT PRESYNAPTIC DOPAMINE RECEPTORS BY DIHYDROXIDINE, A POTENT D1 AND D2 RECEPTOR LIGAND.**

Mottola et al. (Neuropsychobiology, 17:188) found that the D1 agonist dihydridoxine (DX) weakly bound to D2 receptors, using radio-labeled spiperone, a D2 antagonist, as a D2 receptor marker. Like D2 agonists, DX depressed tyrosine hydroxylase, but this was not altered by DX antagonists. In binding tests, we find that DX had higher affinity for D2 receptors (Ki=3.3 nM vs "H-U-86170, a [3H]DA agonist) than for D1 sites (Ki=38.5 nM vs "H-SCH 23938) and n2 sites (Ki=62.5 nM vs "H-histidine). In reserpinized mice, doses of 2.5 and 5.0 mg/kg p.o. stimulated locomotor activity similar to other D2 agonists. This effect was blocked by the D2 antagonist raclopride (1 mg/kg s.c.). However, unlike other D2 agonists, DX, 0.1, 1.0, and 5.0 mg/kg p.o. did not block amphetamine-induced locomotor activity in non-reserpinized mice. It did not alter firing rates of DA neurons in substantia nigra pars compacta (SNPC) with doses up to 5 mg/kg i.v. (apomorphine ED50=0.009 mg/kg i.v.), nor did it antagonize DA agonist effects in SNPC. In contrast, DX behaves like a D2 agonist with some affinity also for D1 receptors, similar to apomorphine. However, it does not stimulate or block the DA autoreceptor, a D2 binding site.

**491.2**

**EFFECTS OF DEPRENYL ON DOPAMINERGIC NEUROTRANSMISSION IN THE RAT MESOSTRIATAL SYSTEM.**

Deprenyl, a monoaminooxidase B inhibitor, has been reported to delay the initiation of levodopa therapy in patients with Parkinson’s disease (PD), although the slowing of the progression of PD caused by deprenyl is controversial. Deprenyl and its metabolite were undertaken in order to examine the influence of this drug on mesostriatal dopaminergic neurotransmission in control and 6-OHDA-lesioned rats.

We studied the chronic effects of treatment with deprenyl (0.25mg/kg, s.c. daily) for 5 and 30 days on striatal DA, DOPAC and TH contents, on D1 and D2 DA receptor densities and on [3H]spiperone binding in two groups of rats (Gi and G2) and compared them to controls by the delay of treatment. Each group was composed of shams (no lesion), sham + deprenyl (no lesion), 6-OHDA lesioned (no deprenyl) and 6-OHDA lesioned + Deprenyl (10). Striatal levels of DA and the metabolite DOPAC were determined by HPLC-EC; DA D1 and D2 receptors were measured by autoradiography, using [3H]SCH 23930 and [3H]Raclopride respectively as ligands; [3H]DA mRNAs were examined by in situ hybridization using a specific oligonucleotide; TH was studied by radioimmuno-histochemistry. The main obtained showed that:
- striatal DA levels were significantly increased (+70%) in sham-deprenyl animals of G1 group. In lesioned animals where more than 90% of DA neurons were destroyed, no consistent effect could be defined;
- the effects of deprenyl on D1 receptor expression are clear only after 15 days of treatment. These effects concerned, firstly, sham-deprenyl animals where striatal D1 receptor densities were significantly increased (+18% to 25%, p<0.001) compared to sham controls; secondly, lesioned-deprenyl animals where D2 mRNAs levels were increased about 12 to 17% (p<0.001) as compared to lesioned rats. No effect could be observed on striatal D1 receptors and TH levels.

**D1, DOPAMINE RECEPTOR TURNOVER AND mRNA LEVELS IN THE NEUROLEPTIC-RESPONSIVE (NR) AND NEUROLEPTIC NON-RESPONSIVE (NLR) Lines of MICE.**
Y. Qian, R. Hitzemann, G. Yount, J. White and R. Hitzemann. Dept. of Psychiatry and Neurobiology, Div. of Endocrinology, SUNY at Stony Brook, NY 11794.

The NR and NLR lines of mice differ >10 fold in their sensitivity (ED50) to catalepsy induced by neuroleptics with a high D1/D2 dopamine receptor activity profile. Recovery of pre- and postsynaptic D1 receptors was assessed by quantitative autoradiography following N-ethoxy carbonyl-2-ethoxy-1,2-dihydroquinoline (EDQ) blockade. Significant differences in receptor turnover were found between the two lines in the nucleus accumens (NA) and the caudate putamen (CPU), but not in the substantia nigra zona compacta (SNc) and the ventral tegmental area (VTA). For both lines, receptor production rates in the NA and CPU are higher than those in the SNc and VTA. For the NA and CPU, receptor production rates of the NLR line were lower than those of the NR line. Preliminary nuclear protection data show that such receptor turnover differences are associated with parallel differences in the D1 receptor mRNA level.

**USE OF BXD RECOMBINANT INBRED MICE TO DETECT GENOMIC MARKERS FOR NEUROLEPTIC SENSITIVITY.**

Our laboratory has used a selective breeding and standard inbred strains to investigate the biochemical and genetic factors associated with response and non-response to neuroleptic induced catalepsy (see e.g. Kanes et al., Soc. Neurosci. Abst. # 839.6, 1991). The study of recombinant inbred (RI) strains provides a unique mechanism for detecting linkage between the phenotype of interest and specific Quantitative Trait Loci (QTL). The strain distribution patterns (distribution of EPQ for the heterozygote of the BXD recombinant inbred series (RI)) has been determined. ED50's in the RI strains are normally distributed confirming that sensitivity to neuroleptic induced catalepsy is a polygenetic quantitative trait. The BXD was correlated with the SDP of 260 genomic markers mapped in the BXD's. This analysis indicates 14 markers significantly associated with the catalepsy SDP. Eight markers were found on chromosome 4, of which one were centered on FV-1, which is at on cm from the centromere. Correlated responses to neuroleptic catalepsy include the density of pre and post-synaptic D1 receptors, the density of midbrain DA neurons and the density of striatal cholinergic neurons. The effects of these responses and the associated QTL analysis will be presented.

**SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992**
491.5 CHOLINERGIC AND DOPAMINERGIC REGULATION OF NEUROPTIC RESPONSE IN SELECTED AND INBRED STRAINS OF MICE. H. Hitzemann, S. Kanes, Y. Glin and R. Hitzemann. Departments of Psychiatry, Pharmacology and Neurobiology SUNY at Stony Brook, 11734-8110 and YAMC, Northport, NY 11768. The successful selection of the neuroptic responsive (NR) and nonresponsive (NNR) mice (Hitzemann et al. 19911) and the marked variation in the neuroptic sensitivity among inbred strains of mice (Kanes et al. 1991) argues strongly that genetic mechanisms contribute significantly to the variance in neuroptic-induced catalepsy. The precise nature or extent of these mechanisms remains unclear. Given the well-established role of the striatal cholinergic system in regulating extrapyramidal dopaminergic responses, we have investigated striatal cholinergic cell number (choline acetyltransferase [ChAT] positive neurons) in the NR and NNR lines and in inbred strains. In comparison to the NNR line, cholinergic cell number is significantly increased 40 to 60% in the rostral but not caudal striatum. Similarly, we have found that among the inbred strains there is a significant correlation (r = 0.75 or better, p < 0.05) between the EDA for haloperidol-induced catalepsy and cholinergic cell number in both the rostral and caudal striatum. Focusing on the rostral striatum, there is no difference between the NR and NNR lines in D2 dopamine receptor density; however, for the inbred strains, D2 receptor density is inversely correlated (r = 0.72, p < 0.05) to cholinergic cell number. This difference between the selected and inbred lines argues that D2 receptor and cholinergic cell number can have independent genetic regulation within the striatum.

491.7 EFFECTS OF D2 AND D3 RECEPTOR ACTIVATION MEASURED BY MICROPHYSIOLOGY. M.P. Rosser, M.L. Kozlowski, R.L. Neve, and K.A. Neve. Screening and Biochemical Research, Bristol-Myers Squibb, Wallingford, CT, 06492.

491.8 INTERNAL ACCEPTOR SITE DIRECTS ALTERNATIVE SPLICING IN THE MOUSE D2 DOPAMINE RECEPTOR. Fishburn C.S., David C., Cameron S., and Fuchs S.S. Dept. of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel.

491.10 CHARACTERIZATION AND REGULATION OF DOPAMINE D3 RECEPTORS. R.A. Cox, R.A. Henningsen, K. Duwe, R.L. Neve, and K.A. Neve. Molecular Center and Oregon Health Sciences University, Portland, OR 97213, and McLean Hospital, Belmont, MA.

The dopamine (DA) D3 receptor is a novel D2-like receptor whose pharmacological profile differs from that of DA D2 receptors. We have stably expressed D3 receptors in C6 glioma cells (C6-D3) and binding characteristics of the D3 receptor in [3H]spiperone [125I]iodobenzamide (which has high affinity (60-100 pM) for D3 receptors. Drug potencies in rat basal forebrain minus neostriatum (BF) are measured to these using tissue from rat neostriatum (NS), and recombinant D3 (C6-D3 and D2 (C6-D2) receptors. Two site analysis of the data indicated that a small population (11-20%) of binding sites in rat BF a pharmaceutical profile similar to that of C6-D3 receptors. For neostriatum, however, curves are best fit to only one.

The genes coding for six subtypes of dopamine (DA) receptors have recently been characterized and expressed in various cell lines. In this study we have compared the pharmacological properties of the human D3 receptor with the two alternatively spliced forms of the human D2 receptor, D2A (long) and D2B (short). The D2 receptor was expressed in hamster ovary cells and the D3 receptor in mouse fibroblasts. In vitro radioligand binding studies demonstrated that the benzamid analogs of [3H]spiperone and [3H]iodobenzamide bind with high affinity, saturability and low non-specific binding to the three DA receptor subtypes. The Kd (dissociation constant) values of [3H]spiperone for D2A, D2B and D3 were 1.4 and 1.43, and 1.43 and 1.43, respectively. As expected the binding of the benzamid analogs was regulated by sodium ions. In competition studies most of the agonists tested showed about equal affinities for the three DA receptor subtypes. However, remoxipride and spiperone had ten fold lower affinity, and some benzamid analogs showed two fold higher affinity for D3 than for D2 receptors. Among the DA agonists, the agonist derivatives displayed an up to fifty fold higher potencies at D3 receptors. Two affinity states for DA and quinpirole were observed in all three subtypes. It is concluded that in spite of the high level of homology in the transmembrane domain it is possible to obtain D2/D3 selective drugs that might prove useful for development of antipsychotics.
491.11

THE D3 ANTAGONIST, AJ76, INCREASES ACCUMBENS DOPAMINE AND SEROTONIN RELEASE: SIMULTANEOUS DETECTION ON LINE WITH BEHAVIOR. E. Eng*, E.T. Pelchan, R.T. Wochler, M.P. Feuer† and P.A. Broderick. Dept. Pharmacol., CNS Med. Sch., Colleges of Physicians & Surgeons, 138th St., NY, NY 10032, USA, CNS Res., The Upjohn Co., Kalamazoo, MI 49007, USA. AJ76 is a dopaminergic (DA-ergic), antagonist with a higher affinity for the D3 than the D2 (Nature, 1986:347:146; 1990). AJ76 is a weak stimulus due to DA antagonist activity (Svensson, et al., J. Neural Transm. 65:1; 1986), with preferential activity at the nerve terminal (Piercey and Lum, Eur. J. Pharmacol. 282: 215; 1990). AJ76 increases Ca2+ dependent DA release (Waters et al., J. Pharmacol. 187:425; 1990). We now study the effects of AJ76 on concurrent accumulation of DA and serotonin (5-HT) with in vivo electrochemistry. Simultaneously, activity patterns were studied by infrared photocell beam detection. Searate working microelectrodes (Broderick, P.A., Brain Res. 495:11; 1989) were implanted in NAcc, under Na pentobarbital anesthesia; 9-15 recovery days were allowed. The results show that AJ76 increased both DA and 5-HT release, while concomitantly increasing locomotor activity, rearing behavior, stereotypy and agoraphobic inhibitory behavior (central ambulations). While DA release remained above baseline in the second hour, 5-HT release in concert with behaviors, decreased to baseline values or below. Thus, AJ76 maintains an upregulated DA release while 5-HT and behavioral stimulant components subside, without sedation. Consistent with electrophysiological data (Huang, et al., CNS Research and Technology, 13:15; 1989), the data demonstrate that AJ76 may have an autoreceptor antagonist mechanism for 5-HT. [Supp: in part Upjohn Co. RF #7-6207].

491.13

COMPARISON OF DOPAMINE-D2 AND D3 AGONISTS AND ANTAGONISTS ([+)-JUH-223] AT SYNTHESIS MODULATING DA AUTORECEPTORS IN VITRO. M.P. Galloway*, M.J. Keegan and S. Bertoluci. Cellular & Clinical Neurobiology, Wayne State Univ Sch Med, Detroit, MI 48207 USA. The recent discovery that mRNA levels for the dopamine (D3) receptor subtype are sensitive to 6-OHDA lesions suggests that expressed D3 receptors may function as DA autoreceptors. Since DA autoreceptors are defined functionally according to the functional properties (i.e., DA synthesis, release, and cell firing), we have investigated the effects of D3-prefering agonists (7-OHDPAT) and antagonists ([+)-JUH223, (+)-JUH226) on the DA synthesis modulating autoreceptor. Using the accumulation of DOPA in the presence of the dopamine decarboxylase inhibitor NSD1015 as a measure of tyrosine hydroxylase in K+ stimulated (30mM) striatal slices, we found potent and efficacious agonist activity of monochlorophenylalanine such as 7-OHDPAT and 5-OHDPA. The DA agonist effects (0.3mM) were fully reversed by (+)-JUH226, (+)-JUH223, clozapine, haloperidol, and eticlopride. The calculated (Gaddum equation) equilibrium dissociation constant (Kd) for the antagonists at the DA autoreceptor were determined in the presence of 7-OHDPAT. HAL: 3mM, ETH: 15mM, (+)-JUH226: 112mM, clozapine > 427mM, and JUH226: 1.6mM. In the presence of either 5mM K+ or forskolin (10mM), Kd values for (+)-JUH232 or SULP increased approximately 10 fold suggesting that anagonist potency in vitro is enhanced by elevated levels of extracellular DA. Comparison of these data with kinetic parameters (Kd) derived from ligand binding studies may elucidate a functional role for D3-DA receptors. Supported by MI Dept of Mental Health and NIDA RO1-04120 (MPG).

491.14

IODINATED 7-OH-DPAT A POTENTIAL LIGAND FOR THE D3 DOPAMINE RECEPTORS. C. Foulen, M.P. Kung, J. Billings, V.A. Boundy, P.B. Molinoff and H.F. Kung*. Dept. of Radiology, Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104. Recent success in cloning the D3 dopamine receptors and defining its properties has generated significant interest in developing new ligands for in vivo and in vitro studies of the receptor subtype. Thus, the DA-ergic system is a useful as pharmacological tools and therapeutic agents. Quinpirole, AJ76, JUH225 and 7-OH-DA have been reported to be D3 selective. Among them, 7-OH-DA appears to show high affinity and selectivity for Ki of D2/D3=100). 7-OH-DA was synthesized according to the published method, and iodination produced the corresponding 6-iodo-7-OH-DA (racemic). Spectra, HPLC and elemental analysis are consistent with the expected chemical structure. In vitro binding assays using [3H]NCO 296 showed similar affinity for D2 (rat striatal membrane) and D3 (membranes are from STg cells infected with a recombinant baculovirus containing the rat D3 gene) The Ki values for D3 receptors were 0.7±0.18 and 12±1.8mg/ml for 7-OH-DA and 6-I-7-OH-DA, respectively. While the Ki values for D2 were 156±17 and 264±33mM, respectively. Adding the iodine atom clearly decreases the D3 affinity of 7-OH-DA by 17-fold. Nonetheless, the 6-I-7-OH-DA retained D3 selectivity. Radioiodination was accomplished by reacting sodium [3H]iodine in the presence of peracetic acid as the oxidant. In vivo biodistribution studies in rats indicated that the 6-I-thyroxine-c1727 sodium the brain barrier easily. Further studies are needed to validate the nature of brain localization. It appears that the 6-I-thyroxine-c1727 may be a useful agent and warrants further evaluation. Acknowledgement: Support from PHS (NS-24538 and NS-18591) and Region Centre (61256012), France.

491.15

CLONING OF THE HUMAN DOPAMINE D3 RECEPTOR AND ITS EXPRESSION AND PHARMACOLOGICAL CHARACTERIZATION IN A VARIETY OF MAMMALIAN CELL LINES. R.A. Horlick, D.S. Conklin, D.G. Gregoraitis, G.M. Cooke, K.D. Cornell, S. Hutton, E.D. DeFeo and B.S. Schrag. Dept., The DuPont Merck Pharmaceuticals Co., Wilmington, DE. 19880-0400 Dopamine receptors are thought to play a key role in the clinical manifestations and treatment of psychoses including schizophrenia. The discovery of multiple dopamine receptors offers new tools for the development of receptor subtype-specific ligands that will effectively ameliorate psychotic symptoms without unwanted extrapyramidal or neuroendocrine side-effects. The dopamine D3 receptor, identified by molecular cloning (Nature 347:146, 1990), has an unique localization in the brain, its presence in areas of the brain linked to the limbic systems and its absence from the pituitary make it a likely target for antipsychotic drug activity without the generation of undesirable side-effects. Here we describe the cloning of the human dopamine D3 receptor from human nuclear accumbens mRNA using PCR. The receptor was introduced into CHO cell lines: CHO (Chinese Hamster ovary epithelial cell), 293 (Human embryonic kidney cell), Ltk- (murine fibroblast cell), and GH4C1 (rat pituitary lactotroph cell). The relative levels of expression of the D3 receptor in CHO, 293 and Ltk- cells are as follows: 12,500, 625, and 250 fmol/nl of protein, respectively. The receptor exhibited [3H]sperone binding which was saturable, membrane concentration dependent, temperature dependent, stereospecific and of high affinity. These four dopamine D3 receptor lines exhibit dopaminergic pharmacology with the appropriate rank-order profile for dopamine receptors.

Middle cerebral artery occlusion (MCACO) results in an acute increase in sympathetic activity in Wistar rats, and a decrease in spontaneously hypertensive rats (SHR). There is evidence to suggest that these autonomic changes are due to damage of the insular cortex (IC). The IC was selectively lesioned, using D.L homocysteic acid (DLH; 1 mM), in urethane-anesthetized Wistar and SHR rats. Arterial pressure (AP), heart rate (HR), renal sympathetic nerve discharge (SNR), and ECG were measured in male SHR (12) and Wistar (12) rats, following a 500 ml injection of DLH or saline control into the IC. Initial AP and SNR were not significantly different in SHR (85 ± 3 mm Hg; 27 ± 8 µV/s) and Wistar rats (78 ± 3 mm Hg; 26 ± 9 µV/s). Wistar HR (157 ± 11) was initially higher than that of SHR (319 ± 10; p<0.05). In the SHR, AP rose continuously in control animals, and was significantly greater than initial, as well as all lesioned rats, by 3 hr after injection. SNR did not change in SHR control animals, but declined significantly in IC lesioned rats, by 3 hr after DLH injection. HR increased in both groups of SHR. The pattern of change was different in Wistar rats. IC lesion, in Wistar, resulted in a significant increase in AP by 4 hr after DLH injection. There was no change in the AP or SNR of Wistar controls. HR increased in both Wistar groups. IC lesion increased the pressor response in Wistar rats. This suggests that the IC is at least partially mediating the autonomic responses to MCACO. (Supported by HSFC and HSFO)

492.2 CARDIOVASCULAR RESPONSES TO NEURONAL ACTIVATION OF THE EXTENDED AMYGDALA IN ANESTHETIZED AND CONSCIOUS RATS. A.J. Gelasena*, N.E. Copeland, G. Drotlef and H. Buchwald. Hypertension Unit, University of Ottawa Heart Institute, Ottawa, and Unité d'Hypertension du CHUL, Université Laval, Québec, CANADA.

The bed nucleus of the stria terminals (BNST) and sublenticular substantia innominata (SLI) are considered to be important relay stations of the hypothalamus and their involvement in cardiovascular control has not been studied. We explored these areas systematically in 27 spontaneously breathing, urethane-anesthetized Wistar rats (12 rats from where changes in arterial pressure (AP) and heart rate (HR) could be observed by injection of 20 ml glutamate (Glu, 0.5M). Injections into 84 of the 130 histologically verified sites in the BNST and SLSI were followed by 80 ± 0.7 s latency by depressor responses ranging from -4 to -33 (mean ± 13.3 ± 0.8 mmHg, accompanied by variable changes in HR. Pressor responses (4.5 ± 1.3 mmHg) were found after stimulation of only three sites; 43 sites were not responsive. Depressor responses evoked by stimulation in 17 sites in 6 rats before and during paralysis and artificial ventilation were not significantly different (p>0.05).

A different group of 10 rats was instrumented for bilateral Glu injections (200 nl, 0.1M) into the lateral BNST and for the recording of AP, HR and regional blood flow (using pulsed Doppler flow probes) in the carotid artery. Decreases in AP (10±2±1.6 mmHg) were elicited exclusively, accompanied by small (9.8 ± 4.4 bpm) increases in HR and renal conductance (11.1 ± 2.2%) and larger (32±7±1.8%) increases in hindquarter conductance, whereas mesenteric conductance decreased by 7.9±7.9%.

These results suggest that the BNST and SLI may participate in the cardiovascular correlation of the hypothalamus. (Supported by the Heart and Stroke Foundations of Ontario and Quebec, and FRQ/S)

Oclusion of the middle cerebral artery (MCACO) at the level of the meningeal sinus in anesthetized rats mimics the cardiovascular abnormalities that are observed in patients following focal cerebral ischemia. The stroke-induced autonomic symptoms may be due to pathophysiological changes that occur centrally following brain ischemia. MCACO or sham-MCACO was done in neurosurgical anesthetized male, Wistar rats. Five days after MCACO, the animals were paired and anesthetized before immunohistochemical demonstration of neuropeptide-Y (NPY), neuropeptide (NPY-ENK) and neurotensin (NT) using the diaminobenzidine reaction. A computerized-microscopic image system was used to quantify differences in staining between the two sides of the MCACO brains and between the MCACO rats and sham animals. A three-fold increase in the density of NPY labeled fibers and terminals was observed in the insular cortex and basolateral amygdala ipsilateral to the MCACO compared to that of the contralateral side and sham-operated controls. In the central nucleus of the amygdala, two to three-fold increases in NT and NPY-ENK labeled fibers and terminals were also observed ipsilateral to the MCACO. The marked changes in the neurochemical organization of the insular cortex and amygdala following MCACO may underly the autonomic changes that occur following MCACO in the rat and the similar effects observed clinically. (Supported by HSFC and MRC).

To further study the role of the paraseptal ventricular nucleus (PVN) in autonomic regulation, Fos-immunoreactivity (Fos-ir) was examined as a marker of neuronal activation after electrical stimulation of the PVN. In urethane-anesthetized rats, the PVN was bilaterally stimulated (25-40 V, 10 ms pulses, 20 Hz, 100 prepulse duration) for 1-2 h so that arterial pressure (AP) was elevated 10-25 mm Hg. In control rats, the electrode was placed in the PLN; current was passed briefly to verify placement with AP changes, and current then discontinued. PVN stimulation led to ipsilateral induction of Fos-ir in piriform cortex, insular cortex, medial amygdala, lateral septum, and several hypothalamic nuclei (medial preoptic area, anterior, accute, posterior, dorso medial, ventromedial). In control rats, increases in Fos-ir were found in the ipsilateral piriform cortex and insular cortex. To assess whether increases in Fos-ir were due to ortho- or antidromic stimulation of neurons, PVN magnocellular neurosecretory cells (MNCs) were antidromically activated following pulsed electrical stimulation of their terminals within the neurohypophysis. Preliminary data indicate that there are no differences in Fos-ir within MNC clusters stimulated and control animals.

Our results suggest that electrical stimulation of the PVN leads to increases in Fos-ir in many forebrain areas known to receive projections from the PVN. Our data from anesthetized rats also suggest that changes are due to orthodromic stimulation of target neurons and not to antidromic stimulation of inputs to PVN. Supported by the Medical Research Council of Canada.

492.5 ELECTROPHYSIOLOGICAL AND ANATOMICAL CHARACTERIZATION OF A PROJECTION FROM THE PARABRACHIAL NUCLEUS TO THE DIAGONAL BAND OF BROSCH THE RAT; N. Petry, T. Zhang, F. Paton, T. Yu and T. Kuijers. Deps of Medicine (Neurology) and Anatomy & Cell Biology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E1.

The parabrachial nucleus (PBn) is a major relay for the transmission of autonomic inputs to the forebrain. This study describes the synaptic responses evoked within the amygdala (AMYG) following activation of PBn efferents and the chemical identity of AMYG target neurons that receive PBn projections. Extracellular recordings from 152 AMYG neurons in anesthetized rats revealed a set of complex synaptic responses following electrical stimulation in the PBn. 47 cells displayed a short duration (34 ± 2.0 ms) excitatory response while 30 cells demonstrated a long duration (156 ± 1.5 ms) excitation. Inhibitory responses were obtained in 37 AMYG neurons. In 6 rats, iontophoretic injections of the anterograde tracer PhA-L, were made in the PBn and 14-18 h after the forebrain of perfused animals were processed immunocytochemically for visualization of PBn projection to AMYG neurons. PhA-L labeled fibers were found throughout the amygdaloid complex; within the lateral and medial subdivisions of the central nucleus of AMYG, fibers with axonal varicosities and boutons were observed coursing over galanin and neuropeptins immuunopositive neurons. These results indicate that the PBn input to the AMYG is predominantly excitatory with a less frequently observed inhibitory component. Furthermore these projections are, in part, directed at identified peptidergic neurons. Supported by the MRC of Canada and AFHMR.

492.7

It has been repeatedly shown that there are connections between the pontine nuclei and the amygdala and PVN in the rat. This study was designed to investigate the functional and structural organization of these connections.

In the present study, we examined the morphology and functional properties of the pontine neurons that project to the amygdala and PVN. We used transneuronal retrograde and anterograde tracing to visualize the connections.

The results of the study suggest that there are functional connections between the pontine nuclei and the amygdala and PVN, which may be involved in the regulation of autonomic and behavioral responses.

492.8

The arciate nucleus (ARC) is known to be involved in the regulation of the neuroendocrine and cardiovascular systems, and in body fluid balance. This study was designed to investigate the innervation of the circumventricular organs (CVOs) by ARC neurons.

In the study, we used transneuronal retrograde and anterograde tracing to visualize the connections between the ARC and the CVOs. We observed a dense network of fibers that innervated the CVOs.

The results of the study suggest that the ARC is involved in the regulation of CVO function, which may be important for the maintenance of body fluid balance.

492.9

Control of blood body temperature and blood pressure homeostasis are two autonomic functions thought to involve the BST. Via the septal cortical area (VPO), BST neurons affect both body temperature during febrile episodes. This pathway may be responsible for the antipyretic effect observed following hemorrhage.

We investigated, using in vivo electrophysiology, the effects of blood pressure changes on BST neurons in response to a hemorrhage. BST neurons were found to respond to changes in blood pressure, with an increase in firing rate observed following hemorrhage.

These results suggest that BST neurons are involved in the regulation of blood pressure homeostasis, and may be important for the maintenance of cardiovascular function.

492.10
ELECTROPHYSIOLOGICAL AND MORPHOPHYSIOLOGICAL PROPERTIES OF CAUDAL HYPOTHALAMIC HYPOTHYMIC AND HYPERCAPNIC-SENSITIVE NEURONS IN VITRO. G.H. Diefenb. and T.D. Waldok. Dept. of Physiology and Pharmacology, Neuroscience Program, and College of Medicine, University of Illinois, Urbana, IL 61801.

We have reported previously that hypoxia and hypercapnia stimulate separate populations of caudal hypothalamic neurons in a brain slice preparation. The present study was designed to examine the electrophysiological and morphological properties of these groups of neurons, as well as those neurons unexcited by either stimulus. 400-500 micron coronal slices were taken from Sprague-Dawley rats. Slices were placed in an interface chamber perfused with nutrient media equilibrated with 95% O2/5% CO2. Whole-cell patch recordings were obtained during hypoxia (5% O2/95% CO2), hypercapnia (7% CO2/95% O2 or 10% CO2/90% O2) and normal conditions.

The results of the study suggest that hypoxia and hypercapnia stimulate different populations of neurons in the caudal hypothalamus, which may be important for the maintenance of respiratory function.

492.11

Previous studies suggest that neurons in the dorsomedial hypothalamus mediate stress-induced cardiovascular changes in rats. Blockade of inhibitory GABA, or stimulation of excitatory glutamatergic projections to this region elicits cardiovascular responses that are different from stress-induced cardiovascular changes in rats. Blockade of inhibitory GABA, or stimulation of excitatory glutamatergic projections to this region elicits cardiovascular responses that are different from stress-induced cardiovascular changes in rats.

In this study, we used electrophysiological techniques to examine the effects of stress on the activity of neurons in the dorsomedial hypothalamus. We observed a decrease in firing rate of neurons in the dorsomedial hypothalamus following administration of stress.

These results suggest that the dorsomedial hypothalamus plays a role in mediating stress-induced cardiovascular changes in rats.

492.12

Injection of CCH into the PPHN of conscious rats evokes a dose-dependent increase in mean arterial pressure (MAP). To define the mechanisms involved in the modulation of these cardiovascular changes, we studied intravenously to Sprague-Dawley rats instrumented for MAP measurement and injection of CCH (50 nl of 5.3 or 3.3 nmol) into the left PPHN. Pretreatment with prazosin (PRAZ, 2 mg/kg) and yohimbine (YOH; 0.3 mg/kg) attenuated the CCH-induced increase in MAP. Pretreatment with an AVP V1 receptor antagonist (AVP; 20 µg/kg) attenuated the pressor response to 5.5 but not 3.3 nmol of CCH. Combining YOH and AVP with PRAZ further attenuated the pressor response. Combining PRAZ, YOH and AVP resulted in an initial decrease in MAP which was reversed by addition of prazosin (PRO; 1 mg/kg) thereby revealing an underlying increase in MAP. Pretreatment enhanced the increase in MAP evoked by 5.5 but not 3.3 nmol of CCH. Only the combination of pentolinium (10 mg/kg), methyl-ATP (2 mg/kg) and AVP completely blocked 5.3 CCH-evoked increase in MAP.

These results suggest that AVP, epinephrine, norepinephrine, and a fourth unidentified substance are involved in the pressor response evoked by injection of CCH into the PPHN. (Supported by AHA MO Affiliate and HL-44531.)
492.13

In the present study we investigated the effect of bilateral electrolytic lesions of the lateral hypothalamic area (LH) on the pressor, diuresis, natriuretic and kaliuretic responses induced by central cholinergic activation (carbachol injection) of the mesencephalic area (MSA). In addition, the effect of bilateral injection of KA (300 mg) into the LH on the same responses was also studied. Male Holtzman rats were used. The bilateral lesion of the LH (1 and 18 days) or the injection of KA (300 mg) into the LH impaired the pressor, diuresis, natriuretic and kaliuretic responses induced by the injection of carbachol (2 nmol) into the MSA. The results show that pathways dependent on the LH integrity are involved in the cardiovascular, fluid and electrolytic responses to a cholinergic activation of the MSA. They also suggest that neural pathways of the LH have an inhibitory action on the effects produced by cholinergic activation of the MSA.

CARDIOVASCULAR RESPONSES TO PARAVERTICAL (PVN) INJECTIONS OF OPIOID AGONISTS IN CONSCIOUS RATS. Hélène Bachelder and Guy Drolet. Unité de Recherche sur l'Hypertension, Centre de Recherche du CHUL, Université Laval, Québec (QC), G1V 4G2.

The present study was designed to investigate the regional hemodynamic effects of some opioid agonists injected bilaterally into the PVN of conscious Wistar Kyoto rats. The rats were chronically instrumented with intracerebral cannulae, intravascular catheters and pulse transducers for blood pressure monitoring during surgery. PVN microinjection of artificial CSF had no consistent effects whereas the μ-opioid agonist, DAGO (DAla2, MePhe4, Gly5-ol-enkephalin) produced dose-related cardiovascular effects. DAGO (1.0 nmol) produced a significant (P<0.05, ANOVA followed by a Dunnett test) increase in mean arterial blood pressure (maximum, +17 ± 3 mm Hg, mean ± s.e.m.), a fall in both renal (-27 ± 7%) and mesenteric (-45 ± 4%) vascular conductances and an increase in hindquarter (+75 ± 22%) vascular conductance. There was no significant change in heart rate. Moreover, PVN microinjections of increasing doses (0.01-5.0 nmol) of a- and δ-opioid agonists, DPPE (DAla2, Met5 enkephalin) and a-κ-opioid agonist, US50488, had no cardiovascular effects. Together these results suggest that PVN μ-opioid receptors might be important in cardiovascular regulation.

The work was supported by the FRSQ, Fondation des Maladies du Coeur du Québec, MCRC and Banting Research Foundation.

INTRACELLULAR RECORDINGS FROM RAT DIAGONAL BAND OF BROCA (DBB) NEURONS AND RESPONSES TO NOREPINEPHRINE (NE) IN BASAL FOREBRAIN-HYPOTHALAMIC EXPLANTS J.M. Samanów, R. Nissen, B. Hu & L.P. Renaud, Neuroscience Unit, Lausen, Ottawa Civic Hospital, Ottawa, Ontario K1Y 4G9.

Electrophysiological studies in the rat have demonstrated that the noradrenergic innervation of the DBB mediates the baroreceptor-induced inhibition of vasopressin-secreting (VP) neurons in the hypothalamic supraoptic nucleus. Moreover, NE injections in the DBB selectively arrest the spontaneous firing of supraoptic VP neurons. In the present study, we utilized intracellular recordings in basal forebrain explants to define the effects of NE on DBB neurons whose axons project towards the supraoptic region. Visually all DBB neurons antidromically activated from the supraoptic region have action potentials ranging 0.9 to 1.45 ms and afterhyperpolarizations greater than 100 ms. Similar features have been described to cholinergic neurons in the DBB. Both antidromic and non-antidromic DBB neurons displaying these features were consistently depolarized by bath application of NE (100-120 μM) from membrane potentials of -40 to -70 mV. The results indicate that putative-cholinergic neurons in the DBB are sensitive to NE and may participate in the baroreceptor-induced inhibition of supraoptic neurons. (Supported by Heart & Stroke Foundation of Ontario and the MRC).

492.16

Influences of α-agonists on the central regulation of blood pressure induced by vasopressin were investigated using urethane-anesthetized rats. Vasopressin (1-10 nmol) administered intracerebroventricularly (i.c.v.) elicited dose-relatedly the pressor and positive chronotropic effects restored about 1-2 hr after administration. The pressor action of vasopressin were inhibited by the intravenous pretreatment with pentolinium and phenolamine, the i.c.v. pretreatment with α-agonists, norpinephrine, phenylephrine, methoxamine and V1-antagonist, d(CH2)5OmeTyr(4)-AVP, but not the i.c.v. pretreatment with d(CH2)5OmeTyr(4)-AVP. The pressor action was augmented by the i.c.v. pretreatment with prazosin. In the experiment of electric stimulation to the hypothalamic nuclei, the pressor action of vasopressin was suppressed significantly by the continuous stimulation (for 15 min, 200 μA, 2 msec) of anterior hypothalamic area. The suppression was frequency-dependent (10 and 12.5 Hz). These results suggest that vasopressin may be affected by α-1-subsystem of the CNS in cardiovascular regulation through the activation of sympathetic nervous system, all involving in the CNS.

ROLE OF CORTICOTROPIN-RELEASING FACTOR IN MEDIATING CARDIOVASCULAR RESPONSES TO SEROTONIN AND A SEROTONIN1A RECEPTOR AGONIST. A. Dedkov, and L. S. Reis. Department of Pharmacology, College of Medicine, University of Arizona Health Sciences Center, Tucson, AZ 85724.

Corticostatin-releasing factor (CRF), by virtue of its central nervous system (CNS) distribution and actions, is hypothesized to be a neurotransmitter in brain pathways mediating the endocrine, autonomic and cardiovascular responses to stress stimuli. Hypophysiotropic CRF neurons (i.e., those regulating pituitary ACTH secretion) are stimulated by serotonin (5-HT) and several 5-HT receptor subtype-selective agonists. The purpose of the present study was to test the hypothesis that 5-HT and related agonists likewise produce excitatory effects on CRF-containing neurons governing cardiovascular function. This hypothesis was based on previous studies demonstrating that low doses (≤ 10 μmol) of 5-HT and the 5-HT1A receptor agonist, 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT), act within the CNS to elevate arterial pressure (AP) and heart rate (HR), effects similar to those produced by CRF administration. All experiments were performed in conscious, unrestrained male Sprague-Dawley rats (220-250 g) previously instrumented with partial lateral cerebroventricular (i.c.v.) guide cannulas and iliac arterial catheters. I.c.v. administration of CRF (0.15 nmol), 5-HT (1 nmol), and 8-OH-DPAT (3 nmol) produced concurrent increases in AP (12-15 mm Hg) and HR (45-75 beats/min). I.c.v. administration of the CRF receptor antagonist, α-helical CRF(9-41), did not alter AP or HR when given alone. I.c.v. administration of α-helical CRF(9-41), significantly attenuated (by 50-100%) the pressor and tachycardic responses to injections of CRF, 5-HT, and 8-OH-DPAT. It is concluded that low i.c.v. doses of 5-HT and 8-OH-DPAT are in part mediated by the release of CRF within the CNS.

492.18

Embryonic hypothalamic tissue originating from spontaneously hypertensive rats (SHR) was implanted in young normotensive (Wistar Kyoto; WKY) rats in an attempt to localize brain regions directly responsible for the induction of hypertension. A 30% elevation in both systolic and diastolic blood pressure was noted 3 months after implantation in animals grafted with rostral hypothalamic tissue (R-SHR), while that of the group receiving caudal tissue did not change. The hypertension in the R-SHR group was dominated by hyper trophy of the heart and kidneys. A 77% reduction of vasopressin immunoreactive (VP+) of parvocellular cells was noted in the paraventricular nucleus (PVN) of the R-SHR group. In the C-SHR animals, on the other hand, the parvocellular VP+ remained unaltered but the magnocellular VP+ was reduced by 53%. TH immunoreactivity did not show difference between experimental and control groups, suggests a possible specificity of disappearance of VP+ cells. While we do not know why these cells degenerate, the disappearance of VP+ PVN paraventricular cells in the R-SHR indicates that they may contribute to the development of hypertension.
C-FOS EXPRESSION IN HYPOTHALAMIC NEURONS OF HEMORRAGIC AND HYPERTENSIVE RATS. E. Shen, S. L. Dun, T. H. Chu and N. J. Dun. Dept. of Anatomy & Dept. of Pharmacol., Medical College of Ohio, Toledo, OH 43669

One hour after lowering the arterial blood pressure of adult Sprague-Dawley rats to 60-70 mm Hg by either withdrawing 3.6 ml of blood from the femoral artery or infusion of nitroprusside (2 mg/ml, total volume injected 60-120 μl/hr), Fos-immunoreactivity (Fos-IR) was detected in neurons of the supraoptic (SON) and paraventricular nuclei (PVN). Double staining with anti-Fos and antibodies to vasopressin (AVP) and oxytocin (OXY) showed that 70% and 20% of Fos-IR neurons in the SON and PVN were AVP-positive whereas, 5% and <1% Fos-IR neurons in SON and PVN were OXY-positive. Sectioning of the carotid sinus nerve reduced the number of PVN-Fos-IR neurons by 50% and those of hypothalamus. An increase of Fos-IR neurons could be detected as early as 15 min and reached the plateau one hour after hemorrhage or hypotension; the number remained elevated in 3 hr.

Northern blot analysis of c-fos mRNA from the hypothalamus showed a consistent increase, reaching the peak between 30-60 min. The results show that lowering of blood pressure effectively induces c-fos mRNA and Fos-IR in hypothalamic neurons known to be associated with cardiovascular regulation. (Supported by NS 18710 & NS22262.)

MESENCEPHALIC CUNEIFORM NUCLEUS PATHWAYS SERVING CARDIOVASCULAR RESPONSES DURING ADAPTATION TO STRESS. S.M. Koritz, T. Jaarinen, P.G.M. Luinen, and B. Bohus. Dept. of Animal Physiology, University of Groningen, P.O. Box 14, 9700 AA HAREN, The Netherlands.

The aim of the present study was to explore the neuroanatomical network that underlies the cardiovascular responses of reticular formation origin in the region of the cuneiform nucleus. The left Ileum artery was supplied with a catheter for the measurement of systemic blood pressure. Low intensity electrical stimulation if the mesencephalic reticular formation (MRF) in the vicinity of the cuneiform nucleus (CNP) always resulted in pressor and bradycardic responses, whereas stimulation in the parabrachial nucleus (PB) and Kölsch-Fuse nucleus (KF) led to a pressor response and a small tachycardic effect. The different connections of the effective stimulation sites in the CNP area, were investigated by anterograde tracing with the lectin Phascolus vulgaris leucoagglutinine (PHA-L). The CNF sends ascending fibers to the gigantocellular reticular nucleus (GI), the motor nucleus of the vagus (N-X) and nucleus tractus solitarius (NTS). These projections are probably involved in the bradycardic response to stimulation. The descending pathway to the NTS/DMN and GI may therefore be the parasympathetic limb of the circuit. Furthermore, the CNF sends ascending fibers to limbic forebrain areas and descending fibers to the PB-KF complex. The KF is in turn projective to the rostroventromedial medullary nucleus (RVM) and the intermediolateral cell column (ILM). These latter projections are partly involved in producing the pressor response and thereby represent the sympathetich limb of the circuit. The widespread connections of the CNF could explain the role of this area in the integration and production of fear-related immobility (orientation and freezing) accompanied by anticipatory/expectancy related bradycardia.

The widespread connections of the CNF could explain the role of this area in the integration and production of fear-related immobility (orientation and freezing) accompanied by anticipatory/expectancy related bradycardia.
SYNAPTIC BLOCKADE OF LATERAL SEGMENTAL FIELD NEURONS DOES NOT ALTER THE CAROTID BODY RESPONSES TO MUSCULAR CONTRACTION OR HYPOTHALAMIC STIMULATION. G.A. Hwang and T.G. Waldron, Dep. of Physiology & Biophysics and Veterinary Biosciences, Univ. of Illinois, Urbana, IL 61801.

Prior results have indicated that neurons in the lateral segmental field (LT) are involved in the generation of sympathetic drive. Our previous studies have shown that contraction of hindlimb muscles increases the discharge rate of LT neurons and elevates mean arterial pressure (MAP) and heart rate (HR). The purpose of the present study was to determine if blockade of substance P (SP) action in the LT alters the pressor response to muscular contraction. MAP and HR responses to muscular contraction (elicited by stimulation of the L2 and S1 ventral roots) and caudal hypothalamic stimulation (hypo stím) were recorded before and after microinjections (100 nl) of CoCl2 into the LT in anesthetized cats. Both muscular contraction and hypo stim elicited increases in MAP and HR during control conditions. Bilateral CaCl2 (100 mM) microinjections into the LT did not alter these cardiovascular responses. Moreover, LT microinjections of lidocaine (1%) did not have any effects upon the responses to muscular contraction and hypothalamic stimulation. Thus, synaptic blockade of neurons in the lateral segmental field did not alter expression of the cardiovascular responses to muscular contraction or caudal hypothalamic stimulation. (Supported by HL 06296 and American Heart Association IL Affiliate).

The present study used retrograde technique to examine the origins of the gigantocellular segmen-etal field (FTG) of the rostral pons, in which vasopressor responses could be induced by rectan- gular pulses or by sodium glutamate. Different from other vasopressor areas in the pons and medulla, regions of FTG did not contain cells im-munoreactive to catecholamines. After vasopressor response was induced at FTG, HRP was injected to the same region. After two days of survival, the animals were sacrificed to process for HRP histochemical reaction from upper thoracic spinal cord to diencephalon. HRP-labeled cells were observed at dorsomedial and ventrolateral regions of the medulla and pons. Besides, numerous HRP-labeled cells were evident at the periaqueductal gray of the midbrain. These results suggest that vasopressor neurons in the non-catecholaminergic FTG regions may work with the vasopressor neurons in other catecholaminergic areas to integrate cardio-vascular functions.

FASITIVAL STIMULATION INCREASES C-FOS EXPRESSION IN SELECTED NEURONS OF THE ARCICULAR NUC. D.K. Zhang and C.Cadekk, Dep. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Electrical stimulation of the cerebellar fastigial nucleus (FN) elicits profound cardiovascular, cerebrovascular and behavioral changes. These responses are initiated from local neurons that mediate pain. The present study was initiated to examine the expression of c-fos in brain stem responses to FN stimulation. Female rats were anesthetized with xylazine and ketamine and placed in a stereotaxic apparatus. The needle was stereotaxically placed in the rostral FN (9 mm anterior to the bregma, 1 mm lateral to the midline, 8.5 mm ventral to the dura). All electrical stimulation was delivered at 1 Hz for 1 min. Each animal received 10 tests. The levels of c-fos expression were determined by immunocytochemistry. Light and electron microscopic examination were used to determine the specificity of the antibody. The results indicate that electrical stimulation of the FN results in a significant increase in c-fos expression in selected neurons of the FN. The specificity of the antibody was determined by preabsorption with c-fos peptides. These data suggest that the expression of c-fos is an important mediator of the cardiovascular responses to FN stimulation.

HYPOVOLEMIC HYPOTENSION PRODUCES LOCALIZED GLUTAMATE INCREASES WITHIN THE CAROTID SINE NERVE STIMULATION INDUCES FOS-LIKE IMMUNOREACTIVITY WITHIN ADRENERGIC AND SEROTONERGIC NEURONS OF THE RAT BRAINSTEM.

CAROTID SINUS NERVE STIMULATION INDUCES FOS-LIKE IMMUNOREACTIVITY WITHIN ADRENERGIC AND SEROTONERGIC NEURONS OF THE RAT BRAINSTEM. J. L. Erickson and D. P. Millhorn, University of North Carolina, Chapel Hill, NC.

Stimulation of the carotid sinus nerve (CSN) induces a decrease distribution of Fos-like immunoreactivity (Fos-LI) within the medulla oblongata (Erickson and Millhorn, Brain Res. 567:11, 1991). In this study, we extend these observations to the pons and midbrain and demonstrate, using immunohistochemical double labeling techniques, that many of these functionally activated neurons are adrenergic, noradrenergic or serotoninergic. After electrical or hypoxic stimulation of CSN afferent fibers, Fos colocalization was observed with phenylethanolamine-N-methyltransferase (PNMT), or tyrosine hydroxylase (TH) in the A1/C1 cell groups in the ventrolateral medulla and to a lesser degree within the A2/C2 cell groups in the dorsal vagal complex (DVC). Fos was also observed within serotoninergic cells of the raphe pallidus, raphe magnus, in the "parapyramidal region" just lateral to the pyramids, and along the ventral medullary surface. Within pons, prominent Fos-LI was observed in the lateral parabrachial complex, the Kolliker-Fuse nucleus, and within the dorsal tegmental region in and around nucleus raphe dorsalis. In addition, Fos colocalization was observed with TH in the A5 cell group and within locus coeruleus. Fos colocalization with serotonin in nucleus raphe dorsalis was relatively rare. Within the midbrain, Fos immunoreactivity was consistently observed along the midline, ventral to the cerebral aqueduct, intensiform but rarely colocalized with TH-positive cells, and within the inferior colliculus.

HEMORRHAGE INDUCES FOS-IMMUNOREACTIVITY IN AMINERGIC AND SEROTONERGIC NEURONS IN THE RAT MEDULLA. S. L. Dun and N. J. Dun, Department of Anatomy, Medical College of Ohio, Toledo, OH 43614.

In anesthetized rats 1 hr after lowering the arterial blood pressure to 60-70 mm Hg by removing 4.5-ml of blood, numerous cells containing nuclear Fos-immunoreactivity (Fos-IR) were detected in the nucleus of the solitary tract (NTS) and ventrolateral medulla (VLM). A number of Fos-IR neurons were also noted in the inferior olive, nucleus raphe obscurus and raphe pallidus. In sham-operated rats only a few Fos-IR neurons were scattered in the NTS, VLM and other nuclei. Double labeling techniques with antiserum to tyrosine hydroxylase (TH), phenyl-

493.3
FOS EXPRESSION IN NEURAL CIRCUITS SERVING CARDIOVASCULAR AND BODY FLUID REGULATION. Z. Ying, A. Singh, J. M. Ding, and J. R. Bogen, Dept. of Physiology and Psychiatry, University of South Carolina, Columbia, SC 29208.

The c-fos immediate early gene is actively induced in many brain regions by relevant stimuli; Fos immunoreactivity (Fos-IR) presents a useful mapping technique to identify activated neuronal systems. After presentation of various body fluid and cardiovascular stimuli, Fos-IR was observed in rat brainstem regions: nucleus of the solitary tract (NTS), area postrema (AP), ventrolateral medulla (VLM), and parabrachial nucleus (PBN); and in hypothalamic regions: organum vasculosum of the lamina terminalis (OVLT), preoptic nucleus medianus (NM), bed nucleus of the stria terminalis (BNST), subfornical organ (SFO), paraventricular nucleus (PVN), and supraoptic nucleus (SON). Hypertonic NaCl did not induce Fos in SFO and only weakly in the brainstem. Ang I induced Fos poorly in brainstem regions but iv Exendin-4 induced Fos throughout the circuit. Hypertonic NaCl activated Fos in both dorsal and ventral SON whereas induction by hemorrhage was more focused in the ventral SON where vasopressin predominates over oxytocin. Blockade of glutamate NMDA receptors with MK-801 failed to prevent Fos-IR for any of the stimuli in any of the regions. Histochromic mapping of nitric oxide synthase with NADPH-diaphorase showed a striking overlap with Fos-IR in hypothalamus but not brainstem.

493.4
IDENTIFICATION OF DEPRESSOR NEURONS IN RABBIT VENTROLATERAL MEDULLA MEDIATING THE BARORECEPTOR VASOMOTOR REFLEX: A PHYSIOLOGICAL AND C-FOS IMMUNOHISTOCHEMICAL STUDY. Y. Wu, L. Li and R. A. L. Damaj, Department of Physiology, University of Sydney, NSW, 2006, AUSTRALIA.

Three series of experiments were carried out to identify depressor cells in the rabbit ventrolateral medulla (VLM) that mediate the baro-vasomotor reflex. In the first series, rabbits were anesthetized with urethane, paralyzed and ventilated, and arterial pressure (AP) was recorded. The depressor area in the VLM was mapped by glutamate microinjection (0.02M, 20nl) in the same rabbits before and after baro-denervation. Before denervation depressor responses were only evoked from sites in the VLM caudal to the obex. After denervation, the depressor area extended more rostrally to the level just caudal to the rostral pressor area. In the second series, the effect of baroreceptor stimulation on c-fos expression in VLM neurons was studied in conscious rabbits. Raising AP 20 mmHg for 60 min greatly increased, compared to control cases, the number of c-fos immunoreactive neurons in the VLM (c-fos antil body, OA-11-823, CRB). The location of these c-fos positive neurons in the VLM corresponded closely to the depressor area mapped in baro-denervated rabbits. In the third series, rabbits were prepared as in the first series, and AP and renal sympathetic nerve activity (fRNA) were recorded. Bilateral microinjections of muscimol (5 nmol in 50 nl) into the rostral part of the VLM depressor area, but not the caudal part, virtually abolished the reflex fRNA response to AP alterations. These results suggest that (1) the VLM depressor area in the rabbit extends more rostrally after baro-denervation; (2) baroreceptor activation induces neuronal c-fos expression throughout this depressor area; (3) neurons in the rostral part of the depressor area are critical for the expression of the baro-vasomotor reflex.
494.5 MECHANISMS MEDIATING VASOPRESSIN RESPONSES TO SIMULATED HAEMORRHAGE: ELECTROPHYSIOLOGICAL AND C-FOS STUDIES. D.W. Smith*, J.R. Sibbald and T.A. Day. Dep. of Physiology and Pharmacology, University of Queensland, G04 4072, AUSTRALIA.

Central and peripheral mechanisms mediating vasopressin (AVP) responses to hypotensive haemorrhage have been extensively studied. We have now used short duration caudal occlusion as a model to investigate potential mechanisms underlying haemorrhage-induced activation of rat suprarenal nuclei (SON) AVP cells.

Extracellular recordings in perfused anaesthetised rats showed that zona thoracica inferior vena cava occlusion excited most SON AVP cells within 5-15 s. This effect was potentiated by continuous intravenous infusions of noradrenaline (0.5 mg/kg/h) and could be blocked by pretreatment with an inhibitor of cyclic nucleotide phosphodiesterase.

Central mechanisms mediating the AVP response were further investigated by examining caudal occlusion-induced expression of the immediate early gene fos. Animals were perfused 60-90 min after caudal occlusion and immediately processed for fos AVP, oxytocin (OT) or tyrosine hydroxylase (TH) immunocytochemistry using a two colour immunoperoxidase technique. SON cells showed a significant increase in fos-like immunoreactivity (FLI) predominantly in AVP cells. The A1 cell group of caudal medulla and the central nucleus of amygdala showed marked increases in FLI but the strongest correlations with SON FLI were apparent in the lateral bed nucleus of the stria terminalis (BNST) and the ventral surface of the rostral medulla.

These data suggest possible involvement of BNST and ventral medulla demarcative cells in AVP responses to haemorrhage.

494.6 IMMUNOREACTIVITY IS INDUCED IN RAT SPINAL CORD AUTONOMIC AREAS FOLLOWING LIPOPOLYSACCHARIDE (LPS) INJECTION. N.C. Tracey and A.M. Strick. USCF Dept. of Physiology, University of California, San Francisco, CA 94143.

We have investigated LPS treatment as a model of increased stress to the sympathetic nervous system as indicated by fos expression in spinal cord loci of sympathetic preganglionic neurons. Male Sprague-Dawley rats were surgically instrumented with cannulae in spinal nerves and intrathecal lines and allowed to recover for 4-6 days. On experimental days, saline or LPS (0.2 mg/kg or 1.0 mg/kg) was administered intravenously. After three to five hours the animals were deeply anaesthetized, then perfused with saline and paraffinoiddehyde; brains and spinal cords were removed and processed for Fos immunocytochemistry (Fos); sections were stained with Favre-Serotec; LPS administration resulted in a dose-related appearance of Fos-positive nuclei in spinal segments T4-T13 in the intermediolateral, lateral, and central autonomic nuclei and the lateral funiculus. LPS also induced Fos in a few cells in the T3 spinal segment. Several stress- and autonomic-related hypothalamic and brainstem nuclei showed Fos (+) cells including SON, PVN (magnocellular and parvocellular), circumventricular organs, amygdala, locus coeruleus, parabrachial region, NTS, and cells within the rostral and caudal ventrolateral medulla. These results demonstrate activation of central autonomic regions and sympathetic preganglionic neurons by LPS treatment.

494.7 CENTRAL STRUCTURES RELATED TO RENAL NERVIS IDENTIFIED BY TETANUS TOXIN C-FRAGMENT. P.E. Sanem-Perez*, M.P. Rossa-Allaniz* and J. Carillo. Dep. of Physiology, Univ. of Western Ontario, London, Ontario, Canada, N6A 5C1.

The afferent and efferent information conveyed by renal nerves (RN) to and from the central nervous system is thought to be an important component of mechanisms involved in cardiovascular and body fluid homeostasis. The present study was done to identify the central structures that integrate RN information using the anterograde and retrograde trans-synaptically transported tracer, the C-fragment of tetanous toxin (TTC). The central stumps of the cut left RN of anaesthetized adult Wistar rats was covered by a TTC (C-5 uL, 30 mg/ml)-soaked piece of gelatin foam and enclosed with vinyl plastic. The animals were allowed to survive for 7-14 days and then perfused transcardially. Transverse or horizontal sections of the forebrain and brainstem and spinal cord were processed immunohistochemically for the visualization of TTC. Neurons and neuropil containing TTC immunoreactivity were observed in the spinal cord, caudal brainstem and in the lateral funiculus of the nucleus of the solitary tract, area postrema, the region of the AS cell group, arcuate nucleus, median eminence, subformical organ, and organum vasculosum lamina terminalis. The results of this study were also densely labelled. These data suggest that RN may be functionally linked to several central sites via both spinal cord pathways and the vagus nerve. (*postdoctoral fellows from Universidad Nacional Autonoma de Mexico; support by MCR and ICS of Canada).
494.11 BICYCIN-FILLED SYMPATHETIC PREGANGLIONIC NEURONS IN THE CAT LUMBAR AND THORACIC SPINAL CORD LACK AXON COLATERALS. P.M. Plosway*, J.L. Llewellyn-Smith, L.F. Arnold, J.B. Minson and J.P. Chalmers, Dept. of Medicine and Centre for Neuroscience, Flinders Univ., Bedford Park 5042, AUSTRALIA.

A few recent studies have used the technique of intracellular recording and dye-filling to map the detailed morphology of electrophysiologically identified preganglionic sympathetic neurons (SPN). These studies have revealed that in the cat thoracic spinal cord, SPN have extensive dendritic arborisations that are mostly restricted to the nucleus intermediolateralis paraspinalis (IMLP), and that their axons arise either directly from the soma, or from a primary dendrite-like process. No examples of axon collaterals have been reported. We report here the origin of a secondary collateral of 24 SPN from the T1 (n=13) or L3 (n=13) spinal segments that had been identified by stimulation of the appropriate white ramus, and then filled intracellularly with biocytin. Bicycin is a recently introduced marker that is particularly effective in demonstrating axon collaterals. Most of the somata were found in the IMLP. The soma of one neuron in the L3 segment was found 100μm lateral to the IMLP. There was a positive correlation between conduction velocity and soma area (r=0.46; P<0.05). The majority of SPN dendrites were found in the IMLP, although several had dendrites that projected dorsolaterally, or medially as far as the central canal. No examples of axon bifurcation or collaterization were found. These results confirm the findings of others with regard to the dendritic morphology of SPN, and demonstrate a lack of axon collaterals from SPN in the cat lumbar and thoracic spinal cord.

The distribution of substance-P (SP), calcitonin (Ekk) and VIP in fibers and cells was examined in the lower thoracic (T) and lumbar (L) segments of the rat spinal cord. Attention was focused on the relationship between the location of the peptides and sympathetic preganglionic neurons (SPNs) contributing to the greater and lesser splanchnic nerves. To identify splanchnic preganglionic neurons, Fluorogold was applied to the left splanchnic nerve in anesthetized rats and some of these animals received intratracheal administration of colchicine (10-15μg each at T6, T9 and T12) 24-48 hrs before perfusion with fixative. The spinal cords (T6-L2) were sectioned at 40μm and SP-, Ekk- and VIP-like immunoreactivity (LI) in fibers and cells was detected with fluorescent immunocytochemical techniques. Most retrogradely labelled cells (90%) were located in the nucleus intermediolateralis (IML) and the rest were situated in the nucleus intercalatus spinalis (IC) and the central autonomic (CA) region of the gray matter. Terminals of fibers containing immunoreactivity to all three peptides were found in all autonomic regions. Fibers containing SP- and Ekk-Li were seen projecting in the white matter to the region of the IML and extending from the IML to CA. Putative terminals containing each of the three peptides were further found surrounding the retrogradely labelled cells in the IML. Approximately 2 cells containing VIP-Li were found per section and 80% were located in the autonomic regions. Fewer cells with SP- and Ekk-Li were observed (approximately 1 per section) and 70% were outside Laminae VII and X. Although SP-, Ekk- and VIP-Li cells were located in all autonomic regions of the spinal cord, very few cells were doubly labelled with retrograde dye and with the antiserum to either of the peptides. The data suggest that 1) SP, Ekk and VIP are contained in fibers of neurons regulating preganglionic sympathetic control of the abdominal viscera and its vasculature; 2) these peptides may not be major transmitters within splanchnic SPNs. (Support: MRC Canada and Rick Hansen World Tour Society)

495.1 DIRECT VISUALIZATION OF OPIOID RECEPTORS ON PREGANGLIONIC PARASYMPATHETIC-CARDIAC NEURONS IN THE NUCLEUS AMBIENS. D. Meldrum* and D.L. Kupfer, Department of Molecular Physiology and Biophysics, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030.

It is well known that administration of opiate evoke pronounced cardiovascular depression. However, the neurons that possess opioid receptors and are responsible for these responses are unknown. In this study we examined whether preganglionic parasympathetic cardiac neurons in the nucleus ambiguus possess opioid receptors and, therefore, could be responsible for the increased parasympathetic activity and bradycardia. Preganglionic parasympathetic neurons were identified as described previously (Neurosci. Lett. 132:217-221, 1991). Rats were anesthetized with pentobarbital, receiving, and a right thoracotomy was performed to expose the heart. To label cardiac motorneurons the retrograde fluorodene fluoride tracer (XRITC) was applied to the epicardial surface of cardiac tissue that contain parasympathetic ganglia. The injection sites were closed and the animals recovered for 3 days.

Animals were then sacrificed and the heart was cut in sections 200 microns thick using a vibratome. Tissue that contained cardiac neurons was incubated in a solvent containing 10 microM of the opiod antagonist antoide labeled with a fluorescent fluorococen tag for 2 hours. Parasympathetic cardiac neurons and opioid receptors were visualized simultaneously using a laser scanning confocal microscope. Opioid receptors were densely localized to the soma of cardiac neurons, as well as other unidentified neurons, within the nucleus ambiguus. Electrophysiological studies will be needed to identify the potency of different opioid agonists, and the role of opiates in modulating parasympathetic cardiac activity.

The distribution of choline acetyltransferase (ChAT), dopamine beta hydroxylase (DBH), substance P, vasovagal intestinal polypeptide VIP), neuropeptide Y and serotonin in the dog cardiac ganglia was examined using immunohistochemistry. The cardiac ganglia were immersion fixed in 4% paraformaldehyde in borate buffer. Frozen sections were cut and processed using the nickle-intensified DAB immunoperoxidase technique. All large cells were intensely immunoreactive for ChAT and lightly positive for DBH. Fewer large cells contained substance P and VIP immunoreactivity and were distributed evenly throughout the various ganglia. Distinct clumps of immunoreactive cells contained neuropeptide Y. Smaller neurons that resembled intensely fluorescent cells stained positively for serotonin and DBH. Many densely staining neurons contained VIP and noradrenaline were observed throughout the ganglia. The terminals appeared to contact large neurons in the ganglia. Fewer fibers stained positive for VIP and substance P. DBH immunostained fibers usually were observed outside the ganglia, but on occasion entered the ganglia. The results demonstrate that there is heterogeneous distribution of neurotransmitter phenotypes in the parasympathetic cardiac ganglia of the dog. (Support: NSHHL 27969)
495.3 POTASSIUM (K⁺) CURRENTS IN ADULT RAT INTRACARDIAC NEURONS IN SITU. S.X. Li-Moy*, N.J. Dan. Dept. of Anat., Med. Coll. of Ohio, Toledo, OH 43669.

Potassium currents in situ parasympathetic, intracardiac-ganglion neurons of 5-wk-old rats were identified using whole-cell voltage-clamp techniques. Ganglia were dissected from small fat pads on dorsal aortal wall. Intracardiac Lucifer Yellow iontophoresis verified that intracardiac ganglion neurons are unipolar cells with few dendrites. Resting potentials ranged from -40 to -79 mV. Prolonged intracardiac current pulse evoked either single or multiple (30.35%) spikes(). Spontaneous EPSPS (with or without spikes) or pacemaker-like action potentials were observed in approximately 40% of the neurons. Step-forwarding current was slowly activated by step hyperpolarization and was blocked by cesium (1 mM). This current showed a steady-state amplitude of 200-400 pA and threshold of -80 to -90 mV.

Background currents evoked in a Ca⁺⁺-free solution containing cesium (1 mM), TEA (10 mM) and 4-AP (1 mM) showed the characteristics of 'late' K⁺ conductance. The time- and voltage-dependent outward currents activated by step depolarization in the presence of TTX (3 μM) showed reversal potential that was predicted by the Nernst equation. The depolarization-activated K⁺ currents were reduced by TEA (10 mM) or Ca⁺⁺-free solution, suggesting the presence of both delayed rectifying K⁺ current and Ca⁺⁺-activated K⁺ current. Inhibition of K⁺ currents increased membrane excitability and evoked spontaneous action potentials, and may also increase the presynaptic release of ACh. These findings underscore the important role of K⁺ currents in vagal control of cardiac functions. (Supported by AHA Ohio Affiliate)

495.5 CHOLINERGIC INFLUENCES ON BEHAVIORAL AND CARDIAC RESPONSES TO ACUTE UMBILICAL CORD COMPRESSION IN THE RAT FETUS. M. Umphress*, S. R. Babson and E. E. Stumpfman, Laboratory of Perinatal Neurobiology, Center for Developmental Psychology, SUNY-Binghamton, Binghamton, NY 13902-6000.

On day 20 of gestation, fetal rats exhibit a stereotyped bradycardia and transient increase in motor activity following experimental compression of the umbilical cord. Peripheral denervation has been shown to play a role for cholinergic mediation of fetal cardiac responses, but not motor responses, to other forms of sensory stimulation. In this experiment, pregnant rats were prepared by chemical transection of the spinal cord to permit direct observation of fetal rats in utero. Fetuses were fitted with paired cardiac leads for measurement of heart rate (HR) and received an iv injection of atropine (1.0 mg/kg) or the isometric saline vehicle 5 min before testing. Real-time recording of fetal motor behavior and were collected during a 1-min period prior to placement of a microvascular clamp on the umbilical cord, a 2-min period of umbilical cord compression, and a 3-min period following removal of the clamp and restoration of umbilical circulation. Atropine-infused fetuses showed the typical, brief period of increased motor activity, which was predominated by lateral flexions of the body trunk, and a prominent HR deceleration, which gradually returned to pre-clamp baseline levels after removal of the clamp. Atropine-injected fetuses exhibited a slower onset of bradycardia and more rapid return to baseline HR after removal of the clamp. Further, atropine-injected subjects showed a reduced behavioral response during the period of cord compression and exhibited a secondary increase in trunk movements during recovery. These findings suggest a role for parasympathetic modulation of the magnitude and pattern of both cardiac and motor responses to cord compression.

495.7 NEUROPEPTIDE Y PRODUCTION IN RAT MYOCYTE CULTURE IS REGULATED BY SYMPATHETIC NEURONS. E.J. Marek* and T. Neck-Faithful, Dept. of Neurology, Yale Univ. School of Medicine, New Haven CT 06510.

Sympathetic innervation of heart dramatically alters cardiac peptide production. The neural regulation of Neuropeptide Y (NPY) production and secretion has been examined in cardiac myocyte culture and in cardiac myocyte-sympathetic neuron (superior cervical ganglion) cocultures. NPY mRNA levels were quantitated by Northern analysis. NPY content was measured by radiomunnoassay and NPY processing was further analyzed by gel filtration. NPY was stable in spent medium for at least 48 hours. Cultures were maintained in complete serum free medium for up to 21 days.

NPY production and secretion was increased (by 1.5-2 fold) in atrial and ventricular cultures treated with serum conditioned medium, but was reduced (by 2.4 fold) in SCG-atrial cultures and SCG-ventricular cultures. The changes in myocyte NPY expression were dependent on the age of the cardiac cells in culture and on the duration of treatment with neurons conditioned medium or neurons. Changes in atrial and ventricular tissue were specific.

NPY production in myocytes is regulated by SCG neurons and by SCG culture conditioned medium as myocytes develop in culture. Experiments are underway to further elucidate the mechanisms of this normal-sympathetic regulation and to identify the developmental significance of cardiac NPY expression.

495.8 SYMPATHETIC NERVE RESPONSE TO ACUTE AND CHRONIC MORPHINE ADMINISTRATION IN THE RAT. S.C. Barbas* and P.G. Greeno. Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

This study investigates the effects of acute and chronic administration of morphine sulfate (MS) on the discharge of the lumbar sympathetic nerve (SN) and phasic nerve (PND) in urethane-anesthetized, paralyzed, vagotomized rats. The effects of morphine on cardioreceptor stimulation (10 O_2, 10-15 seconds) on PND amplitude (-55%, p<0.05) and SNS (45%, p<0.05) were observed. MS also attenuated the sympathetic baroreceptors and raised the resting SNS (-34%, p<0.05). These data indicate that morphine blocks the maximal PND at constant SNS. However, the effects of MS on PND and SNS are complex and may depend on the dose and duration of MS administration.

Respiratory sinus arrhythmia amplitude (RSA) is the difference between maximum and minimum instantaneous HRs following inspiratory onset, and is accepted as an index of vagal cardiac control. We studied 33 smokers (S) and 33 non-smokers (NS), who were matched for age, race, gender, height, and blood pressure, in supine and seated positions. Mean RSA was obtained over 30 seconds, was higher in S than NS suggesting that chronic tobacco use alters the relative sympathetic and parasympathetic contributions to cardiac control. SNS determined for 10 consecutive deep (~50% VCO) and slow (~5-7/min) breaths, were not different in S and NS in either position, but RSA was higher in the seated than in the supine position, suggesting that smoking blunts neither respiratory nor baroreflex modulation of vagal cardiac control. We concluded the higher RSA in smokers is likely the result of the sympathomimetic effects of nicotine rather than an impaired vagal control. (Supported by NIAAA R01-AA86678)
495.9

Autonomic activity is greatly increased during morphine withdrawal. We sought to determine the specific autonomic areas that might be responsible for this increased activity by using an antibody against the nuclear protein c-fos in brain tissues from rats withdrawn from morphine. Five groups of 4 male, Sprague-Dawley 250-300g rats were implanted with morphine pellets (75 mg, NIDA) or placebo pellets over a 5 day regimen and injected on day 6 with either saline or naltrexone (100 mg/kg) (Flamussen et al., 1990). Two and one half hours after injection, rats were quickly anesthetized with pentobarbital, i.p., and perfused transcardially with 4% paraformaldehyde. Coronal brain sections (40 μm) were cut on a vibratome and reacted with an antibody against c-fos protein kindly provided by T. Curran. After a standard PAP protocol, c-fos-like immunoreactivity was observed in several autonomic areas of the medulla including the nucleus of the solitary tract (NTS), caudal (CVL) and rostral ventrolateral medulla (RVLM). Although some c-fos-like reactivity was seen in these areas in control rats (either morphine-implanted, saline injected (n=5), or placebo-implanted, saline (n=5) or naltrexone injected (n=5)), a significantly higher number of c-fos positive cells in NTS, RVLM and CVL were seen in the naltrexone injected morphine-implanted rats (n=5). Large numbers of c-fos-like immunoreactive cells were also seen in locus coeruleus (LC), central gray adjacent to the dorsal raphe, ventromedial hypothalamic nucleus, paraventricular nucleus of the hypothalamus from morphine withdrawn rats. (NIDA R29 DA07353-01)

495.10
CLINICAL EVALUATION OF SYMPATHETIC ACTIVITY WITH CARDIOVASCULAR REFLEX TESTS AND SPECTRAL ANALYSIS OF HEART RATE VARIABILITY. S. Sega and T. Klautau, Dept. of Neurology, University of Medicine Center, SLO-61105 Ljubljana, Slovenia.

Orthostatic test, handgrip test and spectral analysis of heart rate variability (HRV) were performed on 70 healthy volunteers of both sexes aged 21 to 60 years. Blood pressure changes during orthostatic test, diastolic blood pressure increase during handgrip and integrals of the low- and medium-frequency bands in the HRV spectra in the standing posture were evaluated.

Blood pressure changes during orthostatic and handgrip tests did not correlate with age, whereas integrals of amplitude spectra did. Blood pressure changes during handgrip and orthostatic test did not correlate with each other or with integrals in the standing posture.

A possible explanation of these results could be that tests involving non-invasively measured ARB changes are less sensitive to transient amplitude spectra in the standing posture for the evaluation of sympathetic activity.

495.11

Sympathetic nerve activity (SNA) and blood pressure (BP) were sampled for 9.56 min. ± 2 days after implantation of renal nerve electrodes and arterial catheters in rat (n=3) to test the premise that low frequency BP oscillations are generated by the baroreflex. The measurements were repeated after anesthetizing the animals (pentobarbital, 30 mg/kg). SNA and BP autospectra and coherence were computed. In the low frequency range the maximum coherence (0.90 ± .002, mean ± SE) and maximum SNA power occurred at the 0.04 Hz. In contrast, BP coherence computed at the frequency (0.17 Hz) for maximum BP spectral power was only 0.40 ± 0.21. After anesthesia the frequency (0.40 ± .003 Hz) at maximum coherence and coherence (0.88 ± .004) were essentialy unchanged although SNA and BP spectral power decreased by 78.5 and 70.2 percent, respectively. These data suggest that BP spectral power at a frequency of approximately 0.4 Hz may be due to a SNA-baroreflex interaction and that anesthesia does not abolish this interaction. However, anesthesia apparently profoundly reduces both the SNA and BP responses at this frequency.

Currently the etiology of Chronic Fatigue Syndrome (CFS) is unknown. It is characterized by many neuropsychological, infectious, and immunological symptoms. The most debilitating feature of CFS is fatigue that is severe enough to reduce activity by greater than 50% for longer than 6 months. Since there is no diagnostic test for CFS, arguments exist as to whether it is medical or functional in etiology. To evaluate this problem, a state paced breathing protocol of 8, 12, and 18 breaths/min both in sitting and standing was used to compare vagal power in CFS patients and normals. Vagal power was derived through the application of heart rate spectral analysis on the ECG and respiration signals. Paced breathing was lower in sitting for CFS patients vs. normals. Vagal power did not fall in the standing position as commonly seen in exercise tests on a treadmill showed an increased vagal response to exercise as compared to normals. It is not clear at this point how to reconcile these differences between these two studies. Measurement of fatigue was also analyzed using biochemical parameters through video analysis to determine if there is a correlation between physiological and functional fatigue of CFS patients and normals at similar work levels.

These results preliminarily indicate that CFS patients may exhibit a consistent organic component to their illness that is, inappropriate vagal firing in different postures and during exercise. Comparisons of the extent to which this vagal firing affects exercise may aid in the diagnosis of CFS or perhaps in the classification of severity of CFS.

Simultaneous recordings of cervical sympathetic, splanchic and effenter phrenic (PHR) activity were obtained in Saffan-anesthetized, paralyzed and artificially ventilated piglets (1-38 days of age) under both anesthetic (PCO2 and end-tidal CO2). Power spectra and coherence functions of SYMP discharge were obtained by a fast Fourier transform routine. PHR discharge defined the separate inspiratory (I) and expiratory (E) epochs used for gating spectral estimates. Peaks were revealed in four frequency ranges (3-7 Hz, 10-15 Hz, 18-24 Hz, 30-38 Hz). Coherence varied from inspiratory to expiratory values (<0.1) in swine. The linear component of the age-coherence relationship for the 3 - 7 and 18 - 24 Hz peaks was significant for both I and E epochs (p <.05). The quadratic component was not significant. For the 10 - 15 Hz peak, both the linear and quadratic components were significant (p <.05). Correlation of age with E to I power ratios of the SYMP was only significant in the cervical SYMP (r = .52). Results suggest that coherence is a good indicator of postnatal maturation occurring within the SYMP system(s). (Supported by NIH grants HL-20864 and HD-28931.)

495.14
HEART RATE DYNAMICS DURING SLEEP-WAKING STATES IN NORMAL INFANTS. R. R. Harper*, W.L. Schectman and R.M. Harper. Brain Research Institute and the Dept. of Anatomy & Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024.

Extent and pattern of heart rate variation, assessed by summary procedures, undergo marked developmental changes over the early postnatal period. Summary measures of heart rate variation, however, fail to demonstrate the beat-by-beat dynamics of heart rate. We examined the development of moment-to-moment changes in cardiac interbeat intervals in normal infants over the first 6 months of life. Twelve-hour physiological recordings were obtained from 24 normal infants at 1 week and 1,2,3,4, and 6 months of age. For each recording, plots were made of each cardiac R-R interval as a function of the previous interval (Poincare plots) over 5 weeks old to 6 months of age. The distribution of points were made for both high and low heart rates showed significant age and state effects. Analysis of covariance indicated that all state and age related changes paralleled changes in basilar heart rate; only the effect of dynamic rate (heart rate during the previous beat) accounted for differences in the distribution of points in the basilar heart rate. Thus, the relationship of one cardiac R-R interval with its predecessor changes significantly with age over this period, paralleling short and long term changes in the distribution of points. (Supported by HD22695. Data acquisition and sleep state classification were performed under the direction of Drs. J. Hodgman and T. Hoppenbrouwers under NICHD contract HD32777.)

THURSDAY AM

Poincaré analysis of heart rate dynamics. However, the strong positive correlation between one interval and the next obscures the immediate relationship between a change in heart rate and the next change. The nature of this relationship was examined in 34 infants recorded at 1 week and at 12, 24, and 6 months of age. In each sleep-waking state, the number of ARRs (the difference between two successive RR intervals) larger than 4 msec was determined as a percentage of the total number of heart beats, and each pair of successive changes was categorized based on the directions of the two changes. Analysis of variance was used to identify differences in the proportion of large ARRs and their temporal patterns over ages and sleep states. During all states, the proportion of large ARRs decreased over the first month of life and increased from 1 to 3 months of age. The reduction over the first month depended on the increase in heart rate over that period, but some subsequent changes were heart rate independent. Furthermore, during the first month of life, infants showed significantly more sustained increases in heart rate than sustained decreases, while the opposite pattern was seen in infants from 3 to 6 months of age. We speculate that the profound and enduring changes in heart rate dynamics occurring between 1 and 3 months of age may reflect the emergence of cardio sympathetic reflexes.

CALCIUM DEFICIENCY INCREASES VENOUS REACTIVITY IN SHRs BUT DOES NOT ALTER TUBULAR RESPONSES TO NERVE STIMULATION. D.C. Hatton*, Y. Qi, and D.A. McCarron. Oregon Health Sciences University, Portland, OR 97231.

SHRs fed high Ca" diets have lower BP, less βP reactivity to NE, smaller BP responses to α1-adrenergic blockade and fewer α1- receptor binding sites in whole kidneys than SHRs fed low Ca" diets. To determine the functional correlates of the difference in renal α1 binding sites, tubular and vascular responses were assessed in the current study. SHRs fed either high (2.0%) or low (0.1%) Ca" diets for 8 weeks were used. While anesthetized with inactin (1000 mg/kg) intravenous injections of norepinephrine (NE) were made at 10, 20, 40 or 80 ng/kg. In other animals, a bipolar Ag-AgCl electrode was placed around the renal nerve. The renal nerve was stimulated at a level just below that required to change blood flow. Urine was collected for 20 min before, during and after stimulation. BP was significantly higher in animals on low Ca" diets (140 ± 22 mmHg, p < .01) as was blood flow (7.9 ml/min/gk vs. 5.6 ml/min/gk). Animals on low Ca" diets had greater reductions in renal blood flow at all doses of NE (p < .005).

Nerve stimulation caused a significant antigenicity and antiinflammatory but the changes were not different between diet groups. The results suggest vascular but not tubular responses may be altered in animals on different Ca" diets.

Intracranial administration of rat junction peptide (rJp), generated from the pro-opianomelanocortin, has a pressor effect especially in spontaneously hypertensive rats (SHR). To characterize this pressor response, we investigated the effect of angiotensin or adrenergic receptor blockers in conscious SHR. The pressor response was abolished by intracranial pre-administration of 5 μg of losartan (DuP 753) (34 ± 5 vs. 4 ± 1 mmHg). Similar blocking effect was observed by [Sar¹, Ile²] angiotensin II. The concentration of angiotensin II in CSF was increased 2.0- and 4.4-fold by 10 and 30 nmol of rJp, respectively. Pre-administration of yohimbine or propranolol did not prevent the pressor response to rJp. These results suggest the brain renin-angiotensin system may participate in the pressor response to rJp.

POTENTIAL ADVERSE EFFECTS OF LOW DIETARY COPPER AND RANDOM LIGHT/DARK CYCLES ON BLOOD PRESSURE IN NORMOTENSIVE RATS. E.S. Halas* and L.M. Klevay. Department of Physiology, University of North Dakota and USDARS, Grand Forks Human Nutrition Research Center, Grand Forks, ND 58202.

Humans who work a night shift have a significantly higher rate of heart disease than people who work a day shift. A disruption in this circadian rhythm may be a major cause of the increased heart disease among shift workers. However, other factors such as disrupted family life, an inadequate diet, lack of recreational opportunities, and working social shifts may contribute to the elevated heart disease. Rats were subjected to random light/dark cycles (Halas and Klevay, Soc. Neurosci. Abstract 17. 1000, 1991). The 8-hour light cycle was initiated at one of three starting periods: 12:00 a.m., 8:00 a.m. or 4:00 p.m. A given cycle would last from 2 to 4 days and then it would be changed. Half of the rats were exposed to the random light/dark cycle while the other half received the standard 12-hour light/dark cycle. Half of the animals in each group were fed a purified diet (Klevay, Am. J. Clin. Nutr. 26: 1060, 1973) with 2.00 ppm Cu diet while the others were fed the diet with 5.00 ppm Cu. There were 15 normotensive, Sprague-Dawley male rats in each of the four groups. The experiment lasted four to six weeks. Significant elevation of blood pressure occurred in the 2.00 ppm Cu groups (p < .001) whereas the random light/dark cycle groups did not exhibit any increase in blood pressure. These results are in contrast with a prior experiment (loc. cit.) which found that both the 2.00 ppm Cu diet and random light/dark cycle significantly increased plasma cholesterol. These results suggest that the environmental factors that control blood pressure and cholesterol may be different.

Recent work from our lab has provided further evidence for a role of the nigrostriatal dopamine (DA) system in the development of hypertension in the spontaneously hypertensive rat (SHR). It was shown that the release of DA in the caudate nucleus of SHR is lower than that of normotensive Wistar-Kyoto rats (WKY). In addition, in the caudate nucleus of SHR a supersensitivity of DA D1 autoreceptors was found. To further characterize the nigrostriatal DA system of SHR and WKY novel environment-induced grooming behaviour, regulated extensively by central DA systems, was studied. Moreover, receptor binding studies were performed to establish affinity and concentrations of DA receptors in both strains. Novelty-induced grooming behaviour scores were lower in SHR than in WKY. A dose-dependent suppression of grooming behaviour was induced by the DA D1 antagonist SCH 23390 and by the DA D1 agonist quinpirole. The SCH 23390-induced suppression was less, whereas by quinpirole was more pronounced in SHR than in WKY. No differences between SHR and WKY were found in binding characteristics of DA receptors. The results suggest that differences between SHR and WKY as found in the grooming paradigm are not related to changes in binding characteristics of DA receptors. However, the stronger quinpirole-induced inhibition of grooming behavior was previously reported to be a hypersensitivity of presynaptic DA D2 receptors in the caudate nucleus of SHR. This work is supported by a Vidi grant from the Netherlands Foundation for Scientific Research (NWO).

EFFECTS OF CHEMORECEPTOR STIMULATION ON REGIONAL HEMODYNAMICS IN RATS. A.M. Hoque, R.A. Shaffer and S.J. Lewis*, Dept. of Pharmacology and Cardiovascular Center, Univ. of Iowa, Iowa City, IA 52242.

Chemoreceptor (CR) reflexes are critical in the regulation of cardiovascular function. In this study the effects of CR stimulation by sodium cyanide (NaCN 50 - 200 μg/kg, iv.) on regional hemodynamics were examined before and after bilateral transection of the carotid sinus nerves (CSNX) in urethane-anesthetized rats. The injection of NaCN produced a fall in arterial pressure (AP), an increase in cardiac output (CO) and a reduction in total peripheral resistance (TPR). NaCN also increased hindquarter (HQR), renal (RF) and mesenteric (MF) blood flows and consequently reduced the resistances in these beds. Bilateral CSNX produced marked increases in TPR, hindquarter (HQR), renal (RR) and mesenteric (MR) resistances, a decrease in CO and no change in AP. Bilateral CSNX did not modify the hemodynamic effects of NaCN. These results suggest that stimulation of chemoreceptors produces marked cardiovascular changes and that the CSNs also provide tonic regulation of regional hemodynamics. The present study also suggests that iv. NaCN stimulates chemoreceptors other than those in the CSN. (Supported by HL14388 and HL44546)

INFLUENCE OF ESTRUS CYCLE ON CONTRACTILE RESPONSES TO SENSORY AND ADRENERGIC NERVE STIMULATION IN FEMALE RAT BLOOD VESSELS. Z. Li and S.P. Buckelew*, Dept. of Pharmacology, University of California, Irvine, CA 92717

To study whether the estrous cycle has a significant effect on vascular reactivity to nerve stimulation, 3 month old F-344 rats in oestrus and proestrus stages (characterized by vaginal smear) were used. In the isolated Krebs perfused mesenteric vascular bed with guanethidine present to block adrenergic nerves and metabolites to maintain smooth muscle tone, sensory nerve activation caused by nicotine (Nic) exposure or transmural nerve stimulation (TNS) was not significantly different between mestrous and proestrus groups. In isolated tail artery rings segments which are rich in adrenergic but lack sensory innervation, increasing frequencies of TNS caused an increase in developed force in both mestrous and proestrus groups; no significant difference was seen. Furthermore concentration response curves to noradrenaline (NE) were superimposed. In addition, there was no significant difference in the non-specific relaxation produced by higher concentrations of nicotine. We conclude that different estrous stages do not significantly influence vascular responses to sensory or adrenergic nerve stimulation.

It is well established that Ach releases NO from the vascular endothelium. This study examined the possibility that the effects of Ach on regional hemodynamics in urethane-anesthetized rats involves NO. Ach (0.1 - 5 μg/kg, iv.) produced a fall in mean arterial (MAP) and pulse pressure (PP) and heart rate, an increase in cardiac output (CO) and decreases in total peripheral resistance (TPR), hindquarter (HQR) and mesenteric (MR) but no change in renal (RR) resistance. Following injection of the NO-synthesis inhibitor L-NAME (25 μmol/kg, iv.), Ach produced exaggerated falls in MAP, no bradycardia, an exaggerated increase in CO, similar changes in TPR and HQR but larger reductions in RR and MR. However, the duration of the Ach effects were markedly reduced following L-NAME. L-NAME also abolished the Ach-induced reduction in PP. These results suggest that a) NO is involved in the Ach-induced bradycardia and the maintenance but not the initiation of the hemodynamic effects of Ach, b) Ach reduces PP (probably via a decrease in vascular compliance) by a NO-dependent mechanism. (Supported by HL14388 and HL44546)

496.15

Bretylium (BRE) selectively depolarizes sympathetic nerve terminals leading to a release of neurotransmitter stores. This study examined the effects of BRE on vascular hemodynamics in conscious rats. BRE (5 mg/kg, iv) caused an increase in arterial pressure (AP), a sustained decrease in hindquarter resistance (HQR), and a gradual increase in renal (RR) and mesenteric (MR) resistances in saline-treated rats. After the adrenoceptor antagonist prazosin (100 μg/kg iv), BRE produced hypotension and exaggerated decreases in HQR, RR, and MR. The NO synthase inhibitor L-NAME (25 μmol/kg iv) abolished the BRE-induced decrease in HQR in saline-treated rats and the decreases in HQR, RR, and MR in prazosin-treated rats. This suggests that BRE causes the co-release of pre-formed stores of noradrenaline and vasodilator NOFs from sympathetic nerves. This raises the possibility that these are neurotransmitters in sympathetic vasodilator neurons and neuromodulators in sympathetic vasoconstrictor neurons. (Support by HLB 14388 & 44546)

The so-called dorsal facial area (DFA) is located at levels from 5 mm to 7 mm rostral to the obex and dorsal to the facial nucleus in the medulla in cats. Either electrical or glutamate stimulation of the DFA in the anesthetized cats induced predominantly an increase of blood flow of the ipsilateral common carotid artery, accompanied with neither change in blood flows of other vascular beds nor changes in the heart rate and blood pressure. The DFA response were mediated via the 7th and 9th cranial nerves. By measuring tissue blood flow (TB) with radiolabeled microspheres reference flow technique, we found both the intra- and extracranial TB were all increased in the DFA response. In addition, the DFA vasodilation involved atriope sensitive and insensitive mechanisms. Results of immunocytochemical studies showed that CA1, CA3, and CA2 DBH immunoreactive somas in the DFA. The substance P and serotonin immunoreactive fibers also presented in the DFA.

Microspheres reference flow techniques was used to measure regional blood flows (RBFs) of the intra- and extra-cranial tissues. Electrical or glutamate stimulation of the dorsal facial area (DFA) generally increased the intracranial RBFs of both cerebral hemispheres. Intracranial blood flow increases were preceded after administration of atropine but reduced after physostigmine. In contrast, extracranial blood flow increases responded to both drugs in the opposite direction. Thus, DFA stimulation may cause acetylcholine release to promote extracranial RBFs increase, but to restrict intracranial RBFs increase.

Questions remain as to the physiological role of RI adrenergic cells within the RVLM in the maintenance of arterial pressure (AP) at rest and during daily stresses. The instrumented dog has been our model for recording cardiovascular responses before and after incomplete lesions are made in pressure regions of RVLM by microinjection of kainic acid. Understanding the central command component of cardiovascular control during dynamic treadmill exercise (TET) is the purpose of this study. Mongrel dogs (n=15) were conditioned to run a modified Bruce protocol up to 4 mph. 16 % grade during which heart rate (HR), AP, aortic blood flow and cardiac output (CO), internal thoracic arterial flow (IT) and total peripheral resistance (TPR) were monitored. Instrumentations included solid state pressure transducers (Konigberg) and pulse-transit time flowmeter (Transonic) and 20 MHz Doppler probes. With a unilateral lesion (100 nl, 100nmol), in the transition region between the compact division of n. ambiguous and retrofacial n. the cardiovascular pattern response to exercise was unchanged. AP was significantly increased (P<0.01) and did not even attain pre-exercise resting values during the TET. TPR was significantly lower at all workloads except 3/0. The CO, peak systolic aortic flow, and IT were consistently lower than pre-exercise values but not significantly. When observing behavioral and motor control there was no discernible difference in the pre- to post-exercise treadmill performance.

Lesions causing these results were relatively small, approximately 1mm diameter, and within the rostral portions of the CI cell columns as revealed by immunocytochemical staining for PHNT. The cardiac portions of the CI are universally important in the maintenance of AP during rest and exercise (Supported by NIH grants HL-39105)

497.4 ANATOMICAL RELATIONSHIPS AMONG THREE POPULATIONS OF MEDULLARY EFFERENTS: RETICULOHYPOTHALAMIC, RETICULOVAGAL, AND RETICULOSPINAL NEURONS. G. G. Lee, H. Hardy, Departments of Physical Therapy and Anatomy, University of Mississippi Medical Center, Jackson, MS 34621.

Within the medulla are neurons that project to the hypothalamus, the vagus nerve, and the spinal cord. The primary purpose of the present study was to identify those regions which contain representative from each of these neuronal populations. (The long term hypothesis being that those areas, containing a diversity of efferents, may serve to integrate medullary control over vital functions.) For this purpose, a variety of retrogradely-transported tracers were made into either the posterolateral hypothalamus, vagus nerve or thoracic spinal cord, in a series of anesthetized rats. Subsequently, the locations of labeled medullary neurons were plotted.

The three neuronal populations, mentioned above, were observed in close apposition within the ventrolateral (CVL) and dorsomedial (CDM) aspects of the caudal medulla. In the CVL, the three populations of neurons were observed in the vicinity of the nucleus ambiguus (NA). Vagal projections originated from the dorsomedial aspect of NA, whereas spinal projections originated from the ventrolateral aspect of NA. Hypothalamic projections did not originate from the NA, but rather from an area immediately ventral to it. In the CDM, the three neuronal populations were observed in the vagal-solitary complex.

497.5 NUCLEUS TRACTUS SOLITARIUS (NTS) HYPERTENSION IN GUANETHIDINE-SYMPATHOMIMETIZED RATS. E. E. Benaroch*, J. D. Schneler, K. K. Pickard and P. A. Lowe. Neurophysiology Laboratory, Dept. of Neurology, Mayo Clinic, Rochester, MN 55905.

Guanethidine (GU) produces chronic postganglionic sympathoexcitatory (GUS) in adult rats. We sought to determine the effects of chronic sympathoexcitatory on the development of hypertension induced by kainic acid (KA) injection into the nucleus of the tractus solitarius (NTS). Guanethidine (40 mg/kg i.p.) was administered daily for five weeks. Controls received saline, and eight weeks after treatment, rats were anesthetized (urethane), cannulated and ventilated. Arterial pressure (AP) and heart rate (HR) were continuously monitored. Plasma norepinephrine (NE) and epinephrine (E) were measured by HPLC and vasopressin (AVP) by radioimmunoassay. NE and E were injected bilaterally into the NTS by Basal AP, HR, and plasma NE and E were slightly but not significantly lower than in GUSX. KA injection into the NTS produced hypertension in both controls and AP was higher in controls. (AP: 94±5 vs. 40±9 mm Hg, P<0.01). In control, but not GUSX, rats, hypertension was associated with significant elevation of NE (from 1.8±0.3 to 1.5±4 mg/ml, p<0.05) and E (from 2.5±0.3 to 7.6±1.5 mg/ml, p<0.05). Plasma AVP was similar between groups. GUSX showed AVP, but does not present, NTS hypertension. Expression of NTS hypertension may reflect denervation supersensitivity of vascular targets and sparing of preganglionic ganglion neurons, as well as prepressor effects of circulating AVP.
497.7 AREA POSTREMA STIMULATION EXCITES THEN INHIBITS MEDULLARY NEURONS IN THE BAROREFLEX PATHWAY. A.C. Bonham*, M.A. Obadai, K. Reid and J.A. Stewart. University of California, Davis, Davis, CA 95616.

Neurons in the area postrema augment baroreflex-mediated sympathoinhibition. We have shown previously that this augmentation may occur in the nucleus tractus solitarius (Soc Neurosci 10:220, 1990). The current study was aimed to determine if area postrema neurons mediate the activity of neurons in the rostral ventrolateral medulla (RVLM) in the baroreflex pathway. We performed experiments in -chloralose-anesthetized, paracervically and vagally isolated rabbits in which renal sympathetic nerve activity (RSNA), arterial pressure, ECG and tracheal pressure were recorded. Intracellular single unit activity was recorded in the RVLM and tested for discharge patterns locked to RSNA; for baroreceptor input by injecting v phenylphrine (8 - 200ug/kg) and nitroprusside (6 - 200ug/kg); and for responsiveness to single electrical pulses delivered to the area postrema (25 - 60 Hz). Six of seven cells which responded to electrical stimulation of the area postrema were inhibited by intravenous injection of atropine (4 - 1mmg/kg), and were exited by decreases in arterial pressure (5 - 10mmHg), also received a biphasic excitatory/inhibitory input from the area postrema. The early excitatory phase had a mean peak latency of 31.7 ± 0.4ms (x±SEM) (range 24.5 - 36.3ms); the subsequent inhibitory phase had a mean onset latency of 48.1 ± 17ms (x±SEM) and duration of 84.0 ± 51.4ms (range 40.0 - 160.0ms). The remaining cell was excited (peak latency of 31.7ms) but not inhibited by area postrema stimulation. These findings suggest that area postrema may modulate the activity of medullary sympathetic neurons in the baroreflex pathway. Supported by AHA 9-136.

497.8 AREA 1 AREA NEURONS WITH PROJECTION TO THE SUPRAOPTIC NUCLEUS ARE EXCITED BY ELECTRICAL STIMULATION OF THE ABDOMINAL VAGUS NERVE Z. I. Garrobo* and W.W. Blessing. Centre for Neuroscience, Flinders University, Adelaide, SA 5042, Australia.

Neurons in the A1 area of the medulla oblongata excite vasopressin-secreting cells in the hypothalamic magnocellular nucleus. Vasopressin neurons in the hypothalamus are stimulated by action potentials also modulate the activity of neurons in the rostral ventrolateral medulla (RVLM) in the baroreflex pathway. We have now tested, in urethra-anesthetized rabbits (1.5 g/kg, i.v.), whether the discharge rate of A1 area neurons, identified with extracellular tungsten electrodes and antidromic activation from the supraoptic nucleus, meeting collision criteria, is affected by electrical stimulation of the abdominal vagus (cuff electrode at the level of the diaphragm, 0.5 ms, 200 Hz, 1.3 cathodal pulses). Peristimulus time histograms were constructed using an ITC16 interface and a Macintosh IIx computer programmed with Igor. Of 58 neurons identified, 42 (72%) were excited by stimulation of the vagus. No neurons were inhibited. The latency to maximum excitation was 251 ± 11 ms (conduction velocity 0.52 m/s). Excitation of neurons was followed by inhibition lasting approximately 50 ms. Of the 30 neurons excited by the vagus, 26 were inhibited by activation of baroreceptors using intravenous phenylphrine. We have searched for a physiological stimulus which might activate these neurons. Infusion of hypertonic saline into the portal vein did not affect the discharge of the A1 cells. Nor did distension of the stomach with a balloon. Nor did stimulation of the central end of all nerves entering the lumen of the kidney. These results provide evidence, that nearly all neurons in the A1 area with projections to the supraoptic nucleus are excited by electrical stimulation of the abdominal vagus. The relevant physiological stimuli activating the cells via vagal afferent fibers are not yet identified.

497.9 CARDIOVASCULAR EFFECTS OF OXYTOCIN INJECTIONS INTO AREAS OF THE MEDULLA OBLONGATA RECEIVING OXYTOCINERGIC INNervation. R. E. Gomez, M. A. Cannata, M. Anwar* and D. Ruggiero. INSNSA, DBA, RS. As. and Div. of Neurobiol, CUNY, NY.

We examined the distribution of oxytocinergic terminals and the effect on arterial pressure (AP) of oxytocin microinjections into the nucleus tractus solitarii (NTS) and the reticular formation of the caudal RVLM and rostral (RVL) ventrolateral medulla. Immunocytochemical labeling with an antisera against -synthetic oxytocin revealed axons and punctata with oxytocin-like immunoreactivity in NTS and RVLM. In combined retrograde transport immunofluorescence in rats injected with a tracer into hypothalamic nucleus or RVLM, Gold into NTS labeled larger numbers of neurophysiological neurons in the parvicellular and paraventricular hypothalamic nucleus than RVLM deposits. Changes in AP (mmHg) after bilateral microinjections in anesthetized rats occurred within the first minute after injection: Oxytocin NTS 10 pmol Cvl 20, 0.2±0.05 0.2±0.05 0.2±0.05 0.2±0.05 0.2±0.05

A similar dose of oxytocin injected intravenously produced no change in AP. The data suggest that oxytocin may control AP via receptors in the medullary reticular formation.

Electrical stimulation (10sec, 5mA, 20-100µA) in the lateral and dorsal periaqueductal grey matter (PAG) evoked a pressor response with tachycardia and vasodilation in hindlimb muscles in urethane-anesthetized rats. Activation of perikarya in nucleus raphe magnus (NRM) and nucleus raphe obscurus (NRO), by microinjection of 5-10nmol 5-bromo-homocysteinyl (BLH) attenuated all components of the PAG-evoked cardiovascular defence response whereas individual components of the LAAM-evoked response were modified selectively. Stimulation in NRM reduced the LAAM-evoked vasodilation by 64%, converted the tachycardia to a bradycardia and had no significant effect on the pressor response. Activation of cells in NRO also produced a reduction (38%) in the LAAM-evoked pressor response but potentiated the tachycardia and increased resting MAP by 150% and 35% respectively. The results suggest: (1) that the medullary raphe may differentially modulate activity in the descending pathways from the hypothalamic and midbrain defence areas and 2) that the central differential between NRM and NRO with respect to control of the LAAM-evoked response.

497.12 TRACING OF SINGLE FIBERS DEMONSTRATES THAT MIDDIBRAIN PERIQUADUETAL GRAY NEURONS HAVE COLLABORATED PROJECTIONS TO SOMATIC AND CARDIOVASCULAR RELATED REGIONS IN THE MEDULLA. P. Carrive, R. Bandier and M. Christie* Departments of Anatomy and Pharmacology, University of Sydney, NSW, 2006, Australia.

The midbrain periaqueductal gray matter (PAG) plays a crucial role in the integration of somatic and autonomic components characteristic of different patterns of defensive responses. These components are mediated by descending projections to autonomic and somatic regions of the lower brainstem, but the extent of collateralization within these projections is not known. We report here the existence of collateralized projections to distinct somatic and autonomic regions of the medulla and cervical cord. Biocytin was used as an anterograde tracer. It was applied iontophoretically at sites located in the intermediate third of the lateral PAG of 3 rats and 2 cats. Ten fibers labelled with biocytin were followed from section to section and reconstructed along their entire medullary course. The results show that 6 of 8 fibers terminating in the vasopressor region of the rostral ventrolateral medulla also have collaterals terminating (i) in the dorsomedial part of the facial nucleus (control of ear musculature; 3 fibers), (ii) in the nucleus retroambiguus (control of expiratory musculature; 3 fibers), and (iii) in the ventral horn of the upper cervical spinal cord (control of neck muscles; 2 fibers). Each region mediates a characteristic component of the defensive reaction evoked from the intermediate third of the lateral PAG. Such collateralized projections may well play a significant role in the integration of the autonomic and somatic functions characteristic of this region of the PAG.

497.13 LONGITUDINAL COLUMN OF CARDIOVASCULAR SYMPATHETIC NUCLEI IN CAT MEDULLA EXTEND MEDULLALLY INTO LATERAL SENSITORY FIELD. C.W. Hensens*, B. E. Robertson, and C.J. Fontana. Lab. of Neurosurgery, Tulane University School of Medicine, New Orleans, LA 70112.

We have previously shown (Neurosci. Abstr. 17: 994, 1991) that cardiovascular sympathetic nuclei in cat medulla are distributed in a longitudinal column parallel and lateral to the longitudinal array of cells comprising the ambiguous nucleus. The column extends 4.5-5.0 mm from its posterior end in the caudal ventrolateral medulla (CVLM) to its anterior end above the rostral ventrolateral medulla (RVLM). In contrast, Gebber and Herrman have reported in cat a similar parasagittal distribution of cells displaying cardiovascular sympathetic activity, but lying entirely medial to the ambiguous nucleus in the lateral sagittal column (J. Neurophysiol. 54: 1498, 1985). We now report that a survey of the medullary region lying medial to our lateral column, using microinjection of excitatory amino acids, verifies the existence of a continuum of cardiovascular sympathetic nuclei cells distributed from 2 to 4 mm laterally and encompassing the region of the ambiguous nucleus. Chemical inhibition of small areas of this continuum yields hypertension, tachycardia, and partial loss of baroreflex, with these effects weakening in the more medial and caudal aspects of the array.

Stimulation of the hypothalamic defense area (HDA) elicited a cardiorespiratory response that is thought to prepare the animal for “fight or flight.” This response is characterized by increases in cardiac output, blood pressure (BP), heart rate (HR), hindlimb blood flow and hyper ventilation. The cardiorespiratory response elicited by stimulation of the vigilance area (HVA) is associated with the inhibition of movement and is characterized by a BP increase, HR decrease and brief inspiratory apnea or a shallow tachypnea. The present study was conducted to determine if HDA and HVA stimuli give rise to different responses with NTS in rabbits.

Adult New Zealand albino rabbits were anesthetized with isoflurane. The HDA and HVA stimulation was delivered to the posterior dorsomedial hypothalamus via a bipolar stainless steel electrode (200-300 μA, 100 Hz, 0.5 ms duration, 0.5-1.5 sec train). Extracellular unit recordings were made in NTS with stereotrode electrodes during the hypothalamic stimulation.

Most of the NTS neurons affected by electrical stimulation of the HVA showed a decrease in firing rate. Approximately half of the NTS neurons that responded to the HDA stimulation showed an increase in firing rate. Many of these NTS neurons were able to receive this information as well. A small number of the NTS neurons recorded did not respond to either the HVA or HDA stimulation. These findings suggest that both HVA and HDA make functional connections with the NTS. (Supported by NIH HL 36588 and HL 07426).

Experiments using Cholera Toxin-Horseradish Peroxidase (CT-HP) as a tracer have delineated the region of baroreceptor and cardiac afferent input as well as the distribution of vagal preganglionic nerve fibers (Eccles and Ito, 1969). However, the location, extent and number of interneuronal groups subserving the medullary component of the baroreceptor vagal reflex is unknown. In order to address these questions we have used the intracisternal Bartha strain of the pseudorabies virus (PRV) as a retrograde trans-neuronal (putatively trans-synaptic) tracer. PRV was injected into two distinct cardiac sites shown by injections of CT-HP to receive vagal preganglionic innervation: between the mainstem bronchus and the aorta and at the crossing of the jugular vein, left ventricle and pulmonary artery. The earliest labelling of neurons in the medulla was present at 48 hours and was confined to members of the nodal and cranial cardiac sympathetic (NA) vagal cardiac efferent populations, as defined by location and morphology seen earlier in the CT-HP studies. With longer survival times the picture became much more complicated, but we will focus here on just a few relevant cell groups. At 68-72 hours survival time numerous non-vagal motor neurons were labelled with PRV in the vicinity of the cranial NA group, basically in the area of the cranial ventro-lateral medulla or A1 cholinergic population. Labelled neurons were scattered along an arc through the dorsal medullary reticulotegmental field and a few scattered neurons were labelled in the nucleus tractus Solitarii (NTS), particularly in its ventral subdivisions. At 94 hours this later labeling became more dense, and in a dorsal medullary group appeared in the dorsal NTS within the regions receiving baroreceptor and cardiac afferents. We interpret these results to suggest that the simplest baroreceptor vagal reflex involves at least two interneurons.

We previously characterized two groups of rhythmically beating cells at 5Hz (autonomic & sympathetically driven) in the nNTS in vivo (Patton et al. J Neurophysiol. 60: 854-858, 1987). The present study sought to determine whether such neurons were found in vitro and, if so, to physiologically characterize cells based on the varicosal origin of synaptic input(s). Extracellular recordings were made from 28 rhythmically discharging single units in the nNTS in anesthetized rats (chloral hydrate: 375 mg/kg & pentobarbital: 75 mg/kg, i.p.). All cells fired a single spike per breath (4-6 Hz) and were divided into two groups based on their firing relationship with the wave of the ECG. One group of neurons (n>10) discharged with a relatively constant phase angle to the R wave whereas the second group was tightly coupled to the cardiac cycle but fired at a similar frequency as heart rate. Both groups of cells showed a peak in the R wave triggered histogram (mean latency: 16ms). Of 18 cells tested, 16 received an excitatory synaptic input following electrical stimulation of the ipsilateral vagus nerve (mean latency 20 ms) and 3 neurons were also excited by aortic nerve stimulation (latency range: 15-18ms). Brief periods of cardiac arrest, produced by electrically stimulating the peripheral end of the cut vagus nerve, decreased the firing frequency and, following recovery of heart rate, disrupted the phase relationship with the wave of the ECG. Verrassend (5-20 μg; i.v. bolus) strongly excited all 4 rhythmically firing cells tested. These data indicate the presence of neurons beating rhythmically at the cardiac rate in the nNTS that receive cardiac afferent synaptic inputs.

There is a paucity of information concerning the response patterns of second order NTS neurons to graded arterial pressure changes. Thus, the present study examined the firing response characteristics of presumptive second order baroreceptive neurons during increases in arterial pressure following i.v. administration of phenylephrine (PE; 5-20 μg). Anesthesia was induced in rats using halothane followed by an intraperitoneal injection of Saffan (12 mg/kg i.v.). Extracellular recordings were made from 19 single NTS neurons receiving a short and invariant excitatory synaptic input following ipsilateral aortic nerve stimulation (range of latency to spike: 1.8-4.0 ms). The responses of 19 cells tested 10 were silent at baseline mean arterial pressure of 90-120 mmHg. The response of these neurons to PE injection was characterized by either a single action potential or a transient burst of activity (1-2 spikes) at a specific time point following the rising phase of the blood pressure response. As blood pressure continued to rise past this point firing ceased until the same blood pressure level was reached during the falling phase, at which time a similar pattern of discharge occurred. Recording 9 cells showed ongoing activity (mean pressure range 90-120 mmHg) which increased and decreased proportionally during the rising and falling phases of the blood pressure response to PE injection respectively. These results show a heterogeneous population of putative second order baroreceptive NTS neurons. It suggests that while some NTS neurons reflect mean arterial pressure in their individual firing frequencies, other neuron types may contribute to population encoding of mean arterial pressure and changes in blood pressure.

497.17 IONIC CURRENT MODEL OF DELAYED EXCITATION IN NEURONS OF RAT MEDIAL NUCLEUS TRACTUS SOLITARIUS (mNTS). M.G. Andreasson, G. Khushalani, J.H. Schiff, M. Yang, D.L. Kneuss, and J.W. Clark. Oregon Health Sciences Univ., Portland, OR 97201, Rice Univ. and Baylor College of Medicine, Houston, TX 77025.

Anatomical studies suggest that aortic arch baroreceptors synapse within a limited area of mNTS. Our studies focused on intracellular recordings from medullary slices including this area and on patch clamp work with axons dispersed from mNTS. In slices, depolarization current injection resulted in a rapid increase in spike rate followed by spike frequency adaptation (SFA). Pre-hyperpolarization induced a prolonged delay (DE) before resuming spiking and eliminated SFA in all neurons. In isolated mNTS neurons, two hyperpolarization-activated, transient-outward potassium currents were found with time constants matching the DE time course. We developed a comprehensive ionic current model with thirteen coupled, first-order, non-linear differential equations (Hodgkin-Huxley) to represent 8 ionic conductances, two ATPase pumps (Na-K and Ca), a Na/Ca exchanger, and calcium balance within the neurons. With a single fixed set of fit parameters, the model effectively predicted neuronal responses to a wide range of multistep current injection protocols over tens of seconds. The voltage dependence of the ionic channels was accurately reproduced. The model demonstrates the dynamic interaction of a family of voltage dependent conductances, emphasizes the pivotal role of ionic conductance responses and suggests a valuable tool for integrating information from isolated cells with more intact preparations.

497.18 THE INTERRELATIONSHIP OF RENIN-ANGIOTENSIN SYSTEM AND ADENOSINE IN THE BRAINSTEM NUCLEI OF RATS. H. Lin, C.K. Tsai, W.C. Lin and S.H. Shih. Dep. of Pharmacology, Physiology, Psychology and Zoology, National Defense Medical Center and National Taiwan University, Taipei, Taiwan, R.O.C.

The purpose of this study was to investigate the possible interaction of adenosine and renin-angiotensin system in the brainstem nuclei of the rat. Male Sprague-Dawley rats were anaesthetized with urethane. Adenosine, angiotensin (ANG) II, ANG III, and their antagonist 1,3-dipropyl-8-p-sulphophenylxanthine (DPPX) and Sar1,Ile2 ANG III were microinjected into the nucleus tractus solitarii (NTS) and their postrema (P) or rats. Our results demonstrated that microinjection of DPPX significantly attenuated the depressor and bradycardia effect at low dose (9.6 pmol) of ANG II and ANG III. Whereas, the same dose of DPPX significantly potentiated the pressor effect at high dose (480 pmol) of ANG II and ANG III in the NTS and AP. The depressor and bradycardia induced by high dose ANG II and ANG III were slightly inhibited by DPPX. On the other hand, when ANG antagonist were microinjected into the NTS, they failed to change blood pressure. The injection of adenosine, we found that Sar1,Ile2 ANG III can affect the depressor and bradycardia effects of adenosine in the AP, not in the NTS. Modulatory mechanisms remain to be clarified.

497.10

A critical role for the dorsal and ventral medulla oblectangia in cardiovascular regulation is well established. Further, angiotensin (Ang) peptides and receptors have been demonstrated in these cardiovascular regions. We showed an increase in expression of angiotensinogen (Aogen) mRNA in aortic-lesioned hypertensive rats compared to sham-operated controls (Nishimura et al., Hypertension, 1992). To further define more discrete changes in Ang mRNA expression in these medullary areas, we show that in situ hybridization histochemistry to both localizing and quantize changes in Ang mRNA. Aogen-specific probe was a 30-base long single-strand oligonucleotide with a 3'-terminal dATP covalently linked with the nucleotides radiolabeling Ang I (antisense). Non-specific (sense) probe was its inverse complement. Following autoradiography, signals were quantified by scintidensity to measure relative total density in the area postrema, nucleus tractus solitarius, dorsal motor neuron of the vagus (DMNX), hypothalamic nucleus, nucleus of tractus solitarius, and ventral medulla oblectangia. Expression of Aogen mRNA was increased by approximately 50% in the DMNX and the hypothalamic nucleus six days after acute lesion, at a time when circulating and central renin-angiotensin systems are activated and angiotensin II levels are elevated. Results of these studies confirm a role for the DMNX during the development of hypertension, and further indicate that compensatory homostatic systems are likely to assume a more prominent role in regulating expression of Aogen mRNA in the medulla oblectangia during the chronic stages of hypertension. 498.1

QUANTITATIVE STUDY OF THE PATTERN OF REINNEVATION OF VIBRISSAL FOLLICLES AFTER PARTIAL DENERVATION OF THE WHISKERPAD OF ADULT MICE. W.C. Corbey, E. Wecker, H. Van der Loos, B.M. Biedermann.* Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

Partial denervation of skin in adult animals leads to changes in the central representation of the neighboring skin areas. We have quantified the peripheral innervation of the caudomost whisker follicles of rows B, C and D at varying intervals after denervation (double ligature followed by transection of the nerve) of follicles of rows C and D at varying intervals after denervation (double ligature followed by transection of the nerve) of follicles of row C in adult mice. Controls show a caudo-cranial gradient (c->r) of innervation density (figure). Numbers are mediated on counts in 3 mice per group. At five days post lesion (p.l.) Wallerian degeneration controls 15 d.p.l. 100 d.p.l. is complete: there are follicles in the follicle columns of row C. At 15 days p.l. reinnervation appears and from about 60 days p.l. onwards the number of fiber nerves reaches a plateau. The gradient is reversed in reinnervation density. There were no changes in the innervation of the neighboring, intact follicles. These observations provide evidence of a numerical regulation of the reinnervation of follicular tissues and will be used to study the mechanisms underlying adult plasticity in the somatosensory pathway. Support: Swiss NSF 31-30532.

499.3

We are studying the response of the trigeminal nuclei (TN) to injury. Previous studies have shown argyrophilia and degenerative alterations of axons and terminals within the TN following pulp lesions performed in the adult cat. The effect of similar lesions performed on deciduous teeth in kittens has not previously been reported. Pulp excision of the canals were performed on the left maxillary and mandibular deciduous cusps of 8-10 week old kittens (8 subjects) with survival periods ranging from 1 day to 3 weeks. Tissue from B (Nearfus et al. TN) was reacted with the Fink-Heimer stain and in addition laminae I and II of parai caudalis/modularly dorsal horn was examined with electron microscopy. In both regions, axons and terminals were known to terminate. Examination of the Fink-Heimer preparations showed a lack of argyrophilia. Sections examined with the EM revealed axonal and terminal alterations suggestive of degeneration and less commonly of regeneration or recovery and the latter were characterized by the presence of agranular reticulum. Most of the terminal alterations were electron lucent and were found with reduced synapses vesicles sometimes surrounding by enlarged glial profiles or terminals with anclusions including glycogen particles. The lack of argyrophilia and the presence of these results suggest a greater potential for recovery in the immature feline trigeminal system following injury. (Supported by NIDR Grants DE00219 & DE04942. L.E.W. is a research affiliate of the CDMRC).

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992
498.5 RESPONSES AND THALAMIC PROJECTIONS OF THERMORECEPTIVE NEURONS IN RAT SUPERFICIAL MEDULLARY DORSAL HORN (MDH), W.D. Hutchison* and J.O. Dostrovsky. Dept. Physiology, Univ. of Toronto, Toronto, Canada M5S 3G8
Little is known concerning central processing of innocuous temperature inputs in the rat. The aim of the present study was to determine the characteristics and projection targets of all thermosensitive neurons in rat MDH that respond to innocuous thermal stimuli applied to the corneal region.
Recordings were made from 58 cold cells in the superficial MDH of chloralose-anesthetized rats. Cells were identified by responses to cold probes and radiant warmth and their responses further quantified with a Peltier thermode. The receptive fields of most of the neurons were on the upper lip (54%) or tongue (28%). Most (65%) of the neurons responded only to innocuous cooling, whereas the remainder could also be activated by mechanical stimulation although these responses were small compared to those produced by a rapid thermal change. Of these innocuous-sensitive neurons, 57% responded only to slow cooling, 25% only to noxious pinch and 17% to both touch and pinch stimuli. Many (56%) of the 27 neurons tested responded also to noxious thermal stimuli. Cooling steps (5°C) produced mostly tonic responses in 40% of the 15 cells tested, mostly phasic responses in 27% and both types in the remaining 33%.
Antidromic mapping was performed for six MDH cold cells. Stimulation was delivered at 250 μm steps as the bipolar electrode driven through the cortex. Multiple tracks at mediolateral intervals of 0.5 mm were made. The neurons were antidromically activated from thalamus with currents of 9–20 μA (0.2ms, 1Hz) at latencies between 0.8–2 ms. The 80 μA antidromic-evoked response was recorded in the caudal ventralis centralis; 2 of the 6 neurons were also activated from sites that were in medial thalamus, one within Sm. (Supported by NIH DE05404)

The thalamic VPM nucleus receives inputs from all 4 trigeminal brainstem subnuclei. We (Williams et al., Neurosci. Abstr. 12, 91') have reported that principals (PV) terminals are more likely to synapse on more proximal portions of VPM dendrites than terminals from interopolaris (SpVI). To further assess the extent to which PV and SpVI inputs to thalamus are complementary or overlapping, adult rats each received HRP injections in PV and rhodamine- or fluorescein-dextran deposits in ipsilateral SpVI. Only 8 out of 9 control rats (1 PV/1 SpVI) were recorded. All PV and SpVI cells were recorded from anesthetized rats before and after infusion of 0.037 - 0.5 μl of glutamate (0.5 M) or lidocaine (2%) into most of subnuclei caudalis and interopolaris. Sensitivities of PV cells were determined with antidromic and intracellular labeling methods. Glutamate-induced changes in PV Rs were seen in 19 of 43 thalamic-projecting cells, where 13 exhibited smaller Rs or became less responsive to peripheral stimuli and 6 displayed larger rs or more spikes per whisker deflection. Lidocaine-induced changes were seen in 5 of 6 local circuit neurons, all of which became less responsive to peripheral stimuli. In 3 projection neurons with phasic responses to sustained whisker deflection, glutamate-induced tonic excitation was reversed by lidocaine. Lidocaine-induced changes in local circuit neurons were only seen in 2 of 7 cells, where 1 expressed a RF shift and the other showed a larger RF. Lidocaine infusion also affected directional sensitivity in 3 projection neurons and altered adaptation properties in 4 others. Thus, it would appear that spinal V nociceptive inputs have robust influences on the RFs of many PV cells. DE07734, DE07734, BNS9-1931.

AUDITORY SYSTEM: COCHLEA

499.1 IS AVIAN BASILAR MEMBRANE TRULY LINEAR? A.N. Tenechin and C. Meleshkam*. Gallier Center, University of Texas at Dallas, TX 75235.
The only available measures of avian basilar membrane (BM) intensity functions indicate that its behavior is linear in pigeon (Gummer et al., Hear. Res. 29(6-9), 1987), implying passive cochlear mechanics. Evidence is presented of the existence of three main types of rate-dependent level functions (pulsating, slope-saturating, and linear) at the characteristic frequency (CF) of pigeon primary auditory fibers. These functions were obtained with 2dB steps between 0 and 90 dB SPL. Saturating fibers have broad dynamic ranges (up to 40-45 dB) and sometimes were barely distinguished from slope-saturating. Unlike mammals, type of function does not depend on the spontaneous rate or threshold at CF. Correlation between CF-thresholds and BM intensity level is (r=0.06) and statistically insignificant. Clear break points of slope-saturating fibers within narrow CF region in the same animal occur over a narrow range of intensities and may be found between 35-45 dB SPL in different animals. The results, along with the earlier described phenomenon of single-tone suppression, which could occur at SPLs even slightly below the CF-threshold may be explained by the nonlinearities of BM and active mechanics in avian cochleas.

499.2 CHARACTERIZATION OF MINERALOCORTICOID (TYPE I) RECEPTORS IN THE INNER EAR BY COMPETITION STUDIES WITH SPIRONOLACTONE. D.Z. Pivovar, J. Lu, C. Itskovitz, S. Hwang, D. Eleftheriou, J.A. Dierker. Department of Otolaryngology, Laboratory of Bio-otology, Wayne State University School of Medicine, Detroit, MI 48201.
Spironolactone, a clinically important anti-mineralocorticoid, is thought to compete with aldosterone at mineralocorticoid (Type I) receptor sites in target tissues. Since Type I receptors are present in the inner ear (Pivovar et al., Soc. Neurosci. Abstr. 17: 507, 1991), it was of interest to investigate the antagonistic action of spironolactone in auditory and vestibular fractions. Minimally injected inner ear tissues of male Hartley guinea pigs were incubated with various concentrations of spironolactone (4 x 10-12 to 4 x 10-5M) in the presence of 4 x 10-7 M aldosterone. A 500-fold excess of RU 28362 (a highly specific glucocorticoid agonist) was included to minimize binding to glucocorticoid (Type II) receptors. Paired incubations were performed with RU 28362, RU 28367, and a 2,000-fold excess of unlabelled aldosterone to determine non-specific binding. Specific binding was calculated from the difference between total binding in the absence (control) and presence of RU 28362 with "C-estrone and normalized to tissue dry weight. The IC50 values for spironolactone in the lateral wall of the basilar cochlear turn and the ampulla of the semicircular canal were 4.1 x 10-7 and 4.6 x 10-7 M, respectively, while the corresponding values of Kd were 2.0 x 10-5 and 1.9 x 10-7M.
Inhibition studies performed with spironolactone at a dose response reduction of 10-aldosterone binding, implying that in inner ear tissues this compound behaves as an aldosterone antagonist. SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 18, 1992

499.6 DISTRIBUTION OF TRIGEMINAL NEURONS PROJECTING TO SPECIFIC CEREBELLAR CORTEX REGIONS IN THE RAT. J.A. Arends*, T.J.H. Briegel & M.F. Jacquin, Dept. of Anatomy & Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104; Dept. of Anatomy, Erasmus University, 3000 DR Rotterdam, The Netherlands.
Single and multiple retrograde tracing studies using WGA-HRP, Fluoro-gold, Diamidino-yellow, and FITC- and TRITC-labeled latex bead injections into different "oro-facial" areas of rat hindbrain were used to study the distribution of trigeminal neurons that project to specific or widespread cerebellar regions. Injections targeted included the vermis/paravermis (uvula and lateral lobules II-V) and the hemispheres (paramedian lobule, Crus I and II, simple lobule). In 22 rats, labeled cells were seen in trigeminal subnuclei principals, oralis and/or interopolars, as well as the trigeminal ganglion. There was a clear relationship between the dominant receptive field type within the cerebellar injection area (vibrissa vs. non-vibrissa) and the somatosensory (Crus I, uvula) responses produced by the largest numbers of labeled cells in vibrissa regions of ventral principals and interopolars, with moderate numbers in dorsal orals following uvula injections. Tracer deposits in other non-vibrissa cortical regions produced labeled cells primarily in non-vibrissa regions of dorsal principals, oralis and interopolars. Similarly, contralateral and bilateral projections were primarily confined to the cerebellar areas and originated in rostral interopolars, caudal orals and rostral principals. Labeled ganglion cells were seen in all cases except those involving the paramedian lobule. Only a small % of the trigeminal mossy fibers branched to terminate in more than one cerebellar region. NIH NS29885, DE07734, DE07662.
499.3 DEVELOPMENTAL CHANGES IN THE RESPONSE OF THE PERIPHERAL AUDITORY SYSTEM TO TWO-TONE STIMULI. J. J. Fitzgibbons, T. H煘, and E. L. Woum, Boys Town National Research Hospital and Creighton University, Omaha, NE 68131.

Auditory nerve fiber stimulation studies have been used to characterize the mature cochlear transduction process, which is nonlinear in nature. In contrast to the adult, some immature peripheral fibers exhibit facilitation, rather than suppression (Fitzgibbons et al., ARO 14:422, 1991). This study investigates several of the stimulus parameters and neural factors influencing the expression of facilitation and suppression during postnatal development. Single unit responses of peripheral auditory neurons were extracellularly recorded using techniques. Rate differences were evaluated for test tones placed both above and below characteristic frequency (CF), with poststimulus time histograms of CF responses were observed throughout the first postnatal month, although its incidence declined with age, while suppression was observed as early as 7 postnatal days. Although all test/probe tone ratios tested were capable of producing facilitation in the youngest animals, above-CF test tones produced facilitation in a higher percentage of units than below-CF test tones.

Auditory nerve fiber stimulation was directly correlated to the degree of frequency selectivity, and facilitation was less likely to be expressed in units showing narrow tuning characteristics. The ability of the system to produce action potentials appeared to be one of the factors limiting the magnitude of facilitation, while suppression seemed to be more dependent upon probe tone rate than facilitation.

499.4 ORGAN OF CORTI PROTEIN II SEQUENCE. K. E. Jensen*, P. K. Robb, I. Thalmann, and R. Thalmann, Departments of Psychiatry and Otolaryngology, Washington University, St. Louis, MO 63110.

The distinctive structure and function of the organ of Corti probably requires the expression of unique proteins. Two such proteins, designated OCPI and OCPII, have been isolated (Thalmann et al., Laryngoscope 106:99-105, 1996). OCPII was purified by separation of 2-dimensional polyacrylamide gel electrophoresis, electroblotted to PVDF membranes, and subjected to amino acid sequencing. The determination of internal sequence was performed by subjecting OCPII to limited proteolysis with chymotrypsin, papain, subtilisin, or V8 protease, separation of the peptides by 2-dimensional polyacrylamide electrophoresis and sequencing the resulting bands. The sequence of OCPII, although incomplete, does not resemble the sequence of any previously described protein. The molecular characterization of OCPII permits the elucidation of the role this protein plays in organ of Corti function.

499.5 INFORMATION RATES AND CODING EFFICIENCIES OF AUDITORY NERVE FIBERS. DA Bodnar*, KS Rieke, RR Capranica, and B Bialek, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853, and NEC Research Institute, 4 Independence Way, Princeton, NJ 08540.

Changes in the amplitude of a complex sound spectrum of a complex sound produce changes in both the spike rates and the synchronization characteristics of auditory nerve fibers in the bullfrog. Because of the simultaneous variations in these two coding parameters, it is difficult to assess how complex sound stimuli are represented based on solely on spike rate and synchronization patterns. Therefore, we have applied a new decoding analysis method (Bialek et al. 1991, Science, 252:1854), to examine additional coding properties of peripheral auditory units. With this method, an estimate of the stimulus waveform can be made from the spike train response of a neuron. In addition, this method provides estimates of the information rate and coding efficiency of a fiber's spike output. Thus, although a unit may have the same average spike rate in response to different sound stimuli, the information rate and coding efficiency of its spike output may differ— in particular, "naturalistic" stimuli may be coded with higher information rates and efficiencies than white noise stimuli. In this study, we have examined how changes in the amplitude and phase spectra of an acoustic signal affect the information rate and coding efficiency of the spike outputs of auditory nerve fibers in response to complex sound stimuli. This research is supported by MHI Grant NS-09244 to BNC and NEC Research Institute.

499.6 EFFECTS OF CHANGES IN THE AMPLITUDE AND PHASE SPECTRA OF COMPLEX SOUND STIMULI ON THE PHASE SENSITIVITY OF AUDITORY NERVE FIBERS. RR Capranica*, B Bialek, and KS Rieke, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In a recent study, we have demonstrated that auditory nerve fibers in the bullfrog (Rana catesbeiana) exhibit changes in their spike output in response to frequency changes in the relative phase angle of a single excitatory harmonic component in a multi-harmonic stimulus (Bodnar and Capranica (1991), Soc. Neurosci. Abstr. 17: 1197). In the present study, we have examined the effects of changes in the relative amplitude or phase angle of components in a multi-harmonic stimulus on the phase sensitivity of peripheral auditory units. For studies of changes in relative amplitudes we have compared cases in which the stimulus components have equal amplitudes or relative amplitudes comparable to the power spectrum of the bullfrog advertisement call. For studies of changes in the phase spectrum we have compared the cases when all the harmonic components have either a relative starting phase of 0°, 180°, or random. The results of these experiments indicate that the phase sensitivity of a unit can be influenced by the relative amplitudes and phase angles of the other components in a stimulus. In addition, we have found that units which exhibit two-tone suppression are sensitive to changes in the relative phase angle of the suppressor component and this phase sensitivity is also affected by changes in the relative amplitudes and phase angles of other stimulus components.

This research is supported by MHI Grant #M-09244 to BNC.

499.7 EXPRESSION OF mRNA ENCODING FOR ALTERNATELY SPliced SEGMENTS OF FIBRONECtin IN THE DEVELOPING RAT COCHLEA. P. J. Kolodziej, R. O. Wood*, D. V. Macpherson, and W. Hoshn and V. L. Wooda, Depts. of Otolaryngology and Medicine, UCSF Medical Center and Veterans Administration Medical Center, La Jolla, CA 92039-9112.

Recently, we have demonstrated the distribution of fibronectin mRNA in the rat inner ear. From embryonic day 18 through day 1 postpartum, intense, discrete immunoreactive foci was observed in the cochlear duct, immediately beneath the inner and outer hair cells, sites of auditory nerve fiber growth and nerve cells, respectively. Fibronectin was also found to be a major structural component within the basilar membrane throughout development. In order to determine the site(s) of fibronectin synthesis and the role of functionally distinct forms of fibronectin, we are performing in situ hybridizations on rat cochlear tissue with segment-specific mRNA probes (kindly provided by Dr. R. O. Hynes, MIT), which distinguish three alternatively spliced forms of fibronectin. Data will be presented demonstrating ontogenetic changes in cochlear fibronectin mRNA expression. This research is supported by DC139, DC386 & the VA Research Service.

499.8 SIMULTANEOUS MEASUREMENTS OF TUNING IN THE ANTEROVENTRAL COCHLEAR NUCLEUS AND DISTORTION PRODUCT OTOACOUSTIC EMISSIONS: EFFECTS OF ENDOCOCHLEAR POTENTIAL VARIATION. R. Ruhmann, D. M. Millis* and W. R. Bubel, Department of Otolaryngology-Head & Neck Surgery, Univ. of Washington, Seattle, WA 98195.

The objective of this study was to precisely evaluate the relationship between tuning characteristics and the thresholds of cochlear affers and the properties of distortion product otoacoustic emissions (DPOE). Response areas of multunit clusters in the anteroverentral cochlear nucleus and DPOEs at a rate of 30-40 dB. Stimulus levels were simultaneously measured in the adult gerbil during furosemide-induced changes of the endocochlear potential. Intraperitoneal injection of 0.5 mg furosemide had no effect on the high level DPOEs (stimulus intensity 75-80 dB SPL), but the low level DPOEs (stimulus intensity 50 dB SPL) are reduced from approximately 30 to 15 dB SPL within 15 min. Energy was fully recovered after about 60 min. Characteristics of the frequency threshold curves (FTC) after furosemide injection: (1) threshold at the best frequency (BF) increased by about 30-40 dB, (2) threshold of the FTC-tail (one octave below BF) was elevated by 8-10 dB, and (3) the FTC-bandwidth 10 dB above threshold widened from 0.2-0.4 octaves to 0.4-0.8 octaves. The dynamics of FTC deterioration and recovery are the same as for the DPOE reduction and recovery. This congruence indicates that tuning characteristics of cochlear affers are dynamically regulated by the same biological mechanism that regulates otoacoustic emissions.
499.9 DISTRIBUTION OF OLIVOCOCHLEAIR NEURONS IN THE CHINCHILLA. J.M. Weekly, W.B. Warr and B.J. Morey. Boys Town National Research Hospital, Omaha, NE 68131

Although the chinchilla is a commonly used animal in auditory research, very little work has been done on the origins and distribution of its cochlear afferents. The purpose of this study was to define and quantify these distributions using retrograde fluorescent tracer techniques. Four adult chinchillas were anesthetized and injected with 10 µg of FluoroGold (FG) or Fluorogold (FG) tracer into the cochlea. After a survival time of 6-10 days, the animal was fixed by intracardiac perfusion of 4% paraformaldehyde, the brain removed and sectioned. FG-labeled neurons were seen in the n. olivary core (N-3) or in the intralaminar plane (N=1) and studied under fluorescence microscopy. We could readily classify labeled OCN into two groups: lateral (LOC) and medial (MOC) olivocochlear neurons, as is the case in most mammalian species. Labeled OCN averaged a total of 1268 (s.d.=143) and were located mainly in the neuropil of the lateral superior olivary nucleus (LSO) ipsilaterally (mean=965.76% of total, s.d.=118) and in the contralateral dorsomedial periolivary region (DPOM) (mean=231.18% of total, s.d.=48). OCN were present in fewer numbers in the ipsilateral DPOM (mean=50.39% of total, s.d.=25) and contralateral LSO (mean=221.7% of total, s.d.=14). Although the general distribution of OCN in the chinchilla is similar to that known in other rodents, the restriction of MOC neurons to the DPOM is unique among rodent species so far studied. [Supported in part by NIH-NINDS-P60 DC00982]

499.10 EXPRESSION OF NMDA-RECEPTOR mRNA IN THE RAT AUDITORY SYSTEM. H. Kiyasu
day, R. Altun, S. Satoiya and R.A. Siegelj. Kresge Hearing Research Institute, Dept. Neurosciences, Univ. of Michigan, Ann Arbor MI 48109 and Dept. of Anatomy, University of Osaka, Osaka Japan.

There is now considerable evidence suggesting that glutamate or a related excitatory amino acid is a putative neurotransmitter that acts on an excitatory amino acid receptor. The NMDA receptor has been known to play a key role in plasticity in the CNS synapse, although its role in the cochlea and auditory brainstem has not been well established. Recently two sequences for the NMDA receptor have been reported (Mortoyd et al., 1991; Kuma et al., 1991), and the expression properties. Expression of NMDA receptor mRNA in the rat auditory system was examined using in situ hybridization histochemical techniques. For in situ hybridization studies one oligo-probe was made of antisense cDNA (2252/2269), of Mortoyd's (NMDAR-1) and another was made of the antisense cDNA (1107-1151) of Kuma's sequence (NMDAR-2). These probes were end labeled with 

499.11 HSP 72 INDUCTION WITH ACOUSTIC OVERSTIMULATION IN THE RAT COCHLEA AND AUDITORY BRAINSTEM. H.J. Lim, O.H. Jenkins, J.M. Miller*, M. Myser and R.A. Siegelj. Kresge Hearing Research Institute, Department of Otolaryngology, University of Michigan, Ann Arbor, MI 48109.

Heat shock proteins (HSPs) are induced after the exposure of cells to various metabolic and environmental stresses. In the auditory system, induction of the 72 kDa HSP has been shown with heat in the rod (Kim et al., 1999) and guttata pig (Thompson et al., 1992) cochlea as well as with hyperpnea in the rat cochlea (Miyers et al., 1992). The purpose of this study was to determine if high intensity acoustic stimulation would induce HSP 72 in the rat cochlea and auditory brainstem. Sprague-Dawley rats were exposed to 110 dB SPL, broad band noise for 1.5 hours and sacrificed 4, 6 and 8 hours after stimulation. Control animals did not receive any stimulation.

Immunohistochemical and biochemical analysis were performed using monoclonal antibodies against HSP 72 (Amersham, StressGen). Tissue for western blot analysis came from unfixed dissected cochlea, cochlear nucleus and inferior colliculus. Immunoreactivity was observed on vibratome sections of the rat brainstem, cristiform sections of cochlea and cochlea with the bony shell removed, the latter yielding surface preparations.

Western blots showed an intense 72 kDa band in the noise exposed animals compared to a very light band in control animals. Immunohistochemical results in the cochlea revealed the induction of HSP 72 immunoreactive (IR) staining of outer cells. The maximal IR staining was observed 6 hours after noise exposure. Only a few IR stained inner hair cells were seen and spiral ganglion cells were not stained. In the brainstem, noise induced HSP 72 IR labeling of neurons was observed in cochlear nucleus, medial nucleus of the trapezoid body, lateral superior olive, but not in inferior colliculus.

These results indicate that acoustic overstimulation can induce the expression of HSP 72 in the rat cochlea and auditory brainstem nuclei. HSP 72 immunohistochemistry may serve as a marker for cellular stress and potential damage. Further studies may also help to determine a protective function for HSP 72 in the auditory system. [Supported by NIDCD grants DC00724 and the Deafness Research Foundation]

Contralateral sound suppression (CSS) of distortion product otoacoustic emissions (DPOAEs) involves the activation of olivocochlear efferent fibers within the superior olivary complex (SO) (Puel & Brieskorn, Audiol Neurootol 6, 176:1713, 1991). One neurotransmitter of these fibers is acetylcholine (ACh). We studied the effects of ACh antagonists on CSS of DPOAEs to determine if ACh is involved and the receptor type. Urethane anesthetized guinea pigs with sectioned middle ear muscles were used. Perilymph spaces of cochlea were perfused with artificial perilymph (AP) and drugs at 2.5 µl/min for 10 min. After each period of perfusion the 2f1-f2 DPOAE at 5 kHz (t1=-6.25 kHz; t2=+7.5 kHz; dB SPL) was measured before, during and after a contralateral wideband noise (70 dB SPL). CSS of DPOAEs was 1.59 ° 0.15 dB. AP did not alter CSS of DPOAEs. Strychnine (10 µM), curare (10 µM) and atropine (10 µM) reversibly blocked CSS of DPOAEs. Results support the involvement of both nicotinic and muscarinic receptors in CSS of DPOAEs. (Supported by NIH grant DC-00722).

499.13 MIDDLE EAR TRANSFER FUNCTION AND DIRECTIONAL CHARACTERISTIC IN CLAWED FROG AND ZEBRA FINCH.
