We found a significant increase in microvillous-like luminal projections (#/luminal perimeter) in nicotine-treated versus control animals ($t = 12.5$, $p < 0.001$). There were no consistent changes in the other parameters. The lack of morphologic alteration of BBB endothelial cells may reflect either subthreshold exposure to nicotine, or a different response of these cells to the toxin. Nicotine exposure alters both circulating vasopressin levels (Larose et al, J Pharm Exp Ther, 1988, 244:1093) and blood-brain vasopressin transport (Lipovac et al, Soc Neurosci Abstr, 1992). Thus, neurohypophyseal changes may reflect either nicotine-induced alterations specifically related to vasopressinergic changes, or a generalized response of non-BBB endothelial cells to nicotine. IMMUNOLOCALIZATION OF IMMUNOGLOBULIN G (IgG) IN THE NORMAL BRAIN OF ADULT RAT. H. Tanno*, R. P. Nockels, L. H. Pitts and L. J. Noble. Dept. of Neurosurgery, Univ. of California and San Francisco General Hospital, San Francisco, CA 94110.

Recent studies suggest that plasma proteins may enter the brain by vascular route or via the CSF. In this study we immunolocalized IgG in neurons of the normal rat brain and examined the relationship of these labelled cells to the blood-brain and blood-CSF barriers.

IgG was immunolocalized in brain sections using a biotinylated rabbit anti-rat IgG. Immunolabel was detected with the avidin-biotin-horseradish peroxidase complex and diaminobenzidine tetrachloride as the chromogen. Immunocytochemical controls consisted of the same procedures in the absence of antibody and in antibody preabsorbed with rat IgG.

No staining was detected in the immunocytochemical controls. In contrast, IgG was immunolocalized in regions of the brain considered outside the blood-brain barrier and in brain stem nuclei whose long axons project into the periphery. A limited number of blood vessels, scattered throughout the brain, exhibited immunoreactivity. The label was associated with the vascular wall and in the adjacent extracellular space. Neurons adjacent to these blood vessels were frequently immunolabelled. IgG was also immunolocalized in neurons in the external granular layer of the parasagittal cortex, pyramidal neurons in the hippocampus, and in Purkinje cells in the cerebellum. These immunolabelled neurons were randomly distributed and were not typically bilateral in their distribution. The most unifying feature of these labelled neurons was that they were either intimately associated with an immunolabelled blood vessel or that their processes were in close proximity to the subarachnoid space or ventricles.

These findings suggest that 1) the blood-brain barrier expresses limited permeability to IgG and 2) neurons may accumulate IgG from these permeable vascular sites and/or from the CSF.

CHANGES IN THE BRAIN PERMEABILITY OF IgG IN CHRONIC RELAPSING EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (CR-EAE) IN THE GUINEA PIG. M.B. Segal* and D. Skundric. Dept. Physiology, UMDS, St. Thomas' Hosp., London UK, SE1 7EH.

CR-EAE was induced in 20 day old strain 13 guinea pigs by 0.1ml SC inoculation into both hind limbs, with homologous whole spinal cord homogenate in Freund's complete adjuvant (1:1) and 9mg killed mycobacterium tuberculi. Of the 35 animals treated 77% developed the chronic relapsing form of EAE, 18% a hyperacute and 5% no signs. The vascular brain perfusion method of Zlokovic (1986) was used in the various stages of CR-EAE to study the entry of homologous IgG and albumin into the brain. From 7 days post inoculation and during periods of maximum relapse, discrete areas of positive anti-IgG staining were seen in the perivascular spaces of small blood vessels. In these areas anti-albumin staining was negative. There were also scattered regions of demyelination. In controls, weak anti-IgG staining was seen on the endothelium, but not in the perivascular spaces and also, in both groups, in the choroid plexuses ependyma and subpia. The passive restriction of the blood-brain barrier is preserved in CR-EAE while the transfer of IgG is increased in some areas. Zlokovic BV et al (1986) J.Neurochem 46 1444-1451.

INTRA-ISCHEMIC MILD HYPOTHERMIA PROTECTS AGAINST BLOOD-BRAIN BARRIER DAMAGE. Z.G. Huang*, E. Preston, D. Xue, K.E. Smith and A.M. Buchan. Neuroscience Unit, Ottawa Civic Hospital and National Research Council, Ottawa, Canada, K1Y 4E9.

This study was conducted to explore the effects of intra-ischemic mild hypothermia on blood-brain barrier (BBB) opening in a rodent model of MCA occlusion. Male SHR rats were subjected to permanent right common carotid artery occlusion and 2 hrs of reversible right MCA occlusion. Normothermic and halothane control groups were kept at 37.5°C throughout ischemia and reperfusion (RP). The hypothermia group was kept at 32°C under anesthesia during the 2 hrs of ischemia, but raised to 37.5°C throughout RP. Following RP at 2 min, 22 hrs or 46 hrs, a ^{3}H-sucrose solution (20 μCi/100gm) was administered IV, circulated for 30 min, and the animals immediately sacrified. Cortical transfer constants (Ki) for BBB permeation of sucrose were calculated from the ratio of parenchymal ($dpm \cdot g^{-1}$) and time-integrated plasma ($dpm \cdot s \cdot mL^{-1}$) sucrose concentrations. A one-way ANOVA was used.

Ki, Mean ± SE (n): *p<0.05,**p<0.01,***p<0.001.

	RP-2 min	RP-22hrs	RP-46hrs
Normothermia (6)	3.8 ± 0.5	6.7 ± 1.0	25.5 ± 3.4
Halothane (4)	2.6 ± 0.2*	7.0 ± 1.7	
Hypothermia (5)	1.7 ± 0.2**	2.5 ± 0.6*	2.7 ± 0.7***

Intra-ischemic mild hypothermia protects against BBB breakdown, affording an explanation for hypothermic cytoprotection. Mild hypothermia should be employed to prevent vasogenic edema during thrombolytic therapy for stroke patients.

ULTRASTRUCTURE OF THE BLOOD-BRAIN BARRIER IN ALZHEIMER'S DISEASE BRAIN BIOPSIES. L. Claudio*, C.F. Brosnan and D.W. Dickson. Division of Environmental Medicine, Mount Sinai Medical Center, New York, NY 10029 and Department of Pathology, Albert Einstein College of Medicine, New York, NY 10461.

The blood-brain barrier (BBB) is characterized by interendothelial tight junctions, few pinocytotic vesicles and high mitochondrial content in CNS capillary endothelium. We have analyzed ultrastructural and morphometric features of capillaries from five cases of Alzheimer's disease brain biopsies. The data were expressed as the percentage of endothelial cell cytoplasmic area occupied by the respective organelles. The values for vesicular content ranged from 0.49% (± 0.4) to 1.17% (± 0.1) and were inversely correlated with mitochondrial content, which ranged from 7.04% (± 1.31) to 2.88% (± 0.39). These values of mitochondrial content were much lower than those found in normal CNS (from 11% to 13%) and resemble those reported for the systemic circulation. We have shown previously that in inflammatory models of BBB disruption, low levels of endothelial mitochondria are associated with increased transcytotic activity and increased BBB permeability. In Alzheimer's disease, endothelial cells also showed necrotic changes, which were circumscribed to specific cells and did not involve all cells of the microvessels. Other significant features of the BBB in these tissues were alterations of the basement membrane, including large collagen deposits, intense binding of ruthenium red to the luminal and adventitial laminae and detachment of the adventitial laminae. In addition, perivascular astrocytes appeared reactive with extensive accumulation of filament bundles and intracellular lipid granules. This work adds to the increasing amount of evidence suggesting that BBB changes are a component of the pathogenesis of Alzheimer's disease.

PROTEIN KINASE C (PKC) IN ISOLATED MICROVESSELS (MVS) IN AGING AND ALZHEIMER'S DISEASE (AD). P Moore[1], P Grammas[1], T Botchlet[1], AE Roher[2], MJ Ball[3], R Leech*[1]. Univ of Okla HSC, OKC, OK, 73190[1], Wayne St Univ, Detroit, MI 48201[2], Oregon HSC, Portland, OR 97201[3]

PKC, an important enzyme in signal transduction, is a primary factor in determining cellular responsiveness to receptor activation. Several studies have shown changes in enzyme activity, distribution or isoforms in the brain in aging and AD. The objective of this study is to examine PKC in the cerebral microcirculation from AD patients and controls and young and aged (>18 mths) rodents. MVs were isolated from the frontal, temporal, and parietal cortex of AD patients and age-matched controls (post-mortem time 6-12 hrs) and cytosolic and particulate fractions prepared. Evaluation of PKC activity after partial purification on Q-Sepharose indicates that PKC activity in AD MVs (8.64±2.9 pmol/mg/min) was significantly ($p < 0.05$) less (54.7%) of that seen in control MVs (16.1 ± 6.1). In contrast, analysis of MVs from the cerebral cortex of young and aged rodents, by phorbol ester binding, indicates no significant difference in PKC. Our results demonstrate that PKC activity can be determined in human post-mortem samples and that AD microvessels demonstrate significantly less PKC activity compared to age-matched controls. In addition, PKC appears comparable in MVs from young vs. aged rodents. These data suggest that PKC function and responsiveness may be abnormal in AD. (Supported by AHAF, OCAST, NIH NS 30457, and NIH P30AG08017).

627.12

PROTEIN KINASE C (PKC) ISOFORMS IN HUMAN AND RAT BRAIN MICROVESSELS (MVs). D Cooper[1], P Grammas[2], J Watson[1], P Moore[2], O Hanson-Painton[2], R Brumback*[2], VA Hosp, Tampa, FL, 33612[1], U of OK HSC, OKC, OK, 73190[2]

PKC, a cytosolic enzyme important for receptor-mediated cell activation, translocates to the membrane upon activation. The distribution of PKC isoforms appears to be tissue and cell specific. The objective of this study was to determine PKC isoforms in the cerebral MVs. MVs were isolated from the cerebral cortex of young and aged (>18 mths) rats as well as from human autopsy specimens (parietal, temporal, frontal cortex) from Alzheimer's (AD) patients and controls. Cytosolic and particulate fractions were prepared, solubilized in SDS buffer and Western blots run using polyclonal antibodies to PKC isoforms α, β and ɣ. The results indicate that in both rat and human MVs, β is most abundant and is present in both membrane and cytosolic fractions. The α isoform is also present although to a much lower level than the β and it is localized primarily in the cytosolic fraction in both rat and human MVs. Finally, the ɣ isoform was undetectable in rat and human MVs in either fraction. These data demonstrate that both α and β isoforms are present in the cerebral microcirculation and that β is the predominant species. Similarities in the distribution of isoforms in aged and young MVs as well as AD and control MVs suggest that altered PKC responsiveness in aging or AD may reflect changes in enzyme levels or activity rather than a change in isoform type. (Supported by AHAF, OCAST, NIH NS 30457 and VA Res).

BALB/c AND FVB/N MOUSE CNS SUBCORTICAL ENDOTHELIAL CELLS [ECs] CONTAIN INCREASED ALKALINE PHOSPHATASE WHICH IS INDUCIBLE BY MATRIGEL⁻ AND DEXAMETHASONE. J. Vann and B.R. Brooks*, Neurology Service, Wm. S. Middleton VA Hosp. and Neurology Dept., Univ. of Wisconsin, Madison, WI 53705-2286

Alkaline phosphatase, present on CNS microarterioles and capillaries but not venules, is increased during inflammation. Differential alkaline phosphatase activity of CNS ECs in situ was first described by Bannister and Romanual, 1962, who commented on increased alkaline phosphatase in subcortical regions. CNS ECs were prepared from 5-9 day old mice by tituration and collagenase-DNase digestion followed by Dextran-Percoll step gradient sedimentation from mouse cortex, subcortex and cerebellum. ECs are otherwise similar with respect to factor VIII, actin and vimentin antigen as well as lectin binding by immunoblotting and FACS. Compared with murine embryonic SC, fibroblasts [0.3 ± 0.3 (SD) IU/10^5 cells] in vitro, alkaline phosphatase is significantly [$p \leq 0.05$] increased in cortical and cerebellar ECs [2.0 ± 0.8] as well as subcortical ECs [17.0 ± 4.3]. Alkaline phosphatase in subcortical ECs is significantly [$p \leq 0.01$] induced by Matrigel⁻ [27.0 ± 6.5] as well as dexamethasone at 10 [28.5 ± 1.1] or 100 [24.5 ± 3.3] nM. Regional differences in EC alkaline phosphatase activity in vitro suggest that different ECs are isolated from different regions.

627.14

PGD_2 STIMULATES SECRETION OF $PGF_{2\alpha}$, $9_\alpha,11_\beta$-PGF_2 AND THROMBOXANE B_2 IN CAPILLARY ENDOTHELIUM OF HUMAN BRAIN. M. Spatz, D. Stanimirovic, S. Uematsu[1], H. Wagner,* L. J. Roberts II,[2] R. M. McCarron, and J. Bembry. SB, NINDS, NIH, Beth., MD 20892; [1]Johns Hopkins Univ Sch. Med., Baltimore, MD; [2]Vanderbilt Univ., Nashville, TN

Prostaglandin D_2 (PGD_2) is a cyclooxygenase product of arachidonic acid metabolism. Recently, we demonstrated that vasoconstrictive peptides stimulate the production of $PGD_2 > PGF_{2\alpha}$ and thromboxane B_2 (TBX_{B2}) in cultured endothelial cells (EC) derived from capillaries of human brain. Since PGD_2 can be metabolized to $9_\alpha,11_\beta$-PGF_2 in the brain, we examined the possibility that this metabolite is formed among other prostanoids by EC exposed to exogenous PGD_2. Serum-free medium obtained from untreated and treated capillary EC (3-8 experiments in triplicate) served for the determination of prostanoids by immunoassays. The presence of $9_\alpha,11_\beta$-PGF_2 was analyzed by mass spectrometry. PGD_2 (10 nM) induced a 2-5-fold increase of $PGF_{2\alpha}$ and TBX_{B2} (controls = 2.94 ± 0.4 and 1.59 ± 0.2 ng/mg protein, respectively). The PGD_2 stimulation of $PGF_{2\alpha}$ was dose-dependent and was greater than that of TBX_{B2}. Dexamethasone (phospholipase A_2 inhibitor) partially blocked formation of TBX_{B2} but not $PGF_{2\alpha}$. The presence of $9_\alpha,11_\beta$-PGF_2 was confirmed by mass spectrometry. These results indicate that PGD_2 can be converted to its metabolite $9_\alpha,11_\beta$-PGF_2 (a known vasoconstrictor) and stimulate the formation of $PGF_{2\alpha}$ and TBX_{B2} in EC. These findings may have important implications concerned with PGD_2 function in cerebral capillaries under normal and disease conditions.

ENDOCYTOSIS OF HORSERADISH PEROXIDASE (HRP) IN CEREBRAL ENDOTHELIAL CELLS. L.J. Noble*, D. Bunch, M. Nishimura, S. Panter, and J.J. Hall. Dept. of Neurosurg., Univ. of Calif., San Francisco Gen. Hosp., San Francisco, CA 94110.

Recent studies suggest that anionic charges associated with the blood-brain barrier may present a repulsive interface to similarly charged plasma proteins. We have begun to address this relationship by exposing primary cultures of rat cerebral endothelial cells to charged forms of HRP.

Endocytosis of HRP II by endothelial cells was compared to a fibroblast cell line. In addition, endothelial cultures were exposed to HRP isoenzymes (VIII, IX, 200 u/ml) and anionic (aHRP) and cationic (cHRP) derivatives of HRP (1mg/ml) that were initially characterized by isoelectric focussing. Cells were exposed to these proteins for 1 h at 37 C in culture medium containing serum. The cells were lysed, and the amount of HRP was estimated by a kinetic, colorimetric assay.

The amount of endocytosed HRP was significantly higher in fibroblasts than endothelial cells (0.132±0.015 ug HRP/mg protein and 0.060 ± 0.029 ug HRP/mg protein, respectively). The major pI ranges for HRP types were as follows: II and IX (7.2-8.2), VIII and aHRP (<4.65) and cHRP (>8.2). There were no significant differences in the amount of endocytosis between HRP types.

In summary, endocytosis of HRP is relatively low, a finding consistent with *in vivo* studies. The charged nature of HRP, presented in this paradigm, does not appear to influence endocytosis of this protein.

PATCH CLAMP RECORDINGS FROM CULTURED EPENDYMAL CELLS PREPARED FROM FETAL RAT. D.E. Harold* and D.A. Mathers. Dept. of Physiology, University of British Columbia, Vancouver, B.C., Canada, V6T 1W5.

A technique was developed for preparation of cultures with high ependymal cell content using brains isolated from 18-day fetal Wistar rats. Viable ependymocytes were identified by the presence of beating cilia. Single ependymal cells with beating cilia were observed as early as three days in vitro. The ependymocytes appeared to undergo proliferation. After several weeks in vitro the ependymal cells were observed to occur in small clumps or in larger arcs or circles. There appeared to be an absence of cells within the centre of these arcing or circular structures when viewed under a phase contrast microscope. Cultured ependymal cells were regularly maintained for 8 weeks in vitro.

Patch clamp recordings were made from ciliated ependymal cells after two to eight weeks in vitro. Bath saline contained (in mM): 110 Na^+, 3K^+, 1 Ca^{2+}, 1 Mg^{2+}, 92 Cl^-, 25 HCO^{3-}, and 10 HEPES, pH 7.3. Pipette saline contained (in mM): 110 K^+, 1 Na^+, 1 Mg^{2+}, 115 Cl^-, 1 Ca^{2+}, 10 EGTA, and 10 HEPES. Preliminary whole-cell recordings indicate whole cell resistance (33-38 MΩ) is similar to that reported for Necturus (1). Membrane potential ranged from -54 to -72 mV. Recordings of single channel activity were made in the cell-attached mode. Analysis of single channel activity indicated the presence of an inwardly rectifying channel with weak voltage sensitivity (90 pS conductance).

ASSOCIATIVE CONDITIONING DOES NOT FACILITATE THE INDUCTION OF HETEROSYNAPTIC LONG-TERM DEPRESSION IN HIPPOCAMPAL FIELD CA1. D.S. Kerr* and W.C. Abraham. Department of Psychology and Neuroscience Research Centre, University of Otago, Dunedin, New Zealand.

In vitro studies were conducted in order to assess differences in non-associative and associative heterosynaptic long-term depression (LTD) in region CA1. Recent reports have indicated that the presence of negatively correlated co-activity in CA1 inputs during tetanization of separate, converging CA1 inputs, produces a voltage-dependent LTD of untetanized synapses that is differentiable from non-associative LTD (Stanton and Sejnowski, Nature:339,1989; Stanton et al., Neurosci. Lett.:127,1991). Two-pathway stimulation protocols were employed in which one stratum radiatum input received tetanizing stimulation consisting of trains of brief, high frequency bursts delivered 200 msec apart, sufficient to produce robust homosynaptic LTP while another (separate) stratum radiatum input received either single pulses interleaved between tetanizing bursts (associative condition) or no activity at all (non-associative condition). These basic procedures were conducted under a variety of conditions, including pre-conditioning ("priming") of the test pathway with 5 Hz stimulation, reduction of synaptic inhibition by perfusion with picrotoxin, and blockade of NMDA-receptor mediated responses with APV. LTP reversal studies were also carried out in order to assess associative conditioning procedures on non-naive pathways. Under no conditions were we able to induce associative LTD different from or greater than that non-associative LTD which has been generally observed in this region. However, the data do indicate that either mild, tonic disinhibion or prior synaptic activity at theta frequencies can affect subsequent synaptic weight changes. (Supported by New Zealand Health Research Council, Postdoctoral Fellowship grant to D.S.K.).

628.2

A KINETIC MODEL OF SHORT- AND LONG-TERM POTENTIATION. G.F. Ayala* and M. Migliore. I.A.I.F. - Nat.l Res. Council, via Archirafi 36, Palermo, Italy.

We present a kinetic model that can account for several experimental findings on Short- and Long-Term Potentiation (STP and LTP) and their pharmacological modulation. The model, which is consistent with Hebb's postulate, uses the hypothesis that part of the origin of LTP may be a consequence of an increased release of neurotransmitter due to a retrograde signal. The operation of the model is expressed by a set of irreversible reactions, each of which should be thought of as equivalent to a set of more complex reactions. We show that a retrograde signal alone is not sufficient to maintain LTP unless long-term change of the rate constant of some of the reactions involved are caused by high frequency stimulation. Pharmacological manipulation of LTP is interpreted as simple modifications of the rate constants of one or more of the reactions that are thought to be involved in a given mechanism. The model, because of its simplicity, can be useful to test more specific mechanisms by expanding one or more reactions as suggested by new experimental evidence.

628.3

KINETIC MODEL OF THE NMDA RECEPTOR-CHANNEL G. A. Chauvet*, N. Urban, and T. W. Berger *Dept. Biomedical Engineering and Program in Neural, Informational, and Behavioral Science, University of Southern California, Los Angeles, CA 90089, and Institute for Theoretical Biology, University of Angers, France*

A mathematical model of the kinetics of the NMDA receptor-channel complex is proposed which includes from three to five binding sites (one or two each for glutamate and glycine, and one site for Mg^{2+}) and three channel conformations (open, closed, and desensitized). Parameters of the model were constrained by available experimental findings, and were optimized to yield the best fit to experimental data. Individual and selected pairs of parameters then were varied in order to determine the sensitivity of the model to values of parameters chosen. The system was found to be most sensitive to changes in the channel conformation transition rates when glutamate and/or glycine was bound. Even for these parameters, however, the qualitative behavior of the system remained similar through a 10,000-fold variation in values. Model behavior for conditions equivalent to four published outside-out patch clamp experiments were simulated: 1. brief 5 ms application of 10 μM glutamate to an outside-out patch (Lester, et al., 1990); 2. a constant application of 100 μM NMDA to an outside-out patch (Sather et al., 1990); to simulate the rate of onset on desensitization; 3. a constant application of 100 μM NMDA to an outside-out patch followed by removal of NMDA for 750 ms followed by re-application for 700 ms (Sather et al., 1990); to simulate the rates of onset and recovery from desensitization; 4. a 100 ms pulse of glutamate is followed by AP5 or Mg2+ (Lester et al., 1990); to simulate the slow glutamate dissociation rate and the fast onset of the Mg^{2+} blockade of the channel. Results were consistent with the existence of two binding sites for glutamate, and with a minor change in parameters, could account for both glycine-sensitive and glycine-insensitive desensitization. Supported by NIMH (MH45156 and MH00343), ONR, AFOSR, and the AFOSR MRC.

628.4

FREQUENCY AND PATTERN DEPENDENT INDUCTION OF MONOSYNAPTIC AND TRANSSYNAPTIC LTP BY ENTORHINAL AFFERENTS *in vivo*. Mark F. Yeckel* and Theodore W. Berger, *Dept. of Biomedical Engineering, and Program in Neural , Informational, and Behavioral Science, University of Southern California. Los Angeles, CA 90089-2520.*

Layer II entorhinal cortical neurons are the origin of a monosynaptic projection to both the hippocampal dentate gyrus and the CA3 subfields. Pyramidal neurons of CA3 also receive disynaptic excitation from layer II neurons via mossy fiber axons of dentate granule cells. We investigated the possibility, *in vivo*, that different frequencies and patterns of stimulation delivered to entorhinal cortical axons or mossy fibers can differentially induce LTP in the three pathways that comprise this feedforward circuit.

Stimulating electrodes were placed into the perforant path and/or the mossy fibers of halothane anesthetized rabbits. Analysis of input/output functions for monosynaptic population responses recorded in the dentate gyrus and/or in the CA3 pyramidal cell region revealed that: i) 50-400 Hz impulses delivered to entorhinal afferents induced monosynaptic LTP of both the dentate and CA3; ii) 50-400 Hz stimulation of the mossy fibers also induced LTP of monosynaptic input to the CA3 subfield; iii) 15 Hz stimulation did not induce LTP of perforant path input to either the dentate or CA3; iv) however, 15 Hz stimulation of mossy fibers was capable of inducing LTP of CA3 pyramidal cells; v) furthermore, while 15 Hz stimulation of the perforant path did not induce LTP of the monosynaptic projection from the entorhinal cortex to CA3, it did *transsynaptically* induce LTP of the mossy fiber input to CA3; vi) finally, a pattern of tetanization incorporating both high and low frequencies (200 Hz bursts at a 10 Hz frequency) delivered to the perforant path, induced monosynaptic LTP of perforant path input to the dentate and CA3, and transsynaptic LTP of mossy fiber input to CA3. These results demonstrate the possibility that patterns of afferent excitation, generated by entorhinal cortical neurons, can selectively determine the spatial distribution of potentiated synapses within the hippocampus, and thus have profoundly different consequences on the global functional properties of the hippocampal system. Supported by ONR, AFOSR, MH45156, MH00343, and MH10222 (MFY predoc. fellowship).

628.5

SIMULTANEOUS EXPRESSION OF LTP BY AMPA AND NMDA RECEPTOR-MEDIATED EPSP IS OF SIMILAR MAGNITUDE X. Xie*[1], T.W. Berger[1] and G. Barrionuevo[2]. [1]Dept. of Biomedical Engineering and Program in Neuroscience, Univ. of Southern California, Los Angeles, CA 90089, and [2]Depts. of Behavioral Neuroscience & Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

We previously demonstrated that robust LTP could be induced and expressed by the CNQX-isolated NMDA receptor-mediated EPSPs at the perforant path/granule cell synapse in rabbit hippocampal slices (Xie et al., J. Neurophysiol. 67:1009-1013, 1992). LTP continued to be expressed by the AMPA receptor-mediated EPSPs after removal of CNQX. In this study we tested whether a proportional magnitude of LTP can be expressed simultaneously in the EPSP components mediated by both receptor subtypes. In 0.1 mM Mg^{2+}, control field EPSPs (fEPSPs) were obtained that either included both NMDA receptor- and AMPA receptor-mediated components, or only the AMPA receptor-mediated component isolated by the addition of D-APV (50 μM) in the perfusion medium. Tetanic stimuli (50 Hz) then were delivered either in the presence of D-APV, or 20 min after D-APV was removed. When D-APV was present, neither PTP or LTP was expressed. In the absence of D-APV, PTP developed rapidly and was subsequently followed by LTP. At the end of the experiments, D-APV was applied again. In all 10 slices tested, LTP was expressed by both components of fEPSPs. In 4 out of these slices the fEPSP was not contaminated by positive-going population spike. Results from subtractions of the fEPSP from these four slices showed that the total LTP magnitude of the fEPSP area was 121 $\pm$ 50% (SEM) (51 $\pm$ 6% and 49 $\pm$ 7% for the AMPA and NMDA receptor-mediated components respectively). The ratio AMPA/NMDA LTP was 1.04. These results suggest that a common mechanism of LTP expression is shared by these two receptor subtypes. Supported by AFOSR, NS01196, NS24288, MH45156, MH00343 and MRC grant (AFOSR-91-044).

DENDROTOXINS INDUCE A FORM OF LONG LASTING SYNAPTIC POTENTIATION IN HIPPOCAMPAL PYRAMIDAL NEURONES. A.P. Southan & D.G. Owen*, Wyeth Research (UK), Huntercombe Lane South, Taplow, Berks. SL6 OPH, UK.

Brief application of K^+ channel blockers to CA1 neurones of the *in vitro* rat hippocampal slice has been reported to induce a long lasting (TEA, MCDP) or decremental (4-AP, caesium) potentiation of synaptic responses (Aniksztjein & Ben-Ari,1991; Nature 349, 67-69). In this study we have extended these observations to include dendrotoxin (Dtx) homologues extracted from the venom of green and black mambas, which are potent and selective blockers of voltage-activated K^+ currents.

Extracellular field potential responses were recorded from the CA1 region of hippocampal slices using conventional methods and solutions. Potentials were evoked by constant stimulation of the Schaffer collaterals at 0.1Hz/ 0.02ms duration, at 30°C. Drugs were applied in the perfusing medium for a period of ten minutes, slices would then be returned to the control solution. 4-AP (10μM), Toxin I (100nM) and TEA (25mM) induced repetitive firing and increased the amplitude of the first population spike by *ca* 165%, *ca* 24% and *ca* 23% respectively, immediately following a ten minute exposure (n=3 in each case). The effect of 4-AP was rapid in onset but slowly reversed during washout. The enhancement due to exposure to TEA (peak *ca* 225% at 15 min wash) was slightly slower in onset and was poorly reversible (*ca* 150% enhancement at 60 min wash). Slices treated with Toxin I exhibited a slowly developing persistent potentiation which peaked 15 min after removal of the toxin (100% enhancement at 60 min wash). Although MCDP (1μM), γ-Dtx (60nM) and δ-Dtx (10nM) did not induce multiple population spikes (n=3 for each drug), MCDP promoted a rapid and persistent enhancement of the population spike amplitude (*ca* 200% at 60 min wash) and δ-Dtx produced a slowly developing enhancement taking up to 60 min to reach a maximum (*ca* 100% enhancement). γ-Dtx had similar actions to δ-Dtx but was much less potent (*ca* 40% enhancement at 60 min wash). The qualitative differences in activity of the toxins may reflect relative selectivities for pre- and post-synaptic elements.

628.7

ETHANOL-INDUCED SUPPRESSION OF LONG-TERM POTENTIATION IN THE DENTATE GYRUS IS REVERSED BY LESIONS TO THE SEPTOHIPPOCAMPAL NUCLEUS. Steffensen, S.C.*, Yeckel, M.F., Miller, D.M. and Henriksen, S.J., The Scripps Research Institute, La Jolla, CA 92037.

Acute intoxicating levels of ethanol decrease long-term potentiation (LTP) and increase recurrent inhibition in the dentate gyrus of anesthetized and unanesthetized rats. To determine if the ethanol-induced effects result from direct actions on the dentate gyrus or on subcortical inputs to the dentate we studied the effects of systemic and local administration of ethanol on evoked population spike (PS) amplitudes and latencies, population EPSP slopes and amplitudes and single-unit activity in halothane-anesthetized rats following electrolytic lesions to the septohippocampal nucleus (SHN). Intraperitoneal ethanol (1.2 g/kg) increased putative GABAergic interneuron discharges (IDs, ↑144%), increased paired-pulse (PP) inhibition and markedly decreased induction and maintenance of LTP of PS amplitudes. Microelectroosmotic application of ethanol also increased IDs (↑138%) but had no effect on PP responses or LTP. Stimulation of the SHN evoked a small field potential in the dentate and produced interval-dependent depression and facilitation of perforant path to dentate PS amplitudes and PP responses. Electrolytic lesions of the SHN (±3.0 mA, 5.0 s duration) were considered complete when subsequent SHN stimulation failed to evoke any field potential or affect dentate PS amplitudes or PP responses. Intraperitoneal ethanol, administered 30 min following lesioning of the SHN, increased IDs (↑105%) but had no significant effect on PP responses or LTP. These findings demonstrate that septohippocampal input is necessary for ethanol to increase recurrent inhibition and block LTP in the dentate and suggest a role for local and remote GABAergic modulation of hippocampal plasticity.

EFFECTS OF NIFEDIPINE ON LONG TERM POTENTIATION IN AREA CA1. K.D. Parfitt* and D.V. Madison, *Dept. of Molecular & Cellular Physiology, Stanford Univ. Sch. of Med., Stanford CA 94305-5426.*

We have previously reported that phorbol esters (PE) cause an increase in the frequency of spontaneous miniature EPSCs in hippocampal CA1 pyramidal cells, without altering their amplitude, suggesting that PKC activation leads to an increase in transmitter release. This PE stimulation of glutamate release was attenuated approximately 50% by application of nifedipine. Based on our earlier findings that phorbol ester application causes L-type calcium channels to open at negative potentials, we hypothesized that a PE-stimulated increase in resting L-channel activity may underlie part of the PE stimulation of glutamate release. If PE-induced and tetanic stimulation-induced potentiation share a common expression mechanism, then application of nifedipine should also reduce tetanus-induced LTP expression. We have examined the effects of nifedipine on the expression of LTP. Our preliminary results suggest that nifedipine (10 μM), 20 min after LTP induction, may reduce LTP by up to 20%, without a similar decline in basal transmission. In contrast, nifedipine 60 minutes after induction of LTP had no apparent effect on the magnitude of potentiation. We are currently pursuing experiments to show if presynaptic L-type calcium channels play a role in the expression of LTP.

INTRACELLULAR INJECTIONS OF Ca^{2+} CHELATORS FACILITATE LTP OF HIPPOCAMPAL IPSPs. W. Morishita* and B. R. Sastry. Neurosci. Res. Lab., Dept. of Pharmacology and Therapeutics, Univ. of B. C., Vancouver, Canada, V6T 1Z3.

In the present study, the effects of the Ca^{2+}-chelators, EGTA and BAPTA, on the development of long-term potentiation (LTP) of hippocampal inhibitory postsynaptic potentials (IPSPs) were investigated. Postsynaptic potentials evoked by stratum radiatum stimulation were recorded from CA1 neurons in guinea-pig hippocampal slices. Tetanic stimulation of the input (two trains of 100 Hz lasting 1s, 20s interval) produced LTP of the excitatory postsynaptic potential (EPSP) as well as the $GABA_A$ receptor-mediated fast IPSP but not of the $GABA_B$ receptor-mediated slow IPSP (n=8). In contrast, in neurons where postsynaptic Ca^{2+} was chelated with either EGTA (n=6) or BAPTA (n=4), LTPs were observed for both the fast and the slow IPSPs but not the EPSP. During LTP the input resistance of the CA1 neurons and reversal potentials of the fast and the slow IPSPs were not significantly altered in control and Ca^{2+}-chelated cells. In experiments where the fast IPSP was blocked by picrotoxinin (20 μM), tetanic stimulation of the stratum radiatum induced LTP of the EPSP but a depression of the slow IPSP (n=6). In neurons injected with EGTA (n=6) or BAPTA (n=8), the slow IPSP, but not the EPSP displayed LTP; a subsequent application of phaclofen (500 μM) depressed the slow IPSP and increased the height and duration of the EPSP. These results indicate that chelation of postsynaptic Ca^{2+} facilitates LTP of hippocampal IPSPs and that such potentiations may, in turn, affect the degree of LTP of the EPSP. THE EXPRESSION OF LONG-TERM POTENTIATION IN HIPPOCAMPAL AREA CA1 DOES NOT CHANGE PRESYNAPTIC CALCIUM. P. Saggau* and L.G. Wu, Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

We investigated whether changes in transients or residual levels of presynaptic calcium could be responsible for the maintenance of long-term potentiation (LTP) in area CA1 in hippocampal slices of guinea pigs. A novel technique for filling synaptic structures with indicators (Saggau et al., Biophys J 61, 1992) was used. A membrane permeant calcium indicator (Fura-2 AM, 1 mM) was injected into the *stratum radiatum* (SR) resulting in local loading and subsequent diffusion via the Schaffer collateral/ commissural pathway (SCC) to presynaptic terminals. Fluorescence from presynaptic structures, emerging from the region of apical dendrites of area CA1, the postsynaptic target of the loaded terminals, was detected. Presynaptic calcium transients before and after the expression of LTP were investigated. Expression was confirmed about 20 min. after tetanic stimulation of SCC (100 Hz for 1 sec): single-pulse stimulation of SCC (0.1 Hz) then resulted in a 40-70% increase of the slope of the field EPSP, while the presynaptic calcium transients showed no change. We also tested residual levels of presynaptic calcium in relation to LTP. Double-pulse stimulation was used to control the residual presynaptic calcium and to assure the number of recruited SCC fibers to be constant throughout the facilitation. A calibration curve was generated to relate the facilitation of the second field EPSP to the residual presynaptic calcium from the first stimulus. The expression of LTP did not result in any significant residual presynaptic calcium, while the calibration curve predicted a clear residual level. We performed two controls for the sensitivity of our techniques: first, following double-pulse stimulation changes in presynaptic calcium affecting transmitter release were readily detected; second, we added cadmium to the bath and observed a dose-dependent block of synaptic transmission and presynaptic calcium transients. These results directly demonstrate for the first time that the expression of LTP in the area CA1 of the guinea pig hippocampus is independent of any detectable persistent changes in presynaptic calcium.

HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) SELECTIVELY MODIFIES THE BINDING PROPERTIES OF GLUTAMATE RECEPTORS.

S. Maren*, G. Tocco, S. Standley, M. Baudry, and R. F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

Several lines of evidence indicate that LTP is associated with a change in some properties of postsynaptic glutamate receptors. In the present study we have used quantitative autoradiography of radiolabeled ligands selective for the AMPA (α-amino-3-hydroxy-5-methyl-4-isoxazolepropionate) and NMDA (*N*-methyl-D-aspartate) subclasses of glutamate receptors to examine the binding properties of glutamate receptors in frozen brain sections obtained from rats in which perforant path LTP was induced.

Eleven adult male Long-Evans rats were anesthetized and implanted with a stimulating electrode in the perforant path and a recording electrode in the dentate hilus. LTP was induced by delivering either two 25 msec 400 Hz bursts separated by 200 msec (n = 6) or ten 25 msec 400 Hz bursts separated by 10 sec (n = 5) at a current intensity sufficient to elicit a 1-2 mV population spike. One hour following stimulation the rats were sacrificed and their brains rapidly dissected and frozen.

Perforant path LTP induction resulted in a selective increase in [^{3}H]-AMPA binding in the molecular layer of the dentate gyrus ipsilateral to the perforant path stimulation as compared to the contralateral side. The increase in AMPA binding in the dentate gyrus was highly correlated ($r = .93$, $p < .0002$) with the LTP-induced change in EPSP slope recorded in this structure one hour after LTP induction. No changes in the binding of either [^{3}H]-CNQX (6-nitro-7-cyano-quinoxaline-2,3-dione), an antagonist of the AMPA receptor, or [^{3}H]-TCP (*N*-{1-[thienyl]cyclohexyl}piperidine), a ligand for the NMDA receptor/channel, were observed. Together, these results indicate that a modification in postsynaptic AMPA receptors plays a critical role in the expression of synaptic enhancement following LTP induction in the hippocampus. ***IN VIVO* ANXIOLYTIC PRETREATMENT DISRUPTS LONG-TERM POTENTIATION ACQUISITION.**

M. J. Wayner*, J. L. Polan-Curtain, D. L. Armstrong, I. Parra. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78285.

The effects of various doses of anxiolytics on long-term potentiation (LTP) at the perforant path-dentate granule cell synapse were determined. Male, Sprague-Dawley rats under urethane anesthesia received 1.0, 1.75, 2.5, 4.0, 6.0, and 8.0 mg/kg diazepam (DZ) by intraperitoneal injection 15 minutes prior to tetanic stimulation of the perforant path. The effects of the atypical anxiolytic, buspirone, were also investigated: 10.0, 20.0 and 40.0 mg/kg. The interaction of both drugs with ethanol were also investigated: 0.5, 1.0, 1.5, and 2.0 g/kg of 25% ethanol by gavage. Both DZ and ethanol decreased the induction of LTP in a dose dependent manner. Baseline pEPSP amplitudes were not affected under both experimental and control conditions. Enhanced interactive effects were observed with combined doses.

GABA-A INHIBITION OPPOSES MONOSYNAPTIC PERFORANT-PATH EXCITATION OF CA1 PYRAMIDS.

C.M. Colbert* and W.B Levy, Dept. of Neurosurgery, Univ of Virginia, Charlottesville VA, 22908.

Compared to the Schaffer collaterals (SCH), stimulation of the monosynaptic perforant path (PP) input to s. lacunosum-moleculare of CA1 (s. l-m.) is weak and rarely capable of firing CA1 pyramids. PP stimulation does, however, evoke a glutamate-receptor mediated pEPSP in s. l-m. that is distinguishable from the SCH response by several criteria (Colbert & Levy, J. Neurophys., in press). Here we report removal of a GABA-A inhibition reveals PP evoked EPSP's that excite CA1 pyramids to fire. Transverse hippocampal slices from 7 rats were maintained in an interface chamber. Region CA3 and the dentate gyrus were dissected away. Intracellular recording revealed that: PP stimulation in standard perfusion medium evoked an IPSP or no response; distal SCH stimulation evoked an EPSP followed by an IPSP; and simultaneous stimulation of both pathways no more effectively fired cells than SCH stimulation alone. Switching to a medium containing 20μm bicuculline decreased the early IPSP evoked by stimulating either pathway and increased the EPSP evoked by the PP. In 5 of 7 cells, single test pulses to the PP evoked cell firing. Compared to SCH stimulation, the PP latencies were long and variable, but the threshold for firing was similar for both the SCH and the PP. Neither 2-OH-saclofen, DAGO, 4AP, nor TEA alone allowed the PP to fire pyramids. However, each of these agents enhanced the effect of bicuculline on PP evoked cell firing. These results suggest that GABA-A mediated inhibition determines the ability of the excitatory input to s. l-m. to fire the CA1 pyramids. Thus, the inability of the PP to excite the CA1 pyramids may be explained by strong inhibition rather than by weak excitation. Supported by NIH 15488, NIMH 48161 and NIMH 10019.

628.14

ASSOCIATIVE POTENTIATION OF SCHAFFER COLLATERALS BY PAIRED CONDITIONING WITH THE PERFORANT PATH IN HIPPOCAMPAL CA1.

W.B Levy* and C.M. Colbert, Dept. of Neurosurgery, Univ of Virginia, Charlottesville VA, 22908.

As shown in the accompanying abstract (Colbert & Levy), removal of GABA-A inhibition increases the potency of perforant path (PP) stimulated excitation of CA1 pyramids. Using the same dissection, we report that, in the presence of 20μm bicuculline and 2μm DAGO, the PP input can associatively potentiate a weak Schaffer collateral (SCH) response. There are 5 electrodes in these experiments: a recording electrode in CA1 s. lacunosum moleculare (s. l-m.), a recording electrode in distal s. rad., a stimulating electrode in s. l-m., and two nonoverlapping stimulating electrodes in s. rad. (a control electrode that was never conditioned and a test electrode that was conditioned). Conditioning consisted of 3 trains (1/5s) of 8 bursts (1/200ms). Each burst consisted of 2 SCH pulses at 100Hz either alone or combined with 5 PP pulses at 100Hz. For paired conditioning the SCH burst led by 10 ms. The SCH test stimulation intensity was set to produce a small response (<0.3 mV). The paradigm sequentially consisted of a baseline test period, SCH conditioning alone, a second test period, paired SCH+PP conditioning, and a final 30' test period. SCH conditioning alone resulted in no significant changes in any of the pathways. Paired PP and SCH conditioning resulted in statistically significant potentiation at 30' of both the SCH test pathway (29.4 ± 7.1%) and the PP (22.5 ± 6.5%; μ ± sem; N = 5). The unconditioned SCH control did not increase. Although these experiments were run in the presence of two drugs, bicuculline alone is sufficient to permit demonstration of the associative interaction. Supported by NIH 15488, NIMH 48161 and 10019.

628.15

ASSOCIATIVE POTENTIATION OF PERFORANT PATH RESPONSES BY CONDITIONING WITH THE SCHAFFER COLLATERALS IN HIPPOCAMPAL CA1.

D.X. Zhang*, C.M. Colbert and W.B Levy, Dept. of Neurosurgery, Univ. of Virginia, Charlottesville VA 22908.

As shown in another abstract (Levy & Colbert), weak Schaffer collateral responses can be associatively potentiated by paired conditioning with the perforant path (PP) in disinhibited slices. Here we report that, in the presence of 10μM bicuculline, paired conditioning of the PP and Schaffer inputs can associatively potentiate PP responses. Transverse hippocampal slices from 6 rats were maintained in an interface chamber. Region CA3 and the dentate gyrus were dissected away. Recording electrodes were placed in s. lacunosum moleculare of CA1 (s. l-m) and in distal s. rad. Stimulating electrodes were placed in s. l-m and in s. rad. Conditioning consisted of 8 trains (1 train/5 sec.). Each train consisted of 1 PP pulse alone or combined with 5 Schaffer pulses at 400Hz. For paired conditioning the PP pulse was given at the same time as the first pulse of the Schaffer pulses. The paradigm consisted of a baseline test period, PP conditioning alone, a second test period, paired PP and Schaffer conditioning and a final test period. Each test period was 15 min. No significant changes were induced in either pathway by conditioning of the PP pathway alone. Paired conditioning of the Schaffer and the PP pathways resulted in statistically significant potentiation of the PP test pathway (+33.31 ± 10.72%, mean ± S.E.M., $p<0.05$) and the Schaffer pathway (+24.53 ± 7.34%, $p<0.05$). There was no associative potentiation of the PP responses by the Schaffer pathway without the disinhibition induced by bicuculline. This experiment shows that the PP can be associatively potentiated. Supported by NIH 15488, NIMH 48161 and 10019.

628.16

THE FREQUENCY-DEPENDENT ACTIVATION OF OPIOID RECEPTORS IS A NECESSARY FACTOR IN THE INDUCTION OF MOSSY FIBER LTP.

R.V. Hernandez*, B.E. Derrick and J.L. Martinez, Jr.
Department of Psychology, University of California, Berkeley, CA 94720

Mossy fiber LTP (mf LTP) requires both mu opioid receptor activation (Soc. Neurosci. Abst. 16:980, 1990) and high-frequency mossy fiber stimulation (J. Neurophysiol. 64:948, 1990) for its induction. Because opioid peptides are released by the mossy fibers primarily during high-frequency activity (JPET 23:112, 1990), high-frequency activity may be required for induction of mf LTP as a result of the frequency-dependent release of opioid peptides. This possibility was investigated in vivo in anesthetized adult male Sprague-Dawley rats. Induction of mf LTP was found to be insensitive to systemic injections of the NMDA antagonist (+/-) CPP (10 mg/Kg), although this dose was effective in blocking LTP of CA3 responses evoked by stimulation of the contralateral CA3 area (commissural-CA3 responses). Using bursts of 10-200 pulses (at 100 Hz), mf LTP induction was found to have a strict dependence on burst size, with bursts of 25-30 pulses being necessary for LTP induction. Although application of the mu opioid receptor agonist DAGO (1 μmol) in area CA3, or delivery of bursts of 15 pulses, alone were ineffective in inducing mossy fiber LTP, delivery of 15 pulses following application of DAGO reliably induced mossy fiber LTP. Thus, one factor underlying the requirement for high-frequency mossy fiber stimulation for the induction of mossy fiber LTP is opioid receptor activation, and, presumably, the frequency-dependent release of opioid peptides.

NALOXONE BLOCKS THE INDUCTION OF LONG-TERM POTENTIATION OF LATERAL, BUT NOT MEDIAL, PERFORANT PATH RESPONSES IN AREA CA3 OF THE HIPPOCAMPUS

B.E. Derrick*, A. Breindl, S.B. Rodriguez and J.L. Martinez, Jr.
Department of Psychology, University of California, Berkeley CA 94720

The activation of opioid receptors is suggested to play an important role in LTP induction at lateral perforant path-dentate gyrus and mossy fiber-CA3 synapses. Recently, the monosynaptic perforant path projection to area CA3, whose lateral aspect is suggested to contain and release opioid peptides, has been characterized and shown to display LTP. (PNAS 34:345, 1990). In the present study, the sensitivity of LTP induction in perforant path-CA3 responses to naloxone was assessed in vivo in anesthetized adult male Sprague-Dawley rats. Lateral and medial perforant path responses were evoked by stimulation of the angular bundle as determined by field EPSP rise times measured in the dentate gyrus. Perforant path-CA3 responses were recorded in the pyramidal layer of area CA3. Application of naloxone (10 nmol) into the CA3 region 10 min prior to tetanization blocked LTP of lateral, but not medial, perforant path-CA3 responses. Additionally, LTP of lateral perforant path-CA3 responses developed slowly and showed little decay over a 1 hr period, parallelling the time course of LTP observed at the mossy fiber-CA3 synapse (Adv. Biosci. 75:213, 1989). These results suggest that medial and lateral perforant path projections to area CA3 utilize distinct mechanisms of LTP induction and expression and therefore evidence distinct forms of LTP.

THE GENERATION OF AN LTP cDNA LIBRARY FROM THE MOSSY FIBER-CA3 SYNAPSE.

D.T. Rivera, B.E. Derrick and J.L. Martinez, Jr.*, Department of Psychology, University of California, Berkeley, CA 94720.

Long-term synaptic changes (*e.g.* long-term potentiation, LTP) must be supported by changes in gene expression. Previous studies indicated that induction of FOS-related antigens (FRAs) linked to opioid receptor activation is associated with the expression of mossy-fiber (MF) LTP (Draganow *et al.* 1988 *Soc. Neurosc. Abs.* 14:225.8; Martinez *et al.*, 1990. *Soc. Neurosc. Abs.* 16:423.2). The genes that code for FRAs and other immediate-early genes likely regulate the expression of *later genes* which maintain LTP. In an effort to identify these *late genes* (> 3 h), we generated a cDNA library from a rat hippocampus in which mossy fiber LTP was induced *in vivo* in the MF-CA3 area, and the formation of NMDA-dependent LTP was prevented with the administration of CPP (10 mg/kg). The LTP cDNA library will be characterized in various ways including subtraction of cDNAs from the non-tetanized contralateral hippocampus of the same rat.

NONLINEAR SUMMATION OF NMDA RESPONSES TO BURST STIMULATION IN PIRIFORM CORTEX SLICES REQUIRES $GABA_A$ BLOCKADE. A. Kapur*, E.D. Kanter and L.B. Haberly, Neuroscience Training Program and Department of Anatomy, Univ. of Wisconsin, Madison, WI 53706

As previously reported (Kanter and Haberly, Soc Neurosci Abstr, 17:385, 1991) associative LTP in piriform cortex can be induced only after blockade of $GABA_A$ (but not $GABA_B$) receptors. We are now investigating the role of the interaction of GABA-mediated and NMDA-mediated responses in the regulation of synaptic plasticity. Intracellular recordings were made from layer II pyramidal cells in piriform cortex slices. In the presence of the non-NMDA glutamate receptor antagonist DNQX (20 μM), stimulation of either afferent or association fibers evoked responses that consisted of a fast, $GABA_A$-mediated IPSP (depolarizing at resting membrane potential), an NMDA-mediated EPSP and a slow, $GABA_B$-mediated IPSP, as revealed by specific receptor blockers. Responses to bursts of 2-6 pulses were obtained in DNQX with or without the $GABA_A$ antagonist bicuculline methiodide (BIC, 10 μM). After $GABA_A$ blockade the NMDA-mediated responses to bursts were greatly enhanced, exhibiting a nonlinear summation. This phenomenon was observed from stimulation of both afferent fibers (layer Ia) and association fibers (layer Ib or layer III) and was optimally observed at stimulus frequencies of 100 to 200 Hz (30°C). Bursts with inhibition intact produced at best a linear summation of the depolarizing response ($GABA_A$-mediated IPSP + NMDA-mediated EPSP). In some cells the size of the burst response after $GABA_A$ blockade was several fold larger than with $GABA_A$ inhibition intact. Blockade of the slow IPSP with the $GABA_B$ antagonist CGP-35348 (Ciba-Geigy) did not by itself enhance NMDA responses to bursts and did not alter the optimal stimulus frequency for the enhancement produced by $GABA_A$ blockade. Supported by grant NS19865 to LBH.

APICAL DENDRITIC LTP IN CA1 IN BEHAVING RATS: HIGH-FREQUENCY DEPENDENT AND APV-RESISTANT. L. Stan Leung* and B. Shen. Dept. Clin. Neurol. Sci. and Physiology, Univ. Western Ontario, London, N6A 5A5 Canada.

In a previous study on behaving rats, we reported that patterned primed burst (PB) stimulation of the contralateral CA1 or CA3 resulted in robust long-term potentiation (LTP) at the basal dendritic synapse of CA1, but only weak or no LTP at the apical dendritic synapse (Leung et al., Neurosci. 48:63,1992). This abstract reports factors that may enhance the apical dendritic LTP in behaving rats. Septal co-stimulation, at an intensity which caused desynchronization of the hippocampal EEG, or 50 mg/kg i.p. atropine sulfate did not significantly enhance the success of PB-induced LTP. High frequency (HF) trains of 100-200 Hz, at 3x threshold intensity, were successful in eliciting LTP in 8 of 10 rats, a significantly higher success rate than PBs of a similar intensity in the same rats (0%). HF stimulations, however, almost always elicited afterdischarges and posticta depression. The mean apical dendritic LTP peaked at about 115% (of baseline) at >2 hr post-tetanus. The non-decremental time course and low magnitude of the apical dendritic LTP is clearly different from the decremental, high-amplitude basal dendritic LTP in CA1. Furthermore, the N-methyl-D-aspartate antagonist APV did not significantly change the HF-induced apical dendritic LTP in 5 rats, while it strongly attenuated the basal dendritic LTP induced by HF or PB (Leung and Shen, Neurosci. Abstr.17:511). The time course, magnitude and HF-dependency of the apical dendritic LTP are consistent with the properties of an APV-resistant LTP in vitro (Grover and Teyler, Nature 347:477). However, in vitro, the propensity and properties of LTP seem to be the same at the basal and apical dendrites in CA1. Ipsilateral stimulation and recording in CA1, placed as in an in vitro slice, was done in 16 behaving rats. The results corroborated those using contralateral hippocampal activation, in that LTP was robust at the basal but not the apical dendrites. (Supported by NSERC).

K^+-INDUCED FACILITATION OF HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) MAY BE MEDIATED THROUGH AN ACTION ON NMDA RECEPTORS. B.A. Ballyk* and J.W. Goh, Department of Pharmacology & Toxicology, Queen's University, Kingston, Canada K7L 3N6.

In the hippocampus, repetitive activation of CA_1 afferents, which induces LTP, results in elevated extracellular K^+ concentrations. We have shown that elevating extracellular K^+ during a weak tetanus either by bath application or by iontophoresis at the CA_1 synaptic zone facilitates the induction of LTP. We hypothesize that K^+ exerts this facilitation through an action on the NMDA receptor. Dendritic population EPSPs were recorded in the CA_1 region of guinea pig hippocampal slices by stimulation of stratum radiatum. Weak EPSPs (<300μV) failed to exhibit LTP following a 100Hz, 1s tetanus (104± 3% (SEM) of control, 30min post tetanus, n=6). K^+, iontophoretically applied at the site of recording for 10s, did not in itself produce long-lasting effects on EPSPs (98± 2% of control, 30min post K^+, n=6). In the presence of 25μM D-2-amino-5-phosphonopentanoic acid, delivery of the weak tetanus with simultaneous iontophoretic (200nA) application of K^+ in the dendrites did not result in significant potentiation of EPSPs (105± 3% of control, 30min post K^+ & tetanus, n=6). However, following washout of the NMDA receptor antagonist, the combination of weak tetanus and K^+ resulted in significant potentiation of EPSPs (135± 6% of control, 30min post K^+ & tetanus, n=6). In other experiments, intracellular records were obtained from CA_1 pyramidal neurons, and responses to NMDA, applied iontophoretically at the dendrites, recorded. Increasing bath K^+ from 3.1mM to 15mM reversibly increased the duration of the NMDA response by 85± 8% (n=3). We suggest that elevated extracellular K^+ at the synaptic zone resulting from an afferent tetanus enhances NMDA receptor activation required for successful induction of LTP.

LONG-LASTING PLASTICITY OF EXCITATORY SYNAPTIC INPUT IN SEPTAL NEURONS OF THE RAT. T. DeFazio, R. Dunia, F. Hefti, and J.P. Walsh*. Andrus Gerontology Center & Department of Biological Sciences, USC, Los Angeles, CA 90089-0191.

The plasticity of synaptic input to the septum was investigated in an *in vitro* slice preparation. Septal neurons were recorded intracellularly and labelled with biocytin. An extracellular stimulating electrode was placed in the medial septum of coronal slices and a recording electrode was placed about 1 mm lateral to the stimulating electrode. Extracellular stimulation evoked a rapid EPSP followed by an IPSP that lasted 50-200 msecs. Addition of the $GABA_A$ receptor antagonist bicuculline (BIC) (30 μM) revealed an EPSP that lasted 40-80 msec and reversed in polarity near 0 mV. The EPSP was blocked by kynurenic acid (2 mM) indicating that excitatory amino acids mediate this synaptic potential.

We next investigated plasticity of the EPSP using two separate paradigms, both in the presence of BIC. First, the slices were briefly (5-10 min) exposed to 10-100 nM kainate. This caused a potentiation of the EPSP that lasted for 20-30 min. The second paradigm consisted of high frequency tetanic stimulation of afferents to determine whether excitatory synaptic input to the septum could express long-term forms of use-dependent synaptic plasticity. A population of cells that received the tetanus in the presence of BIC expressed a long-term enhancement of the EPSP that lasted for 30 min. This study was funded by a grant from the American Federation for Aging Research (AFAR).

FREQUENCY-DEPENDENT ENHANCEMENT OF MONOSYNAPTIC INHIBITORY POSTSYNAPTIC EVENTS IN THE RAT NUCLEUS TRACTUS SOLITARIUS (NTS).

P.A. Brooks*#, S.R. Glaum, K.M. Spyer# & R.J. Miller. #Dept. Physiology, RFHSM, London, U.K. NW3 2PF; Dept. Pharm. and Physiol., Univ. of Chicago, 60637.

Whole cell patch recordings in the NTS were made in transverse slices of rat brainstem (age 2-8 weeks). Postsynaptic potentials and currents were evoked by low frequency (0.2Hz), electrical stimulation in the area of the tractus solitarius. Since most NTS neurones received a mixed excitatory and inhibitory input, inhibitory postsynaptic potentials (IPSPs) and currents (IPSCs) were studied in isolation by applying blockers of excitatory amino acid receptors. CNQX or DNQX completely blocked excitatory synaptic responses in most neurones but in some cases APV or AP-5 were also applied to block a residual excitatory component. The inhibitory synaptic events were completely blocked by bicuculline. No evidence of a $GABA_B$- mediated IPSP was obtained although baclofen had both pre- and postsynaptic effects.

IPSPs and IPSCs were studied at potentials of -50 to -60mV during and after stimulation at higher frequencies (1-20Hz). In 8 out of 12 cases the IPSc or IPSP was increased in amplitude after stimulation at frequencies of 5Hz or higher. Depression of the inhibitory event after the higher frequency stimulation was not observed. The potentiation was long-lasting (up to 1 hour) and could be evoked more than once during a recording. The reversal potential of the inhibitory IPSP/IPSC was not altered after potentiation.

The induction and maintenance of the potentiation was resistant to blockade of NMDA receptors with AP-5 and in addition was not affected by the $GABA_B$ antagonist 2-OH-saclofen.

LTP EXPRESSION MECHANISMS: EVIDENCE FOR A TIME WINDOW DURING WHICH LTP CAN BE REVERSED.

D. Muller* and P. Bittar. Department of Pharmacology, CMU, 1211 Geneva 4, Switzerland.

One hypothesis concerning LTP expression mechanisms is that biochemical events could take place during a transitory phase to generate more stable modifications responsible for the increase in synaptic efficacy. If this is the case, then one would expect to be able to reverse LTP during this specific time window. Using a specially designed recording chamber built with peltier elements, we have tested the effects of fast and brief cooling shocks on the maintenance of LTP in area CA1 of hippocampus. Slices were prepared and maintained at a standard temperature of 33°C and brief shocks to 30°C, 27°C and 24°C for 2 or 5 min were applied. These cooling episodes resulted in marked modifications of the size and time course of synaptic responses. Changing the temperature for 5 min from 33°C to 24°C reduced by about 80% the size of evoked synaptic responses and prolonged by a factor of 2-4 their rise time. These two parameters fully recovered over a period of 10-20 min. Applying these cooling shocks 10-20 min after LTP induction completely reversed the potentiation effect. A second application of high frequency stimulation re-instated LTP. Several induction / abolition sequences could thus be generated. In contrast, application of the cooling shocks later than 20 min after LTP induction did not affect the degree of potentiation. These results indicate that LTP can be reversed during a specific time window following induction and that a metabolic process might be involved during an initial phase of 10-20 min to generate more stable modifications. ACTIVITY-DEPENDENT PLASTICITY OF INHIBITION IN THE DENTATE COMMISSURAL PATHWAY: RELATIONSHIP TO EPSP/SPIKE DISSOCIATION

R.A.Tomasulo*, O.Steward, J.J.Ramirez, W.B.Levy. Dept. of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908.

We tested the hypothesis that a decrease in feed-forward inhibition contributes to LTP-associated EPSP/spike (E-S) dissociation in the hippocampus. Because the dentate commissural pathway (CP) and the perforant path (PP) activate a common pool of interneurons, a change of synaptic efficacy due to activation of one input could induce changes in the other.

In urethane-anaesthetized rats we measured the inhibition of PP population spikes by the CP at interstimulus intervals of 6 and 12 msec. This measure and an E-S function were obtained before and after a) PP tetany (400 Hz, 18 msec) and b) CP tetany (200 Hz, 30 msec).

Low intensity PP conditioning (spike threshold) led to decreases of CP inhibition and large E-S shifts to the left; higher intensity PP tetany produced increases in CP inhibition and smaller leftward E-S shifts. CP conditioning led to increases in CP inhibition and variable E-S shifts. Post-hoc analysis of the CP-tetany cases revealed that leftward E-S shifts accompanied depression of the PP pEPSP (0 to -9%), and right E-S shifts accompanied potentiation of the PP pEPSP (2 to 8%).

The inhibitory circuit of the dentate gyrus expresses activity-dependent plasticity under conditions which alter the E-S relationship. This suggests that changes in inhibition contribute to EPSP/spike dissociation. The pattern of changes is best explained by independent plasticity of excitatory and inhibitory synapses. A DEVELOPMENTAL ANALYSIS OF LONG-TERM POTENTIATION IN THE FREELY-MOVING RAT.

J.D. Bronzino*, R.J. Austin-LaFrance and P.J. Morgane. Dept. of Engineering and Computer Science, Trinity College, Hartford, CT 06106 and Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

The ability of rats to establish and support LTP of the perforant path/dentate granule cell synapse was examined at 15, 30 and 90 days of age. Hippocampal dentate granule cell field potentials were recorded, before, and at timepoints out to 24 hrs after tetanization of the perforant pathway. Waveforms were analyzed for changes in population EPSP slope (a measure of synaptic drive) and population spike amplitude (a measure of population discharge). 90-day old animals exhibited an 18% enhancement of the population EPSP slope 30 mins after tetanization, rising to approximately 40% above baseline 5 hrs. after tetanization and remaining at this level at 24 hrs. In contrast, EPSP slope measures obtained from 30-day olds declined nearly 25% from baseline 30 mins after tetanization, failing to regain baseline over the 24 hr test period. Population spike amplitude measures in the 30-day old group enhanced beginning 1 hr post-potentiation. This measure rose to > 100% after 24 hrs. The rate of population spike enhancement obtained from 30-day old animals closely paralleled that of the 90-day old group, however, 90-day old animals consistently attained levels of enhancement 20% higher than those in the 30-day old group. Preliminary results in 15-day olds also indicate potentiation of the population spike component in association with decreases in EPSP slope measures. The results indicate a dissociation between the EPSP slope and population spike components in younger animals, which may reflect functional immaturity of transmitter systems modulating dentate granule cell excitability.

HOMOSYNAPTIC NMDA RECEPTOR-DEPENDENT LONG TERM DEPRESSION IN RAT HIPPOCAMPAL SLICES.

R.M. Mulkey* and R.C. Malenka. Dept's of Psychiatry & Physiology, Univ. of California, San Francisco, CA 94143.

Low frequency stimulation (LFS) has been reported to induce long-term depression (LTD) in area CA1 of hippocampus (Bear et al., Soc Neurosci Abst, 17, 1329). Experiments were performed to examine the mechanisms underlying LTD. In hippocampal slices prepared from young rats (12-21 days), afferent stimulation in stratum radiatum at 1 Hz for 5 to 15 min produced a synapse-specific depression of synaptic transmission (31 ± 1.7%; n = 53) that lasted for at least 30 minutes. NMDA receptor activation appears necessary for LTD as 25 μM APV reversibly blocked this phenomenon (n = 7), whereas the voltage-dependent calcium channel antagonist nifedipine (20 μM) did not (n = 5). To investigate whether an increase in postsynaptic calcium is required for LTD induction, the calcium chelator BAPTA (10 mM) was included in whole cell patch pipettes while simultaneously recording field EPSPs. LTD was blocked in 8 of 11 cells even though it was reliably elicited in the field EPSPs. In addition, strong hyperpolarization (to -105 mV) during intracellular recording reversibly blocked LTD (n = 3). As one control for excitotoxicity at individual dendritic spines, the effects of manipulating extracellular calcium ($[Ca^{2+}]_o$) were examined. Applying a tetanus (20 Hz, 30 sec) after decreasing extracellular calcium to 0.5 mM caused LTD in slices in which the same tetanus in 2.5 mM $[Ca^{2+}]_o$ previously elicited LTP (n = 2) or no change in synaptic transmission (n = 3). Paired-pulse facilitation was unaffected during LTD. These findings suggest that this form of LTD requires NMDA receptor activation and an increase in postsynaptic calcium distinct from that required for LTP.

EPSPS IN HIPPOCAMPAL INTERNEURONES EXHIBIT LONG-TERM ENHANCEMENT.

L.J. Reece* and S.J. Redman. Division of Neuroscience, JCSMR, Australian National University, Canberra, A.C.T. 2601, Australia.

Tetanic stimulation of Schaffer collaterals has been reported to potentiate some EPSPs evoked in CA1 basket cell (BC) interneurones (1). Because synapses from Schaffer collaterals on BCs are not formed on spines (2), whereas they are largely found on spines in pyramidal cells, the ability to potentiate EPSPs in CA1 BCs, and the specificity of that potentiation, was further examined. Intracellular recordings were made from BCs in conventional hippocampal slices. Control and test EPSPs were evoked by extracellular stimulation of stratum radiatum at 1 Hz. Conditioning procedures consisted of 100 pairs of 1 Hz stimulation with post-synaptic depolarization. If the EPSP did not potentiate, a tetanus of 20 stimuli at 100 Hz was paired with post-synaptic depolarization four times (.1 Hz). Depolarizing currents were always sufficient to discharge the neuron repetitively. Under these conditions, ten EPSPs (53%) exhibited potentiation of 50 to 100% with either pairing or tetanization. Seven of these EPSPs were recorded for 25 to 60 minutes after conditioning with no sign of a return to control values. The cells of the other potentiated EPSPs were lost within 10 minutes after conditioning but the recordings showed no return to control values in this period. In the nine remaining BC recordings, seven demonstrated an initial potentiation of as much as 100%, but returned to control values within 10 minutes. Two EPSPs exhibited depression. Preliminary results have shown that when two inputs were tested, the untetanized one did not potentiate. These results indicate potentiation of these EPSPs resembles LTP in CA1 pyramidal cells. The results also indicate that it is not necessary for the synapses to be formed on spines for this potentiation to occur.

REVERSIBLE INACTIVATION OF THE LOCUS COERULEUS, BUT NOT THE MEDIAL SEPTUM, PREVENTS HIPPOCAMPAL LONG-TERM POTENTIATION. E.J. Barea*, S.E. Krahl, and D.C. Smith. Department of Psychology and School of Medicine, Southern Illinois University, Carbondale, Illinois 62901.

Several studies have suggested that norepinephrine (NE) may play an important modulatory role in the induction of long-term potentiation (LTP) in the dentate gyrus (DG) of the hippocampus (cf. Neuman & Harley, *Brain Res.*, *273*:162, 1983). The present study investigated whether the microinfusion of 2% lidocaine hydrochloride, a reversible local anesthetic, into the locus coeruleus (LC) prevents the induction of DG-LTP in the urethane-anesthetized, adult male rat.

Long Evans rats were implanted with a unilateral guide cannula immediately above the LC or medial septum (MS), and with an electrode in the ipsilateral DG from which EPSPs, evoked by 80-300 μA biphasic square-wave pulses from a perforant path (PP) bipolar stimulating electrode, were recorded. Following a 1-hr stabilization period, both groups were microinfused with 0.5 μl of saline or lidocaine over a 2-min period. Eight minutes later, the animals received high-frequency stimulation (8 trains of 8 pulses at 400 Hz) of the PP.

Saline-infused controls displayed significant EPSP potentiation following high-frequency stimulation in both the LC, $F(1,9)=5.14$, $p<.05$, and MS groups, $F(1,7)=10.51$, $p<.05$. In contrast, lidocaine infused into the LC prevented EPSP potentiation when compared to pre-potentiation levels, $F(1,9)=1.21$, $p>.05$, or saline-infused potentiated controls, $F(1,26)=3.98$, $p<.05$. Lidocaine infused into the MS did not alter EPSP potentiation as compared to saline-infused controls, $F(1,24)=0.00$, $p>.05$. These findings suggest that the release of NE from the locus coeruleus is necessary for the induction of DG-LTP.

A MULTI-ELECTRODE ARRAY CAPABLE OF DELIVERING TETANIC STIMULATION TO AN ENTIRE HIPPOCAMPAL CA1 MINI-SLICE. C.I. Moore, B.A. Duff, E.M. Dudek, T.V. Dunwiddie, G.M. Rose and M. Browning*, Dept. of Pharmacology, U. Colorado Health Sci. Ctr, Denver, CO.

Recently our laboratory has found that several pharmacological treatments which produce LTP-like synaptic enhancement also produce increases in synapsin phosphorylation. Greengard's group has shown that synapsin I may play a role in regulation of transmitter release. Thus it is possible that synapsin may play a role in the increased transmitter release seen in LTP. A critical test of this hypothesis is to determine whether synapsin phosphorylation is correlated with LTP induced by classical means, i.e. tetanic stimulation. Unfortunately, tetany delivered via a single electrode induces LTP in only small fraction of the synapses in a slice, resulting in signal detection problems in biochemical studies. To address this problem we have begun using a mini-slice preparation in which the CA1 region is microdissected from a typical hippocampal slice. In addition, we have also begun using an electrode array (Longreach Scientific Resources, Orr's Island, ME) 1consisting of four monopolar stimulating electrodes placed side by side and spaced 100 microns apart. When the stimulating electrodes are separated in the array by 150 microns or less, such electrodes can be paired to produce paired pulse facilitation when a 50 msec inter-stimulus interval is used. Moreover, tetanic stimulation delivered to one of the electrodes produced LTP in the adjacent unstimulated electrode in 13 of 19 experiments. These effects can be seen in stratum radiatum when the electrode is positioned either parallel or perpendicular to the CA1 cell layer. We have examined the biochemical effects of synchronous tetany (400 Hz for 1 sec) delivered to all four electrodes at two positions in the stratum radiatum of a CA1 mini-slice. Such stimulation produced an increase in synapsin I phosphorylation at its CAM kinase II sites in 7 of 10 experiments.

NMDA-ACTIVATED CONDUCTANCES PROVIDE SHORT-TERM MEMORY FOR DENDRITIC SPINE LOGIC COMPUTATIONS. Roderick V. Jensen+ and Gordon M. Shepherd* (Section of Neurobiology,Yale University School of Medicine, New Haven, CT 06510) (+Department of Physics, Wesleyan University, Middletown, CT 06457)

Active conductances in or near dendritic spines may permit elaborate computational processing of multiple synaptic inputs long before these signals reach the soma. Numerical models of dendritic trees indicate that the interactions of postsynaptic potentials in active spines can generate simple logic operations such as AND, OR and NAND gates. However, because the spine head EPSP's closely follow the underlying, short-duration (1-5 ms), synaptic conductances, previous studies concluded that precise timing of synaptic inputs would be critical for these logic operations to occur. We show that this temporal limitation on dendritic computation can be relaxed by the inclusion of slow (100-300 ms), voltage-dependent, NMDA-receptor mediated conductances in the spine heads. Our numerical simulations show that this simple mechanism provides a short term memory (~100 ms) for logic AND gates with time-delayed inputs on one or more spines.

HOMOSYNAPTIC LONG-TERM DEPRESSION IN CA1 *IN VITRO*: DEVELOPMENT, MECHANISM, AND INTERACTION WITH LTP. S.M. Dudek* and M.F. BEAR. Center for Neural Science, Brown University, Providence, RI 02912.

Last year, we showed that 900 pulses delivered to the Schaffer collaterals at 1-3 Hz consistently yielded a depression of the CA1 population EPSP that persisted without signs of recovery for > 1 hour following cessation of the conditioning stimulation. This long-term depression (LTD) was specific to the conditioned input, ruling out generalized changes in postsynaptic responsiveness or excitability. LTD was dependent on the stimulation frequency; 900 pulses at 10 Hz caused no lasting change, and at 50 Hz a synaptic potentiation was usually observed. This, coupled with the observation that the depressed synapses continued to support long-term potentiation in response to a high frequency tetanus, suggested that LTD is accounted for by a modification of synaptic effectiveness rather than damage to or fatigue of the stimulated inputs.

We have extended these results in three ways. *First*, we have found that AP5 blocks induction of LTD. Because the release of neurotransmitter at the Schaffer collateral - CA1 synapse is not directly affected by AP5, this observation suggests that depletion of neurotransmitter is not a likely explanation for LTD. Moreover, our data suggest that synaptic depression can be triggered by prolonged NMDA receptor activation that is below the threshold for inducing synaptic potentiation. *Second*, we have found that LTD, like LTP, is of greater magnitude during early postnatal development. *Third*, we have evidence that LTP may be "unsaturated" by LTD, suggesting that the site of modification for LTP and LTD is the same. We propose that this mechanism is important – perhaps as important as LTP - for the modifications of hippocampal response properties that underlie some forms of learning and memory.

COMMON FORMS OF PLASTICITY IN HIPPOCAMPUS AND VISUAL CORTEX *IN VITRO*. A. Kirkwood, C. D. Aizenman and M.F. Bear*. Department of Neuroscience, Brown University, Providence, RI 02912.

The best studied model for synaptic plasticity *in vitro* is the CA1 region of adult rat hippocampus, where both homosynaptic long-term potentiation (LTP) and homosynaptic long term depression (LTD) have been shown to occur. Using a novel stimulation-recording arrangement in visual cortex, we have found that remarkably similar forms of plasticity can be elicited with precisely the same types of stimulation that are effective in hippocampus.

Previous work in visual cortex has shown that the synaptic responses of layer III cells to white matter (WM) stimulation can undergo LTP, but only under conditions in which synaptic inhibition is partly blocked by bicuculline. We have found that LTP can be induced reliably without bicuculline if layer IV rather that WM is stimulated. "Theta-burst" stimulation (TBS) induces non-decremental LTP in the amplitude of layer IV->III field reponses. Measured at 20 min after TBS, the average increase was 34 ± 4% (n = 42); and in 35 out the 42 cases (>80%) the increase exceeded 15%. In contrast, the same stimulation (without bicuculline) potentiated the WM->III responses by only 6 ± 4 % (n=17). However, in agreement with previous studies, if synaptic inhibition was blocked by including 10 mM bicuculline in the recording electrode then WM->III responses did potentiate by 30 ± 6% (n = 15).

Recent work in this laboratory has shown that homosynaptic LTD can be induced by low frequency stimulation (LFS) in CA1. Similarly, depression of the layer IV->III responses can be induced by LFS (900 pulses at 1 Hz). The average magnitude of the LTD at 30 min. after LFS was -29 ± 7% (n=5). As in CA1, the LTD was dependent on the frequency of conditioning stimulation; 900 pulses at 4 Hz produced no change (-3 ±10%, n=5).

The combined results suggest that hippocampus should no longer be considered a privileged site for synaptic plasticity in the adult brain. Even the mature primary visual cortex can exhibit plasticity of comparable magnitude and robustness.

EFFECTS OF NEUROTENSIN ON MAGNOCELLULAR CHOLINERGIC NEURONS FROM THE NUCLEUS BASALIS. R.Farkas, J.J.Grigg, S.Nakajima and Y.Nakajima* Dept. of Anat. and Cell Biol. and Dept. of Pharmacol., Univ. of Illinois, College of Med. at Chicago, Chicago, IL, 60612.

The magnocellular cholinergic neurons of the rat basal forebrain are known to be rich in neurotensin (NT) receptors. The whole-cell clamp method was used to investigate the effect of NT on dissociated cultured neurons from the nucleus basalis (NB) of newborn rats. Membrane potential was held at -74mV and recurring depolarizing (20mV, 100ms) and hyperpolarizing (50mV, 100ms) voltage pulses were imposed. Application of NT (1μM) produced a long-lasting decline of conductance (154s for 90% recovery, n=9) together with a slow inward current, reflecting cellular excitation. This NT sensitive current revealed inwardly directed rectification with a reversal potential approximately equal to or more negative than E_k. Occasionally the reversal potential was substantially more negative than E_k, suggesting the concomitant activation of a non-selective ion channel. In cells preloaded with the hydrolysis resistant GTP analog GTP-γS (100μM), application of NT produced an almost irreversible reduction in membrane conductance and inward shift of the base-line current. In NB cultures pretreated with pertussis toxin (500ng/ml, 15-22 hrs) the NT effect was not decreased from controls. These findings suggest that the conductance decrease produced by NT is mediated through a pertussis toxin-insensitive G protein. Supported by PHS grants AG06093 and 1F30MH10167.

DOPAMINE SENSITIVE AND INSENSITIVE K^+ CHANNELS IN RAT STRIATAL NEURONS. Gabriela J. Greif*, Yong-Jian Lin and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

We have performed cell-attached patch-clamp recordings on freshly dissociated rat corpus striatum (caudate and putamen) neurons in order to characterize the different types of K^+ channels present, and to determine whether they are modulated by dopamine receptors. As previously described, an 85 pS channel was observed when dopamine or the $D_{2/3/4}$ agonist quinpirole was present in the patch pipette, but was not observed in the absence of drug, or when agonist was applied via a macropipette to the cell membrane outside the patch. Two other classes of channels were also observed near resting membrane potential with 140 mM KCl in the patch pipette. First, there were inwardly-rectifying K^+ channels with conductances between 8-30 pS. Secondly, there were voltage-sensitive K^+ channels of 100-200 pS, which appeared to be large conductance Ca^{2+}-activated K^+ channels. Neither of these two types appeared to be modulated by dopaminergic drugs. These results may help clarify which subtypes of K^+ conductances are involved in dopamine receptor function in the caudate and putamen. (Supported by the Pharmaceutical Manufacturers Association, Tourette Syndrome Association, and NIH FIRST award MH-48545.)

629.3

SULFONYLUREA BLOCKADE OF DOPAMINE D_2 RECEPTOR ACTIVATED K^+ CHANNELS. Yong-Jian Lin*, Gabriela J. Greif and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

In order to further characterize the 85 pS K^+ channel which we have previously reported to be activated by D_2 or related dopamine receptors in rat corpus striatum, we have used cell-attached patch-clamp recordings to study the effects of sulfonylurea drugs on single channel currents. Channels were recorded with 10 μM quinpirole (a $D_{2/3/4}$ agonist) in the patch pipette, in the presence and absence of glibenclamide (glyburide). There was no apparent effect of 1 μM glibenclamide on channel current. At 10 μM, there was a partial blockade. In some patches, blockade was progressive over ~10 minutes of exposure. The most prominent feature of blockade was a change to shorter open times with longer closed times, as opposed to the long burst openings seen in the absence of blockade. These results suggest some similarity between this channel and the sulfonylurea-sensitive ATP-modulated K^+ channels described by others, although we needed relatively high concentrations of glibenclamide for blockade. (Supported by the Tourette Syndrome Association, Pharmaceutical Manufacturers Association, and NIH FIRST award MH-48545.)

EGF INDUCES EXPRESSION OF FUNCTIONAL DOPAMINE RECEPTORS IN GH3/B6 CELLS. J. R. Schwarz , S. Reichmann and C. K. Bauer (SPON: European Neuroscience Association), Inst. Physiol., Univ. Hamburg, 2000 Hamburg 20, Germany

The GH3 cell line serves as a model system to study the cellular control of TRH-induced prolactin secretion. One difference between this cell line and normal lactotrophs is the lack of dopamine (DA) receptors in GH3 cells. Recently, the expression of DA receptors in GH3 cells induced by treatment with epidermal growth factor (EGF) was shown by binding studies (Missale et al., Endocrinol 128, 1991).

In normal rat lactotrophs, DA induces a transient hyperpolarization and stop of action potentials (Israel et al., J. Physiol. 390, 1987). In GH3/B6 control cells (whole cell patch clamp), no changes in the electrical activity could be induced by the application of 5 μM DA. After prolonged (>4 d) treatment with 100 nM EGF and 100 μM progesterone, the GH3/B6 cells consistently responded to DA with a decrease in frequency of action potentials, and an increase in action potential duration leading to more hyperpolarized afterpotentials. This effect lasted several minutes.

D2 receptors present in rat lactotrophs are shown to be coupled to pertussis toxin (PTX)-sensitive G-proteins (Lledo et al., Brain Res. 558, 1991). In EGF-treated GH3/B6 cells, the DA response was not inhibited by preincubation of the cells with PTX (500 ng/ml, 5h).

Our results show that EGF treatment resulted in the functional expression of DA receptors in GH3/B6 cells, but differences in electrophysiological response and PTX-sensitivity suggest that these DA receptors are not identical to those of normal rat lactotroph cells.

MODULATION OF AN OUTWARD MEMBRANE CURRENT BY OXYGEN IN RAT PHEOCHROMOCYTOMA (PC12) CELLS . W. H. Zhu,* M.J. Stutts, M.F. Czyzyk-Krzeska, E.E. Lawson and D.E.Millhorn. University of North Carolina, Chapel Hill, NC .

PC12 cells are dopamine secreting cells that are morphologically and chemically similar to the Type I oxygen-sensitive cells of mammalian carotid body. Type I cells depolarize and release dopamine when exposed to low O_2 (hypoxia). It was reported recently that depolarization of type I cells occurs as a result of a decrease in conductance of a O_2 sensitive potassium channel (Science 241,1988). However, the actual mechanism by which type I cells detect low O_2 and tranduce this signal into altered cellular function remains unknown. The present study was undertaken to determine if PC12 cells respond to hypoxia in a manner similar to type I cells. If so, this cell line might prove valuable for studying fundamental mechanisms associated with O_2 detection and signal transduction. Whole-cell recordings were performed on rat PC12 cells exposed to control gas (hyperoxia; 95% O_2; room air, 21% O_2) or hypoxia (<10% O_2). Membane potential was voltage clamped at -80mv and change in current was measured in response to positive voltage steps (20mv, 300ms) from -80mv to +80mv. We measured a voltage sensitive outward current that was maximum (800-900 pA) at the largest voltage step. The magnitude of this outward current was decreased substantially when cells were exposed to hypoxia and recovered to prehypoxia levels when reexposed to control gas. Current-voltage plots showed that this outward current is voltage-sensitive and has reversal potential of about -80mv. These findings suggest that the oxygen-sensitive current in PC12 cells is a voltage-dependent potassium current. In addition, we measured dopamine concentration in media of cells exposed to control gas and low O_2 and found that hypoxia evoked a 2-3 fold increase in dopamine release from PC12.

MEMBRANE POTENTIAL CHANGES INDUCED BY ANOXIA IN RAT DORSAL VAGAL MOTONEURONES ARE INFLUENCED BY INTRACELLULAR pH. A. I. Cowan, R. L. Martin & S. J. Redman*. Division of Neuroscience, JCSMR, and Division of Botany and Zoology, Australian National University, Canberra, A.C.T. 2601, Australia.

This study was undertaken to investigate the influence of intracellular pH (pH_i) on the membrane potential changes induced by anoxia. Intracellular recording from dorsal vagal motoneurones (DVMs) in brainstem slices prepared from rats aged 35-45 days demonstrated that 44% of DVMs hyperpolarized and 45% depolarized during anoxia in bicarbonate/CO_2 buffered artificial cerebrospinal fluid (ACSF). However, in *N*-2-hydroxyethylpiperazine-*N*-2-ethanesulfonic acid (HEPES) buffered ACSF (which is expected to cause an increase in intracellular pH (1)), anoxia resulted in a depolarization of 9.5±1.2 mV (sem) in all 31 neurones tested. There was an increase in input resistance of 24.3±0.1% in 42% of the neurones and a decrease in input resistance of 15.2±0.1% in the remainder. The effects persisted when spike dependent synaptic transmission was blocked with tetrodotoxin. Addition of tetraethylammonium chloride, 4-aminopyridine, tetrodotoxin, ouabain or manganese, singly or in combination, showed that the membrane potential changes involve an increase in a calcium current which is counteracted to some extent by a small increase in the delayed rectifier current. A residual depolarization associated with an increase in input resistance is not due to an effect on the A current or on chloride channels. Inhibition of the Na-K ATPase also does not appear to be involved. These results contrast with the effects of anoxia on membrane potential in bicarbonate/CO_2 buffered ACSF (2) in which pH_i is presumed to be lower. It is concluded that changes in pH_i of neurones during anoxia may be responsible for the early changes in their electrical properties.

ANOXIC CHANGES IN MEMBRANE NOISE OF HIPPOCAMPAL NEURONS. M. Glavinović, P. Miu and K. Krnjević*. Anaesthesia Research Dept., McGill University, Montréal, Qué, H3G 1Y6 Canada.

Brief periods of anoxia elicit a characteristic hyperpolarization of pyramidal cells (Hansen et al. 1982, *Acta physiol. scand.* 115: 301). To obtain further information on the nature of the underlying conductance changes, we recorded in CA1 neurons, by single electrode voltage-clamp, the currents and (at higher gain) the changes in electrical noise generated by anoxia (2-3 min of 95% N_2 + CO_2), in the presence of TTX. The experiments were done in slices (from Sprague-Dawley rats) kept at 33°.

In the majority of cells, the anoxic outward currents seen at holding potentials (V_H) between -70 and -30 mV were associated with an **increase** in variance (σ^2) of the base-line noise. This indicates the opening of ionic channels, in keeping with the observed simultaneous increase in macroscopic conductance. Also in keeping with the macroscopic currents, the unitary currents reversed from outward to inward at -78 ± 6.6 mV (n=3; mean ± SD). The corresponding single channel conductance varied over a wide range: 20.2 ± 16.4 pS.

In two cells, the anoxic outward current was accompanied by a **reduction** in electrical noise. This inverse relation between σ^2 and current confirms previous evidence that anoxia can elicit both opening and closing of certain ionic channels.

During astrocytic swelling caused by extracellular hypoosmotic or high K^+ solutions non-selective cation channels open, astrocytes become depolarized, Ca^{2+} ions enter the cell and this in turn is followed by cell regulatory volume decrease (RVD) when both K^+ and Cl^- ions and amino-acids flow out of the cell. A high-conductance (200-250 pS) anion channel has been shown to be more readily activated in astrocytes when hypoosmotic rather than isoosmotic recording solutions are used. To study the potential-dependency of the increased anion conductance we have recorded the activity of single anion channels from primary astrocytes in cultures using the patch-clamp technique. With symmetrical and non-symmetrical Cl^- concentrations in the pipette and bath the channels in excised inside-out patches showed the highest probability to stay open at or near zero membrane potential, thus indicating that membrane depolarization induces the channel to open. The activated Cl^- channel is able to attain at least five discrete open sublevels. When the maximal open state is reached the channel has a tendency to stay open for seconds and then closes abruptly in one step. Opening to any of the sublevels leaves the channel in an unstable state which is characterized by fast flickering openings and closures. The channel is blocked by the anion transport inhibitor L-644,711, which also blocks RVD. Such a channel may function to let Cl^- out during RVD. To verify the existence of these channels in other than cultured mammalian astrocytes we are also using cortical tissue print cells from 21-day-old rats identified by GFAP staining to be astrocytes. GLIAL MODULATION OF TRANSIENT POTASSIUM CURRENT EXPRESSION IN CULTURED MOUSE HIPPOCAMPAL NEURONS. R.-L. Wu* and M. E. Barish. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

Rodent hippocampal neurons express multiple transient potassium currents that influence action potential duration and accommodation to sustained depolarization. We have studied pyramidally-shaped neurons in dissociated cell cultures prepared from mouse hippocampus on embryonic days 15-16 using whole-cell gigaohm-seal voltage clamp techniques. These neurons exhibit two transient potassium currents, termed A- and D-currents, that can be separated based on steady state inactivation characteristics and sensitivity to 4-aminopyridine (Wu and Barish, *J. Neurosci.*, in press). We have observed that after 5-7 days in culture A-current density (current normalized to membrane area) is larger than D-current density in neurons growing on glial cells (primarily GFAP-immunoreactive astrocytes), while D-current density is larger in neurons growing only on the poly-lysine/laminin-coated glass substrate. This variation is approximately reciprocal; the sum of A- and D-current densities is similar in both types of neurons. The glia-derived signal probably acts by cell surface interaction or restricted diffusion of a soluble factor, as neighboring cells show differences in potassium current expression based on glial contact. Living glia may be required, as currents in neurons growing on dried glial membranes or methanol-fixed glia resemble those in neurons that do not touch glia. We suggest glia-induced plasticity of A- and D-current expression as a novel mechanism of long-term modulation of hippocampal neuron excitability.

NOVEL ETHANOL ENHANCEMENT OF THE DELAYED RECTIFIER POTASSIUM CURRENT IN RAT HIPPOCAMPAL CA1 NEURONS.

J.L. Weiner*, L. Zhang and P.L. Carlen. Playfair Neuroscience Unit, Toronto Hospital, Department of Pharmacology, University of Toronto & Addiction Research Foundation, Toronto, Ontario, Canada.

Recent biochemical studies have demonstrated that ethanol, at relatively high concentrations (>50 mM), interacts with several second messenger systems. The role of these effects in the mediation of ethanol intoxication remain unknown.

We have recently characterized the sequence of events coupling muscarinic receptor activation to the potentiation of the delayed rectifier potassium current (I_K) in rat hippocampal CA1 neurons. I_K was recorded from mature rat CA1 neurons in brain slices using the whole cell patch clamp recording method. Under voltage clamp recording conditions in which other ionic currents were suppressed, bath application of 10 μM carbachol reversibly potentiated I_K (mean=80%) with an onset of action of 1-3 minutes. A reversible decrease in holding current with no associated change in resting conductance was also observed during carbachol application. The intracellular mediators of this enhancement were shown to include a G protein, IP_3, DAG, and PKC.

This kinase-modulated current was used as an assay to characterize possible actions of ethanol on second messenger systems. Bath application of 20 mM ethanol also enhanced I_K with a slower onset of action and recovery rate than carbachol and no associated change in holding current. In addition, incubation of slices with 20 mM ethanol for 10-25 minutes did not consistently inhibit subsequent carbachol enhancement of I_K. Ethanol pretreatment did however reduce the carbachol-induced reduction in holding current.

These preliminary results demonstrate that ethanol, at a clinically relevant concentration, can potentiate I_K in central mammalian neurons. The cellular mechanisms underlying this enhancement are currently under investigation.

Multiple components of I_{AHP} following trains of action potentials in bullfrog sympathetic ganglion neurons. P. Pennefather* and M.V. Sanchez-Vives[1]. MRC Nerve Cell on Synapse Group, University of Toronto, Toronto, Canada, M5S 2S2, [1]Dept. of Physiology, University of Alicante, 030380, Alicante, Spain.

B neurons were recorded from using 20-60 MΩ standard electrodes. When the recording mode is switched from single electrode current clamp to single electrode voltage clamp (hydrid clamp) immediately following a train of evoked action potentials, a calcium and apamin dependent K current is observed that decays slowly back to baseline. This current, I_{AHP}, underlies the slow afterhyperpolarization observed in these neurons. We have analyzed the time course of I_{AHP} at -60 mV using the Clampfit program (Axon Instruments) and have detected multiple components whose amplitude and time course are a function of the amount of calcium entering per action potential and the number of action potentials in the train used to evoke I_{AHP}. We conclude that I_{AHP} is made up of two main components. A major component with an amplitude of ≈ 1nA and a τ ranging for 60-1500 ms and a minor component with an amplitude < 70 nA and a τ of ≈ 5000 ms. Under certain conditions an apparent fast component due to the activation of I_M is observed. Using a versatile interactive simulation program (see K. Miller and P. Pennefather this meeting), we will show how these properties can be explained by the modulation of the calcium signal responsible for I_{AHP} by two pools of calcium buffers, a high capacity (≈ 300 μM) slow buffer and a lower capacity (≈ 50 μM) fast buffer. Uptake into the slow buffer determines the limiting τ of the major component of I_{AHP} following long trains as well as the amplitude of the late slow component. Release of calcium from that pool determines the τ of the late slow component. As explained previously, (Pennefather, Sala and Hernandez-Cruz, 1990, Soc. Neurosci. Abst. XVI, 187) the changes of amplitude and τ of the major component with action potential number is determined primarily by the properties of the fast buffer. Thus a detailed analysis of the relation between I_{AHP} time course and calcium load induced by action potentials can provide insights into how calcium entering neurons during action potentials is buffered.

EFFECTS OF PHOSPHOLIPASE A_2-INHIBITORS ON COUPLING OF α_2-ADRENOCEPTORS TO INWARDLY RECTIFYING POTASSIUM CONDUCTANCE IN SUBMUCOSAL NEURONES. R.J.Evans & A. Surprenant*. Vollum Institute, O.H.S.U., Portland, OR 97201

Noradrenaline and somatostatin hyperpolarise enteric submucosal neurones by activating a set of inwardly rectifying potassium channels. Receptor-channel coupling appears to involve only a pertussus toxin-sensitive G-protein because agonists activate the K channels in outside-out membrane patches (Shen et al. J.Physiol. **445**, 1992). This study investigated whether the production of arachidonic acid and its metablolites may be involved in mediating the response using the PLA_2 inhibitors quinacrine and 4-bromophenacyl bromide (4-BPB), and the cycloxygenase and lipoxygenase inhibitor eicosatetraynoic acid (ETYA). Quinacrine (10 μM) reduced the noradrenergic IPSP and hyperpolarisations to the α_2 adrenoceptor agonist UK 14304 (100 nM) and somatostatin (10 nM) by 85, 70 and 65% respectively. A similar reduction in the IPSP and the UK 14304 response was found with 4-BPB (10 μM). Quinacrine had no effect on the slow EPSP or the depolarisation in response to substance P, which result from closure of resting and calcium-activated potassium channels, nor on the nicotinic fast EPSP. The agonist induced current to UK 14304 and somatostatin shows substantial inward rectification at potentials negative to E_K; this rectification was reduced by 90% in the presence of quinacrine. ETYA (20 μM) had no effect on the response to UK14304. Our results to date indicate that prostagliandin and eicosanoid metabolites of arachidonic acid are not involved in mediating signal transduction from α_2-receptor to potassium channel activation.

PLUGGING THE LEAK: ADRENERGIC MODULATION OF LEAKAGE POTASSIUM CHANNELS IN RAT THALAMUS.
Peter B. Reiner* and Xue-Ping Wang, Kinsmen Laboratory of Neurological Research, Department of Psychiatry, University of British Columbia, Vancouver, BC V6T 1Z3 Canada.

The predominant determinant of the resting potential of excitable cells is a voltage-independent "leakage" potassium current, I_{KL}. Neurotransmitters are capable of inhibiting I_{KL} in mammalian neurons, resulting in a depolarization accompanied by an increase in whole-cell input resistance. Using cell-attached and cell-free patch clamp recordings, we have characterized I_{KL} channels in thalamic neurons studied in slices of rat brain. The channel exhibits a slope conductance of ~24 pS and is highly selective for potassium ions. I_{KL} channels are active at the resting potential and exhibit little voltage-dependence. $Alpha_1$ adrenergic agonists, known to inhibit macroscopic I_{KL}, reduce the probability of opening of single I_{KL} channels. Modulation of I_{KL} appears to be mediated by a soluble intracellular messenger, as bath application of agonist alters channel kinetics in cell-attached patches. In thalamic neurons, transmitter-induced modulation of I_{KL} channels results in a depolarization which is critically involved in desynchronization of the cortical EEG.

SENSITIVITY OF CALCIUM AND POTASSIUM CURRENTS IN DROSOPHILA EMBRYONIC NEURONS TO CYCLIC AMP.
W.B. Alshuaib* and L. Byerly, Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

Modulation of membrane currents by intracellular cAMP has been connected to learning in *Aplysia*. Abnormal cAMP metabolism in *Drosophila* learning mutants suggests that a similar mechanism may also underlie learning in *Drosophila*. We are studying the effect of cAMP on Ba and K currents in cultured *Drosophila* embryonic neurons.

Since these neurons are only 5 μm in diameter, Ca current and modulation mechanisms involving intracelluar molecules are likely to washout rapidly when the conventional whole-cell patch clamp technique is used. Therefore, we employ the perforated-patch whole-cell technique, using amphotericin-B to permeabilize the patch. Permeabilization was unreliable in small-opening patch electrodes required for the 5 μm neurons; however, it works much better in large-opening patch electrodes that are used on the 10-15 μm "giant" neurons obtained by arresting cell cleavage with cytochalasin-B.

Our present results suggest that cAMP enhances Ba current but has no effect on K current. With the perforated-patch technique *Drosophila* Ba current shows no washout. Supported by NSF Grant BNS-8903312.

β-Adrenergic Receptor Stimulation and Cell Density Regulate the Level of Connexin43 mRNA in C_6 Glioma Cells
C. Hough*, R. L. Margolis and D.-M. Chuang
Biological Psychiatry Branch, National Institute of Mental Health, Bethesda, MD 20892

The gap junction is a route of rapid intercellular communication among astrocytes and between astrocytes and neurons. The gap junction protein, connexin43, is expressed endogenously in C_6 glioma cells. We investigated the regulation of connexin43 mRNA levels in C_6 cells in response to a variety of treatments to better understand the factors controlling gap junction expression in astrocytes and neurons. Connexin43 mRNA levels per cell increased with time in culture, reaching levels 62-fold greater than those expressed on the first day of subculture. 1 μM isoproterenol stimulated a 3 to 4 fold increase in connexin43 mRNA levels within 4 hours in cells of moderate density. β-Adrenergic receptor mRNA was simultaneously down-regulated by this treatment. Somewhat less stimulation by isoproterenol of connexin43 mRNA accumulation was obtained from cells grown at higher cell densities. The increase in connexin43 mRNA induced by isoproterenol could be attenuated 50% or more by the presence of 10 μM colchicine during isoproterenol stimulation, while colchicine alone had little effect. Additional studies using β-adrenergic antagonists and cyclic AMP analogs are underway to determine in more detail the nature of the induction of connexin43 mRNA levels.

INTERACTIONS BETWEEN SP AND NMDA-ACTIVATED CURRENTS IN SPINAL TRIGEMINAL NEURONS. Y. Gu*[1] and L-Y. M. Huang[1,2]. Marine Biomedical Institute[1] and Department of Physiology and Biophysics[2], The University of Texas Medical Branch, Galveston, Texas 77555-0843.

Substance P (SP) is present in small primary afferent fibers and participates in the transmission of sensory information, including pain, in the caudal medulla and the spinal dorsal horn. To understand the role of SP in nociception, we studied the interaction between SP and the excitatory amino acid, N-methyl-D-asparate (NMDA) in dissociated trigeminal neurons. The cells were isolated from the spinal trigeminal nuclei in the caudal medulla of rats, and the whole cell currents were measured with patch clamp pipets. The fast perfusion method was used to deliver NMDA to the cell. SP increased NMDA responses in 56% of the cells tested, and had no effect on the rest. For those cells in which NMDA responses were enhanced, the effect of SP was rapidly reversible in 60% of the cases. In the other 40% of the cells, the enhancement by SP persisted for 10-30 min after SP was removed from the external solution. We also found that the enhancing effect of SP was sensitive to external glycine. The increase in NMDA responses by SP was abolished when glycine was added to the external solution, and the enhancement reappeared when the glycine antagonist 7-chlorokynurenic acid was introduced in the solution. The mechanism underlying the SP actions will be discussed. (Supported by NIH NS11255 and NS012050).

DYNORPHIN REDUCES NMDA-ACTIVATED CURRENTS. L. Chen[1] and L-Y. M. Huang*[1,2]. Marine Biomedical Institute[1] and Department of Physiology and Biophysics[2], The University of Texas Medical Branch, Galveston, Texas 77555-0843.

Opioids, such as morphine, has been used widely in the control of pain. Mu-opioid receptors, the preferential binding sites for morphine, clearly play a role in analgesia. We have previously shown the μ-opioid receptor agonist D-Ala^2-MdPhe^4-Gly-ol^5-enkephalin (DAGO) causes a sustained increase in N-methyl-D-asparate (NMDA)-activated currents by activating protein kinase C inside trigeminal neurons [Neuron, 7:319-326, 1991]. Recent studies of κ-opioid receptors indicate that those receptors may also participate in pain modulation. To understand how a κ-opioid receptor agonist affects the excitability of dorsal horn neurons, we examined the action of dynorphin on excitatory amino acid-activated currents. The experiments were performed on trigeminal neurons acutely isolated from 10-15 day rats. The whole cell currents were measured using the patch clamp recording technique. The amino acids were applied to the cell with a fast perfusion method. Dynorphin had no effect on kainate-activated currents, but it reduced NMDA-activated currents in almost all the cells tested. It decreased NMDA responses by 10% at 10 nM, by 20% at 100 nM and by 40% at 1 μM. The inhibition was rapidly reversed when the opioid was removed from the external solution. Dynorphin changed neither the voltage-dependence nor the kinetics of the NMDA-activated currents. Thus, the effect of κ-opioid receptor agonist dynorphin on NMDA-activated currents is quite different from that of μ-opioid receptor agonist. (Supported by NIH NS23061, NS01050).

ELECTRICAL PROPERTIES OF GLUTAMATE-RESISTANT AND GLUTAMATE-SENSITIVE CEREBELLAR GRANULE CELLS.
C.Zona*,M.T.Ciotti,D.Mercanti,A.Angelini, P.Calissano - *Institute of Physiology, University of Roma "Tor Vergata", Institute of Neurobiology C.N.R., Roma, Italy

Cerebellar granule cells in vitro, in the presence of a protein complex isolated from rabbit serum (NOAC) develop a phenotype which is in several properties identical to that ensuing in 10% FCS but is markedly different in terms of glutamate sensitivity. NOAC-cultured neurons exhibit a full resistance to the otherwise lethal action of excitatory aminoacids (EAA-phenotype). This EAA- phenotype can be induced to become EAA sensitive (EAA+) when neurons are incubated with another protein complex isolated from rabbit serum. Membrane ionic currents have been recorded in EAA- and in EAA+ neurons using the whole cell patch-clamp techinique. When K currents were blocked, depolarization commands evoked Na and Ca currents in EAA- and EAA+ neurons. The amplitude of the Na currents was significantly bigger in EAA+ neurons than in EAA- neurons while there was not significantly difference in amplitude in Ca currents in the two groups of neurons. Our preliminary data show that the electrical properties of EAA- and EAA+ neurons are different.

629.19

ZINC POTENTIATES ATP-ACTIVATED INWARD CURRENT IN RAT NODOSE GANGLION NEURONS. Chaoying Li*, Robert W. Peoples, Zhiwang Li and Forrest F. Weight. Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

The effects of micromolar zinc on membrane inward current activated by extracellular adenosine 5'-triphosphate (ATP) were studied in freshly isolated adult rat nodose ganglion neurons using the whole-cell patch-clamp technique. In 48 of 60 neurons tested, zinc, 5 or 10 μM, increased the peak amplitude of current activated by 10 μM ATP by 30% (n=9) and 120% (n=16), respectively, and reduced the rate of decay of the current simultaneously. In 12 of 60 neurons, zinc decreased the rate of decay of ATP-activated current but had little effect on the peak amplitude of the current. Enhancement of peak amplitude of ATP-activated current by zinc (1-50 μM) was concentration-dependent with an EC_{50}=11 μM. In this concentration range zinc did not have any other detectable effect, and did not change the reversal potential of ATP-activated inward current. The potentiation of membrane conductance was not voltage-dependent between -80 and +60 mV (P>0.25, n=5). Zinc shifted the concentration-response curve for ATP to the left and significantly decreased the EC_{50} of ATP from 30 to 8 μM. These observations suggest that the modulatory site for zinc action may be located on or near the exterior surface of the ATP receptor-ion channel complex. They also suggest that zinc may enhance the ATP-activated current by increasing the affinity of the receptor for ATP.

629.20

EFFECTS OF CALCIUM AND MAGNESIUM IONS ON SPONTANEOUS OSCILLATION OF MEMBRANE CURRENT IN MAMMALIAN PARASYMPATHETIC NEURONS. T. Nishimura* & T. Akasu. Department of Physiology, Kurume University School of Medicine, 67 Asahi-machi, Kurume 830, Japan.

A spontaneous rhythmic outward current (Iso) was recorded from neurons in rabbit vesical parasympathetic ganglia (VPG), using single electrode voltage clamp techniques in vitro. After penetration of cells with an electrode containing 3 M KCl, cells were clamped at a given resting potential (-45 to -65 mV). The Iso occurred at fairly constant intervals ranging between 30 s and 5 min in the Krebs solution. Ionic mechanisms of the Iso are activation of calcium-dependent potassium conductance and inactivation of calcium-dependent chloride conductance (Nishimura et al., J. Physiol., 437: 673-690, 1991). The frequency of the Iso was increased by removal of magnesium ions (1.2 mM) from the Krebs solution, while it was decreased by raising magnesium ions to 6 mM. In either case removal of calcium ions (2.5 mM) from the perfusate eliminated the Iso. Application of a calcium-rich solution (4 mM) or caffeine (1-3 mM) increased the frequency of the Iso. Effects of the calcium-rich solution and caffeine on the Iso were antagonized by raising external magnesium ions (6 mM). Nifedipine (10 μM), verapamil (10 μM) and ω-conotoxin (1 μM) did not alter the Iso. Application of BAPTA-AM (300 μM, 30 min), a calcium-chelator acting in cytosol, eliminated the Iso. Subsequent calcium-load into cells restored the Iso. Inhibitors for calcium-induced calcium release (CICR), ryanodine (0.1-1 μM)and procaine (30-300 μM)reversibly blocked the Iso. An inhibitor for calcium-pump, cyclopiazonic acid (3-10 μM)also reversibly blocked the Iso. These data imply that the magnesium-sensitive calcium influx occurring at resting potential regulates the CICR from ryanodine-sensitive calcium-store sites and the calcium-extrusion system which generate the Iso in rabbit VPG neurons.

629.21

EFFECTS OF INTRACELLULAR SODIUM AND CHLORIDE ACTIVITIES ON THE MEMBRANE PROPERTIES OF CA1 NEURONS Kevin J. Staley* Neurology Dept, University of Colorado Health Sciences Center, Denver, CO 80262

Whole cell recordings from different laboratories using various concentrations of electrode Na^+ and Cl^- have produced quite different values for the resting membrane potential (RMP) and input resistance (R_N) of hippocampal neurons, suggesting that the intracellular activities of Na^+ and Cl^- may modulate these "membrane properties".

The RMP and R_N of CA1 neurons were measured in adult hippocampal slice preparations using whole-cell recordings. All electrode solutions were pH 7.25 and included (in mM) K^+HEPES 10, $MgCl_2$ 2, and variable Na^+ and Cl^- (tabulated below); K^+gluconate was added so that the sum of K^+, Na^+, Cl^-, and gluconate was 284 meq. RMPs were corrected for junction potentials. 34ºC, pH 7.4 artificial cerebrospinal fluid (ACSF) included NaCl, 126; KCl, 2.5; $NaHCO_3$, 26; $CaCl_2$, 2; $MgCl_2$, 2; NaH_2PO_4 1.25; and glucose, 10. 800 μM ethacrynic acid (ECA) was added to the ACSF in some experiments.

ECA	-	-	-	-	-	+
Cl^-	4	12	40	80	139	139
Na^+	0	8	0-8	8	8	8
RMP (mV)	-68	-72	-67	-68	-60	-63
R_N (MΩ)	70	45	87	84	85	46
N	10	5	10	7	6	4

In the high chloride cells, ECA both decreased the R_N and diminished a large, slow depolarizing shift of the RMP. Effects of intracellular calcium buffering (10 mM K_2EGTA) were small. These results suggest that electroneutral NaCl cotransport may reduce internal Na^+ in cells recorded with high Cl^- electrode solutions, thereby decreasing a Na^+ -dependent K^+ conductance which is active at RMP and which significantly affects the R_N.

COMPUTER SIMULATION OF A CA3 HIPPOCAMPAL NEURON. M. Migliore*, David Jaffe and Daniel Johnston. Div. of Neuroscience, Baylor College of Medicine, Houston, TX.

Computer simulations of the firing properties of a hippocampal CA3 pyramidal neuron were performed using the program NEURON/NMODL, which was developed by Mike Hines at Duke University. The model neuron (Jaffe et el., Soc. Neurosci. abstr. **17**, 1991) was constructed from a camera lucida drawing of a golgi stained CA3 neuron and consisted of 149 compartments, representing the soma and apical and basal dendrites. To study the interplay among ionic currents during spike frequency adaptation and bursts, several ionic currents have been included in the model. Based on available voltage- and current-clamp experimental data, we modeled the Ca-independent potassium currents IK_A, IK_{DR} and IK_M, the Ca-dependent potassium currents, IK_C and IK_{AHP}, a fast Na current, *INa*, and three Ca currents, ICa_N, ICa_L and ICa_T. Calcium buffering, pumping and radial and longitudinal diffusion have also been incorporated into the model. Using a combination of electrophysiological and fluorescence imaging results, distributions of several of these channels were nonuniformly placed in different regions of the dendrites. The results from the simulations can qualitatively reproduce a number of the repetitive firing characteristics of these pyramidal neurons under different conditions of injected current and pharmacological manipulations. (Supported by NIHM grants MH44754 and 48431 and the Keck Foundation.)

629.23

THE EFFECT OF AXOTOMY ON THE ELECTRICAL PROPERTIES OF NEUROSECRETORY CELLS. R. Godínez, R.F. Valdiosera and P. Huizar*. Dept. of Physiology, CINVESTAV-IPN. Apartado Postal 14-740, México, D.F. 07000. MEXICO.

The effect of axotomy on the electrical properties of X-organ neurons of the crayfish was investigated with microelectrode techniques. These neurons are monopolar and their axons start branching at about 200-500 μm from the cell body to form a neuropil where they recieve their synaptic inputs. The axons were cut at about 150 μm from the cell body so most or all of their connections were removed. The isolated X-organ was placed in a bath and recordings were made 15 to 30 min afterwards. After axotomy, the synaptic activity disappeared and the resting potential increased from a control value in intact neurons of -52.6 ± 6 mV (n=10) to -80.6 ± 5 mV (n=7). This hyperpolarization was accompanied by a reduction of input resistance to about half the control value. The action potential, either disappeared or a slow depolarizing response remained. Under these conditions, the perfusion with Dibutyryl cyclic AMP (2 mM) from a micropipette nearby produced a depolarization near to control levels accompanied by a threefold increase in input resistance. The action potential either reappeared or increased in size and became faster. These results indicate that axotomy has important effects on the state of K^+ and Ca^{++} channels.

A MUTATION AFFECTING THE SODUM PUMP OF *DROSOPHILA*. M. Schubiger[1], D.M. Fambrough[2] and J. Palka[1]*. [1]Dept. Zoology, Univ. Washington, Seattle, WA 98195 USA; [2]Dept. Biology, Johns Hopkins Univ., Baltimore, MD 21218 USA.

In a behavioral screen of 2,000 enhancer trap lines we isolated one (designated 2206) in which the P-element had inserted into region 93B of the salivary gland chromosomes, the site of the previously cloned gene for the α-subunit of the *Drosophila* Na^+,K^+-ATPase. The following evidence indicates that 2206 is a hypomorphic mutation resulting from the insertion of the P-element into the regulatory region of the gene: (1) 2206 homozygotes are nearly an order of magnitude more sensitive to ouabain, a highly specific pump poison, than are control flies. (2) They are bang-sensitive, undergoing brief paralysis in response to mechanical agitation. This behavior is mimicked by injection of ouabain into wild type flies. (3) Excision of the transposon leads to a reversion of the bang-sensitive phenotype and restores wild type resistance to ouabain. (4) A monoclonal antibody to the α-subunit stains much less intensely in certain tissues of 2206 than it does in control flies. Quantitative protein immunoblots show that in the mutants only about 30% of the wild type quantity of pump protein is made. (5) In Northern blots the cDNA to the coding region recognizes the previously reported mRNAs but shows quantitatively reduced hybridization. (6) While no novel restriction lengths within the pump gene coding region are seen in Southern blots of 2206 DNA, a cosmid has been isolated that spans the coding region and the site of insertion of the P-element. This will enable us to localize the insert. Thus, the evidence argues that 2206 carries an insertion that disrupts the normal functioning of the regulatory region of the α-subunit gene. The isolation of a hypomorphic mutation with a behavioral phenotype invites further studies on the regulation of pump gene expression.

630.1

OVER EXPRESSION, AFFINITY PURIFICATION AND CRYSTALLIZATION OF RECOMBINANT RAT CHOLINE ACETYLTRANSFERASE.

D.H.Wu, D.L.Calloway, L.A. Carbini, M. Hahn, T. Joh, W. Lian, J. Deisenhofer and L.B. Hersh*
Department of Biochemistry, UT. Southwestern, Dallas, Texas 75235-9038.

Choline acetyltransferase (ChAT, E.C. 2.3.1.6) catalyzes the biosynthesis of the neurotransmitter acetylcholine using choline and acetylCoA and serves as the most specific marker yet known for cholinergic neurons. The detailed characterization of this enzyme at the molecular level has been hampered by its low abundance from natural sources. Previous attempts to express recombinant *Drosophila* or rat ChAT in E. coli resulted in high levels of inactive insoluble enzyme and only modest levels of soluble active enzyme. We report here the optimization of expression of rat ChAT in its active form in E. coli, yielding approximately 50 mg of enzyme per liter of culture (estimated to be equivalent to the amount of enzyme contained in 20,000 rat brains). A facile purification scheme was developed for the recombinant enzyme using a poly-histidine affinity tag which permits homogeneous enzyme to be obtained in a single day. Finally, the crystallization of the recombinant enzyme has been achieved which should pave the way for the determination of the enzyme structure.

630.2

FEEDBACK REGULATION OF CHOLINE ACETYLTRANSFERASE EXPRESSION IN *DROSOPHILA*.

V. Andrisani, T. Kitamoto and P. M. Salvaterra*. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA91010.

We have examined the possibility that transcriptional regulation plays an important part in feedback regulation of the *Drosophila* choline acetyltransferase (ChAT) gene. We constructed transgenic flies carrying a *lacZ* reporter gene whose expression was directed by the 5' flanking DNA of the ChAT gene. The fusion gene was introduced into *Drosophila* with either a wild type or temperature sensitive *Cha* genetic background. Compared to wild type flies, temperature sensitive *Cha* mutants show lower ChAT activity and higher ChAT mRNA levels. At a restrictive temperature, ChAT activity and ChAT mRNA levels decrease in mutants but increase in wild-type flies. If the 5' flanking DNA directing reporter gene expression contains elements responsible for this feedback regulation, the levels of mRNA coding for reporter gene should change in parallel with those of ChAT mRNA. It will also be possible to map the elements responsible for feedback regulation by using different amount of 5' flanking DNA. We are now analyzing the reporter gene expression directed by 7.4 kb of 5' flanking DNA. This DNA has been shown to contain most, if not all, of the cis elements required for correct temporal and spatial expression of ChAT. Our preliminary results indicate that higher β-galactosidase activity is present in temperature sensitive *Cha* mutants relative to wild type at a permissive temperature. The β-galactosidase activity also decrease in flies at a restrictive temperature. These results may suggest that 7.4 kb of 5' flanking DNA is involved in feedback regulation of ChAT.

630.3

DISTRIBUTION OF CHOLINERGIC NEURONS IN WHOLE MOUNT PREPARATIONS OF *DROSOPHILA*.

T. Kitamoto*, K. Ikeda and P.M. Salvaterra. Div. Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

We have analyzed the distribution of putative cholinergic neurons in whole mount preparations of *Drosophila melanogaster*. Cholinergic neurons were visualized by X-gal staining of P-element transformed flies constructed with a fusion gene containing bacterial *LacZ*. *LacZ* expression was controlled by various amounts of the 5' flanking DNA of the *Drosophila* choline acetyltransferase gene. We have previously demonstrated that cryostat sections of transgenic flies containing 7.4 kb of 5' flanking DNA express *LacZ* in a detailed pattern similar to the known distribution of ChAT protein. Whole mount staining of these same flies should thus represent the overall distribution of cholinergic neurons in the fly. X-gal staining could be observed in most, but not all, areas of the CNS and PNS. Removal of the distal part of the 5' flanking DNA resulted in a dramatic reduction of X-gal staining in the PNS. For example, the 7.4 kb DNA directed strong *lacZ* expression in leg sensory neurons but the 1.2 kb DNA did not. Our results suggest that ChAT expression is regulated differentially in the CNS and PNS.

630.4

EXPRESSION AND LOCALIZATION OF CHOLINE ACETYLTRANSFERASE AND THE *unc-17* GENE PRODUCT IN THE NEMATODE, *C. elegans*.

J. S. Duerr*, H.-P. Han, and J. B. Rand, Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104.

In *C. elegans*, *cha-1*, the gene that encodes choline acetyltransferase (ChAT), is part of a complex genetic locus with *unc-17*. The function of the *unc-17* gene product is unknown, but defects in this gene, like defects in *cha-1*, cause uncoordinated locomotion and resistance to cholinesterase inhibitors. To study the function and distribution of these two gene products, we are expressing them as fusion proteins and generating specific antibodies for immunolocalization studies.

The full length coding sequences from the *cha-1* and *unc-17* cDNAs were cloned into pMAL plasmid expression vectors to produce fusion proteins in *E. coli*. The fusion proteins were induced, purified, and cleaved to yield ChAT or unc-17 protein; these cleaved proteins were used as immunogens. Peptides designed from the known cDNA sequences were also used as immunogens. Polyclonal sera were produced in rabbits and chickens; a subset of these sera specifically recognized the ChAT or unc-17 fusion protein on Western blots. However, the sera exhibited high nonspecific staining of *C. elegans*. Therefore, they have been affinity purified with the fusion proteins before use in immunocytochemistry. The affinity-purified sera are being used to identify the ChAT and unc-17 containing neurons in the ventral nerve cord and ganglia, as well as to identify staining in any non-neuronal cells. This identification will be simplified by the fact that the identity and origin of all of the cells in *C. elegans* have been described. Supported by grants from NSF and NIGMS.

630.5

MOLECULAR ANALYSIS OF TWO NESTED GENES INVOLVED IN ACETYLCHOLINE METABOLISM AND RELEASE: THE *cha-1/unc-17* GENE COMPLEX IN THE NEMATODE *C. elegans*.

A. Alfonso*, K. Grundahl, J.M. Asbury, J.R. McManus and J.B. Rand, Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104

cha-1 and *unc-17* are parts of a complex locus and transcription unit. *cha-1* encodes choline acetyltransferase, and *unc-17* encodes a unique 58 kDa protein of unknown function, believed to be involved in acetylcholine metabolism or release. *unc-17* is nested within a long *cha-1* intron, and the two transcripts share some 5' sequences. The entire genomic region (~11.5 kb) has been sequenced.

We screened 3 cDNA libraries, and isolated 3 independent *cha-1* cDNAs and 4 independent *unc-17* cDNAs. Although *cha-1* and *unc-17* contain no coding sequence in common, all of the cDNAs share a 66 bp 5'-untranslated exon. The 2 cDNAs extending furthest in the 5' direction (1 *cha-1* and 1 *unc-17*) also contain sequences apparently derived from the trans-spliced leader SL1. Primer extension analysis reveals heterogeneity within each transcript class. A *cha-1* specific primer yields a minor product which is the predicted length for a trans-spliced RNA, and a major product ~60 bases longer. The *unc-17* specific primer gives rise to several extension products: the most abundant one is the predicted size for trans-spliced RNA, and a minor product corresponds to the length of the major *cha-1* extension product. Supported by a grant from NIGMS.

630.6

NEW CHOLINERGIC GENES IN THE NEMATODE *C. elegans*.

J. B. Rand*, A. Alfonso, and M. Nguyen. Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104.

We have identified and mapped 4 new genetic loci in *C. elegans*, which are characterized by resistance to inhibitors of cholinesterase (the *ric* phenotype). We are interested in determining the roles of these genes in acetylcholine metabolism and cholinergic function. These genes are unlinked to each other, and give rise to recessive drug resistance, uncoordinated locomotion, and slow growth. For mutants in each of these genes (and also in the 14 previously identified genes), we performed growth curves and acetylcholine measurements, and we quantified the resistance to two different AChE inhibitors: the carbamate aldicarb and the organophosphate trichlorfon.

Mutations in each of these 18 genes confer comparable resistance to aldicarb and trichlorfon, which suggests that all of these genes encode gene products involved in cholinergic metabolism and/or function. Mutations in *ric-1* through *ric-4*, as well as 8 other genes, lead to 2- to 4-fold increases in acetylcholine levels, suggesting that these genes act presynaptically. Molecular analysis of *ric-2* is now in progress.

Supported by a grant from the Oklahoma Center for the Advancement of Science and Technology.

FIRST AND SECOND GENERATION CHOLINESTERASE INHIBITORS: THEIR EFFECTS ON CORTICAL ACETYLCHOLINE. E. Giacobini*, E. Messamore and X-D. Zhu. Dept. Pharmacology, Southern Illinois Univ. Sch. Med., Springfield, IL 62794-9230.

Several cholinesterase inhibitors (ChEI) are presently being clinically evaluated for enhancement of cholinergic function in Alzheimer disease (AD) patients. We postulated that the ability of ChEI to ameliorate the cholinergic deficit in AD is related to their ability to maintain long-lasting, non-toxic steady state levels of ACh in cortex (Becker and Giacobini, 1988). We have modified the HPLC-ECD method for acetylcholine (ACh) to detect femtomole levels of ACh in microdialysates from rat frontal cortex without using a ChEI in the probe to elevate ACh levels. Using this methodology we have compared the effects of two first generation ChEI, physostigmine (PHY) and tetrahydroaminoacridine (THA) and two second generation ChEI, heptyl-physostigmine (HEP) and MDL 73,745, in increasing and maintaining cortical extracellular ACh levels in the rat. Dissimilar magnitudes of ChEI and effects on ACh levels were seen. Although all four ChEI are capable to significantly raise cortical ACh levels, the effects of HEP and MDL 73,745 on ACh are more long-lasting and are associated to less cholinergic side effects than PHY and THA at doses producing comparable AChE inhibition. It appears that ChE activity inhibition is not the sole determinant of extracellular ACh levels and cholinergic side effects. Physostigmine or HEP elicited the same maximal effect on ACh levels in the dialysate, however, ChE inhibition differed markedly between the two. This may reflect differences in the pharmacological profiles of these ChEI. Therefore, measurement of ChE inhibition as currently used is not sufficient to predict effects on extracellular cerebral ACh levels. Additional factors may influence this relationship and identification of these factors may improve prediction of therapeutic efficacy of ChEI treatment in AD. (Supported in part by NIA Core Grant #P30 AG08014). REFERENCE: Becker, R. and E. Giacobini, Mechanisms of cholinesterase inhibition in senile dementia of the Alzheimer type: clinical, pharmacological and therapeutic aspects. Drug Dev. Res. 12:163-195, 1988.

STANDARDS FOR ACETYLCHOLINESTERASE HISTOCHEMISTRY PERMIT QUANTIFICATION OF ENZYME IN TISSUE SECTIONS USING COMPUTER AIDED DENSITOMETRY. B. W. Fenton*, M. B. Moss, D. L. Rosene. Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA, 02118.

Acetyl cholinesterase (AChE) histochemistry is an important method for determining the distribution of cholinergic nerve terminals, but is impractical for quantification of AChE in regions unavailable for dissection and biochemical assay, such as the subfields of the hippocampus. We have developed a series of AChE standards that can be verified biochemically and used to calibrate the optical density of AChE reaction product in tissue sections. Membrane bound AChE (EC 3.1.1.7 Sigma) was extracted using Triton X100 and tolulene, suspended in a gelatin solution which was then frozen in isopentane, cut on a cryostat at 15 µm and processed histochemically by the method of Tago along with 15 µm fresh frozen brain sections. The concentration of AChE in the standards was determined by ^{14}C-acetylcholine degradation (measured as µmol ACh degraded /min /gram at 37°C and pH 8). The variability of optical density in different slides of the standards was less than 7%, indicating uniform distribution of the enzyme. The relationship of optical density to the biochemically determined AChE concentrations in the standards was best fit by a linear model ($p<0.01$). Optical density of standards is also linearly related ($p<0.05$) to duration of histochemical incubation. Measurements of hippocampal sections calibrated to standards provided results that are within 10% of previously reported radiochemical measurements. Using standards to calibrate optical density, AChE concentration was determined in 25 hippocampal subfields of normal adult rats. Highest concentrations of AChE were found in the pyramidal layers of Ammon's horn (13 to 11 units of AChE) and the infragranular region of the dentate gyrus (11 units), while stratum radiatum contained the lowest concentrations (3.7 to 5.2 units). The ability to detect subtle quantitative changes can help refine knowledge of the hippocampus, which may have several smaller routes of cholinergic innervation other than the fornix. 630.9

DISTRIBUTION OF BUTYRYLCHOLINESTERASE IN THE RAT BRAIN. S. Darvesh, A.J. Smereczynsky and D.A. Hopkins*. Department of Anatomy and Neurobiology, Dalhousie University, Halifax, N.S. Canada B3H 4H7.

Butyrylcholinesterase (BuChE, EC 3.1.1.8) has a widespread distribution not only in brain blood vessels and glia but also in neurons and neuropil of selected regions of the central nervous system (Friede, 1967). The function of this enzyme in neurotransmission is unknown but BuChE has been implicated in neural development, neuropathology and drug metabolism. The distribution of BuChE in the rat was mapped following standard histochemical methods and compared with the distribution of cholinergic neurons. BuChE is co-localized with some but not all cholinergic neurons and is found in distinct populations of non-cholinergic neurons. Similar relationships were seen for neuropil staining. In the medulla oblongata, BuChE staining was prominent in some but not all motoneurons, the subnucleus interpolaris of spinal V, medial reticular formation and parts of the vestibular complex. In the pons, BuChE was concentrated in the caudal cholinergic cell column and reticular formation. In the mesencephalon, the enzyme was present in parasympathetic motoneurons and the neuropil of the interpeduncular nucleus and superior colliculus. Several thalamic nuclei were heavily stained as were parts of the basal forebrain. Sporadic neurons of the neocortex were intensely stained as was the neuropil of the cingulate cortex. A detailed map of BuChE distribution in the rat brain will provide a guide for investigations into possible neural functions of this enzyme. Supported by MRC (MT-7369) and the Scottish Rite Charitable Foundation of Canada.

630.10

REACTIVATION OF TABUN-INHIBITED AChE BY BISQUATERNARY OXIMES, RELATED TO PYRIDOSTIGMINE PRETREATMENT. G. Amitai, I. Rabinovitz, G. Cohen, G. Zomber, R. Adani and L. Raveh, IIBR, P.O.Box 19, 70450 Ness Ziona, Israel.

Certain oximes such as toxogonin and HI-6 together with anticholinergics serve as antidotes against poisoning by organophosphates. Pretreatment with pyridostigmine (PYR) increases their protection ratio (PR). We have studied the reactivation of tabun-inhibited FBS-AChE elicited by toxogonin, HLö-7, AB-13, HI-6 and AB-8. The bimolecular rate constants for reactivation obtained for toxogonin, HLö-7 and AB- 13 were: 157, 18.7 and 12.5 $M^{-1} min^{-1}$, respectively, whereas AB-8 and HI-6 showed low reactivation potency. The reactivation data correlated well with the PR values obtained in conjunction with atropine and benactyzine in mice and guinea pigs following tabun poisoning. When PYR was added as a pretreatment the PR values markedly increased (e.g. in guinea pigs, HI-6 from 3.8 to 50 and AB-8 from 3.3 to 45.8) but could not be correlated to the reactivation data. Reactivation of PYR-inhibited FBS-AChE displayed similar kinetics for HI-6, HLö-7 and toxogonin ($t_{1/2}$=15-30 min) whereas the rate obtained for AB-8 and AB-13 was equal to spontaneous reactivation ($t_{1/2}$=60 min). Thus, it seems that the antidotal efficacy against tabun with PYR pretreatment can not be related only to the reactivation rate of carbamoyl-AChE. It is conceivable that different conformational changes occur upon formation of ternary binding complexes comprised of PYR-AChE-oxime.

630.11

THE EFFECT OF NORPYRIDOSTIGMINE (3-PYRIDINOL DIMETHYLCARBAMATE), ON ACh AND AChE IN THE RAT BRAIN. M.E. Bach*, A.B. Naini, L.J. Côté, S. Ginsburg, J.L. Bach[2] & M.Sano. Dept. of Neur., College of P& S, Columbia Univ., NY, NY 10032 & [2]Ciba-Geigy Co., Summit, NJ

Norpyridostigmine, is a new centrally active, reversible acetylcholinesterase (AChE) inhibitor. Norpyridostigmine is a derivative of pyridostigmine, the latter does not cross the blood-brain barrier. We assessed the effectiveness of Norpyridostigmine, on the level of acetylcholine (ACh) and the activity of AChE in rat brain. ACh and AChE were measured following an injection (i.p.) of Norpyridostigmine tosylate (30mg/kg). Control rats received a saline injection. ACh levels were measured across five time intervals (15-180 min) following injection. Rats were killed with a focused microwave apparatus, to instantly denature AChE. A HPLC-EC technique, with an immobolized enzyme column (Bioanalytical Systems, Inc.), was used to measure the level of ACh. AChE activity was measured across four time intervals (15-120min), using a radioenzyme assay. ACh was increased by almost 50% at 20 min, and was still above control at 3 hr. AChE activity was decreased by almost 70% at 30 min, and was still inhibited by 37% at 120 min. Norpyridostigmine effectively inhibits the breakdown of ACh by AChE for several hours. Behavioral studies done in our laboratory, demonstrated that Norpyridostigmine attenuated the learning and memory deficit produced by a lesion in the nucleus basalis magnocellularis in the rat. In Alzheimer's disease (AD), a profound cholinergic deficit exists, which has been linked to the memory impairment associated with the disease. Our data suggests that Norpyridostigmine might be useful in the treatment of AD.

631.1

NICOTINIC RECEPTOR SUBUNIT EXPRESSION AND FUNCTIONAL BLOCK BY ANTISENSE IN CHICK CNS NEURONS X. Yang, A. Brussaard, J. Doyle, D. Colman* & L. Role. Anat. & Cell Biol. & Ctr for Neurobiol. & Behav., Columbia Univ., P&S, 630 W.168 St. NY,NY 10032

Previous studies on peripheral neurons reveal important developmental changes in nAChRs (Moss et al., *Neuron* 3:597,1989; see abstract Devay & Role, this volume) leading us to test for similar regulation of AChR channel expression in the chick CNS. AChR subunit gene expression in the habenular complex of ED11 chick embryos was initially assessed by the PCR technique. We observed cDNA dependent PCR products in reactions which contained synthetic oligonucleotide primers specific for α3, α4, α5, α8, β2 and β4 AChR subunit genes. By Southern blot and/or restriction digestion maps, we have confirmed the identity of these amplified fragments. Examination of the expression of other subunits is underway.

In biophysical studies we have investigated the role of expressed AChR α subunit genes in AChR channel function. Four classes of nicotine-gated channels are seen in chick habenular neurons, all of which are blocked by neuronal bungarotoxin. Treatment of the neurons with a specific antisense oligonucleotide to the α4 start sequence (Listerud et al *Science*:254:1518,1991) selectively deletes the smallest conductance channel. Both the developmental profile of AChR subunit expression and developmental changes in the functional role of individual subunits will be evaluated. (Funding: NS29071 & Council for Tobacco Research).

631.2

REGULATION OF nAChR SUBUNIT EXPRESSION IN CHICK LUMBAR SYMPATHETIC GANGLIA DURING EMBRYOGENESIS. P. Devay*, X. Qu, S. Peng and L. Role. Dept. of Anat. and Cell Biol. & Cntr. for Neurobiol. & Behav., Columbia Univ., P&S, NY, NY 10032

The biophysical properties and distribution of ACh-activated channels (AChRs) in chick lumbar sympathetic neurons change during embryonic development (Moss et al Neuron 3: 597, 1989). To examine the relative role of presynaptic input vs target contact in the regulation of AChR expression, we have studied the time course of establishment of both pre and postsynaptic contacts concurrent with changes in AChR subunit expression.

Following injection of DiI into the sympathetic chain we could detect anterogradely labelled sympathetic nerve endings in some target tissues (skin, renal capsule) as early as embryonic day (ED)10. At the time of these first contacts with target <5% of the sympathetic neurons have received presynaptic input (as indicated by their being surrounded by fluorescent boutons following injection of DiI into the region of the preganglionic nucleus). Examination of the array of AChR subunit genes expressed by the lumbar sympathetic neurons during embryogenesis reveals that α3, α4, α5, α7, β2 and β4 are detected at stages both before and after synaptogenesisRNase protection assay reveals increases in the level of expression of specific nAChR subunit mRNAs over the same period of development. The relative role of presynaptic input vs target contact in AChR subunit expression and AChR channel function will be examined *in vitro*. Funding: NIH (NS29071) & Council forTobacco Research.

631.3

ANTISENSE OLIGONUCLEOTIDE UPTAKE INTO NEURONS C. Yu, X. Yang, & L. Role*. Dept. of Anat. & Cell Biol. in the Ctr for Neurobiol. and Behav., Columbia Univ., P & S, 630 W. 168 St. New York, NY 10032

Previous work using antisense oligonucleotides to selectively delete individual AChR subunits have revealed distinct functional contributions of the α3, α4 and α7 subunits to the AChRs in peripheral and central neurons (Listerud et al, *Science* 254:1518,1991; Yang et al., abstract this volume). To further characterize the mechanism of antisense oligonucleotide block of AChR subunit gene expression, we are examining the mechanism of oligonucleotide uptake. Our initial studies examine the stability and time course of oligonucleotide uptake into primary neurons.

Antisense oligonucleotides (15 bases) were added directly to the bathing medium of dispersed sympathetic neurons and uptake was measured within 3-48 hrs. Intact 15mer can be detected in the neurons within 6 hrs and the uptake plateaus within 24 hrs. After 48 hrs, the time at which functional block of AChR channels was assayed, the oligonucleotide can still be detected in the neurons as intact 15mer. Unmodified 15mers are detectably degraded within 3 hours in normal culture media containing heat inactivated horse serum and 5% chicken embryo extract (CEE). Heat inactivation of the CEE decreased the degradation rate by 2-5 fold. Comparison of the time course and pharmacology of the neuronal uptake of oligonucleotides with that previously described in non-neuronal cells suggest the transport systems might be quite similar. Funding: NIH(NS29071) & Council for Tobacco Research.

631.4

THE α5 GENE PRODUCT ASSEMBLES WITH MULTIPLE ACETYCHOLINE RECEPTOR SUBUNITS TO FORM DISTINCTIVE NEURONAL RECEPTOR SUBTYPES *IN VIVO*. **W.G. Conroy, A.B. Vernallis, and D.K. Berg*, Dept. of Biology, UC San Diego; La Jolla, CA 92093.**

The acetylcholine receptor (AChR) α5 gene has been classified as a member of the AChR gene family based on sequence homology, but expression studies have yet to confirm a function for the encoded protein. We find that the α5 gene product is identical to a 49 kD protein that co-purifies with AChRs from brain and ciliary ganglia. It combines with several combinations of AChR subunits.

The 49 kD protein was identified as the α5 gene product by showing that the protein shares three epitopes associated with the α5 gene product translated *in vitro*. The epitopes were absent from all other neuronal AChR gene products tested (six). Immunoprecipitation experiments with subunit-specific monoclonal antibodies indicated that in ciliary ganglia much of the α5 gene product is co-assembled with α3 and β4 subunits together, but not with α4 subunits. In brain the α5 gene product was found associated with α4 subunits, with α3 subunits, and, to a small extent, with both together. No α5 was found associated with α7 or α8 subunits. Other AChR gene products have yet to be tested for co-assembly with α5. The results show that neuronal AChRs can have as many as three kinds of subunits with at least two being of the α-type. (NS 12601 & 25916)

631.5

COORDINATE EXPRESSION OF ACH RECEPTOR GENES DURING DEVELOPMENT IN CILIARY GANGLIA. **R.A. Corriveau* and D.K. Berg. Dept. of Biology, University of California, San Diego; La Jolla, CA 92093.**

Chick ciliary ganglion neurons have at least two classes of nicotinic acetylcholine receptors (AChRs). One class is largely synaptic in location, generates nicotinic responses mediating synaptic transmission, and contains the AChR gene products α3, β4, and α5. The other class is 5- to 10-fold more abundant, is located primarily in non-synaptic membrane, and increases intracellular calcium when activated. It contains the AChR α7 gene product. Other possible AChR gene products have yet to be identified. The known AChRs increase 12- and 6-fold, respectively, per neuron between embryonic days 8 (E8) and 17-19 (E17-19).

Quantitative RNAase protection experiments showed that E17-19 ganglia contain moderate mRNA levels from AChR genes α3, α5, α7, β2, and β4. α7 transcripts are most abundant (ca. 2000 copies/neuron) and β2 least abundant (ca. 150 copies/neuron). In each case transcript number per neuron increases 4- to 8-fold between E8 and E17-19. Northern blot analysis detected no differences in transcript sizes between E8 and E17-19. mRNAs from several other AChR genes were either undetectable or present in only trace amounts. The proportionality between transcript levels and receptor number suggests that during development receptor mRNA may, in part, be rate-limiting for AChR accumulation in the ganglion. (NS 12601 & 25916)

MUSCLE MEMBRANE BUT NOT FORSKOLIN RESTORES ACh SENSITIVITY TO CULTURED CILIARY GANGLION CELLS.

J.M. Spitsbergen* and J.B. Tuttle, Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908.

Ciliary ganglion neurons cultured in the absence of muscle cells rapidly lose sensitivity to ACh, while cultures grown with muscle or muscle cell membranes maintain sensitivity to ACh for extended periods of time. The present study asked whether sensitivity to ACh could be restored to cultured neurons, by addition of muscle cell membranes or stimulation of adenylate cyclase with forskolin, once sensitivity had been lost. Ciliary ganglion neurons from 11-13 day old chick embryos were grown on collagen coated substrate in the absence of muscle cells. Sensitivity to ACh was assessed by measuring current responses following application of 100 μM ACh to neurons under whole-cell voltage clamp. ACh induced currents decreased from peak values of 646±37 pA the day of plating to 116±11 pA after 4 days in culture. Exposure of cultures to forskolin (1 μM) and IBMX (1 mM), soon after plating, had a variable effect on peak ACh currents, increasing currents in some cells, while having no effect on current amplitude in others. However, by 3 to 4 days postplating forskolin and IBMX had no effect on currents induced by ACh. Exposure of neurons to muscle membranes for 24 hours increased ACh induced currents from 128±45 pA on day 3 in culture to 427±46 pA on day 4. In conclusion, growth of ciliary ganglion neurons in the absence of muscle leads to a decrease in ACh sensitivity within 3-4 days. At this time forskolin and IBMX have no effect on the amplitude of ACh induced currents, yet they still increase cyclic AMP levels. Conversely, exposure of ciliary ganglion neurons to muscle membranes, the normal target of these neurons, restores ACh responsiveness.

631.7

BOTH INNERVATION AND TARGET TISSUE INTERACTIONS REGULATE ACETYLCHOLINE RECEPTOR TRANSCRIPT LEVELS IN DEVELOPING NEURONS. M. Schwartz Levey*, C. Brumwell and M.H. Jacob. Worcester Fnd. for Exp. Biol., Shrewsbury, MA 01545.

Innervation regulates nicotinic acetylcholine receptor (nAChR) protein and mRNA levels in muscle. In developing motoneurons, innervation as well as intrinsic factors and retrograde signals from the target tissue may be important regulatory influences. To establish the role of cell-cell interactions in inducing nAChR expression in chick ciliary ganglion motoneurons *in situ*, we have surgically removed the preganglionic nucleus (at ED 3.5-4) or the target tissue (the eye, at ED 2) prior to synapse formation. Ganglia were sampled at ED 8. Previous studies have demonstrated that ciliary ganglion neurons develop normally in the absence of inputs or target tissue interactions up to ED 9.

Alpha3 and $\beta 4$ mRNA levels were quantitated using RT-PCR and mutated internal standards. In input-deprived ganglia, both $\alpha 3$ and $\beta 4$ mRNA levels are reduced 30% as compared to control ganglion values at ED 8. Target tissue-deprived ganglia have 20% lower $\alpha 3$ and $\beta 4$ mRNA levels relative to control ganglia. In comparison, ganglia deprived of both the source of inputs and the target tissue have even greater reductions in $\alpha 3$ and $\beta 4$ mRNA levels, exhibiting 80% declines relative to controls. Qualitatively similar changes were observed in internal nAChR levels by labeling frozen sections of operated and control ganglia with an anti-AChR mAb. The results demonstrate that both presynaptic input and retrograde signals from the target tissue regulate nAChR protein and mRNA levels in developing neurons. Supported by NIH NS 21725, the Pfeiffer Fnd. and MDA.

631.8

NICOTINIC NEURONAL ACETYLCHOLINE RECEPTOR α-3 SUBUNIT TRANSCRIPTION IN NORMAL THYMUS, MYASTHENIC HYPERTROPHIC THYMUS AND THYMOMA. M. Mihovilovic*, C. Hulette, J. Mittlestaedt and A.D. Roses. Dept. of Medicine/Neurology, Duke Univ. Med. Ctr., Durham, NC 27710.

A putative thymic nicotinic neuronal acetylcholine receptor (AcChR) may serve as modulator or transducer of signals delivered to the thymus through the autonomic nervous system. To investigate this hypothesis we are studying the relationship that may exist between the transcript expression of the AcChR α-3 subunit and thymic compartamentalization. Thymic tissues from normals and Myasthenia gravis (MG) patients have been studied.

Transcripts encoding both normal and variant forms of the α-3 subunit of an AcChR are expressed in thymic tissues. Normal and MG hypertrophic thymi express equivvalent levels of both normal and variant α-3 transcripts. On the other hand, thymomas express reduced levels of α-3 subunit transcripts. Histological examination of thymomas indicates that the reduction of the transcriptional level for this subunit is associated with expansion of the thymic epithelia. Trace amounts of α-3 transcripts have been found in a thymoma that upon histological examination has remnants of thymic tissue and large areas of fibrosis. Overall, these findings indicate that the disruption of the thymic cortical and medullary compartments is associated with a decrease in the level of AcChR α-3 subunit transcripts.

631.9

THE RAT $\alpha 7$ SUBUNIT ENCODES A NICOTINIC ION CHANNEL HIGHLY PERMEABLE TO CALCIUM. P. Séguéla, J. Wadiche, K. Miller, A.C.S. Costa#*, J. A. Dani# and J. W. Patrick. Division of Neuroscience, #Department of Molecular Physiology & Biophysics, Baylor College of Medicine, Houston TX 77030.

We isolated a full-length clone coding for the rat neuronal nicotinic receptor $\alpha 7$ subunit and tested its pharmacological and functional properties in the *Xenopus* oocyte expression system. Homo-oligomeric $\alpha 7$ nicotinic receptors displayed a characteristic profile of sensitivity to agonists (nicotine > cytisine > DMPP > acetylcholine) and antagonists (α-BTX> D-tubocurarine= strychnine). Permeability of $\alpha 7$ channels to Ca^{++} ions was suggested by a dramatic decrease of nicotine-induced current after specific blockade of the endogeneous Ca^{++}-activated chloride channels with niflumic acid and flufenamic acid. In the presence of high external Cl^-, application of agonist produces an inward current followed by an outward current sensitive to Cl^- channels blockers. We compared the reversal potential shift of the ligand-induced current in 1mM vs 10 mM external Ca^{++} under conditions where Cl^- currents are minimal. We measured a +25-30 mV shift, larger than previously reported for muscle and neuronal nicotinic receptors. We conclude that the $\alpha 7$ receptors are highly permeable to Ca^{++}, with an apparent ratio pCa/pNa comparable to the one of the NMDA subtype of glutamate receptor. The functional properties and the expression pattern of this subunit in the rat brain suggest that $\alpha 7$-containing acetylcholine-gated channels play a significant role in triggering post-synaptic Ca^{++}-mediated events in the limbic system in general and in the hippocampus in particular. Supported by NINDS, NIDA, NIH and DOD.

631.10

CHOLINERGIC STIMULATION AND CATION INFLUX INDUCE A DIFFERENTIAL PATTERN OF IMMEDIATE EARLY GENE EXPRESSION IN MUSCLE CELLS. S. Abu-Shakra*, R.N. Adams, A.J. Cole and D.B. Drachman. Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205

Muscle acetylcholine receptor (AChR) synthesis is closely regulated by the state of neuromuscular activity. Denervation causes an increase in AChR subunit gene expression, while direct electrical stimulation of muscle down regulates AChR subunits. We have previously shown that carbachol (a cholinergic agonist) decreases AChR α-subunit message levels in primary rat muscle cultures at 24 hours post-treatment. However, the early genomic regulatory events induced by cholinergic treatment are unknown. Immediate early genes (IEGs), that encode transcription factors and are induced rapidly after cell surface stimulation, are candidates for such a role. We studied the expression of 4 IEGs (zif268, c-jun, nur77 and junB) in the mouse skeletal muscle cell line - C2 - which normally fuses and expresses AChRs. Treatment of C2 mouse skeletal muscle cells with carbachol induces increased zif268, c-jun and nur77 mRNA levels, while junB message levels showed no consistent change. The mRNA levels were increased at 1 hour, peaked at 3 hours, and were back to basal levels by 6 hours. This effect was blocked by α-bungarotoxin pre-treatment. In addition, A23187 and Veratridine, which cause an influx of Ca^{+2} and Na^+ ions respectively, induced a similar pattern of IEG expression. This suggests a role for IEG expression in regulating skeletal muscle properties in response to neuromuscular activity.

Cyclophilin-mediated Prolyl Peptidyl Isomerization Modulates the Expression of the $\alpha 7$ Homo-oligomeric Neuronal nAChR in *Xenopus* Oocytes. Santosh A. Helekar* and Jim Patrick, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

One of the noteworthy features of the primary structure of oligomeric cell surface receptor subunits is the presence of a number of highly conserved proline residues. Since prolyl peptide bonds undergo cis-trans isomerization by an enzyme-mediated mechanism we tested the possibility that this mechanism might play a role in the synthesis and function of the nicotinic acetylcholine receptor (nAChR), using as a model the rat $\alpha 7$ homo-oligomeric receptor. Subunit cDNA subcloned into pcDNA plasmid vectors was intranuclearly injected into *Xenopus* oocytes and receptor expression was assayed on the 4th - 6th day following injection by recording acetylcholine- (ACh) and nicotine- (NIC) induced currents under two-electrode voltage-clamp. Incubation of the injected oocytes in Barth's saline containing cyclosporine (1 - 30 μM, CSP), a selective blocker of one class of prolyl isomerases, namely cyclophilins (CPH), showed a dose-dependent reduction in the expression of nAChRs. Short-term (1 - 2 hours) incubation in CSP did not block agonist-induced responses in control oocytes. CSP did not appear to nonspecifically block translation or transcription of plasmid DNA since injection of β-galactosidase (β-gal) cDNA-containing vectors resulted in normal levels of β-gal activity in the presence of this agent. Finally, the blockade of $\alpha 7$ receptor expression by 30 μM CSP was reversed by co-expression of CPH cDNA, indicating that CSP is likely to be acting specifically through its blockade of CPH activity. Furthermore, CPH co-expression in the absence of CSP produced greater than 90 % reduction in the expression of the receptor. These findings indicate that post-translational CPH-mediated isomerization of prolyl peptide bonds may be critically involved in the functional expression of the homo-oligomeric nAChR.

A ROLE FOR THE α-BUNGAROTOXIN/THYMOPOIETIN RECEPTOR IN NEURITE OUTGROWTH IN PC12 CELLS. J.Chan*, G.Goldstein, and M.Quik. Dept. Pharmacol., McGill U., Montreal, Can. and Immunobiol. Res. Inst., NJ, U.S.A.

The function of the neuronal nicotinic α-bungarotoxin (α-BGT) receptor is currently unclear however the α-toxin site has been implicated in growth related activities. Present studies show that nicotine (10^{-5} M and 10^{-4} M) decreased nerve growth factor induced neuritic outgrowth in PC12 cells in culture. This effect was observed as early as 1 day after exposure to the agonist and persisted for at least 7 days. Interestingly, α-BGT, at $3x10^{-8}$ M and 10^{-8} M, was able to prevent the decrease in process formation which occurred after nicotine exposure. These concentrations of the α-toxin correlated very well with those which resulted in a block of ^{125}I-α-BGT binding to PC12 cells. Thymopoietin (10^{-8} M), a thymic polypeptide, which interacts potently and specifically at the α-toxin site, also prevented the nicotine induced decline in process formation; again the concentration required to affect process outgrowth correlated well with that required to inhibit ^{125}I-α-BGT binding. Cell numbers were not altered after exposure to any of these agents, thus alterations in neurite outgrowth were not due to changes in cell proliferation. The effect of thymopoietin was also tested on nicotinic receptor mediated neurotransmitter release; no change was observed indicating that thymopoietin specifically affects the nicotinic α-BGT receptor population. The present results suggest a functional role for the neuronal nicotinic α-BGT receptor in regulating neurite outgrowth and for thymopoietin as an endogenous ligand with such a role at the α-BGT site. COMPARISON OF A VERTEBRATE AND AN INVERTEBRATE HOMO-OLIGOMERIC NICOTINIC ACETYLCHOLINE RECEPTOR. P Thomas, M Amar, M Goosey[1], S Wonnacott* and G G Lunt. Dept of Biochem, Univ of Bath, Bath, UK and [1]Shell Research Ltd, Sittingbourne, Kent.

A vertebrate α-bungarotoxin (αBgt)-sensitive nicotinic acetylcholine receptor (nAChR) subunit, α7, has been cloned and forms homo-oligomeric channels when expressed in Xenopus oocytes[1]. Expression of an analogous receptor subunit from a locust, ARL2, also results in functional homo-oligomeric channels sensitive to αBgt[2]. We have compared the properties of these two putative nAChR using cDNA expression in oocytes. In both cases, agonist-evoked current (V_H = -70 mV) for (-)nicotine, acetylcholine and cytisine produced sigmoid relationships between current amplitude and agonist concentration. α7 was much more sensitive to (-)nicotine than ARL2. Strong inward rectification of the current-voltage relationship was evident in both cases. Whereas α7 channels activate and desensitize rapidly over approx 2s, ARL2 activates slowly and shows no desensitization in the presence of agonist for 45s. Both types of channel are irreversibly blocked by α-cobratoxin and reversibly by methyllycaconitine. These expressed subunits allow direct comparison of the specific, activating pharmacophore of each receptor, using families of semi-rigid ligands including cytisine, anatoxin and piperazine-based compounds.

EXTERNAL Ca^{2+} POTENTLY ENHANCES NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR CURRENTS. Mariano Amador and John A. Dani*. Division of Neurosci., and Dept. of Molecu. Physiol. & Biop., Baylor College of Medicine, Houston, TX 77030.

Recently, we found that some subtypes of neuronal nicotinic acetylcholine receptors (NnAChRs) are highly permeable to Ca^{2+} and are modulated by external Ca^{2+} (Vernino et al., 1992 Neuron 8:127). As the external concentration of Ca^{2+} is increased, whole-cell currents through muscle nAChRs decrease but currents through neuronal nAChRs increase. As the external Ca^{2+} is decreased, whole-cell neuronal nAChR currents decrease, but small currents are still seen in Ca^{2+}-free solutions.

Patch-clamp studies of chromaffine cells indicate that Ca^{2+} acts externally on the NnAChRs rather than activating an intracellular enzyme cascade. Ca^{2+} enhancement of NnAChR currents is very rapid, is reversible and repeatable in cells internally perfused with 20 mM BAPTA, does not require exogenous enzymes or a source of phosphate, is not voltage dependent, and is seen in cell-free patches of membrane. In addition, the amplitude of the single-channel currents decreases (not increases) as external Ca^{2+} is increased. These results suggest that an influx of Ca^{2+} is not required to observe the enhancement of agonist-induced NnAChR responses.

Activity-dependent fluctuations in extracellular Ca^{2+} have been reported throughout the central nervous system, and the Ca^{2+}-dependent modulation of NnAChRs occurs over a range that includes physiologic levels of Ca^{2+}. Therefore, activity-dependent changes in the concentration of external Ca^{2+} could alter NnAChR responses and thereby influence the efficacy of neuronal nicotinic synapses.

REGIONS OF THE β SUBUNIT OF THE NEURONAL NICOTINIC RECEPTOR AFFECTING AGONIST SELECTIVITY. A. FIGL, B. N. COHEN, M. W. QUICK, X.-C. YANG*, AND H. A. LESTER, Division of Biology 156-29, Caltech, Pasadena, CA 91125.

To identify regions of the β subunit that influence the pharmacological selectivity of neuronal nicotinic receptors we constructed chimeras of the β2 and β4 subunits and expressed them with the α3 subunit in *Xenopus* oocytes. Peak macroscopic currents elicited by 30 μM acetylcholine (ACh), cytisine (CYT), nicotine (NIC), and 100 μM tetramethylammonium (TMA) were measured using a two-electrode voltage clamp. For the α3β2 wild-type receptor, the relative amplitudes of the CYT, NIC, and TMA responses compared to ACh were 0.02 ± 0.01 (3) [mean ± sd (n)], 0.3 ± 0.2 (2), and 0.6 ± 0.1 (5). For the α3β4 wild-type, the relative responses were 2.6 ± 0.2 (5), 1.3 ± 0.2 (3), and 1.8 ± 0.5 (3). The external regions of β2 and β4 (N-terminal to M1) account for almost all of the effect of the β subunits on selectivity. For TMA, chimeras with the first 109 or fewer amino acids from β4 and the remainder from β2 showed β2-like sensitivity. Chimeras with the first 111 or more amino acids from β4 showed β4-like sensitivity. For CYT, chimeras with the first 92 or fewer amino acids from β4 showed β2-like sensitivity, although there was an increase in the relative response for chimeras with ≥ the first 20 residues of β4. Chimeras with the first 109 or more amino acids from β4 behaved as the β4 wild-type. There was no distinct region that accounted for NIC sensitivity. The results show that the 109-111 region accounts for most of the difference in TMA sensitivity, the 92-109 region accounts for most of the difference in CYT sensitivity, and that no single region of the external portion of the β subunit accounts for the difference in NIC sensitivity. (Support: NS-11756, Ca. TRDRP, MDA)

631.16

SUBTYPES OF THE β SUBUNIT CONFER DIFFERENT ANTAGONIST SENSITIVITIES ON NEURONAL NICOTINIC RECEPTORS. B. N. COHEN, A. FIGL, M. W. QUICK, A. T. ISHIDA*, AND H. A. LESTER, Division of Biology 156-29, Caltech, Pasadena, CA 91125.

The β subunit partially determines the agonist sensitivity of neuronal nicotinic receptors. To determine if the β subunit also affects antagonist sensitivity, we examined block of the α3β2 and α3β4 receptors expressed in *Xenopus* oocytes by hexamethonium (HEX), mecamylamine (MEC), and trimethaphan (TRI). The oocytes were voltage clamped at potentials of -80 to -60 mV in a solution containing 98 mM NaCl, 1 mM $MgCl_2$, and 5 mM HEPES (pH 7.4). All antagonists inhibited α3β4 better than α3β2. HEX (30 μM) blocked 25 ± 25% (6) [mean ± sd (n)] of the α3β2 response to 30 μM acetylcholine (ACh) and 96 ± 3% (6) of the α3β4 response. The IC50 for HEX was 1.4 μM for α3β4 and 30 μM for α3β2 at 30 μM ACh. Raising [ACh] from 30 to 60 μM relieved the block of both receptors by 10 μM HEX suggesting that HEX competes with ACh binding. MEC (30 μM) blocked 94% of the α3β4 response to 60 μM ACh but had little effect on the α3β2 response. TRI (10 μM) blocked 87% of the α3β4 response to 30 μM ACh but hardly affected the α3β2 response. Block of α3β4 by 10 μM TRI was independent of [ACh] from 30-300 μM suggesting either that TRI binds with high affinity to α3β4 or that it blocks noncompetitively. TRI (10 μM) blocked 35-51% of the 30 μM ACh response from receptors formed from α3 and a chimeric subunit containing ≤ 114 N-terminal residues from β4 and the remaining C-terminal residues from β2; but, TRI blocked 90% of ACh response of a chimeric receptor with 120 N-terminal residues from β4. These results show that the β subunit of neuronal nicotinic receptors affects antagonist sensitivity and that positions 114-120 in β4 play a role in TRI antagonism. (Support: NS-11756, Ca. TRDRP, MDA)

GENE TRANSCRIPTS FOR THE nAChR SUBUNIT, B4, ARE DISTRIBUTED IN MULTIPLE AREAS OF THE RAT CNS. K. Dineley-Miller, S. B. Sands* and J. Patrick, Division of Neuroscience, Baylor College of Medicine, Houston TX 77030.

Previous *in situ* hybridization experiments found that beta4 (β4) neuronal nicotinic acetylcholine receptor (nAChR) transcripts were found only in the medial habenula (MHB). Co-expression in *Xenopus* oocytes of the β4 subunit and any one of three ligand-binding or alpha subunits results in the formation of functional nAChR's. Comparisons between the pharmacology of nAChR's expressed in oocytes and the pharmacology of nAChR's found in the rat CNS prompted a further investigation of the localization of transcripts encoding the β4 nAChR subunit. Using two β4-specific cRNA probes, *in situ* hybridization was performed in rat brain. β4 mRNA was detected at high levels in the presubiculum, parasubiculum, subiculum and dentate gyrus of the hippocampal formation, in layer IV of the isocortex, in the medial habenula, in the interpeduncular nucleus, and in the oculomotor and trigeminal motor nerve nuclei. Moderate hybridization signals were seen in the isocortex (layers I-III), in olfactory regions, in fields CA1 through CA4 of Ammon's horn and the entorhinal cortex of the hippocampal formation, in the supramammillary nucleus, in the pontine nucleus, in the cerebellum, and in the locus coeruleus. No hybridization above background was detected in the septum, basal ganglia, sensory portions of the brainstem, or spinal cord.

SUBUNIT SPECIFIC ANTISERA PREPARED AGAINST NEURONAL nAChR's. K. Dineley-Miller, S. E. Neff, D. Char, and J. Patrick*, Division of Neuroscience, Baylor College of Medicine, Houston TX 77030.

The nicotinic acetylcholine receptor (nAChR) gene family includes, to date, ten genes whose transcripts are found in a variety of central and peripheral nervous system structures. Molecular cloning has allowed the expression and study of these receptors *in vitro* but elucidation of receptor composition and localization in rat brain has been hampered by a lack of biochemical probes specific for the extracellular domain of the native form of each subunit.

Our strategy for preparing polyclonal antisera selective for seven of these highly related proteins consisted of 1) immunizing rabbits with bacterially expressed recombinant protein representing the N-terminal extracellular region of each nAChR subunit; 2) affinity purification of antibodies against a synthetic peptide prepared for each subunit in the region corresponding to amino acid residues 69-83 of the alpha (α1) subunit of the muscle nAChR (this portion of the α1 subunit is within the main immunogenic region recognized by antibodies of myasthenia gravis patients); 3) subtracting cross-reactive antibodies by adsorbing against recombinant protein of homologous subunits.

Subunit specificity of antisera have been evaluated by immunoblot of recombinant protein, immunohistochemistry, and affinity purification of receptor subunits from expressed in *Xenopus* oocytes rat brain.

LESSER RECTIFICATION OF THE NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) OF RAT HIPPOCAMPAL NEURONS DISTINGUISHES IT FROM OTHER NEURONAL SUBTYPES. E.X. Albuquerque* and M. Alkondon. Dept. Pharmacol. Exp. Ther., Univ. Maryland, Sch. Medicine, Baltimore, MD 21201.

Rectification is a property found in several neuronal subtypes of nAChR such that very small or no detectable outward macroscopic currents can be recorded. In the present study, we tried to characterize the extent of rectification found in the nAChR of fetal rat hippocampal neurons grown in culture (30-60 days), using the whole cell patch clamp technique. The external solution consisted of (mM): NaCl 165; KCl 5; $CaCl_2$ 2; HEPES 5; D-glucose 10 plus TTX (0.3 μM) & atropine (1μM), and the internal solution had (mM): CsCl 80; CsF 80; CsEGTA 10; HEPES 10. Several nicotinic agonists such as acetylcholine, (+)anatoxin-a, DMPP, cytisine and carbachol were used. The current-voltage plots revealed the following: i) the peak whole cell current grew with the transmembrane voltage on either direction, however, the outward currents were smaller than the inward currents at comparable potentials; ii) the ratio of the current amplitude at +50 mV to that obtained at -50 mV increased from ~0.2 at 15 min of the recording to ~0.75 during the later part of the recording (75 min or later); iii) the reversal potential derived from the linear segment between -20 and +10 mV gave values in the range of 4-7 mV; iv) addition of 2 mM Mg^{2+} to the intracellular solution abolished the outward currents to nondetectable levels. Thus, the presence of significant outward currents, and the sensitivity of the nicotinic currents to αBGT makes the nAChR of fetal rat hippocampal neurons a unique one among the different neuronal nAChR known. EXCITATORY AMINO ACIDS: RECEPTORS VIII

632.1

CALCIUM DEPENDENT DESENSITIZATION OF HIPPOCAMPAL NMDA RECEPTORS. G. Lonart* and K.M. Johnson. *Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77555-1031.*

Prolonged stimulation of NMDA receptors can lead to desensitization. In this study, NMDA stimulated fractional release of [^{3}H]-norepinephrine ([^{3}H]-NE) from cross-chopped rat hippocampal slices was utilized as a functional measure of NMDA receptor activity. In the second 5 min fraction of continuous superfusion with 100 μM NMDA, [^{3}H]-NE release reached a maximum level (6-fold increase above baseline) and then rapidly declined. The response to 3 μM ionomycin, a calcium ionophore, did not decline during the same time course. Introduction of additional NMDA (300 μM, 30 sec pulse) at the 30th min of superfusion with 100 μM NMDA had no significant effect. However, addition of 300 μM kainate under the same conditions produced a significant increase in the [^{3}H]-NE release. These observations indicate that NMDA induces a homologous desensitization and that a non-specific change in the substrates underlying vesicular release does not account for the decay in the NMDA response. Under conditions of reduced extracellular Ca^{2+}, the response to 100 μM NMDA declined with a slower rate, and subsequent stimulation with 300 μM NMDA produced a significant increase in the [^{3}H]-NE release. This suggests that the NMDA receptors are desensitized by a mechanism which is dependent upon extracellular Ca^{2+} concentration. Ongoing experiments are being carried out to test possible involvement of protein kinases and phosphatases in this paradigm. Supported by DA-02073.

632.2

THE ROLE OF EXCITATORY AMINO ACID RECEPTORS AND CALCIUM POOLS IN THE REGULATION OF NITRIC OXIDE SYNTHASE (NOS) IN CORTICAL SLICES. S. Alagarsamy*, G. Lonart and K.M. Johnson. *Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77555-1031.*

Nitric oxide (NO) is a putative, calcium-dependent, diffusible second messenger, synthesized from arginine (ARG) by NOS in the brain. Cross-chopped cortical slices (450 X 450 μm) prepared from male Sprague-Dawley rats, were washed and incubated for 60 min in modified Krebs bicarbonate buffer containing 0.3mM CaCl. Gravity packed slices (50 μl) were added to 270 μl Krebs buffer containing ^{3}H-ARG. Additions of agonists/antagonists were made in a volume of 30 μl. Activity was measured by the conversion of ^{3}H-ARG to ^{3}H-citrulline. A five minute incubation with NMDA was found to stimulate NOS in a calcium-dependent and dose-dependent manner, with a maximal effect (160% of control) at 300μM with an approximate EC 50 of 50μM. The response to NMDA was stabilized by 10μM D-serine and was therefore added routinely in subsequent experiments. The response to 300μM NMDA was completely blocked by 10μM phencyclidine, 1.2mM Mg^{++}, 10μM CGS 19755 (NMDA receptor antagonists) and 10μM nitro-arginine (an irreversible inhibitor of NOS). Raising intracellular calcium levels by addition of 50mM K^+, 10μM ionomycin, 30μM A23187 stimulated NOS activity by 250-300% of control. However, 10mM caffeine was without effect, suggesting that different calcium pools may regulate NOS. 1mM 1S,3R-ACPD (a metabotropic glutamate receptor agonist) also stimulated NOS in a dose-dependent manner, with a maximal effect (150% of control) at 1mM. 100μM NMDA enhanced the 1S,3R-ACPD response, suggesting independent mechanisms for these two glutamate receptor agonists. Ongoing experiments are being carried out to verify this, as well as to establish the role of other amino acid and monoamine receptors in the regulation of this enzyme. Supported by DA-02073.

632.3

CHARACTERIZATION OF EXCITATORY AMINO ACID STIMULATED cGMP IN CEREBELLAR SLICES.
R.J. Stumpo*, M. Britt, K.A. Paschetto, and L.M. Pullan
Pharmacology, ICI Americas, Inc., Wilmington, DE 19897

In cerebellar slices from adult male Sprague-Dawley rats, kainate, AMPA, or NMDA increase cGMP levels. Noncompetitive NMDA receptor antagonists (MK-801), glycine antagonists (7-chlorokynurenic acid), or competitive NMDA antagonists (CPP) inhibit the NMDA stimulated cGMP. At concentrations that inhibit NMDA stimulated cGMP, NMDA receptor antagonists do not inhibit the increases in cGMP with kainate. The AMPA receptor antagonist NBQX inhibits kainate stimulated cGMP but not NMDA stimulated cGMP. The response to kainate is larger than that seen with AMPA, and AMPA inhibits the response to kainate, consistent with mediation through a single receptor. Treatment with the lectin concanavalin A can increase the magnitude of cGMP increases with AMPA, while not increasing the responses to kainate. Antagonists to voltage sensitive calcium channels inhibit the increase in cGMP with NMDA, but do not inhibit the binding of the noncompetitive NMDA antagonist [3H]TCP. The results are consistent with excitatory amino acid receptors regulating guanylate cyclase in a calcium dependent manner. Kainate and AMPA seem to interact with a single receptor in this preparation.

632.4

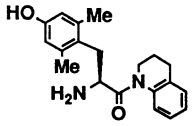
BOAA BLOCKS EXPRESSION BUT NOT INDUCTION OF LTP OF RAT MOTOR CORTEX. H. Son, N. Hori, M. Fejtl and D.O. Carpenter*. Wadsworth Laboratories and School of Public Health, Albany, NY 12201.

β-oxalylamino-L-alanine (BOAA) causes lathyrism, a human disease of upper motor neurons. BOAA is thought to be an excitatory amino acid agonist, and may act at the AMPA receptor. We have characterized long term potentiation (LTP) in rat motor cortex slices and evaluated the effects of bath perfusion of BOAA on the magnitude of the population evoked response on white matter stimulation, and on the induction and expression of LTP. Since NMDA receptors are required for LTP induction and AMPA receptors for LTP expression, our hypothesis is that if BOAA activates and desensitizes AMPA receptors on upper motor neurons, there should be a reduction in LTP expression without effect on induction. The peak of the population evoked response in motor cortex was reversibly reduced by 50% upon perfusion of BOAA at 10^{-5} M. Tetanic stimulation (TS 100 Hz, 2s) induced LTP of the population spike recorded in layer (L) II. This potentiation persisted for up to 5 hours and its induction was blocked by 10^{-5} M AP-5, when applied before TS. In L V however, the same TS induced LTP only when the normal Ringer solution was replaced with a solution containing low Mg^{2+} (0.5 mM), which should increase currents through NMDA channels. This may be due to the difference in the number of NMDA receptors within the cortical layers. The density of NMDA receptors is high in L II, whereas kainate receptors are more abundant in L V. When BOAA (10^{-5} M) was applied before, during and after TS, it did not block the induction of LTP, but did block the expression of LTP for as long as BOAA was present. Lower concentration of BOAA (10^{-6} M) had no effect on either induction or expression of LTP in L II. These data indicate that as at other sites, the induction of LTP in motor cortex requires NMDA receptor activation. BOAA blocks the expression but not the induction of LTP in a concentration-dependent manner, probably through desensitization of the AMPA receptor. Supported by NS23807.

632.5

TYROSYL AMIDES AS LIGANDS AT THE PHENCYCLIDINE RECEPTOR LOCATED ON THE NMDA-SENSITIVE GLUTAMATE SITE. B. S. Pitzele*, N. S. Chandrakumar, P. C. Contreras, S. E. Allen, M. Clare, M. A. Savage, D. L. Hammond, M. E. Nevins, S. A. Nash, P. M. Beardsley, D. Ragan, T. H. Lanthorn, Searle, 4901 Searle Pkwy, Skokie, IL 60077.

As part of an enkephalin analog program, a number of amides of (L)-2,6-dimethyltyrosine were synthesized and tested broadly. Since these compounds were superimposable on metazocine, testing included binding assays in sigma (^{3}H-PPP) and phencyclidine (^{3}H-TCP) assays. One compound, SC-48443, was found to bind potently, selectively, and competitively to the phencyclidine site. Structure-Activity data and physiological and behavioral results will be discussed.



SC-48443

INTERACTIONS OF 4-METHYLPYRAZOLE, AN ALCOHOL DEHYDROGENASE INHIBITOR, WITH SEVERAL LIGAND-GATED ION CHANNELS. M. Marchioro[1], Y. Aracava[1,2], E.S. Rocha[1,2], J. Yang*[2] & E.X. Albuquerque[1,2]. [1]Lab. Mol. Pharmacol., UFRJ, RJ, 21944 Brazil; [2]Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

We have shown that 4-methylpyrazole (4-MP) interacts with the NMDA receptor of the cultured hippocampal neurons, activating single channel currents that resemble those evoked by NMDA (*Soc. Neurosci. Abs.*, 17: 1538, 1991). Applying the whole cell patch-clamp technique to cultured fetal hippocampal neurons from 18-to-20-day gestation rats, we further analyzed the interactions of 4-MP with the NMDA receptor and with the strychnine-sensitive glycine receptor. 4-MP (1 mM) blocks reversibly the strychnine-sensitive whole cell current activated by 50 μM glycine. Also, whole cell currents activated by 50 μM NMDA in the presence of 50 μM glycine and 100 μM strychnine were blocked by the same concentration of 4-MP. In addition, biochemical studies were carried out in rat brain synaptosomes. 4-MP alone caused a very small increase in the basal Ca^{2+} uptake into the synaptosomes, but, it clearly reduced the uptake induced by 100 μM NMDA. Moreover, at *Torpedo* nicotinic receptors (nAChR), in the absence of carbamylcholine, 4-MP enhanced the binding of perhydrohistrionicotoxin, an effect similar to that elicited by the nicotinic agonists. However, 4-MP did not displace α-bungarotoxin from its binding site, thus suggesting an allosteric activation of nAChR via a site distinct from that of ACh. These data indicated that 4-MP is recognized by different binding sites on several receptors, and that such effects could account for its therapeutic efficacy in the treatment of alcoholic intoxication.

632.7

SENSITIVITY OF N-METHYL-D-ASPARTATE (NMDA) RECEPTORS TO 9-AMINOACRIDINES. M.E. Nelson[1], E.F.R. Pereira[1,2*], and E.X. Albuquerque[1,2]. [1]Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD, USA 21201; [2]Lab. Mol. Pharmacol. II, IBCCF, RJ, Brazil 21944.

The anticholinesterase, 1,2,3,4-tetrahydro-9-aminoacridine (THA; Tacrine), used with some success to treat Alzheimer's disease patients, has been shown to block NMDA-elicited whole cell and single channel currents with concentration and voltage dependence (*Neurosci. Soc. Abs.*, 15:1166, 1989). However, the concentrations of THA that blocked NMDA currents were greater than those shown to be clinically effective. We now characterize the effects of a series of alkylene bridged bis-9,9'-aminoacridines on NMDA receptors of cultured fetal rat hippocampal neurons. We have previously shown that these compounds are potent non-competitive antagonists of the muscle nicotinic receptor (*FASEB J.* 4:A470, 1990). Here, we tested 1,2-propyl- and 1,4-butyl-9,9'-aminoacridine (1,2-PAA and 1,4-BAA) as well as THA on NMDA-activated single channel currents in outside-out patches. The current-voltage relationship revealed that the single channels activated by NMDA (20 μM) had at least two conductance values. The 50-pS channels, being the most predominant, were chosen to test the effects of these drugs. At -80 mV, these currents had a mean open time (τ_{open}) of 1.88 $\pm$ 0.33 ms, and appeared as bursts whose time constants (τ_{burst}) were 1.42 $\pm$ 0.77 ms and 8.04 $\pm$ 1.88 ms. In the presence of either 50 μM THA, 10 μM 1,2-PAA, or 10 μM 1,4-BAA, τ_{open} was reduced to 0.54 $\pm$ 0.12, 0.78 $\pm$ 0.12, and 0.89 $\pm$ 0.16 ms, respectively. Additionally, only one type of burst was detected with time constants of 2.96 $\pm$ 1.45, 1.39 $\pm$ 0.31, and 1.14 $\pm$ 0.24 ms, respectively. These effects were voltage dependent, suggesting that these compounds act as open channel blockers at the NMDA receptor. Our findings indicate that the alkylene bridged bis-9,9'-aminoacridines are more potent blockers of NMDA receptors than the mono-9-aminoacridine, THA. (Support: US Army Med. Res. & Devel. Comm. Contr. DAMD17-88-C-8119; USPHS Grant NS25296)

EFFECTS OF DIPYRONE ON THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR: A POSSIBLE MECHANISM OF ANALGESIA. A.M.N. Costa[1], Y. Aracava*[1,2], E.S. Rocha[1,2] & E.X. Albuquerque[1,2]. [1]Lab. Pharmacol. Mol. II, IBCCF, Rio de Janeiro, RJ, 21944 Brazil; [2]Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

Dipyrone, a pyrazolone compound with analgesic, antipyretic and antiinflammatory properties, is reported to modulate nociceptive inputs to the central nervous system. Recently, single channel current studies on cultured rat hippocampal neurons, indicated that dipyrone activates the NMDA subtype of glutamate receptors (*Neurosci. Soc. Abs.*, 17:394, 1991). Dipyrone's actions were further evaluated at the single channel and whole cell currents recorded from cultured fetal hippocampal neurons from 18-to-20-day gestation rats. The conductances, τ_{closed}, and τ_{burst} of the single channel currents elicited by either NMDA or dipyrone were quite similar. In contrast to NMDA, increasing dipyrone concentration did not clearly enhance the channel opening frequency. Indeed, no discernable whole cell current was induced by dipyrone, up to 500 μM, either alone or in the presence of glycine (1-10 μM). However, dipyrone (50 μM-1 mM) blocked the whole cell currents induced by NMDA (10-50 μM) in the presence of glycine (1-50 μM) and strychnine (100 μM). In addition, dipyrone caused a small increase in the basal $^{45}Ca^{2+}$ uptake into the rat brain synaptosomes, whereas it reduced the Ca^{2+} flux induced by 100 μM NMDA. At the nicotinic receptors of *Torpedo* membranes, dipyrone did not displace α-bungarotoxin (αBGT), but it enhanced the perhydrohistrionicotoxin (H_{12}HTX) binding in the absence of nicotinic agonist. These results indicated that at the NMDA receptor, dipyrone is a weak agonist, acting as an antagonist when NMDA is present. Furthermore, the agonist-like increase of H_{12}HTX binding may arise from the interaction with a site distinct from that of αBGT. Our findings suggest implication of excitatory receptor systems in the central anti-nociceptive action of dipyrone.

EXCITATORY AMINO ACIDS INCREASE INTRACELLULAR CALCIUM IN CULTURED PURKINJE NEURONS. D.L. Gruol*, K. L. Parsons and R. M. Krieger. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The effect of selective excitatory amino acid receptor agonists on intracellular Ca^{2+} levels of cultured cerebellar Purkinje neurons was examined using digital imaging techniques and the Ca^{2+} sensitive dye fura-2. Several agonists were tested: (a) the ionotropic receptor agonists AMPA and domoate (Dom), (b) the metabotropic receptor agonist (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD), and (c) quisqualate (Quis) which activates both the ionotropic and metabotropic receptors. The agonists were applied from drug pipettes by brief (200 msec) micropressure pulses. Ca^{2+} levels were measured at 3 sec intervals. In both the somatic and dendritic regions, Quis, AMPA and Dom evoked increases in intracellular Ca^{2+} consisting of an initial peak, occurring within ~ 4 to 11 sec from agonist application, and a prolonged recovery phase. The Dom response was smaller in amplitude and shorter duration than that of Quis or AMPA. Peak somatic levels were 133$\pm$9 nM (n=27), 136$\pm$9 nM (22) and 88$\pm$9 nM (16) for Quis, AMPA and Dom, respectively (rest = ~ 40 nM). High K+ saline applied in the same manner elicited Ca^{2+} responses 2-3 fold larger (411$\pm$5 nM, n=10). Peak dendritic levels were somewhat smaller for all agonists. With repetitive application, the second Ca^{2+} response was always smaller in amplitude than the first response. In contrast, ACPD evoked Ca^{2+} oscillations (5-50 nM) in ~ half of the neurons tested (n=20). The remaining showed small (5-10 nM), gradual Ca^{2+} increases or no response. These results suggest that changes in intracellular Ca^{2+} can play a prominent role in the ionotropic and metabotropic responses of the cultured Purkinje neurons. *Supported by AAA6665*

CALCIUM MEASUREMENTS AND ELECTROPHYSIOLOGY OF CHICK CEREBELLAR PURKINJE CELLS IN RESPONSE TO EXCITATORY AMINO ACIDS. Cliffer, K.D.*, Merritt, T., and Christensen, B.N. Department of Physiology and Biophysics, The University of Texas Medical Branch, Galveston, TX 77555-0641.

We tested cerebellar Purkinje cells acutely isolated from chick embryos (E16 to P2) for changes in intracellular calcium ($[Ca^{++}]_i$) in response to excitatory amino acids (EAAs) kainate (KA), (±)-1-aminocyclopentane-trans-1,3-dicarboxylic acid (ACPD), and n-methyl-D-aspartate (NMDA). Application of each of the amino acids elicited a rise in $[Ca^{++}]_i$ measured in cells loaded with fura-2. Electrophysiology of voltage-clamped cells (without fura) indicated that inward currents were elicited by KA (EC_{50}=118μM) or NMDA (EC_{50}=27μM), whereas no current was elicited by ACPD. The current in response to KA was inhibited by CNQX (a specific antagonist at ionotropic quisqualate receptors); that in response to NMDA was inhibited by AP5 (a specific antagonist at NMDA receptors). Application of caffeine elicited increases in $[Ca^{++}]_i$, indicating a potential contribution to EAA-induced increases in $[Ca^{++}]_i$ from caffeine-sensitive intracellular stores. The results indicate that EAAs can raise the $[Ca^{++}]_i$ in isolated chick Purkinje cells by acting via any of the three main types of EAA receptors, either metabotropic or ionotropic quisqualate receptors or NMDA receptors, and that release from intracellular stores may be induced.

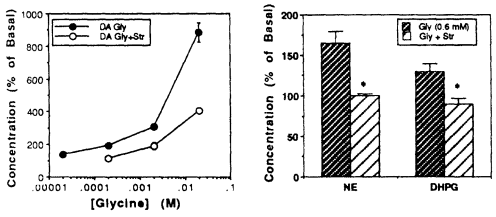
IN VIVO STIMULATORY EFFECT OF GLYCINE IN STRIATUM AND HIPPOCAMPUS. G. Yadid, K. Pacak, J.D. Harvey-White, I.J. Kopin* and D.S. Goldstein. Clinical Neuroscience Branch, NINDS, 10/5N214, Bethesda, MD 20892.

Glycine (Gly) is an inhibitory neurotransmitter in the spinal cord and medulla. Binding to specific Gly receptors increases transmembrane Cl^- conductance and hyperpolarizes neurons. Strychnine (Str) selectively antagonizes this effect. Gly's role in release of catecholamines in higher brain areas was examined by microdialysis in the striatum and the hippocampal CA3 region of freely-moving rats. After probe insertion, artificial CSF was infused for 20-24 h, and after 3 30-min basal microdialysate samples were obtained, the infusate was changed to CSF containing Gly (0.02-20mM) with or without Str (10 μM). Gly produced dose-related increases in release of dopamine (DA) and its metabolites in striatum and of norepinephrine (NE) and dihydroxyphenylglycol (DHPG) in hippocampus. Str blunted there increases in hippocampus (* = P<0.01) and shifted the dose-response curves to the right by about 1 log unit (Figures). The results indicate a stimulatory effect of Gly on catecholamine release in the striatum and hippocampus, via Str-sensitive receptors.



632.12

THE INTERACTION OF GLUTAMIC ACID AND ASPARTIC ACID WITH EXCITATORY AMINO ACID RECEPTORS IN THE MAMMALIAN CENTRAL NERVOUS SYSTEM. I.O. Adeoshun, E.P. Mtui* Department of Physiological Sciences, Faculty of Health Sciences, Obafemi Awolowo University, Ile-Ife, Oshun State, Nigeria.

The number of amino acid molecules required to react with a receptor to cause its activation was investigated using a 6-barrel iontophoretic electrode assembly filled with glutamate, aspartate and DL-homocysteate.

The experiments were performed on rats anaesthetized with urethane (1.5 g/kg). Extracellular recordings were obtained from the thalamocortical relay cells of the ventrolateral thalamus identified by their response to stimulation of hindlimb nerve and the somatosensory cortex.

Hill plots of log (amino acid currents) vs log $(^y/_{(1-y)})$ where "y" is the ratio of the observed rate of firing to the maximum attainable rate were done on neurones tested with both glutamate and aspartate. The results yeilded average slopes of 2.8 ± 0.2 SE (glutamate, n=17) and 3.4 ± 0.6 SE (aspartate, n=11).

This study suggests that more than one amino acid molecule must react with a receptor to cause its activation.

632.13

TIME DEPENDENCE OF QUISQUALATE INDUCED SENSITIZATION OF HIPPOCAMPAL SLICES TO L-AP5. M.K. Schulte*, R.J. Roon and J.F. Koerner. Dept. of Biochemistry, University of MN, Minneapolis, MN 55455.

A brief exposure of pyramidal and granule cell neurons of the rat hippocampus to the excitatory amino acid agonist L-quisqualic acid (L-QUIS) results in a 30-100 fold increase in sensitivity to depolarization by L-AP4, L-AP5 and related phosphonates (QUIS-effect). We have reported that exposure of slices to L-homocysteine sulfinic acid (L-HCSA), L-serine-O-sulfate (L-SOS) and L-α-amino adipic acid (L-αAA) can "pre-block" induction of this effect and reverse it once it has been induced. The molecular mechanisms involved in induction, pre-blocking and reversal of the QUIS-effect are unknown. One hypothesis suggests that L-QUIS is taken up into cells as a necessary first step in induction. We have suggested that those compounds which pre-block or reverse the effect may also act internally. We have recently shown that active uptake of L-QUIS does occur in hippocampal slices. L-HCSA, L-α-AA and L-SOS are also taken up and treatment of slices with these compounds does not decrease the rate of L-QUIS uptake. The question remains, however, whether or not L-QUIS uptake is required for induction of the QUIS-effect. Using low levels of L-QUIS (<4 μM) we have investigated the time dependence of induction of the QUIS-effect. We observe that the degree of sensitivity to L-AP5 is proportional to the total time the slice is exposed to L-QUIS. The increases in sensitivity to 200 μM L-AP5 as a function of time for 3 different concentrations of L-QUIS are as follows: 2 μM - 3.9 % inhibition/min; 1 μM - 1.9 % inhibition/min; 0.5 μM - 0.8 % inhibition/min. We have also investigated the time dependence of pre-blocking and reversal and found that, like induction, they too are both concentration and time dependent. These results are consistent with a model for induction of the QUIS-effect which requires uptake of L-QUIS and in which compounds pre-block or reverse the effect by either competing with QUIS at an internal binding site or by producing an opposing action at another internal site.

OPIATE RECEPTOR LIGANDS

633.1

ETONITAZENE: A MU RECEPTOR SELECTIVE LIGAND. M.S. Moolten*, J.C. Chen, J.B. Fishman and K.R. Carlson. Pharmacology Dept., U. Massachusetts Medical Center, Worcester, MA 01655.

Etonitazene (ETZ) is a synthetic opiate approximately 1000 times more potent than morphine as an analgesic. Due to its high potency ETZ can be diluted to palatable but behaviorally active concentrations, making its use widespread in oral self-administration studies in rats. Although ETZ competes with high affinity for[^{3}H]-naloxone binding (Pert and Snyder, Mol. Pharm. 10:868-879 1974), its affinity for the various known opiate receptor sites has not been determined. Accordingly, we measured the ability of ETZ, fentanyl, and morphine to compete with [^{3}H]-DADLE (+DPDPE), [^{3}H]-DAGO (+DSLET), [^{3}H]-DPDPE, [^{3}H]-U-69,593, and [^{3}H]-SKF-10,047, in order to label mu_1, mu_2, delta, kappa, and sigma receptors, respectively, in membrane preparations from rat brain. ETZ had a 2500 fold greater affinity than morphine at the mu_1 site (Ki: ETZ=0.00041nM; fentanyl=0.007nM; morphine=1.11 nM). Affinities for the mu2 site were 10-fold greater for ETZ than fentanyl or morphine (Ki=0.4nM, 6.5nM, and 4.5nM, respectively). Affinities for delta, kappa and sigma receptors were similar for all three drugs.

These results demonstrate that ETZ is a high affinity ligand at mu receptor sites. The in vitro binding characteristics of ETZ are consistent with its activity as an analgesic and reinforcer of operant behavior

AFFINITY LABELING HUMAN OPIOID RECEPTORS WITH A NOVEL IODINATED DERIVATIVE OF NalBzoH. K.M. Standifer,* G. Ciszewska, J. Cheng, J.Z. Ginos, J.L. Biedler, and G.W. Pasternak, Cotzias Laboratory of Neuro-Oncology and Laboratory of Cellular and Biochemical Genetics, Memorial Sloan-Kettering Cancer Center, New York, NY 10021.

The BE(2)-C clone of SK-N-BE(2) human neuroblastoma cell line contains high levels of opioid binding sites which were quite similar to levels in brain. Selective binding assays revealed the presence of mu, delta and $kappa_3$ receptors in a 2:1:2 ratio. FPLC of CHAPS-solubilized ^{3}H-NalBzoH affinity-labeled receptors from these cells over a Mono-Q column demonstrates the presence of at least 5 separable peaks of labeling. Substitutions on the benzoylhydrazone moiety of NalBzoH can still be potent opiates. The 3-^{125}I-4-amino- benzoylhydrazone of naloxone (^{125}I-NalAmBzoH) labels opioid binding sites on the BE(2)-C cells with high affinity (K_D 1 nM; B_{max} 190 fmol/mg protein). The sensitivity of the binding towards DADL, DAMGO and DPDPE implies the labeling of mu, delta and $kappa_3$ sites. U50,488H does not compete binding, confirming the absence of $kappa_1$ receptors in these membranes. Like ^{3}H-NalBzoH, ^{125}I-NalAmBzoH can covalently label binding sites following exposure to UV light. SDS PAGE of labeled membranes reveals two major and two minor specific bands between 50,000 and 100,000 daltons which are also competed by low nanomolar concentrations of opioids.

633.3

CHARACTERIZATION OF AN IODINATED ANALOGUE OF THE δ OPIOID ANTAGONIST TYR-TIC-PHE-PHE (TIPP) BY BINDING ASSAY. R. Horvath, M.A. Jarosinski, R.J. Knapp, I. Sora*, V.J. Hruby, and H.I. Yamamura, Univ. of Arizona Pharmacol. & Chemistry Dept's, Tucson, AZ 85724.

TIPP was shown to be a selective δ opioid receptor antagonist using the guinea pig ileum and mouse vas deferens bioassays (Schiller et al., 1992 FASEB abstract #3699). A radiolabeled analogue of this peptide would be valuable for studies of the δ opioid receptor since it is more selective than naltrindole which is the only available δ receptor ligand whose affinity is suitable for radioligand binding assay. One approach to radiolabeling is radioiodination of the Phe^3 ring using a diazonium intermediate (Sharma et al., J. Org. Chem. 56: 4981, 1991). The binding affinities of [4'-I-Phe^3]TIPP were tested at sites labeled by selective opioid receptor radioligands for this reason.

Radioligand	TIPP IC_{50} (nM ± SEM)	[4'-I-Phe^3]TIPP IC_{50} (nM ± SEM)
δ Selective		
naltrindole	29.9	14.4
pCl-DPDPE	6.2 ± 1.4	6.1 ± 0.3
μ Selective		
CTOP	154,600 ± 19,800	53,525 ± 9,375
κ Selective		
U-69593	160,900	not determined

The results show that iodination of the Phe^3 aromatic ring preserves most of the δ opioid receptor binding affinity and selectivity of the parent peptide. Radioiodinated TIPP is being prepared and its binding properties for δ opioid receptors studied. Supported in part by NIDA grants.

633.4

SELECTIVE LABELING AND RESOLUTION OF KAPPA2 RECEPTOR SUBTYPES BY [^{125}I]IOXY. O. Ni[1], J.S. Partilla[1], H. Xu[2], B.R. de Costa[2], K.C. Rice[2*] and R.B. Rothman[1]. [1]NIDA Addiction Research Center, PO Box 5180, Baltimore MD 21224. [2]LMC, NIDDK, NIH, Bethesda, MD 20892.

Previous work demonstrated that, using membranes depleted of μ and δ sites by pretreatment with BIT and FIT, [^{3}H]bremazocine labels two populations of κ_2 binding sites termed κ_{2a} and κ_{2b}, whose anatomical distribution and ligand-selectivity pattern differs from that of μ and δ binding sites. The present study was undertaken to characterize κ_2 binding sites with the novel antagonist ligand, [^{125}I]IOXY. [^{125}I]IOXY (SA=2200 Ci/mmol) was prepared by iodination of BD869, deacetylation, and purification by HPLC. Assays were conducted for 4 to 6 hr at 4^0 C in 50 mM TRIS-HCl, pH 7.4, and 10 mM NaCl. Binding surfaces generated with IOXY, (-)-(1*S*,2*S*)-U50,488, DAMGO and [Leu^5]enkephalin (LE) (274 data points) were fit to one- and two-site binding models. The two site model fit the data considerably better than a one site model ($p<0.001$). The two site fit resolved two sites, present at relative concentrations of 0.64 (κ_{2b}) and 0.44 (κ_{2a}). The Kd/Ki values (nM) for the drugs at the two sites were: IOXY (0.46, 0.73), (-)-(1*S*,2*S*)-U50,488 (3527, 5051), DAMGO (11.9, 1262) and LE (57.7, 12295). Structure-activity studies (in progress) indicate that the two sites labeled by [^{125}I]IOXY are the same as the two sites labeled by [^{3}H]bremazocine. Viewed collectively, these data provide further evidence for the existence of subtypes of the κ_2 binding site.

633.5

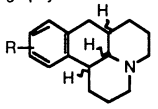
NALTRINDOLE BENZOFURAN IS NOT A δ-OPIOID SELECTIVE ANTAGONIST IN THE RAT SPINAL CORD. P.E. Stewart* & D.L. Hammond. Dept. of Anesthesia and Critical Care, The University of Chicago, Chicago, IL 60637.

Recent studies with the δ-selective opioid antagonist Naltrindole support the presence of δ-mediated antinociception in the spinal cord of the mouse and the rat. Naltrindole benzofuran (NTB) is also reported to be a δ opioid receptor antagonist in the mouse. This study examined the selectivity of NTB in the rat spinal cord using the tail-flick (TF) and hot plate (HP) tests. Sprague-Dawley rats were injected intrathecally (i.t.) with the δ-selective agonist cyclic[D-penicillamine^2, D-penicillamine^5] enkephalin (DPDPE) or the μ-selective agonist [D-Ala^2, $MePhe^4$, Gly-ol^5]enkephalin (DAMGO) and dose-response curves were generated in the presence or absence of NTB. DPDPE and DAMGO each dose-dependently increased TF and HP latencies. NTB (3-10 μg i.t.) dose-dependently antagonized the increase in TF and HP latencies produced by DPDPE. The antagonism did not appear to be competitive. The increase in TF and HP latencies produced by DAMGO was also antagonized by these same doses of NTB. The antagonism was not competitive. Similar results were obtained with s.c. administered NTB (10-30 mg/kg). These data suggest that NTB is not a selective δ-opioid antagonist in the rat spinal cord. Supported by PHS Grant DA 06736.

633.6

SYNTHESIS AND PHARMACOLOGICAL EVALUATION OF A PREVIOUSLY UNKNOWN CLASS OF RIGID TETRACYCLIC NEURORECEPTOR LIGANDS, OCTAHYDRONAPHTHOQUINOLIZINES. D.I. Schuster*, B. Cai, Y. Pan, G. Singh, M. Cornebise, A. Fariborzian, G. Stoupakis, J. Dewan and R. B. Murphy, Department of Chemistry and Center for Neural Science, New York University, New York, NY10003.

We have prepared a series of rigid tetracyclic analogues of 3-PPP, dopamine and other neuroreceptor ligands, namely octahydronaphthoquinolizines (OHNQs) (structure shown below). Each OHNQ exists as four diastereomers which are topologically very different. These compounds differ from conformationally flexible analogues which have activity at sigma receptor binding sites (SRBSs), D_2 and other neuroreceptor sites. Binding data show that OHNQs have modest to high affinities to SRBS in bovine cerebellar homogenates labeled with [^{3}H]-haloperidol or [^{3}H]DTG, and have low affinity toward D_2 receptors in bovine striatal preparations. Additional biological activity has been assessed under the NOVASCREEN program. The structure-activity relationships of these compounds toward different neuroreceptors will be presented. These compounds are synthesized in three steps from corresponding 2-tetralones; the key step involves reductive ring closure by high pressure hydrogenation with Raney nickel. All four diastereomers are formed, the structures of which have been assigned by X-ray crystallography and ^{13}C NMR spectroscopy .



633.7

KAPPA OPIOID AGONISTIC AND MU ANTAGONISTIC EFFECTS OF N-CYCLOPROPYLMETHYLNOR-14BETA(BROMOACETAMIDO)-7,8-DIHYDROMORPHINONE IN THE MOUSE. **Q. Jiang[*], A. Seyed-Mozaffari, [1]S. Archer and J.M. Bidlack.** Dept. of Pharmacology, Univ. of Rochester, Rochester, NY 14642 and [1]Dept. of Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12181.

Opioid effects of N-cyclopropylmethylnor-14beta(bromoacetamido)-7,8-dihydromorphinone (N-CPM-H_2BAMO) were investigated in the mouse 55 °C warm-water tail flick and acetic acid writhing assays. All opioid agonists and antagonists were given by intracerebroventrical (*i.c.v.*) administration 10 min before antinociceptive tests. In the mouse writhing assay, N-CPM-H_2BAMO produced a dose- and time-dependent antinociception. The antinociceptive effect of N-CPM-H_2BAMO lasted up to 1 hr, with a maximal effect at 10 min after *i.c.v.* administration. The antinociceptive D_{50} value (and 95% C.L.) for *i.c.v.* N-CPM-H_2BAMO was 0.28 (0.19 - 0.39) nmol. This antinociceptive effect of N-CPM-H_2BAMO was antagonized by co-administration of nor-binaltorphimine (nor-BNI), the κ-selective antagonist, in a dose-dependent manner. In the mouse tail flick assay, N-CPM-H_2BAMO failed to produce antinociception. However, when co-administered with morphine, N-CPM-H_2BAMO produced a dose-dependent antagonism of morphine-induced antinociception, but not that of [D-$Pen^{2,5}$]enkephalin, the δ-selective agonist. Nor-BNI (0.3 nmol, which totally antagonized the agonistic effect of N-CPM-H_2BAMO in the writhing assay) failed to prevent the antagonistic effect of N-CPM-H_2BAMO on morphine-induced antinociception. Therefore, these data suggest that N-CPM-H_2BAMO acts at supraspinal κ opioid receptors to produce antinociception in the mouse writhing assay and acts at μ opioid receptors as a μ antagonist in the mouse tail flick assay. (Supported by Grants DA03742 and DA01674).

DESIGN OF POTENT AND SELECTIVE DYNORPHIN A-RELATED PEPTIDES DEVOID OF MOTOR EFFECTS. S. Lemaire*, R. Michelot, Y. Chen, I. Ibrahim, C. Lapierre and V.K. Shukla. Department of Pharmacology, University of Ottawa, 451 Smyth Rd., Ottawa, Ont. K1H 8M5.

Dynorphin A-(1-13)-Tyr-Leu-Phe-Asn-Gly-Pro, (Dyn Ia), was previously shown to be a highly potent and selective κ opioid peptide. Four analogues of Dyn Ia have been synthesized by the solid-phase procedure: #1, [Ψ-CH_2,$NH^{6,7}$]Dyn Ia; #2. [Ψ-CH_2-$NH^{6,7}$,D-Leu^8]Dyn Ia; #3. [$MeTyr^1$, Ψ-CH_2-$NH^{6,7}$]Dyn Ia and #4. [$MeTyr^1$,Ψ-CH_2-$NH^{6,7}$, D-Leu^8]Dyn Ia. The peptides were purified and compared with Dyn Ia for their ability to compete with the binding of selective κ, μ and δ opioid ligands and to display antinociceptive activity in an acetic acid induced writhing test. All synthetic compounds displayed a high affinity for the κ receptor (Ki against [^{3}H]EKC binding:0.5-1.8 nM) but compounds #3 and 4 were more selective. Compound #2 possessed the highest antinociceptive activity (AD_{50}:1.57 nmol/mouse) and the lowest motor effect (convulsion; CD_{50}:15.4 nmol/mouse). Its κ selectivity ratio (1:5.7:12.9;κ:μ:δ) was comparable to that of Dyn A-(1-13) (1:4.5:40). Compound #2 is thus a potent and selective Dyn A related peptide devoid of motor effect at analgesic doses. Supported by MRC.

633.9

CHRONIC INTRACEREBROVENTRICULAR INFUSION OF THE ANTI-OPIOID PEPTIDE, Phe-Leu-Phe-Gln-Pro-Gln-Arg-Phe-NH_2 (NPFF), DOWN-REGULATES MU OPIOID BINDING SITES IN RAT BRAIN. R.B. Rothman*[1], L.S. Brady[2], H. Xu[1], and J.B. Long[3]. [1]NIDA Addiction Research Center, Baltimore, MD 21224. [2]LNP, NIMH, Bethesda, MD 20892. [3]Dept. of Med. Neurosci., WRAIR, Washington, DC 20307-5100.

NPFF, an endogenous mammalian anti-opioid peptide, has been shown by other laboratories to attenuate 1) the acute antinociceptive effects of morphine, 2) the development of morphine tolerance, and 3) naloxone-induced withdrawal in morphine dependent rats. The present study determined the effect of chronic NPFF on mu opioid receptors, and mRNA for the endogenous opioids dynorphin and enkephalin. Rats received i.c.v. infusions of either saline or NPFF (5 μg/hr) for 13 days via ALZET 2002 osmotic minipumps. Homogenate binding studies, which used whole brain membranes, demonstrated that NPFF decreased the Bmax of mu binding sites (labeled by [^{3}H]DAMGO) from 262±12 to 192±12 fmol/mg protein, and increased the Kd from 1.1 nM to 2.3 nM. Quantitative receptor autoradiography and in situ hybridization experiments were conducted with sections collected at the level of the striatum. The density of mu opioid binding sites labeled by [^{3}H]DAMGO was decreased in all brain areas measured except the corpus callosum, and there was no change in the mRNA for dynorphin or enkephalin in caudate, the N. accumbens or the ventral pallidum. Studies in progress are examining the effect of chronic i.c.v. NPFF on the acute antinociceptive effects of morphine, as well as the development of morphine tolerance and dependence.

633.10

TYR-MIF-1, TYR-W-MIF-1, AND HEMORPHIN HAVE OPIATE AGONIST AS WELL AS ANTAGONIST PROPERTIES IN THE GUINEA PIG ILEUM. J.E. Zadina*, A. J. Kastin, D. Kersh, J. Erchegyi, L.-J. Ge.
VA Med. Ctr. and Tulane Univ. Sch. of Med., New Orleans, LA 70146

Tyr-MIF-1 (Tyr-Pro-Leu-Gly-NH_2) is a brain peptide known for its ability to modulate, and particularly antagonize, opiate effects. We have recently isolated a structurally related peptide, Tyr-W-MIF-1 (Tyr-Pro-Trp-Gly-NH_2) from brain. This peptide also has structural similarity to hemorphin (Tyr-Pro-Trp-Thr), a peptide derived from blood digests known (and named) for its opiate agonist activity. These peptides and some analogs and fragments were tested for activity in the guinea pig ileum and opiate receptor binding assays. Each of the peptides showed dose-dependent, opiate agonist activity (inhibition of contraction), that was reversed by naloxone and the mu antagonist CTOP but not by the kappa antagonist nor-BNI. The rank order of agonist potency in the ileum assay and in binding to mu opiate receptors was Tyr-W-MIF-1 > hemorphin > Tyr-MIF-1. In addition, however, the peptides exhibited antagonist activity that was best detected in ileal preparations from animals made tolerant to morphine or treated with the opiate receptor alkylating agent β-CNA to reduce opiate receptor reserve. The peptides reduced the inhibition of contractions induced by morphine and the mu-selective agonist DAMGO. Hemorphin and the free acid of Tyr-W-MIF-1 were particularly potent at inhibiting the actions of opiate agonists. MIF-1 (Pro-Leu-Gly-NH_2) and morphiceptin were ineffective at antagonizing mu agonist activity. The results show that endogenous brain peptides (Tyr-MIF-1 and Tyr-W-MIF-1) and hemorphin can act as both agonists and antagonists. The antagonist action is best observed in the ileum with reduced receptor reserve or from a morphine tolerant animal. The results support the idea that increased sensitivity to the opiate antagonist actions of endogenous peptides occurs in the tolerant state.

DEVELOPMENT AND VALIDATION OF A FUNCTIONAL ASSAY *IN VITRO* FOR OPIOID ACTION. L.N. Williamson, D.J. Mayer, M.A. Savage*, H. Bakopoulos, B.S. Pitzele, D.W. Hansen, N.S. Chandradumar, and M. Reichman. G.D. Searle, Skokie, IL 60077

Our goal was to develop an automated, high-capacity functional assay *in vitro* that would report on the intrinsic efficacy of opioids. To this end, we characterized the inhibitory effects of opioids on prostaglandin E_1 (PGE_1)-stimulated formation of cyclic adenosine monophosphate (cAMP) in NG108-15 neuroblastoma x glioma (NG) cells. The NG cells were pre-incubated with diverse structural classes of opioids for 15 minutes in assay buffer containing IBMX, a phosphodiesterase inhibitor. We then measured the activities of the opioids for inhibiting prostaglandin E_1-stimulated cAMP formation. The cAMP was measured by RIA methods involving a charcoal-based separation, or the newer scintillation proximity assay. Validation of the assay was accomplished by comparing the EC_{50} values obtained in NG cells to those obtained in the standard *in vitro* assay; opioid-elicited inhibition of electrically-stimulated contractions in mouse *vas deferens*. The results from our automated, high capacity, cell-based assay agree well with the more traditional, labor-intensive, animal-based assay. We are applying these methods to other bioassays.

633.12

EXPRESSION OF c-fos & PREPROENKEPHALIN (PPenk) mRNA IN HUMAN NEUROBLASTOMA SK-N-BE(2) CELLS. J. Cheng*, Y. Zhu, C.E. Inturrisi, K.M. Standifer, J.L. Biedler, G.W. Pasternak. The Cotzias Laboratory of Neuro-Oncology & Laboratory of Cellular and Biochemical Genetics, Memorial Sloan-Kettering Cancer Center and Departments of Neurology & Neuroscience and Pharmacology, Cornell University Medical College, New York, NY 10021

The human neuroblastoma clonal cell line BE(2)-C from the SK-N-BE(2) line expresses functional mu, $kappa_3$ and delta opiate receptors. Binding studies reveal total binding levels similar to brain with a mu:$kappa_3$:delta distribution of 2:2:1. In addition, selective agonists for each receptor subclass inhibit forskolin-stimulated cAMP accumulation. We now demonstrate that this cell line also expresses mRNA for opioid peptides and c-fos. Using solution hybridization, we quantitated the levels of PPenk mRNA and c-fos mRNA in BE(2)-C cells and their regulation by forskolin. The basal level of PPenk mRNA equivalents is 0.14 ± 0.04 pg/μg RNA using a ^{32}P-labeled riboprobe transcribed from a rat cDNA. Preprodynorphin and c-fos mRNA's are also measurable in these cells. Cells exposed to forskolin (100 μM) for 2 hr showed a 4-fold increase in c-fos mRNA levels. This elevation returns to basal levels by 6 hr. This same forskolin treatment also increases PPenk mRNA levels, but far more slowly than c-fos. Thus, BE(2)-C cells contain multiple classes of opioid receptors as well as mRNA's of several opioid peptides and the c-fos proto-oncogene and should prove useful for the study of opioids and their receptors.

633.13

DIFFERENTIAL EFFECT OF CHRONIC MORPHINE TREATMENT ON THE EXPRESSION OF G-PROTEIN AND ENDOGENOUS OPIOID PEPTIDES IN ADULT RAT BRAIN. R.Basheer and A. Tempel*. Lab of Molecular Pharmacology, Hillside Hospital, Long Island Jewish Medical Ctr./Albert Einstein College of Medicine, Glen Oaks, NY 11004.

The molecular mechanism involved in the development of opiate tolerance and dependence is still unclear. The majority of studies have failed to show any correlative alterations in receptor density in adult rats following chronic morphine treatment in vivo. Hence the postreceptor events in the opioid system are gaining importance in elucidating mechanisms involved in opioid tolerance and dependence. The opioid receptor subtypes are linked to G-proteins. Involvement of both pertussis toxin sensitive G subunits (G_i and G_o) and the cholera toxin sensitive G_s subunit in mediating opioid effects has been reported by others. The mechanism of opiate tolerance and dependence may involve a balance between inhibitory and stimulatory G-proteins as well as interactions with different second messenger systems. In order to study the molecular changes in the Central Nervous System following morphine treatment in adult rats the levels of expression of G_s mRNA were measured in hypothalamus, frontal cortex, striatum and hippocampus. In addition, the mRNA levels for endogenous opioid peptides, preproenkephalin (PPE) and dynorphin (Dyn) were also measured. G_s message showed a 97% increase ($p<.02$) in hypothalamus whereas Dyn message levels decreased by 22% ($p<.01$) in hypothalamus following morphine treatment. PPE message levels were decreased by 55% ($p<.01$) in striatum, which is in agreement with earlier reports. These results suggest that chronic morphine treatment differentially alters the expression of G-protein and endogenous opioids in different brain regions (supported by NIDA grant DA-05440).

TOPOGRAPHICAL ORGANIZATION OF MIDBRAIN DOPAMINE AFFERENTS TO THE MEDIAL PREFRONTAL CORTEX OF THE RAT. A. Bourdelais* and A. Y. Deutch. Department of Psychiatry, Yale University School of Medicine, New Haven, CT 06508, and VA Medical Center, West Haven, CT 06516.

We have previously demonstrated that the responsiveness of the prefrontal cortical dopamine (DA) innervation to mild stress differs across the different cytoarchitectonic fields of the medial prefrontal cortex (PFC). This may be due to either distinct populations of midbrain DA neurons projecting to different parts of the PFC, or alternatively to changes restricted to the axon terminal region (presynaptic regulation of DA release). We therefore examined the distribution of midbrain DA neurons projecting to the PFC by placing small iontophoretic deposits on fluorogold (FG) in the PFC, and dual-labelling for FG and tyrosine hydroxylase (TH).

Retrogradely-labelled (FG-positive) cells were most frequently seen in the rostral VTA (supramammillary region). FG labelled neurons were next most frequently observed in the nuc. parabrachialis pigmentosus (PBP), followed by the caudal linear (CL) and then the rostral linear (RL) nuclei. Only rarely were cells seen in the interfascicularis and paranigral nuclei.

More medial injections of the PFC (i.e., infralimbic and prelimbic) resulted in more double-labelled (FG+TH) cells in the medial VTA (RL and CL). More laterally placed injections resulted in more double-labelled cells in more lateral portions of the VTA (PBP). There also appeared to be a rough anteroposterior gradient. However, our preliminary data suggest only a crude topographical organization, one that may not be consistent with separate populations of midbrain DA neurons innervating different portions of the PFC. Supported by MH-45124 and the West Haven, CT VA.

IN VIVO SPECT COMPARISON OF THREE HIGH AFFINITY RADIOLIGANDS FOR DOPAMINE D2 RECEPTOR. M.S. Al-Tikriti*, R.M. Baldwin, Y. Zea-Ponce, E. Sybirska, S.S. Zoghbi, M. Laruelle, R.T. Malison, H.F. Kung, R.M. Kessler, T. de Paulis, I. Nakatsuka, H.Saji, E.O.Smith D.S.Charney, P.B. Hoffer, R. B. Innis. Yale University/VA Medical Center,West Haven, CT 06516, University of Pennsylvania, Philadelphia, PA, Vanderbilt University, Nashville, TN, Sumitomo Chemical Co., Osaka, Japan and Kyoto University, Japan.

The regional distribution and pharmacological specificity of iodobenzofuran (IBF), epidepride (EPID) and 2'-iodospiperone (2'-ISP) were measured with serial SPECT scans in non-human primates. A series of 13 IBF, 6 EPID and 8 2'-ISP studies were conducted on 6 ovariectomized female baboons (9-13 kg) under isoflurane anesthesia. Animals were injected with 5-16 mCi ^{123}I-labeled agent i.v. and scanned in the Strichman 810X Imager. All three ligands showed specific striatal uptake which reached peak at 37, 140 and 55 min postinjection (PI) for IBF, EPID and 2'-ISP, respectively, with striatal ratios to nonspecific (cortex or cerebellum) 3, 12 and 2.2, these ratios increased to 10, 19, and 3.4 after 4 hr. *Ex vivo* autoradiographic studies in one animal for each ligand sacrificed at 30, 120 and 80 min PI demonstrated the highest uptake in caudate and putamen, and striatum:cortex ratios were 6, 10 and 5, respectively. From the peak striatal activities, washout rates for those ligands were 32, 8 and 15%/hr. IBF and 2'-ISP plateaued for 30-50 min while EPID for 2 hr, followed by a steady but gradual washout over a period of 3 hr. Raclopride (1 mg/kg) produced complete displacement from striatum of all agents with washout rates increased to 126%, 61% and 38%/hr. Ritanserin and d-amphetamine (1 mg/kg) had no significant effect on striatal washout rates.

634.3

DOPAMINE AUTORECEPTOR ANTAGONIST AJ76 DISRUPTS AUDITORY SENSORY GATING IN RATS. K.E. Stevens*, K.R. Harris, J.C. Lehman, S.L. Stryker and G.M. Rose. Department of Pharmacology, UCHSC and Medical Research, VAMC, Denver, CO 80262

The midlatency auditory evoked potential recorded to the second of a closely-spaced (0.5 sec interval) pair of clicks is reduced as compared to the first, in unmedicated rats and in normal humans. Administration of amphetamine to rats or humans disrupts this "gating", producing a schizophrenia-like pattern of response. Similar alterations in gating have been elicited by elevation of endogenous norepinephrine levels through administration of yohimbine, a presynaptic alpha$_2$-selective adrenergic antagonist. To determine if elevation of endogenous dopamine levels thorough blockade of the autoreceptor would also produce alterations in sensory gating, the dopamine receptor antagonist AJ76 was administered at a dose thought to act only presynaptically (3.5 mg/kg, sc). AJ76 was administered to rats with chronic indwelling recording electrodes located on the brain surface at "vertex". At 20 and 45 min post injection, AJ76-treated rats showed a loss of sensory gating as compared to unmedicated trials. This was due to an increase in the amplitude of the N40 wave in response to the second (test) stimulus with no change in the amplitude of the response to the first (condition) stimulus. There were no significant changes observed at 65 min post injection. Thus, increases in endogenous dopamine levels can impair sensory gating in rats. (Supported by P50 MH44212-03.)

ANTAGONISM OF COCAINE, AMPHETAMINE AND OTHER DOPAMINERGIC STIMULANTS BY THE PREFERENTIAL DOPAMINE AUTORECEPTOR ANTAGONIST (+)-UH232 IN THE INTRACRANIAL SELF-STIMULATION AND LOCOMOTOR ACTIVITY MODELS. Torben Kling-Petersen*, Elisabeth Ljung and Kjell Svensson. Dept of Pharmacology, Univ. of Göteborg, POB 330 31, 400 33 Göteborg, SWEDEN

The preferential dopamine autoreceptor antagonist (+)-UH232, exerts a weak stimulatory effect when tested in locomotor activity experiments using habituated animals. However, (+)-UH232 also blocks d-amphetamine, cocaine and apomorphine induced hyperactivity. Thus, the behavioral effects of (+)-UH232 appears to be dependent upon the baseline activity of the animal.

Various behavioral models have been utilized in order to investigate the possible positive reinforcing properties of (+)-UH232 . In the intracranial self-stimulation (ICSS) paradigm in the rat, bipolar electrodes aimed at the median forebrain bundle delivers mono-phasic, cathodal current of varying intensities. By establishing a threshold value (called EC50) using a rate/intensity-model, results from different experiments can be statistically compared. (+)-UH232 produced a weak inhibitory effect over a wide dose range (1-16 mg/kg s.c.). Cocaine (1-16 mg/kg i.p.) and d-amphetamine (0.25-1 mg/kg s.c.) on the other hand produced a clear lowering of the EC50 values, indicating stimulatory effects. (+)-UH232 (16 mg/kg s.c.) blocked the stimulatory effects of both cocaine (4-16 mg/kg) and d-amphetamine (0.25-4 mg/kg). It is possible that there is a qualitative difference in the antagonism of these two dopamine stimulants.

We are presently investigating the interactions of (+)-UH232 with the DA reuptake inhibitor GBR-12909 and DA D2 receptor agonist quinpirole in the ICSS paradigm and locomotor activity model. (Supported by The Upjohn Company, Kalamazoo, MI.)

DESTRUCTION OF MESOLIMBIC DOPAMINE NEURONS BY INTRA-VTA INJECTIONS OF 6-OHDA DOES NOT BLOCK THE LOCOMOTOR ACTIVATING EFFECTS OF NICOTINE.
J-P. Tassin, P. Vézina, T. Jay*, J. Glowinski and D. Hervé. Chaire de Neuropharmacologie, INSERM U.114, Collège de France, Paris, France and Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Canada.

Recently we reported that while acute systemic injections of nicotine substantially increase dopamine (DA) utilization in the nucleus accumbens (N. Acc.), repeating these injections abolishes this effect even though this drug's locomotor effects become enhanced (Vézina et al., J.P.E.T., in press). This suggests that nicotine may elicit at least some of its locomotor effects via non mesolimbic DA systems. In the present study, this possibility was investigated by assessing the locomotor response to nicotine following destruction of the mesolimbic DA system. Rats received bilateral injections of 6-OHDA (4µg/1µl/side) into the ventral tegmental area (VTA). Four weeks later, the locomotor response of these animals to (-)-nicotine bitartrate (0.4 mg/kg, base, s.c.) was compared to that of non-lesioned controls. Depletions of N.Acc. DA of up to 100 % of control concentrations did not block the acute locomotor response to nicotine. Such depletions also did not prevent the progressire enhancement of nicotine's locomotor effects when injections were repeated daily for nine days. These results, together with others demonstrating that such 6-OHDA-induced depletions of N.Acc. DA completely block the locomotor response to amphetamine up to 33 days post-lesion, extend our earlier findings with N.Acc. DA utilization and suggest that mesolimbic DA is not necessary for the elicitation of locomotor activation by nicotine.

CENTRAL CORTICOSTEROID RECEPTORS AND STRESS RESPONSIVENESS IN TWO PHARMACOGENETICALLY SELECTED RAT LINES. J.A.M. van Eekelen[1], N.Y. Rots[1,2], E.R. de Kloet[1] and A.R. Cools*[2]. [1]Cent.Bio-Pharm. Sci., Leiden Univ., 2300 RA Leiden; [2]Dept. Pharmacol., Nijmegen Univ., 6500 HB Nijmegen, Netherlands.

Two rat lines derived from a normal outbred Wistar population were selected on their susceptibility to the dopamine agonist apomorphine. The drug susceptible (apo-sus) rats are characterized by a fleeing response following defeat, whereas the apo-unsus rats freeze. This difference in behavior suggests a different responsiveness of apo-sus and apo-unsus rats to stress. The hypothalamic-pituitary adrenal (HPA) activity in response to a conditioned emotional stimulus (CER) was determined by blood collection from chronically cannulated rats over 4 hours following CER. In Apo-sus rats, CER-induced plasma ACTH and basal plasma ACTH were elevated. However, this rat line did not show icreased stress-induced or basal plasma B levels. Apo-sus rats also displayed a more pronounced neuroendocrine response to HPA-stimulation with exogenous CRF. Apo-sus and Apo-unsus rats show differences in central MR and GR as studied by in situ hybridization and ligand binding assay. Thus, pharmacogenetically selected rats with different functional dopaminergic activity in the brain reveal enhanced reactivity of the corticosteroid controlled HPA-system.

NOVELTY OR FAMILIARITY DIFFERENTIALLY AFFECTS IN VIVO STRIATAL/SEPTAL D2 RECEPTOR BINDING IN ISOLATED NEONATAL RATS. K.M.WARD & P.KEHOE * Trinity College, Psychology, Hartford, CT 06106.

Infants separated from their caretaker emit behavioral and physiological responses associated with stress/arousal. Neurochemical mediation of these responses may be affected by the novelty of the isolation environment. Dopamine has been found to increase in young monkeys and guinea pig pups isolated in a novel environment. The present study on neonatal rats examines dopamine receptor occupation following isolation in environments with the degree of novelty varied. In vivo septal /striatal D2 receptor binding was done in Day 10 rats taken from the nest or following 5 min of isolation in a small cup with cage bedding or in a novel 20 x 20cm chamber. Twenty min following an ip injection of 3H-raclopride, a D2 antagonist, the pups were decapitated and brains dissected for striatal, septal and cere-bellar tissue. Compared to nest controls, pups in the cup of bedding demonstrated significantly more septal 3H-raclopride binding while those in the novel chamber had less. These data suggest that isolation in a more familiar environment led to less septal D2 receptor occupation in contrast to novelty which produced the most presumably by the release of dopamine at these terminals.

634.8

METABOLIC MAPPING OF THE "PRIMING" PHENOMENON IN RATS BEARING UNILATERAL 6-HYDROXYDOPAMINE LESION OF THE NIGROSTRIATAL PATHWAY. F.E. Pontieri*, M. Morelli°, R. Terenzi and G. Di Chiara°. Dept. Neurosciences University "La Sapienza", Rome and °Dept. Toxicology, University of Cagliari (Italy).

In rats bearing unilateral 6-hydroxydopamine (6-OHDA) lesion of the dopaminergic nigrostriatal neurons, "priming" with a single administration of the D_2 agonist, LY-171555 (0.2 mg/kg, s.c.), strongly potentiates the contralateral turning induced by the D_1 agonist, SKF-38393 (2.5 mg/kg, s.c.). The 2[^{14}C]-deoxyglucose (2DG) method for the measurement of local cerebral glucose utilization (LCGU) was applied to identify the neural substrates of this phenomenon. Lesioned animals received two injections, three days apart, as follows: Group 1: saline/saline. Group 2: LY-171555/saline. Group 3: saline/SKF-38393. Group 4: LY-171555/SKF-38393. The 2DG experimental procedure was begun 20 minutes after the second administration of drug or vehicle. Unilateral 6-OHDA lesion per-se (Sal-Sal) produced increases in LCGU in the globus pallidus (GP) and in the lateral habenula (LH) of the lesioned hemisphere. Rates of glucose metabolism in LY-Sal treated rats were similar to those measured in the vehicle-treated animals. Single administration of SKF-38393 (Sal-SKF) abolished the lesion-induced metabolic asymmetry in the LH but did not have any effect on the GP; furthermore, it increased LCGU in the substantia nigra pars reticulata (SNr) of the lesioned side. LY-SKF treatment produced marked metabolic asymmetries by increasing LCGU in the SNr and entopeduncular nucleus (EPN), and decreasing it in the LH of the lesioned side. These changes were significant also when compared to the corresponding values of the other experimental groups. Again, LY-SKF failed to modify the lesion-induced metabolic asymmetry in the GP. These results indicate that the behavioral changes observed after SKF-38393 in primed rats are associated with a marked enhancement of the metabolic response in the SNr, EPN and LH and suggest that priming exerts a facilitatory influence on the ability of D_1 receptors to stimulate the activity of the striato-nigral and striato-entopeduncular pathways.

634.9

INTRAPERITONEAL SALINE INJECTION DECREASES DARPP-32 (DOPAMINE- AND CYCLIC AMP-REGULATED PHOSPHOPROTEIN OF M_R=32,000) mRNA LEVELS IN SPECIFIC REGIONS OF MOUSE BRAIN. R. M. Lewis* and R. G. Perez. Dept. of NACS, University of Pittsburgh, Pittsburgh, PA 15261.

DARPP-32 is a cytosolic phosphoprotein phosphatase inhibitor that is phosphorylated by cyclic AMP-dependent protein kinase in response to dopamine. Phosphorylated DARPP-32 down-regulates Na^+,K^+-ATPase. Calcineurin dephosphorylates DARPP-32 in response to NMDA. DARPP-32 is enriched in regions of the brain that have D1 dopamine receptors. Neither expression of DARPP-32 during development of the brain, nor maintenance of DARPP-32 levels in the adult appears to require dopamine. We tested whether excess dopamine could down-regulate the expression of DARPP-32 mRNA. Mice were injected daily with 0.5 ml of 0.9% NaCl (i.p.), or 100 or 200 mg/kg L-DOPA in 0.5 ml of 0.9% NaCl (i.p., 30' after 50 mg/kg Ro 4-4602 in 0.5 ml of 0.9% NaCl, i.p.) for one to five days. Uninjected mice served as controls. Mice were sacrificed six hours after the last injection. Levels of DARPP-32 mRNA were assessed by *in situ* hybridization in sagittal sections of brain. The amount of DARPP-32 mRNA in layer VI of cortex, piriform cortex, and anterior olfactory nucleus of mice injected only with saline was lower than the amount of DARPP-32 mRNA in uninjected mice. No other regions of the brain were affected. Injection of 100 or 200 mg/kg L-DOPA in saline had the same effect as saline alone. We are testing each parameter of the injection protocol to determine the cause of this decrease in DARPP-32 mRNA levels in specific brain regions.

634.10

EVIDENCE FOR COUPLING OF RAT SUBSTANTIA NIGRA (SN) DOPAMINE D1 RECEPTORS TO PHOSPHOINOSITOL (PI) HYDROLYSIS. L.P. Martin* and B.L. Waszczak. Pharmacology Section, Northeastern University, Boston, MA 02115.

We have previously demonstrated that iontophoresis of the D1 agonists SKF 38393 (SKF) and A68930 produce increases in the firing rates of SN pars reticulata (SNpr) neurons. This excitatory response was lost after striatal lesions or injections of the receptor inactivator EEDQ into the SN, suggesting that the effect of SKF on SNpr neurons is mediated through stimulation of D1 receptors on impinging striatonigral terminals. Further studies revealed that adenylate cyclase might not mediate the D1 agonist effect. Specifically, iontophoresis of cAMP analogues did not mimic the agonist effect, whereas intranigral injection of pertussis toxin (PT), an inactivator of Gi and Go proteins, completely abolished the excitatory response to SKF. An ADP ribosylation assay on SN punches taken from PT-treated rats revealed a 64% decrease in the ability of nigral G-proteins to incorporate ^{32}P-NAD, confirming success of the PT injections. These results were surprising since D1 receptors have traditionally been thought to act through Gs to stimulate adenylate cyclase. Consequently, we were prompted to investigate whether PI hydrolysis might provide a second messenger coupling mechanism for the nigral D1 receptor. For these experiments, the SN and striata from 5 rats were pooled, slices were prepared with a tissue chopper, and then incubated in 1.7 μM ^{3}H-myo-inositol for 1 hour. Aliquots of packed slices were incubated for 30 min with or without agonist (500 μM SKF). ^{3}H-Inositol phosphates (^{3}H-IPs) were quantified by anion exchange HPLC. Preliminary results revealed a 4-fold higher basal level of ^{3}H-IPs in SN than striatum (per mg protein). Moreover, SKF appears to stimulate production of total ^{3}H-IPs in both nigra and striatum to a similar extent (56 and 71%, respectively; n=4). These findings, while preliminary, support the possibility that SN receptors involved in the excitatory effect of D1 agonists on SNpr neurons may be coupled to the PI second messenger pathway. (Supported by NS 23541)

634.11

A RAPID, VISUAL, FUNCTIONAL ASSAY FOR THE QUANTITATION OF LIGAND-MEDIATED STIMULATION OF G_i-LINKED RECEPTORS. M. N. Potenza* and M. R. Lerner. Depts. of Cell Bio., Int. Med., & Pharm., & HHMI, Yale Univ. Sch. of Med., New Haven, CT 06510.

The pigment containing cells of certain lower invertebrates have the ability to alter their coloration in response to specific environmental, neuronal, and hormonal stimuli. We have cultured a clonal cell line of melanophores from *Xenopus laevis*. These cells maintain the ability to translocate their melanosomes in a tightly controlled manner. Specifically, decreases in cAMP levels, produced by exposure to low doses of melatonin, induce pigment aggregation, while increases, produced by exposure to low levels of light or doses of MSH, induce pigment dispersion. Employing a cDNA clone encoding a typical G_i-coupled receptor (a human Dopamine $_2$ receptor (D_2R)), we can efficiently introduce and express the D_2R in the melanophores. D_2R-selective-agonist-induced stimulation of the D_2R-transfected, but not wild-type, melanophores produces dose-dependent pigment aggregation, which is blocked in a dose-dependent manner by D_2R-selective agonists. As the pigment translocation process occurs rapidly (essentially complete within 30 minutes), detailed and reproducible dose-response curves for many distinct agonists and/or antagonists can be determined in less than 30 minutes using a standard microtiter plate and plate reader. This system has the potential to rapidly assess drugs for their properties as agonists or antagonists upon any specific G_i-coupled receptor for which a cDNA clone is available. Moreover, the system should allow for the classification of "orphan" G_i-coupled receptors, and for the expression cloning of G_i-coupled receptors (see McClintock, *et. al.*).

634.12

COUPLING OF D_3-LIKE RECEPTORS TO GUANINE NUCLEOTIDE BINDING PROTEINS: A QUANTITATIVE AUTORADIOGRAPHY STUDY M.L. Coco and C.D. Kilts. Depts. of Pharmacology and Psychiatry, Duke Univ. Med. Ctr. Durham, NC 27710.

The recently cloned D_3 receptor has been shown to bind D_2 receptor ligands when expressed in CHO or COS-7 cells (Sokoloff et al., 1990), with the agonist quinpirole demonstrating a 113-fold greater affinity for D_3 vs. D_2 receptors. Additionally, both Sokoloff et al. and Gehlert et al. (1992) report that D_3 receptors, unlike D_1 or D_2, do not appear to shift to a lower agonist affinity state in the presence of GTP or analogues such as Gpp(NH)p. Previously, we sought to examine the D_3-like pharmacology of receptors located in limbic and non-limbic areas of the rat brain using quinpirole and domperidone (a D_2 antagonist with a reported 32-fold greater affinity for D_2 vs. D_3 receptors) to displace [^{125}I]iodosulpiride binding in 10 μm thick coronal brain sections (Soc. Neurosci. Abstr., 17:87,1991). Presently, we are involved in examining the ability of Gpp(NH)p to shift D_3-like receptors to a lower agonist affinity state. Quinpirole (0-1000 μM) displacement of 0.25 nM [^{125}I]iodosulpiride binding in the presence and absence of Gpp(NH)p (10 μM) was measured on serial 10 μM thick coronal brain sections. Gpp(NH)p induced a significant rightward shift in the quinpirole displacement curve for a number ofsubdivisions of the caudate nucleus -- confirming the negative allosteric interaction between G proteins and striatal D_2 receptors. We are presently applying this approach to dopamine projection fields exhibiting high affinity, quinpirole displaceable [^{125}I]iodosulpiride binding (D_3 receptors). (Funded by MH39967)

DA AUTORECEPTOR MODULATION OF DIFFERENT CALCIUM CURRENTS IN DA NEURONS. L.-X. Liu*, G. Kapatos, and L.A. Chiodo. Cellular & Clinical Neurobiology Prgm., Dept. Psychiatry Wayne State Univ. Sch. Med., Detroit Michigan 48201.

DA neurons normally display a spontaneous activity which is irregular and alternates between a single-spike mode of discharge and one which includes bursts of action potentials. In an attempt to better understand the ionic currents which may be responsible for maintaining these distinct patterns of activity, we have begun to study the inward calcium currents present in the cell body of mesencephalic DA neurons maintained in culture. Voltage-clamp studies were conducted using whole-cell patch-clamp methods. DA neurons were identified and studied in cultures which were 13-21 days old with the following procedure: cultures were incubated for 30-60 minutes in N2 medium containing 0.1% ascorbic acid and 25 μM 5,7-dihydroxytryptamine. DA neurons were found contain three types of calcium currents. A T-type current was observed which exhibited a low threshold for activation (-50 mV), displayed rapid inactivation and was partially blocked by both external application of either amiloride or Ni^{2+}. A classic L-type calcium current was observed which could be activated from a holding potential of -40 mV, slowly and incompletely inactivated and was extremely sensitive to nifedipine. Finally, a N-type current was observed which was activated at same threshold as the L-type current but required prior hyperpolarization of the membrane, was transient and was blocked by external application of omega-conotoxin. DA (50-100 μm) stimulation of the D2 autoreceptors present on these cells resulted in a significant reduction in both L- and N-type calcium currents observed. Studies on the signal transduction pathways involved in mediating this autoreceptor modulation of calcium currents are currently in progress. [MH41557 (LAC), NS26081 (GK)]

634.14

COUPLING OF D2-SHORT RECEPTOR ISOFORM TO ION CHANNELS. M.A. Castellano[1,2], L-X. Liu[2], F.J. Monsma, Jr.[3], D.R. Sibley[3], L.A. Chiodo[2] and G. Kapatos[2]*. [1]Dept. Psychobiology, Univ. La Laguna, Canary Isl. (Spain), [2]Dept. Psychiat. Wayne State Sch. Med. Detroit, MI., [3]NINDS, Bethesda, MD.

Two isoforms of the dopamine (DA) D2 receptor, termed D2-short (D2S) and D2-long (D2L), have been discovered. Because both forms display the same pharmacological characteristics and are present in the same tissues it is impossible to study their individual signal transduction mechanisms. To begin such an analysis, NG108-15 neuroblastoma-glioma hybrid cells transfected to stably express D2S were used to investigate the coupling of D2S with the whole-cell patch technique. Transfected NG108-15 cells maintained in G-418 were found to express inward currents mediated by both T- and L-type Ca^{2+} channels, as defined by voltage-dependence of activation, rate of inactivation and sensitivity to antagonists. Pressure application of DA (100 μM) or the D2 DA agonist quinpirole (QUIN 100 μM) reduced both T- and L-type currents. Application of DA or QUIN also reduced the amplitude of a K^+-dependent outward current. This latter effect was blocked in a concentration-dependent manner by inclusion of the Ca^{2+}-chelator BAPTA in the pipette solution, was not altered by Co^{2+} in the bath solution and could be mimicked by pressure application of thapsigargin (10 μM). These effects were blocked by the D2 receptor antagonist eticlopride and were not observed in nontransfected cells. These results suggest that Ca^{2+}, mobilized from intracellular stores, is involved in the reduction of the K^+ current by D2S receptor stimulation. The inhibitory effect of D2S stimulation on two distinct Ca^{2+}-dependent inward currents and a K^+-dependent outward current suggests that a common mechanism, possibly mediated by mobilization of intracellular Ca^{2+}, may be involved. Similar studies of NG108-15 cells transfected with the D2L form are currently in progress and should determine whether the actions of these two D2 receptor isoforms are mediated by similar transduction mechanisms. $G_{o\alpha}$ MEDIATES TRANSDUCTION OF DA AUTORECEPTOR MODULATION OF THREE DIFFERENT K^+ CURRENTS IN DA NEURONS. L.A. Chiodo*, L-X. Liu, and G. Kapatos. Cellular & Clinical Neurobiology Prgm., Dept. Psychiatry, Wayne State Univ. Sch. Med., Detroit, Michigan 48201

Dopamine (DA) autoreceptors are known to be critically involved in the regulation of the physiology of mesencephalic DA neurons. Recently, we have observed three different K^+ currents present in these cells, I_A, I_K and I_{ANOM}, are modulated by stimulation of the D2 DA autoreceptor. Because it is known that DA receptors belong to the larger superfamily of G-protein-coupled receptors, we examined the signal transduction pathways involved in mediating this modulation. Whole-cell patch-clamp techniques were used to examine these different currents in DA cells maintained in culture. All three currents were significantly increase by stimulation of DA autoreceptors with either DA or quinpirole (50-100 μM). Preincubation of the DA cells with pertussis toxin (500 ng/ml for 4-5 hrs) completely blocked the DA autoreceptor modulation of these currents. Intracellular application of 100 μM GDPβS also blocked the DA-modulation of these currents while intracellular application of GTPγS mimicked the activation produced by DA. In addition, the intracellular application of a polyclonal antibody that specifically recognizes $G_{o\alpha}$ subunits (antiserum 3, Granneman and Kapatos, J. Neurochem. 54:1995, 1990) completely blocked the ability of DA autoreceptors to modulate these potassium currents while the preimmune serum was without effect. Taken together, these findings demonstrate that I_A, I_K and I_{ANOM} currents are increased by DA autoreceptor activation via a common mechanism which involves modulation by the $G_{o\alpha}$ subunit of the associated K^+ channel proteins. DIETARY PROTEIN MODULATES DOPAMINE LEVELS IN THE RAT BRAIN. J. Brock, S. Farooqui*, E. S. Onaivi, A. Hamdi, and C. Prasad. Pennington Biomed.Res.C., Baton Rouge, LA, 70808; Dept. Medicine, LSUMC, New Orleans, LA, 70112.

Rats that consume 50% protein exhibit hyper-activity and hyperresponsiveness to nociceptive stimuli, in which facilitation of dopaminergic activity has been implicated. We studied the regional distribution of dopamine (DA) and its metabolites, dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) in brains of rats maintained on high-protein (50%), normal-protein (20%), and low-protein (8%) diets for 36 weeks. Brain nuclei which represented different DAergic systems were punch-dissected, analyzed using HPLC, and resulted as follows ($p<0.05$). The 50% protein diet caused elevated DA levels in the substantia nigra, the dentate gyrus, and the striatum. DOPAC:DA ratios covaried with dietary protein in tuberculum olfactorium and amygdala, but increased in the parietal cortex by the 50% and 8% diets. Both diets decreased HVA:DA ratios in frontal cortex, amygdala, striatum, & inter-peduncular nucleus, & were inversely related to dietary protein in the dentate gyrus. These data suggest that the nigrostriatal & mesohippocampal systems were more sensitive than mesocortical and mesolimbic systems to dietary protein.

CHANGES IN STRIATAL DOPAMINE SYNTHESIS IN PREWEANLING AND ADULT RATS AFTER IRREVERSIBLE RECEPTOR BLOCKADE. C. A. Crawford*, S. A. McDougall, J. K. Rowlett, and M. T. Bardo. Dept. of Psychology, Univ. of Kentucky, Lexington, KY 40506 and Dept. of Psychology, California State Univ., San Bernardino, San Bernardino, CA 92407.

Treatment with the alkylating agent N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) results in presynaptic changes in dopamine (DA) and dihydroxyphenylacetic acid (DOPAC) concentrations,as well as changes in D1 and D2 postsynaptic receptors. The present study was designed to determine if presynaptic changes after EEDQ were the result of changes in DA synthesis rates and if this change was receptor mediated. Preweanling (16-day-old) and adult (89-day-old) rats were treated with EEDQ (7.5 mg/kg) or vehicle, with half the rats in the both age groups receiving a combination of sulpiride (100 mg/kg) and SCH 23390 (1.0 mg/kg) 30 min prior to EEDQ treatment to protect DA receptors. Twenty-four hours after EEDQ treatment, all animals received an injection of the DOPA decarboxylase inhibitor NSD 1015 (100 mg/kg) and were sacrificed 30 min later. The striatum from all animals were removed and DOPA levels were measured by HPLC. Results showed that preweanling rats had significantly lower levels of DOPA than did adult rats and that EEDQ increased DOPA levels for both age groups. Antagonist pretreatment attenuated the DOPA increase by EEDQ, indicating that the increase was receptor mediated. These results suggest that the EEDQ-induced changes in DA and DOPAC levels reported previously were not the result of a change in DA synthesis rates.

The Effect of Dizocilpine on Basal and Stress-induced Dopamine Metabolism Bret A. Morrow*, Shelly J. Rosenberg, and Robert H. Roth, Yale University School of Medicine, Deptartments of Pharmacology and Psychiatry, New Haven, CT 06510.

Restraint selectivly activates the dopamine (DA) nuerons in the medial prefrontal cortex (mPFC) and nucleus accumbens (NAS) as assessed by postmortem tissue measurements of DA and its metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) (Roth et al., Ann. N.Y. Acad. Sci. 537:138-147, 1988). This report examines the non-competative N-methyl-D-aspartate (NMDA) antagonist, dizocilpine (MK801) on the stress-induced activation of the mesocortical and mesoaccumbal DA systems. Rats were treated with MK801, 0.01 mg/kg i.p., or saline and, after a 20 min delay, were restrained or left in the home cage for 30 min. The rats were then sacrificed and the brains removed and dissected. Brain samples were homogenized, purified over an alumina column and assayed for DOPAC and DA using high performance liquid chromatography with electrochemical detection. Restraint stress, as expected, significantly increased DA metabolism, as indicated by the DOPAC/DA ratio, in both the mPFC and NAS ($p<0.05$). Pretreatment with 0.01 mg/kg i.p. MK801 prevented this effect in the mPFC ($p<0.05$) but not the NAS ($p>0.05$). MK801 at this dose did not have any significant effect on DA metabolism in the mPFC, NAS or striatum. Previous results indicated that (+)HA-966, an antagonist for the glycine site of the NMDA receptor, prevented cortical stress-induced changes in DA metabolism. These data indicate that the stress induced increase in DA utilization can be prevented by blockade of the NMDA receptor complex.

CHRONIC MORPHINE IMPAIRS AXOPLASMIC TRANSPORT IN THE MESOLIMBIC DOPAMINE SYSTEM OF THE RAT BRAIN D. Beitner-Johnson* and E.J. Nestler. Laboratory of Molecular Psychiatry, Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Dopaminergic neurons in the ventral tegmental area (VTA) appear to mediate some of the rewarding properties of opiates, cocaine, and other drugs of abuse. In previous studies, we have demonstrated that chronic morphine and cocaine treatments induce increased protein levels of tyrosine hydroxylase (J Neurochem, 1991, 57:344) and decreased levels of three neurofilament proteins NF-200, NF-160, and NF-68 (J Neurosci, 1992, 12:2165) in the rat VTA. Since NF proteins are associated with axonal transport, it was of interest to determine whether chronic morphine alters axonal transport rates in these neurons. Rats were unilaterally injected with 9 μCi of [^{35}S]-methionine into the VTA, and were then allowed to recover for 3 to 11 days. Serial coronal slices of brain were taken starting from the midbrain and proceeding anteriorly through the medial forebrain bundle (MFB) to the nucleus accumbens (NAc). The VTA, MFB, or NAc was removed from each brain slice, and [^{35}S]-labelled proteins were isolated by TCA precipitation. A time-dependent transport of [^{35}S]-labelled proteins from the VTA to the NAc was observed in control animals. Chronic treatment of rats with subcutaneous morphine pellets impaired this transport by 50% ($p<0.04$, N=10), compared to rats which had received chronic placebo pellets.

Long-term exposure to morphine may impair the brain's endogenous reward system by reducing the ability of these cells to properly transmit dopaminergic and other signals to neuronal elements in the NAc.

REGULATION OF SEROTONIN RECEPTORS

635.1

5-HT2 RECEPTOR LEVELS IN A7r5 CELLS ARE INVERSELY REGULATED BY RECEPTOR STIMULATION.

Wu Yang*, Timothy Gallaher and Jean C. Shih. Dept. Mol. Pharmacol. Toxicol. University of Southern California, School of Pharmacy. Los Angeles, CA 90033

Preliminary studies of the 5-HT2 receptor in a rat aorta cell line (A7r5) indicate that the number of receptors and receptor stimulated PI formation can be regulated by growth in the presence of agonists or antagonists. Growth of the cells in Modified Eagle's Medium supplemented with 0.5% Fetal Bovine serum (FBS) for 24 or 48 hours results in a two-fold increase in the specific binding activity of [3H]ketanserin compared to cells grown for the same time in 10% FBS supplemented media. However, growth for 48 hours in the 0.5% supplemented media in the presence of 1 μM DOI or 5-HT results in decreased [3H]ketanserin binding, comparable to that grown in 10% supplemented media. Conversely, growth for 48 hours with 10% supplemented media in the presence of 1 μM ketanserin results in a two-fold increase in [3H]ketanserin binding, comparable to that grown in 0.5% FBS supplemented media. Cells grown in 10% FBS media in the presence of 1 μM ketanserin also show a similar increase in the level of PI formation relative to cells grown in 10% media but not treated with ketanserin. FBS contains many hormones including 5-HT. These results suggest that the activity of 5-HT2 receptors is regulated by a mechanism which is inversely sensitive to its stimulation. SIGNALLING VIA THE SEROTONIN-RECEPTOR OF C6BU-1 CELLS H. Sommermeyer and T. Glaser*. Inst. of Neurobiology, Troponwerke GmbH & Co.KG., Berliner Str. 156, 5000 Köln 80, Germany

The serotonin-stimulated accumulation of inositol-phosphates in the rat glioma cell line C6BU-1 was characterized using a simple and rapid experimental procedure. Addition of serotonin (5-HT) to C6BU-1 cells prelabeled with [^{3}H]-inositol increased the inositol-phosphates content 2.5 to 3.5-fold with an EC_{50} value of 0.8 μM. The stimulatory effect of 5-HT was highly dependent on the presence of LiCl which was half-maximal effective at a concentration of 4 mM. The maximal effect of LiCl was achieved at 10 mM.

The 5-HT-stimulated PI-response was inhibited by 5-HT_2-/5-HT_{1C}-receptor antagonists. The order of potency was spiperone = risperidone > ritanserin > pelanserin > ketanserin = mianserin > pipamperone = metitepine. Several well known neuroleptics, like cis-flupentixol, haloperidol and clozapine antagonized the 5-HT-induced PI-response. Cis-flupentixol was about 10 times more potent than haloperidol or clozapine. The latter two exhibited their antagonistic properties only at relative high concentrations in the μM-range. Neither the 5-HT-uptake inhibitor citalopram, the muscarinic cholinergic antagonist pirenzepine, the α_1-adrenoceptor antagonist prazosin, nor the D_2-dopaminergic antagonist sulpiride inhibited the 5-HT-induced PI-response in C6BU-1 cells.

635.3

LACK OF EFFECT OF LONG-TERM ESTROGEN TREATMENT ON SEROTONIN-INDUCED OUTWARD CURRENT IN HIPPOCAMPAL PYRAMIDAL CELLS OF MALE CASTRATED RATS.

F.A. Dijcks, J.H. Couvée and G.S.F. Ruigt*. Organon Int., Dept. of Neuropharmacology, POB 20, 5340 BH Oss, The Netherlands.

Several lines of evidence suggest an interaction between sex hormones and serotonergic neurotransmission in the central nervous system. In an electrophysiological study using current-clamp techniques Beck et al. (*Neurosc. Lett. 106:181-187; 1989*) showed that chronic estrogen treatment (E2 for 3-6 days) restored the blunted 5-HT_{1A}-mediated hyperpolarization in CA1 pyramidal cells of ovariectomized rats. Given the fact that the central effects of testosteron are mainly mediated through estrogen receptors (testosteron is aromatized to E2 in the CNS) we were interested to know whether the serotonergic response in male rat hippocampus would be affected by castration and steroid suppletion.

In the present experiment we examined the influence of castration and long-term E2 treatment (2-3 wks) on serotonine-induced currents in CA1 hippocampal pyramidal cells of the male rat. Rats were either castrated or sham-operated. Sham-operated animals (SHAM) received a subcutaneous implant containing cholesterol, whereas castrated animals received either cholesterol (CAS) or cholesterol/estrogen (CAS/E2) implants. Intracellular and extracellular (population spike) recordings were performed in the CA1 pyramidal cell layer. Neurons showing a resting membrane potential (RMP) ≤ -55 mV, a spike amplitude (SA) ≥ 80 mV and an input resistance (R_{in}) ≥ 25 MΩ were included in the analysis. We recorded 44 cells from 24 animals with characteristics as shown in the next table (data as avg±sem):

treatm	n	RMP (mV)	Rin (MΩ)	$I_{5\text{-}HT}$ (nA)	E2 (pg/ml)	weight (g)
SHAM	14	-65±2	56±4	0.30±0.04	6±1	278±17
CAS	16	-66±1	59±3	0.26±0.03	7±1	233±12
CAS/E2	14	-69±1	61±3	0.27±0.03	33±4	181±8

From these results and the fact that 3 μM spiperone fully antagonized the serotonin-induced currents we conclude that chronic physiological levels of sex steroids do not affect the serotonin (5-HT_{1A})-induced outward current in hippocampal pyramidal cells of the male rat.

5-HT1-LIKE RECEPTORS ARE LINKED TO INHIBITION OF ADENYLYL CYCLASE AND INCREASE IN INTRACELLULAR CALCIUM CONCENTRATION IN VASCULAR SMOOTH MUSCLE (VSM) CELLS FROM BOVINE BASILAR ARTERY.

B.J. Ebersole[1]*, C.A. Diglio[2], D. Wosner[1], and K.A. Berg[1]. [1]Dept. of Anesthesiology , Mt. Sinai School of Medicine of CUNY, NY, NY 10029 and [2]Dept. of Pathology, Wayne State University School of Medicine, Detroit, MI 48201.

VSM cells derived from bovine basilar arteries by the explant method were grown in culture for up to 20 passages. In the presence of 1 μM forskolin and the phosphodiesterase inhibitor rolipram, 5-HT1-like agonists inhibited by 85-95% the accumulation of cAMP in intact cells with the rank order of potency 5-carboxamidotryptamine (5-CT, EC50=1.2 nM) > 5-HT (3.2 nM) > 5-benzyloxytryptamine (25 nM) > RU24969 (63 nM) > 8-OH-DPAT (205 nM). In suspensions of cells loaded with the calcium-sensitive probe fura-2, 5-CT and 5-HT caused transient increases in $[Ca^{2+}]i$ of 2-3 times resting levels. Both the inhibition of cAMP formation and increase in $[Ca^{2+}]i$ were blocked by the antagonist methiothepin (50-100 nM), but not by 100 nM ketanserin or spiperone. 5-CT-mediated inhibition of cAMP accumulation was not blocked by 10 μM pindolol. Both responses were blocked by pretreatment with pertussis toxin. The rank order of agonist potency, as well as the antagonist sensitivity, indicates responses mediated by 5-HT1-like (perhaps 5-HT1D) receptors. Because these cells constituitively express 5-HT1-like receptors, they may serve as a useful model for the study of 5-HT1-like receptor-mediated signal transduction mechanisms in VSM. Supported by GM34852 and AHA Grant-in-Aid 890750.

PHARMACOLOGICAL CHARACTERIZATION OF 5-HYDROXYTRYPTAMINE (5-HT_3) RECEPTOR SUBTYPES IN SPRAGUE-DAWLEY RAT CORTEX, C57BL/6 MOUSE CORTEX, CD-1 (ICR) MOUSE CORTEX AND CD-1(ICR) MOUSE ILEUM. E. Stefanich, D.W. Bonhaus, R.M. Eglen and E.H.F. Wong*. Dept. of Neurosciences, Inst. of Pharmacology, Syntex Research, Palo Alto, CA 94304.

5-HT_3 receptors are widely distributed in the central and peripheral nervous systems; thus 5-HT_3 receptor antagonists may have clinical applications in both central and G.I. disorders. Previous studies have demonstrated species-dependent variants of 5-HT_3 receptors. The current study characterizes 5-HT_3 bindings sites in two strains mouse and in two tissues (cortex and ileum) within a single strain (CD-1) of mouse.

Membranes were prepared from sprague-dawley rat cortex, C57BL/6 mouse cortex, CD-1 (ICR) mouse cortex and CD-1(ICR) mouse ileum. 5-HT_3 receptors were labeled with [^{3}H](-)-(S)-N-(1-azabicyclo [2.2.2.] oct-3-yl)-2,4,5,6-tetrahydro-1-H-benzo [de] isoquinolin-1-one hydrochloride mono ethanolate (RS 42358-197) a selective high affinity 5-HT_3 receptor antagonist (Wong et al., Br. J. Pharmacol. 105:33P; 1992).

The radioligand bound with similar affinities (0.08 to 0.20 nM) to homogeneous populations of saturable binding sites (Bmax values of 30 to 44 fmol/mg protein) in each of the tissues. However, affinities of specific antagonists differed by more than 10 fold both between strains of mice and within a single strain of mouse (when comparing 5-HT_3 receptors in brain cortex to those in ileum). These results demonstrate, for the first time, subtypes of 5-HT_3 binding sites both between strains of mouse and between tissues within a single strain of mouse.

635.6

ALLOSTERIC INTERACTIONS OF AGONISTS AND ANTAGONISTS AT 5-HYDROXYTRYPTAMINE (5-HT_3) RECEPTORS D.W. Bonhaus*, R.M. Eglen and E.H.F. Wong. Dept. of Neurosciences, Inst. of Pharmacology, Syntex Research, Palo Alto, CA 94304.

5-HT_3 receptors are ligand-gated ion channels and, as such, may be subject to allosteric regulatory mechanisms. To investigate the nature of ligand interactions at the 5-HT_3 receptor the effects 5-HT_3 receptor agonists and antagonists on the dissociation of a selective high affinity 5-HT_3 antagonist, ([^{3}H](-)-(S)-N-(1-azabicyclo[2.2.2.]oct-3-yl)-2,4,5,6-tetrahydro-1-H-benzo[de] isoquinolin-1-one hydrochloride mono ethanolate; [^{3}H]RS 42358-197 (Wong et al., Br. J. Pharmacol. 105:33P; 1992), was examined.

The dissociation of [^{3}H]RS 42358-197 from NG108 cell membranes was significantly slower in the presence of saturating concentrations of 5-HT_3 (0.06 $\pm$ 0.01 min^{-1}) or other agonists than in the presence of unlabelled RS 42358-197 (0.16 $\pm$ 0.01 min^{-1}) or other 5-HT_3 antagonists. One explanation for these findings is that 5-HT_3 receptor agonists bind to sites distinct from the antagonist binding site to decrease [^{3}H]RS 42358-197 binding by an allosteric interaction. Alternatively agonists may allosterically **increase** the affinity of the binding site to which the antagonist is bound thereby slowing [^{3}H]RS 42358-197 dissociation. This latter interpretation is consistent with the finding that Hill slopes of competition curves for antagonists at the 5-HT_3 receptor are not different from unity whereas agonists produce Hill slopes greater than 1.0. Regardless of mechanism, these findings indicate that the dissociation rate constants for [^{3}H]RS 42358-197 are determined by the nature of the displacing ligand, a finding inconsistent with a competitive interaction. This, in turn, raises the possibility that there are multiple sites on the 5-HT_3 receptor-gated channel towards which ligands can be directed.

635.7

DECREASED SEROTONIN 5HT_2 RECEPTORS IN THE FRONTAL CORTEX OF BRAINS SPECIFIC TO NEUROLEPTIC TREATED PATIENTS WITH CHRONIC SCHIZOPHRENIA R.R. Conley, G.N. Pandey, F.J. Peretti, W.T. Carpenter*, C.A. Tamminga, and R.C. Roberts. Univ. of Maryland, Baltimore, MD 21201.

Changes in serotonin 5HT_2 receptor number in the brains of chronic schizophrenic patients was investigated using ^{3}H-LSD and ^{3}H-ketanserin as ligands. Thirteen subjects were studied: eight had taken neuroleptics up to their death; five had been off neuroleptics, by clinical case review, for more than one year prior to death. Ketanserin binding was saturatable with a Kd of 1.3 nM and a Bmax of 195 fmol/mg protein in drug free cases and a Kd of 1.6 nM and Bmax of 148 fmol/mg protein for on drug cases (p=NS). LSD binding was saturatable with a Kd of 0.75 nM and a Bmax of 379 fmol/mg protein in drug free subjects and a Kd of 0.75 nM and Bmax of 162 fmol/mg protein in on drug cases (p>.01). An analysis of six matched normal controls yielded a Bmax of 153 fmol/mg protein for ketanserin (Kd 1.4 nM) and Bmax of 302 fmol/mg protein for LSD (p<.02 vs. on drug cases)(Kd 0.63 nM). Neuroleptic treatment is associated with a reversible decrease in serotonin receptors in neocortical tissue from chronic schizophrenic subjects.

635.8

OVEREXPRESSION OF THE THIRD INTRACELLULAR LOOP PROTEINS OF RAT 5-HT RECEPTORS: DEVELOPMENT OF SUBTYPE-SPECIFIC ANTIBODIES AND NUCLEOPROBES. **M.-C. Miquel, J.A. Gingrich, E. Doucet, E.J. Kidd, C. Gérard, H. Gozlan, B. Berger* and M. Hamon, INSERM U.288, CHU Pitié Salpêtrière, 91 Boulevard de l'Hôpital, 75013 PARIS, FRANCE.**

In order to develop a systematic series of tools to permit the localization of 5-hydroxytryptamine (5-HT) receptors in the central nervous system, we have used the technique of polymerase chain reaction (PCR) to amplify and clone regions corresponding to the putative third intracellular loop of these receptor proteins. These PCR fragments when cloned into pBluescript were either used to generate labelled riboprobes (sense and antisense) or cDNA probes. The same fragments were also cloned into the plasmid pGEX2-KG, and were used to generate in-frame fusion proteins with the glutathione-S-transferase enzyme. These proteins were then overexpressed, purified, and used as antigens to immunize rabbits. The protein was either fixed with formaldehyde or left in its native form in order to obtain antibodies which can be used for electron microscopy on fixed tissues and for immunoautoradiography on unfixed tissue. We first applied this method to the recently sequenced 5-HT_{1A} receptor (Albert et al., 1990). Our results show that both the "fixed" and "native" antibodies are able to immunoprecipitate CHAPS-solubilized 5-HT_{1A} receptors labelled with [^{3}H]-8-OH-DPAT. In addition, both sets of antibodies recognize the same protein as our antipeptide antibodies (El Mestikawy et al., 1990), and their regional distributions are well correlated with that of the mRNA for the 5-HT_{1A} receptor (Miquel et al., 1991). Fusion proteins from the same regions of the other G-protein coupled 5-HT receptors (5-HT_{1B}, 5-HT_{1D}, 5-HT_2) have been obtained in our laboratory and are currently being injected into rabbits. Albert et al. (1990) *J. Biol. Chem.*, **265**, 5825-5832; El Mestikawy et al. (1990) *Neurosci. Lett.*, **118**, 189-192; Miquel et al. (1991) *Neurochem. Int.*, **19**,453-465.

635.9

CHARACTERIZATION OF A FUNCTIONAL 5-HT_2 RECEPTOR IN THE HUMAN NEUROBLASTOMA CELL LINE IMR-32 A. Cholewinski, M. Elliott, T. Flanigan, N. Newberry, R. Newton, S. Phipps, A. Reavley, D. Grahame-Smith, and R. Leslie.* Oxford Univ.-SmithKline Beecham Centre for Applied Neuropsychobiology, Oxford OX2 6HE, U.K.

Scatchard transformation of saturation binding to IMR-32 cell membranes with [^{3}H]ketanserin revealed a linear, single-site with a K_d of 0.57nM and a B_{max} of 147 $\pm$ 18fmol/mg protein. Displacement studies with 5-HT antagonists demonstrated a 5-HT_2 receptor subtype rather than a 5-HT_{1C} (spiperone = ketanserin < mesulergine < 5-HT). Northern blot analysis of poly(A)$^+$ mRNA from IMR-32 cells identified two transcripts of 5.6 and 6.0kb which hybridised with a rat 5-HT_2 cDNA probe. Measurements of phosphoinositide turnover during 5-HT stimulation showed a concentration-dependent increase with an EC_{50} = 1.9μM and a maximal response of three times over basal. The effect was inhibited by spiperone (1μM) and ketanserin (1μM). Brief applications of 5-HT stimulated increases in $[Ca^{2+}]_i$ in a concentration-dependent manner (EC_{50} = 0.5μM). These increases occurred in calcium-containing and calcium-free media, implying release of calcium from intracellular stores. Responses were blocked by ketanserin (10nM), spiperone (10nM), mesulergine (1μM) and DOI (1μM), but not by pindolol (1μM) and granisetron (1μM). 5-HT (10μM) hyperpolarised 34/50 IMR-32 cells (median -7mV). This response was associated with an input resistance reduction and was ketanserin(30nM)-sensitive. These data demonstrate a functional 5-HT_2 receptor on IMR-32 cells.

635.10

HOMOLOGOUS DESENSITIZATION OF SEROTONIN-2 RECEPTORS IN RAT GLIOMA C6BU-1 CELLS. A.Kagaya*, M.Mikuni, S.Muraoka, H.Shinno, K.Saitoh, T.Ogawa, S.Yamawaki and K.Takahashi. Dept. Neurol. Psychiat. Hiroshima Univ. Schl. Med., Hiroshima and Div. Mental Disorder Res. Natl. Inst. Neurosci. NCNP, Tokyo Japan.

It has been characterized that serotonin-2 receptors are responsible for serotonin-induced intracellular calcium mobilization in rat glioma C6BU-1 cells. As several studies suggest that serotonin-2 receptors can be desensitized and down regulated in various tissues, investigators have directed their attention to the function of these receptors. However, the precise mechanism of the desensitization of serotonin-2 receptors is so far not understood. We have now investigated the desensitization of serotonin-2 receptor-mediated intracellular calcium mobilization in C6 cells. The receptors were desensitized after pretreatment of the cells with serotonin in dose and time dependent manner. The desensitization was reversed by W-7, a calmodulin antagonist, which was co-pretreated with serotonin. Isoproterenol or thrombin did not affect the calcium response to serotonin when they were pretreated. These results suggest that serotonin-2 receptor-mediated signalling system was desensitized homologously and that the desensitization was mediated at lease in part by calmodulin dependent pathway.

635.11

5-HT AGONIST REGULATION OF THE RAT 5-HT_{1C} RECEPTOR . A. Sharma*,and K.C.F.Fone. Dept. Physiol. & Pharmacol., Queen's Medical Centre, Nottingham, NG7 2UH, U.K. (SPON: BRAIN RESEARCH ASSOCIATION).

5-HT_2 receptors are downregulated by both agonist and antagonists (Leysen et al., 1989) but similar regulation of the 5-HT_{1C} receptor has yet to be studied. To explore this further, the behavioural response and 5-HT_{1C} receptor protein-like immunoreactivity (5-HT_{1C}-LI) were measured in selected rat brain and cord regions following repeated treatment with the 5-HT_2/5-HT_{1C} agonist (DOM) and the 5-HT_{1C}/5-HT_{1B} agonist (m-CPP).

Adult male Wistar rats (300-335g) received twice daily injections of either DOM (2.5mg/kg i.p), m-CPP (5mg/kg i.p), or saline (0.154M 1ml/kg i.p., n=6 each) for 5 days. Following the first and alternate injections, rats were placed in a behavioural chamber, and a series of motor behaviours (wet-dog shakes, back-muscles contractions, rears and 90° turns) and yawns were measured separately but continuously for 30 mins. After (30mins) the final injection, rats were decapitated and the 5-HT_{1C}-LI measured using a polyclonal antiserum raised against the rat 5-HT_{1C} receptor protein (Sharma et al.,1992). Results were analysed by ANOVA followed by Dunnett t-test (behaviour) or Student's t-test (5-HT_{1C}-LI). Repeated DOM injection reduced back muscle contractions ($P<0.05$) and wet-dog shakes (n.s), whilst 5-HT_{1C}-LI was elevated in the dorsal spinal cord ($P<0.01$) and reduced in both the hypothalamus ($P<0.05$) and ventral spinal cord (n.s). With repeated injection m-CPP continued to attenuate turns and rears compared with saline ($P<0.01$ and $P<0.001$ respectively) while yawns increased progressively ($P<0.05$) and 5-HT_{1C}-LI was unchanged in any brain or cord region.

A DOM-induced motor behavioural tolerance was observed confirming previously reported rapid agonist-induced downregulation of 5-HT_2 receptors (Leysen et al., 1989) with selected changes in 5-HT-LI. In contrast, no downregulation of either the hypolocomotor effect (reported to be 5-HT_{1C}-mediated, Kennett & Curzon, 1988) or 5-HT_{1C}-LI was observed despite repeated m-CPP administration.

635.12

DOWNREGULATION AND TURNOVER OF CORTICAL 5-HT2 RECEPTORS MEDIATED BY ACTIVATION OF 5-HT1A RECEPTORS AND LESION: SELECTIVE REDUCTIONS IN 5-HT2 RECEPTOR PRODUCTION RATES

G. Battaglia*, F. Tung, and J. Yracheta Department of Pharmacology, Loyola University Chicago, Stritch School of Medicine, Maywood, IL 60153

These studies investigated the effects of serotonergic lesion and 5-HT_{1A} receptor activation on the regulation of cortical 5-HT_2 receptors. Rats received a single i.p. injection of either vehicle (50% ETOH/H_2O), or the irreversible receptor inactivator EEDQ (10 mg/kg), and were sacrificed at 0.25-14 days to determine 5-HT_2 receptor recovery. Another group of rats were similarly treated, but also received daily 1 mg/kg s.c. injections of the selective 5-HT_{1A} agonist, 8-hydroxydipropylaminotetralin (DPAT), from day 1 throughout the recovery time-course. To investigate the influence of presynaptic input and postsynaptic 5-HT_{1A} activation on 5-HT_2 receptor turnover, treatment paradigms identical to those above were also carried out in 5,7-DHT-lesioned rats. Decreases in ^{3}H-paroxetine-labeled 5-HT uptake sites confirmed a 95% lesion throughout the recovery. DPAT or lesion alone was found to reduce the density of 5-HT_2 receptors by 17% and 23%, respectively. These effects appeared to be additive as DPAT, in lesioned rats, downregulated 5-HT_2 receptors by 36%. Receptor turnover studies indicated that in either lesioned or DPAT-treated rats, the 5-HT_2 downregulation was due to selective decreases (28-32%) in receptor production rates. Likewise, 5-HT_2 receptor production rates were decreased by 34% in lesioned DPAT-treated rats compared with lesioned saline-treated controls. NO significant changes in 5-HT_2 receptor degradation rate constants were observed in any of the groups. These data demonstrate that removal of 5-HT presynaptic input, as well as, the direct activation of postsynaptic 5-HT_{1A} receptors can downregulate cortical 5-HT_2 receptors. Downregulation by lesion or 5-HT_{1A} receptor activation is mediated by selective decreases in 5-HT_2 receptor production rates, presumably via decreased 5-HT_2 mRNA levels.

SEROTONIN RECEPTORS: PHARMACOLOGIC CHARACTERIZATION

636.1

IN VIVO ACTIVITY OF CP-94,253, A SELECTIVE SEROTONIN 5-HT_{1B} RECEPTOR AGONIST. F.D. Tingley, A.W. Schmidt, J.E. Macor, and D.W. Schulz*. Pfizer Central Research, Groton, CT 06340.

Characterization of the functional properties of 5-HT_{1B} receptors *in vivo* has been hampered by a lack of agonists having adequate selectivity for this receptor. CP-94253, (3-[1,2,5,6-tetrahydro-pyrid-4-yl]-5-propoxypyrrolo[3,2-b]pyridine) binds with high affinity to 5-HT_{1B} receptors (K_i= 2 nM) and is 45-fold selective for 5-HT_{1B} vs 5-HT_{1A} receptors (Koe *et al.*, Drug Dev. Res., in press). Moreover, it causes anorexia in rats (Koe *et al.*), a behavior attributed to activation of 5-HT_{1B} receptors (Kennett *et al.*, Eur. J. Pharmacol. 141:429). We have characterized the functional activity of CP-94,253 *in vitro*, and have examined its effects *in vivo* by measuring serotonin utilization in rat and guinea pig brain.

CP-94,253 behaved as a full agonist at 5-HT_1 receptors, inhibiting forskolin-stimulated adenylate cyclase activity in a receptor-selective manner (EC_{50}: 5-HT_{1A} 1800 nM, 5-HT_{1B} 10 nM, 5-HT_{1D} 190 nM). One hour following ip injection, serotonin turnover in rat hypothalamus and cortex was inhibited dose-dependently (ED_{50} = 2 mg/kg ip). While the selective 5-HT_{1A} agonist 8-OH-DPAT was approximately equipotent in both species, a dose of 32 mg/kg CP-94,253 was required in order to diminish 5-HT turnover in guinea pigs, a species lacking 5-HT_{1B} receptors. These data suggest that CP-94,253 acts selectively at release-modulating 5-HT_{1B} receptors, rather than somatodendritic 5-HT_{1A} autoreceptors.

636.2

PRECLINICAL PHARMACOLOGICAL CHARACTERIZATION OF LY228729, A SELECTIVE 5-HT_{1A} AGONIST. M.M. FOREMAN*, R.W. FULLER, D.T. WONG, D.L. NELSON, D.O. CALLIGARO, J.D.LEANDER AND M.E. FLAUGH , Lilly Research Laboratories, Eli Lilly Corporate Center, Indianapolis, IN, USA

LY228729 (6-carboxamido-4-dipropylaminotetrahydrobenzindole) is a rigid tryptamine derivative with a carboxamide serving as a protophilic group to mimic the hydroxyl in 5-HT. In radioligand diplacement assays, LY228729 had a Ki of 0.19 nM for the 5-HT_{1A} receptor and much lower affinities for other monoaminergic receptors with Ki values at least 1000 times higher. LY228729 significantly reduced hypothalamic 5-HIAA levels (0.03 mg/kg s.c.) and increased serum corticosterone levels (0.3 mg/kg s.c.) in rats. LY228729 (0.03 mg/kg s.c.) significantly reduced hypothalamic 5-HTP accumulation after decarboxylase inhibition. LY228729 (0.01 mg/kg s.c.) decreased ejaculatory latency in rats. Maximal 5-HT_{1A} syndrome responses in rats, e.g. lower lip retraction and flat posture, were observed between 0.1 and 1 mg/kg s.c., and p.o. doses were 10 times higher for equivalent responses. LY228729 increased punished responding at 0.08 mg/kg s.c. and lowered unpunished responding at 0.32 mg/kg s.c. in rats. These results indicate that LY228729 is a selective 5-HT_{1A} agonist with appropriate potency and bioavailability properties for clinical evaluation.

636.3

[^{3}H]5-CARBOXAMIDOTRYPTAMINE LABELS MULTIPLE HIGH AFFINITY BINDING SITES IN VERTEBRATE BRAIN. C.D. Mahle*, H.P. Nowak, D.J. Bucci, R. B. Carter, and F. D. Yocca. Dept. Neuropharmacology, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492.

Binding sites displaying high (5-HT_{1D}) and low (5-HT_{1E}) affinity for 5-carboxamidotryptamine (5-CT) have been revealed using [^{3}H]5-HT and selectively masking 5-HT_{1A} and 5-HT_{1C} receptors. To probe the possible heterogeneity in 5-HT_{1D} binding sites, we have eliminated a portion of the complex nature of [^{3}H]5-HT binding by utilizing [^{3}H]5-CT. In corticolimbic regions of guinea pig brain, when using a low concentration of [^{3}H]-5-CT selectively labelling 5-HT_{1D} sites, 5-CT competed monophasically in striatum (K_i=0.68±0.04 nM), frontal cortex (K_i=1.85±0.35 nM), and hippocampus (K_i=3.89±0.42 nM). Sumatriptan further differentiated amongst high affinity [^{3}H]5-CT binding sites however, in both guinea pig and bovine striatum, frontal cortex and hippocampus, where biphasic displacement curves yielded a high affinity 5-HT_{1D} site, as well as a low affinity sumatriptan-insensitive site. Although pigeon brain contains a high density of 5-HT_{1D} receptors, 5-HT, 5-CT and sumatriptan competition for [^{3}H]5-CT binding in optic tectum, brain stem, and telencephalon yielded apparently monophasic displacement curves. These results have been confirmed autoradiographically, demonstrating lack of heterogeneity in [^{3}H]-5-CT binding in pigeon brain, yet localization of multiple [^{3}H]-5-CT binding sites in corticolimbic regions of guinea pig brain. Preliminary reults suggest multiplicity of [^{3}H]5-CT binding sites in corticolimbic regions of human brain. These results suggest species differences exist with regard to the heterogeneity of 5-HT_{1D}-like binding sites in vertebrate brain.

636.4

SEROTONIN AND SEROTONIN$_3$ RECEPTOR AGONISTS POTENTIATE THE INHIBITORY ACTION OF DOPAMINE ON MEDIAL PREFRONTAL CORTICAL CELLS IN RATS. Jian Yu Zhang* and Rex Y. Wang. Dept. of Psychiatry and Behavioral Sciences, SUNY at Stony Brook, Stony Brook, NY 11794.

The effects of serotonin (5-HT) and selective 5-HT_3 receptor agonists 2-methylserotonin and 5-HTQ on the suppressant action of dopamine (DA) on medial prefrontal cortical (mPFc) cells was studied using the techniques of single cell recording and microiontophoresis. The microiontophoretic application of DA (5-80 nA) produced a current-dependent suppression of mPFc cell firing. When subthreshold currents of 5-HT, 2-methyl-5HT or 5-HTQ were administered concurrently with DA, they potentiated the inhibition produced by DA but not that of GABA. Similarly, the electrical stimulation of the ascending 5-HT fiber pathway via the caudal linear raphe nucleus also potentiated the inhibition induced by DA. The effects of potentiation were blocked by the selective 5-HT_3 receptor antagonist granisetron. The potentiated effects were not altered in rats pretreated with either parachlorophenylalanine (PCPA) or α-methyl-p-tyrosine. However, the pretreatment with either PCPA or 5,7-dihydroxytryptamine markedly attenuated the inhibitory action of DA on mPFc cells. Taken together, our preliminary results show that the inhibitory action of DA on mPFc cells depends upon 5-HT input, i.e. 5-HT may have a permissive role. Furthermore, the modulatory effect of 5-HT on DA's action is primarily mediated by 5-HT_3-like receptors. If our results can be extended to other brain regions, the blockade of the potentiating effect of 5-HT and 5-HT_3 receptor agonists on the inhibitory action of DA by 5-HT_3 antagonists may partially account for their antipsychotic potential and potential for treating drug addicts.

636.5

EFFECTS OF 5-HT_3 RECEPTOR ANTAGONISTS IN ETHANOL- AND DIAZEPAM-WITHDRAWN RATS. A.K. Mehta* and M.K. Ticku. Univ. TX Hlth. Sci. Ctrs., Dept. of Pharmacology, San Antonio TX 78284-7764

The effect of 5-HT_3 receptor antagonists such as ICS 205-930, MDL 72222, metoclopramide and zacopride was investigated on ethanol as well as diazepam withdrawal phenomena in the present study. There was a significant increase in locomotor activity in the ethanol as well as diazepam withdrawn rats. The treatment of rats with 5-HT_3 receptor antagonists during withdrawal phase did not modify the effect in spite of the fact these agents had a slight (10-20%) depressant effect per se on locomotor activity in control rats. The ethanol-withdrawn rats were more sensitive to pentylenetetrazole (PTZ)-induced convulsions as compared to control animals. 5-HT_3 receptor antagonists did not attenuate the increased sensitivity of ethanol-withdrawn rats to PTZ. Furthermore, 5-HT_3 receptor antagonists did not elicit any significant effect per se on PTZ-induced convulsions in control rats. These observations indicated that 5-HT_3 receptor antagonists are ineffective in attenuating hyperlocomotor-activity following abrupt termination of chronic administration of ethanol or diazepam, and increased sensitivity to PTZ in the ethanol-withdrawn rats.

636.6

5-HT_2 RECEPTOR-MEDIATED ACTIVATION OF INTERNEURONS IN PIRIFORM CORTEX IS POTENTLY ANTAGONIZED BY RISPERIDONE, A NEW ATYPICAL ANTIPSYCHOTIC DRUG. R.L. Gellman* and G.K. Aghajanian. Depts. of Pharmacology and Psychiatry; Yale University, New Haven, CT 06510.

Potent 5-HT_2 receptor antagonism is hypothesized to underly the therapeutic action of new, clinically effective, atypical neuroleptic drugs such as risperidone (Leysen, et. al., 1992). Using electrophysiological techniques, we have recently shown that 5-HT activates, via 5-HT_2 receptors, a subpopulation of GABAergic interneurons located on the layer II/III border of piriform cortex (Sheldon & Aghajanian, 1991). Activation of these interneurons induces IPSPs in layer II pyramidal cells. In the present study we investigated the ability of several antipsychotic drugs, including risperidone, clozapine and haloperidol, to antagonize the 5-HT_2-mediated activation of interneurons and 5-HT_2-elicited IPSPs in pyramidal cells.

In brain slices, 5-HT-activated interneurons were identified by extracellular recording using previously established criteria (Sheldon & Aghajanian, 1991). The response to a bath application of 5-HT (100 μM, 1-2 minutes) was measured at baseline and in the presence of increasing concentrations of the antipsychotic drug. Risperidone dose-dependently blocked the excitatory 5-HT response with an IC_{50} of ~9 nM. Clozapine also dose-dependently blocked the 5-HT response with an IC_{50} of ~2 μM. In contrast to the complete antagonism of the 5-HT response by risperidone and clozapine, haloperidol did not completely block the excitatory 5-HT response even at the highest concentration used (10 μM). Parallel results were found for 5-HT-elicited IPSPs recorded intracellularly from layer II pyramidal cells. Antagonism of excitatory 5-HT_2 receptors on a specific subpopulation of interneurons in cortical regions may be one site at which atypical antipsychotic drugs such as risperidone exert their therapeutic effects.

636.7

SUMATRIPTAN: LACK OF EFFECT ON MEMBRANE POTENTIAL OF GUINEA-PIG ISOLATED TRIGEMINAL GANGLION. H.E. Connor and C.T. O'Shaughnessy*, Department of Neuropharmacology, Glaxo Group Research Ltd, Ware, Herts, SG12 0DP, UK. (SPON: Brain Research Association)

The aim of this study was to investigate the effect of sumatriptan, a selective 5-HT_1 receptor agonist, on membrane potential of guinea-pig isolated trigeminal ganglion (TG). TGs were divided into 3 longitudinally and placed in 2-compartment baths. The d.c. potential between compartments was recorded extracellularly. Drugs were applied to the Krebs superfusion fluid of one compartment. KCl (3mM) and GABA (0.1mM) caused depolarisations of the TG (0.30 ± 0.05 and 0.55 ± 0.08mV respectively n=11-19). 5-HT (1-10μM) caused small depolarisations (0.06 ± 0.02mV). Responses to each of these agents was enhanced by pretreatment of the TG with collagenase to enhance desheathing. Sumatriptan (0.1-10μM) had no effect on TG membrane potential: collagenase pretreatment or changing the composition of the Krebs solution failed to reveal any effect of sumatriptan. These data provide no evidence to suggest that sumatriptan inhibits neurotransmission in trigeminal ganglion. Further studies are required to investigate the possiblity that the anti-migraine action of sumatriptan results from a 5-HT_1 receptor mediated inhibition of sensory neurotransmission in trigeminal craniovascular sensory nerves.

636.8

EFFECTS OF RENZAPRIDE AND CISAPRIDE ON FAST SYNAPTIC TRANSMISSION IN GUINEA PIG ILEUM MYENTERIC PLEXUS. H. Pan* and J.J. Galligan. Dept. of Pharmacol./Toxicol., Michigan State University, E. Lansing, MI 48824

The effects of renzapride (Renz) and cisapride (Cis) on fast nicotinic excitatory postsynaptic potentials (epsps) were studied using conventional techniques in vitro. Epsps were evoked by single focal stimuli applied to interganglionic nerve strands. Drugs were applied by superfusion or by ejection from a pipette (ACh, 1 mM). Renz (n=16) at .01, .03, 0.1 and 0.3 μM potentiated epsps by 22±7%, 52±14%, 79±21% and 85±20% respectively. The 5-HT_3/5-HT_4 antagonist ICS 205-930 (1 μM, n=4) shifted Renz dose-response curve to the right ~30-fold. ICS alone did not affect epsp amplitude. Renz had no effect in 3 cells. Cis (n=8) at .01, 0.1 and 1 μM potentiated epsps by 20±11%, 69±25% and 88±23% respectively; this effect was blocked by ICS (1 μM). Cis had no effect in 9 cells. Renz and Cis did not affect ACh responses and resting membrane potential or resistance. These data indicate Renz and Cis can act as agonists at presynaptic 5-HT_4 receptors on some myenteric neurons. Stimulation of presynaptic 5-HT_4 receptors enhances ACh release. (Supported by DK 40210)

636.9

HETEROGENEOUS NEURONOTROPHIC RESPONSES OF EMBRYONIC GLIA TO STIMULATION BY 5-HT RECEPTOR AGONISTS. J.Liu*, M.B.Wilkie, E.Weiss and J.M. Lauder. Univ. N.C. Sch. Med., Chapel Hill, NC 27599-7090.

These studies were designed to test the hypothesis that glial 5-HT receptors mediate trophic effects of 5-HT. We found 5-HT receptor mRNAs and proteins were expressed by embryonic day 14 raphe (RR) or substantia nigra (SN) glia in vitro. RR & SN glia conditioned media with different neuronotrophic activities for 5-HT and TH neurons following treatment with 5-HT receptor agonists (10 nM 5-HT, 8-OH-DPAT or DOI). When 5-HT or TH neurons were co-cultured with homotypic or heterotypic glia, different neuronotrophic effects of 5-HT agonists were seen. Synthesis of S-100β and IGFs in glial cultures seemed to be differentially stimulated in response to selective 5-HT agonists, and 5-HT and TH neurons had typical responses to S-100β and IGF-II. RR and SN glia exhibited specific cAMP responses to 5-HT agonists, suggesting that embryonic glial 5-HT receptors are functional. These results indicate that during embryogenesis 5-HT receptors may mediate release of glial-derived factors which have neuronotrophic activity for 5-HT neurons, as well as other cells in the vicinity.

636.10

CHARACTERIZATION OF NOVEL SEROTONIN 5HT_2 RECEPTOR AGONISTS. **C.G. Johnson, J.E. Macor, C.B. Fox, L.A. Lebel, B.K. Koe, and S.H. Zorn*, Central Research Div., Department of Neuroscience, Pfizer Inc, Groton, CT 06340.**

A series of rotationally restricted phenolic analogs of the neurotransmitter serotonin (5HT) have been synthesized in which the 5-hydroxyindole portion of 5HT is replaced by a dihydropyano[3,2-e]indole. CP-118,952, CP-123,479, CP-123,028, and CP-132,484 possess lower affinity for 5HT_{1A} receptors than 5HT ([^{3}H]8-OH-DPAT, IC_{50} nM: 1900, 610, 5400, 5300, 5.2 respectively) and comparable affinity to 5HT at 5HT_2 receptors ([^{125}I]DOI, IC_{50} nM: 63, 14, 81, 14, 20, respectively). In the rat brain cerebral cortical slice preparation where agonist stimulation of 5HT_2 receptors results in the hydrolysis of phosphatidyl inositol, 100 μM concentrations of 5HT, the synthetic 5HT_2 agonist DOI, CP-118,952, CP-123,479, CP-123,028, and CP-132,484 stimulated the accumulation of inositol phosphates (IP) that is 76%, 66%, 32%, 42%, 54% and 155% above basal levels, respectively. The response to each agonist was concentration dependent, and CP-132,484 produced a maximal response that was 2-3 fold greater than that produced by 5HT. The response to CP-132,484 is selectively antagonized by 5HT_2 receptor antagonists, but not by antagonists of muscarinic or α_1 adrenergic receptors. The results indicate that a new class of compounds exemplified by CP-132,484 are 5HT_2 agonists, and as such will be useful tools in the further study of 5HT receptors.

636.11

COMPARATIVE ACTIONS OF NOVEL ANTAGONISTS AND HIGH EFFICACY AGONISTS AT 5-HT_{1A} AUTORECEPTORS: AN ELECTROPHYSIOLOGICAL AND NEUROCHEMICAL ANALYSIS. J.-M. Rivet, F. Lejeune, A. Gobert, H. Canton*, G. Lavielle, J.-L. Peglion and M. J. Millan. I.D.R.S., 7 rue Ampère, 92800 Puteaux, Paris, France.

Inhibitory serotonin (5-HT)$_{1A}$ autoreceptors are localized on neurones of the dorsal raphe nucleus (DRN), the origin of ascending serotoninergic projections in the brain. Several ligands which act as antagonists of *post*-synaptic 5-HT_{1A} receptors behave as agonists at *pre*-synaptic sites owing to the greater receptor reserve of the latter. Here, we examined actions of novel 5-HT_{1A} ligands at DRN-localized autoreceptors by 1/, recording of their electrical activity in chloral hydrate-anaesthetized rats and 2/, evaluation of 5-HT turnover (5-hydroxytryptophan accumulation in NSD-1015-treated-rats) in the striatum. The high efficacy 5-HT_{1A} agonists, S 14671, S 14506, 8-OH-DPAT and WY 50,324, the partial agonists, buspirone and LY 165,163 and the 'antagonist'/partial agonists, BMY 7378 and NAN 190 all inhibited DRN firing and 5-HT turnover. S 14671 was exceptionally potent; ID_{50} = 0.16 µg/kg, i.v. for electrical activity and 0.63 µg/kg, s.c. for turnover. In contrast, WAY 100,135, (-)-tertatolol and spiperone failed to modify DRN activity alone and reversed S 14671-effected inhibition of DRN firing. The novel and pure post-synaptic 5-HT_{1A} antagonists, S 15535 and S 15931 each inhibited DRN electrical activity and 5-HT turnover at doses close to those at which they block post-synaptic 5-HT_{1A} receptors (see adjacent presentation). Further, in distinction to BMY 7378, NAN-190, WAY 100,135 and spiperone, they failed to enhance striatal accumulation of di-hydroxyphenylalanine suggesting a lack of D_2-antagonist properties. In conclusion, 5-HT_{1A} ligands can act either as autoreceptor and post-synaptic agonists (e.g., S 14671 and 8-OH-DPAT), as autoreceptor agonists and post-synaptic partial agonists (e.g., BMY 7378 and NAN 190) or as autoreceptor and post-synaptic antagonists (WAY 100,135, spiperone and (-)-tertatolol). In contrast, the novel ligands, S 15535 and S 15931 act as autoreceptor agonists and pure post-synaptic antagonists; these properties may confer an original therapeutic profile

636.12

S 15535 AND S 15931: NOVEL BENZODIOXOPIPERAZINE ANTAGONISTS OF POST-SYNAPTIC 5-HT_{1A} RECEPTORS DISPLAYING HIGH POTENCY, PURITY AND SELECTIVITY M. J. Millan*, H. Canton, A. Gobert, J.-M. Rivet, F. Lejeune, K. Bervoets, M. Brocco and J.-L. Peglion. I.D.R.S., 7 rue Ampère, 92800 Puteaux, Paris, France.

Of proposed antagonists of post-synaptic 5-HT_{1A} receptors, several are also 5-HT_{1B} /β-adrenoceptor antagonists ((-)-tertatolol), D_2 antagonists (BMY 7378, spiperone and WAY 100,135) or α_1-adrenoceptor antagonists (NAN 190). Further, certain are partial agonists (BMY 7378 and NAN 190). We have, thus, synthesized benzodioxopiperazine derivatives as novel 5-HT_{1A} antagonists. Affinity at 5-HT_{1A} sites (pKi) and *in vivo* potency for inhibition of 8-OH-DPAT-induced flat-body posture, corticosterone secretion and hypothermia in rats were determined. S 15535 and S 15931 yielded values of 8.7/2.3 mg/kg (mean ID_{50}, s.c., across all tests) and 8.8/1.4 mg/kg, respectively. Maximal antagonism of 8-OH-DPAT-induced hypothermia was 95% and 97% for S 15535 and S 15931, respectively. These values were superior to those for BMY 7378 and NAN 190; 66% and 71%, respectively. Further, ≥ 50-fold higher doses of S 15535 and S 15931 than required for inhibition of 8-OH-DPAT-induced hypothermia failed to reduce core temperature when given alone. They were, thus, pure antagonists. Affinities of S 15535 and S 15931 for other 5-HT receptor types, α_1-, α_2- and β-adrenoceptors, D_1- and D_2-receptors were ≥ 100-fold lower than for 5-HT_{1A} receptors. Further, *in vivo*, whereas BMY 7378 acted as a D_2 antagonist (e.g., inhibition of dopaminergic stereotypies) at similar doses as for 5-HT_{1A} antagonism, S 15535 and S 15931 showed ≥ 25-fold separation. In addition, while NAN-190 induced ptosis (reflecting α_1-antagonism) at doses 20-fold *lower* than for 5-HT_{1A} antagonism, S 15535 and S 15931 were active only at 25- and 7.5-fold *higher* doses, respectively. In conclusion, S 15535 and S 15931 are potent, pure and selective antagonists at post-synaptic 5-HT_{1A} receptors. Apart from their utility as pharmacological tools, they may have therapeutic potential as, for example, promnesics or anxiolytics devoid of the secondary actions of post-synaptic 5-HT_{1A} agonists.

636.13

STEREOSELECTIVE BLOCKADE OF THE GUINEA PIG 5-HT TERMINAL AUTORECEPTOR AND THE 5-HT_{1D} BINDING SITE BY THE OPTICAL ISOMERS OF METITEPINE. L.M. Hawkins, L.O. Wilkinson,* M.S. Beer, M. Hibert§ and D.N. Middlemiss. Merck, Sharp and Dohme, Terlings Park, Harlow, Essex, U.K. and §Marion Merrell-Dow, Strasbourg, France

These experiments used the chiral 5-HT antagonist metitepine to examine the stereoselectivity of the 5-HT_{1D} binding site and the 5-HT terminal autoreceptor in guinea pig, a proposed model of 5-HT_{1D} receptor activation. The 5-HT_{1D} binding site (labelled by [^{125}I] GTI using 1 µM 5-HT to define non-specific) and K^+ stimulated [^{3}H]-5-HT release (25 mM) were measured in guinea pig frontal cortex.

	Apparent pA_2 against 5-HT	Sumatriptan	pIC_{50}
(+) Metitepine	6.7	7.1	7.2
(-) Metitepine	7.8	7.8	7.7

These data support the identification of the terminal 5-HT autoreceptor in guinea pig frontal cortex as a 5-HT_{1D} receptor and reinforce similarities between the 5-HT_{1D} and the 5-HT_{1B} receptor, which has similar stereoselectivity for the isomers of metitepine.

636.14

SPECIES DIFFERENCES IN THE RECOGNITION OF TRYPTAMINES BY THE ANTAGONIST-LABELLED 5-HT_2 RECEPTOR. D.B. Wainscott, J.E. Audia, J.S. Nissen and D.L. Nelson*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

This laboratory has reported that selected ergolines displayed species differences in their affinity for the antagonist-labelled 5-HT_2 receptor (Nelson et al., *Soc. Neurosci. Abstr.* **17**: Abstr. #168.1, 1991). Substitutions at the N1-position were responsible for the species selectivity seen. Since ergolines contain the tryptamine pharmacophore, the present work was undertaken to determine if simple molecules, such as the tryptamines, also show a similar structure-activity relationship. Selected tryptamines were therefore examined at the rat and human [^{3}H]ketanserin-labelled 5-HT_2 receptor with the following results.

	IC_{50} Rat, (nM)	IC_{50} Human, (nM)
Tryptamine	10929 ± 315	3000 ± 240
N1-Isopropyltryptamine	3858 ± 602	7034 ± 532
5-Methoxytryptamine	3791 ± 143	943 ± 109
N1-Isopropyl-5-MeO-tryptamine	3561 ± 266	6327 ± 133

The tested N1-unsubstituted tryptamines had higher affinity for the human versus the rat 5-HT_2 receptor, while the N1-isopropyltryptamines had higher affinity for the rat versus the human 5-HT_2 receptor. Addition of an N1-isopropyl group decreased affinity at the human 5-HT_2 receptor and either increased affinity at the rat 5-HT_2 receptor or had no effect. These results show that the tryptamines have a similar species selectivity as the ergolines and provide evidence that the ergolines bind to the antagonist-labelled 5-HT_2 receptor in an orientation similar to that of the tryptamines.

636.15

SPECIES SELECTIVITY OF CERTAIN SUBSTITUTED ERGOLINES AND TRYPTAMINES FOR THE AGONIST LABELLED 5-HT_2 RECEPTOR. M. P. Johnson*, D. L. Nelson and M. Baez. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Previously it had been reported (Nelson et al., *Soc. Neurosci. Abstr.* **17**: Abstr. #168.1, 1991) that a simple structural modification at the N(1) position of selected substituted ergolines showed differences in affinity for the antagonist [^{3}H]ketanserin labelled 5-HT_2 receptor depending upon the species examined. The present study was undertaken to determine whether the same structure-activity relationship exists for the agonist [^{125}I]1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) labelled 5-HT_2 receptor. Several standard compounds including 5-HT, spiperone and DOI itself were found to have equal affinity for the agonist-labelled 5-HT_2 receptor in rat and squirrel monkey homogenates. As seen with the antagonist-labelled receptor, N(1) alkyl substituted ergolines, such as mesulergine, LY 53857 and LY 237733, showed a 4-10 fold higher affinity for the rat versus monkey 5-HT_2 receptor. In contrast, N(1) unsubstituted ergolines, such as ergonovine, LY 86057 and LY 193525, showed 7-10 fold higher affinity for the monkey versus rat agonist-labelled 5-HT_2 receptor. Tryptamine and 5-methoxytryptamine (5-MT) were also found to have slightly higher affinity for the monkey rather than rat 5-HT_2 receptor. Similarly, N(1) isopropyl substitution of tryptamine and 5-MT resulted in a 6-16 fold higher affinity for the rat 5-HT_2 receptor. Interestingly, 5-MT was found to have 100-fold higher affinity than N(1) isopropyl 5-MT for the agonist-labelled monkey 5-HT_2 receptor. The present results confirm that the same structure-activity relationship is seen for the antagonist- and agonist-labelled 5-HT_2 receptor. Also, the present results suggest that certain substituted ergolines bind in a 'tryptamine-like' conformation to the 5-HT_2 receptor.

Preliminary experiments using molecular biology techniques suggest that there are relatively few transmembrane changes between species variants of the 5-HT_2 receptor. Studies designed to investigate which amino acid(s) changes are responsible for the ergoline and tryptamine structure-activity relationships seen are currently underway.

636.16

UPREGULATION OF 5-HT_2 RECEPTORS IN RODENT BRAIN BY REPEATED ORAL ADMINISTRATION OF SR 46349B A SELECTIVE 5-HT_2 ANTAGONIST. M. Rinaldi-Carmona, J. Simiand+, F. Oury-Donat, P. Soubrié, J.C. Brellière, J.P. Chambon* and G. Le Fur. Sanofi Recherche, 371 rue du Professeur J. Blayac, 34184 Montpellier Cédex 04, France. + Sanofi Recherche, 195 route d'Espagne 31036 Toulouse Cédex France.

Adaptive changes in 5-HT_2 receptor were investigated in rodents after repeated administration of SR 46349B, a potent, selective and competitive 5-HT_2 receptor antagonist (K_i = 0.72 ± 0.05nM). Chronic administration (twice a day for 3 days and on the morning of the 4th day) of SR 46349B (10mg/kg, orally) causes 24h later a marked increase of the maximum binding capacity (B_{max}) of ketanserin, measured "*ex vivo*" in brain cortical membranes, without any change in its affinity constant.

5-HT_2 receptor number is increased by 31% in rats and by 100% in mice. Further, 5-HT_2 agonist administration (1mg/kg, i.p. ± DOI) produced in chronic SR 46349B (10mg/kg, orally) treated mice a significant increase (+ 41%) of the amount of (^{3}H) inositol phosphate compared to corresponding controls. In addition, subacute administration of SR 46349B (10mg/kg, orally) causes a 4 or 2 fold increase of the head-twitch responses to 5-HTP (200mg/kg, i.p. ; in mice) or to (±) DOI (0.5mg/kg, i.p. ; in rats), respectively.

These results show that chronic administration of SR 46349B produced a parallel enhancement in 5-HT_2 receptor number, in 5-HT_2 receptor-linked signal transduction and in 5-HT_2 receptor-mediated behavioural responses, in rodents. These findings suggest for the first time that an upregulation of 5-HT_2 receptors occurs following repeated treatment with a selective antagonist.

636.17

IDENTIFICATION AND CHARACTERIZATION OF BINDING SITES FOR ^{3}H-SERTINDOLE.

E. Meier, J. Hyttel*, Pharmacological Research, H. Lundbeck A/S, Ottiliavej 9, DK-2500 Copenhagen-Valby, Denmark.

An important new advance in the pharmacotherapy of schizophrenia has been the introduction of drugs which have anti-psychotic activity without extrapyramidal side effects (e.g., dystonia, parkinsonism, and akathisia) usually seen with classical neuroleptic drugs. The exact molecular mechanism of action of atypical neuroleptic drugs is still unknown. The apparent lack of a common receptor binding profile (Sanchez et al., 1991; Drug Devel. Res. **22**, 239) that is correlated with the anti-psychotic effects of atypical neuroleptics suggests that a yet unknown receptor mechanism may be involved. To pursue this, the binding of the tritiated form of a new atypical neuroleptic, sertindole (Skarsfeldt & Perregaard, Eur. J. Pharmacol. **182**, 1990, 613) to rat brain homogenate or membrane preparations, has been studied.

^{3}H-sertindole binding is trypsin sensitive with very high affinity for sertindole (7.1 x 10^{10} M^{-1}). Sertindole binding is found throughout the brain in densities between 15 and 22 fmol/mg_{tissue} with the highest densities found in the superficial layer of the frontal cortex. The affinity of a large number of standard compounds reveals that barbiturates, opiates (including sigma compounds), benzodiazepines, phencyclidines, Ca-antagonists as well as GABAergic, glutamatergic, cholinergic, histaminergic, peptidergic, and dopaminergic compounds have low or no affinity for the sertindole binding sites. However, compounds with a 5-HT_2 and α_1 component show high affinity for sertindole binding sites especially neuroleptics characterized as atypical.

636.18

TYPICAL TRICYCLIC ANTIDEPRESSANTS POSSESS POTENT 5-HT_{1c} RECEPTOR ACTIVITY.

B.L. Roth*, H.Y. Meltzer and S. Craigo, Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

For several years, we have known that many typical tricyclic antidepressants possess potent 5-HT_2 antagonist activity and induce a down-regulation of 5-HT_2 receptors. Whether tricyclic antidepressants bind to other 5-hydroxytryptamine (5-HT) receptors has been relatively unexplored. With the recent cloning of several types of 5-HT receptors, we have begun to systematically re-examine the affinities and agonist-antagonists profiles of clinically-useful compounds in an effort to clarify their mechanisms of action. Using 5-HT_{1c} receptors transiently expressed in COS-7 cells or stable cell lines, we discovered that typical tricyclic antidepressants possessed high affinities for the cloned 5-HT_{1c} receptor. Nortryptyline, amoxapine and amitriptyline had the highest affinities (Kd's<5 nM) while clomipramine, desipramine, imipramine, doxepin, maprotiline and iprindole had intermediate affinities (Kd's 20-100 nM). Zimelidine, sertraline, nomifensine, clorgyline and fluoxetine all had weak affinities (Kd's>>1000 nM) for the cloned 5-HT_{1c} receptors. These results suggest that 5-HT_{1c} receptor blockade could contribute to the unique action of many antidepressants (supported by the PMA Foundation).

SEROTONIN RECEPTORS: ACTION ON NEUROTRANSMISSION

637.1

IN VITRO BINDING PROFILE OF COMPOUNDS HAVING AFFINITY FOR BOTH DOPAMINE AND SEROTONIN RECEPTORS

E.Daniele, S;Govoni, MD,Lograno, F.Matteo,V.Olgiati*# F.Berardi and R.Perrone. Pharmacobiology and Pharmacochemistry depts. Univ. of Bari, #Pierrel R&D dept. Milano, Italy.

In recent years efforts have been devoted to the development of novel antipsychotic drugs because of the several unwanted side effects of classical neuroleptics among which extrapiramidal symptoms are prominent. It appears that the severity of side effects is reduced with drugs which are also 5HT-2 antagonists. As a consequence much effort has been oriented towards obtaining drugs simultaneously affecting both systems. Within this context we have adopted a dual approach investigating the pharmacological activity of compounds in which a sulpiride like moiety was combined to a functional group having affinity for the serotonin receptor and for a series of p-dimethoxybenzoquinoline isosters, where the carbon atom in position 4 was replaced by an heteroatom. The pharmacological profile of the above mentioned compounds was investigated by means of radioreceptor binding techniques. In particular activity on D1 and D2 receptors was evaluated using rat striatum membrane preparations. Tritiated SCH 23390 (D1) and spiroperidol (sulpiride displaceable, D2) were used as selective ligands. Cortical membranes and tritiated ketanserin were used to determine the activity on 5HT-2 receptors. In some occasion the activity on 5HT-1 and 5HT-3 receptors was also assayed using the appropriate ligand and tissue preparation. The binding studies indicate that p-dimethoxy-4-naphtho-oxazine and the p-dimethoxy-4-naphtho-thiazine compounds had the dual activity on dopaminergic and serotoninergic receptors with IC_{50} ranging between1.8x10^{-7} and 1.5x10^{-6}M. It appears that in this series of compounds the p-dimethoxybenzene moiety confers the affinity for both dopamine and serotonin receptors.

637.2

ENHANCED PLATELET INTRACELLULAR CALCIUM RESPONSE TO SEROTONIN IN BIPOLAR DISORDER AND MELANCHOLIC MAJOR DEPRESSION.

I.Kusumi*, T.Koyama, S.Matsubara and I.Yamashita. Dept. of Psychiatry and Neurology, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

There has been extensive interest in central serotonergic dysfunction as an important factor in the etiology of affective disorders. The readily accessible human platelet possesses serotonin-2(5-HT2) receptors and has been suggested as a possible model for the central serotonergic neuron. In this study, 5-HT-stimulated intracellular calcium(Ca) mobilization was measured in the platelets of depressed patients to assess 5-HT2 receptor function, using the Ca-sensitive fluorescent probe fura-2. Informed consent was obtained from all patients and normal subjects. The 5-HT-induced Ca response was significantly higher in unmedicated patients with bipolar disorder and melancholic major depression than in those with non-melancholic major depression and normal controls. The enhanced Ca response to 5-HT failed to correlate with severity of depressive symptoms. In patients with bipolar disorder and melancholic major depression, there was no significant difference in 5-HT-stimulated Ca response between unmedicated group and euthymic-treated group. These results suggest that 5-HT2 receptor function is increased in some type of depression and that the enhanced Ca response to 5-HT may be trait dependent rather than state dependent.

637.3

ENDOGENOUS SEROTONIN UPTAKE INHIBITORS ISOLATED BY CALMODULIN-SEPHAROSE AFFINITY CHROMATOGRAPHY

J. Chudzik[1] and S. W. Tang[2*] [1]Department of Neuropharmacology, Royal Ottawa Hospital, 1145 Carling, Ottawa, K1Z 7K4; [2]Long Beach VA Medical Center, Long Beach, CA 90822 and University of California, Irvine, Irvine, CA, 92717

In our previous attempts to isolate endogenous serotonin uptake inhibitors, we discovered endogenous compounds which were recognized by rabbit anti-imipramine antibodies. The specificity of our antisera indicated that they possess high affinity for drugs sharing a common structural component - N,N-dimethylaminopropyl aliphatic chain linked to the 5-nitrogen atom of the 10,11-dihydroazepine ring. Many tricyclic antidepressants contain such a backbone structure. The structurally related compound chlorpromazine or its derivatives immobilized on various gels were previously used for affinity chromatography purification of calmodulin. We therefore examined the use of Sepharose-immobilized calmodulin to isolate the endogenous serotonin uptake inhibitors, assuming that they possess the common structural component as described above. Calf brain and human plasma extracts and human urine were chromatographed on Calmodulin-Sepharose affinity columns. Multiple substances which inhibit platelet serotonin uptake, ^{3}H-imipramine binding and or ^{3}H-paroxetine binding were isolated and appeared to be confined to the fractions displaced by EGTA. Further purification by Bio-Gel P-2 exclusion chromatography yielded substances which were recognized by anti-imipramine and or anti-paroxetine antibodies. The interaction of these endogenous compounds with calmodulin implicates the Ca^{++} dependent/calmodulin regulatory mechanism of serotonin uptake.

637.4

ANTIBODY RECOGNITION OF ENDOGENOUS SEROTONIN UPTAKE INHIBITORS

D. M. Helmeste* and S. W. Tang Long Beach VA Medical Center, Long Beach, CA 90822 and University of California, Irvine, Irvine, CA, 92717

Radioimmunoassay (RIA) enables the quantification of very low concentration of hormones or drugs in human serum or tissue extracts. In our previous attempts to isolate endogenous serotonin uptake inhibitors, we identified substances in calf brain and human plasma extracts which reacted positively with anti-imipramine antibodies (Psychiatry Research, 34:205, 1990). In order to further characterize the RIA positive substances, we characterized several polyclonal antibody preparations against other common psychotropic drugs: a neuroleptic (haloperidol), a potent non-tricyclic uptake inhibitor (paroxetine), a tricyclic antidepressant with potent norepinephrine but weaker serotonin uptake inhibition effect (desipramine) and chlorimipramine, an imipramine analogue. The affinity of these antibodies for a variety of serotonergic and related compounds as expressed in IC_{50s} differ profoundly. Calf brain and human plasma extracts after Bio-Gel P-2 chromatography yielded fractions which differed in their antibody reactive profile. The relationship of these antibody-reactive substances to fractions which also demonstrated inhibition of serotonin uptake and ^{3}H-imipramine binding is presented.

EFFECTS OF GLUTAMATE AND/OR DEXAMETHASONE ON SEROTONIN-INDUCED INTRACELLULAR CALUCIUM MOBILIZATION IN C6 GLIOMA CELLS. H.Shinno, M.Mikuni*, A.Kagaya, K.Saitoh, S.Yamawaki and K.Takahashi. Div. Mental Disorder Res., Natl. Inst. Neurosci., NCNP, Tokyo, 187, Japan and Dep. Neurol. Psychiat., Hiroshima Univ. Sch. Med., Hiroshima, 734, Japan.

We have investigated 5-HT-induced Ca mobilization in rat glioma C6 cells. As we reported in this society last year, treatment of C6 cells cultured in DMEM(Dulbecco's Modified Eagle's Medium) with 100nM dexamethasone for 24-48 hours significantly potentiated the ability of 5-HT to cause intracellular Ca mobilization in a dose and time dependent manner without alteration of the unstimulated levels of the intracellular Ca.

On the other hand, the treatment of C6 cells cultured in RPMI(Roswell Park Memorial Institute)-1640 which contains excitatory amino acids with dexamethasone lowered 5-HT-induced Ca mobilization. In addition, pretreatment of C6 cells in DMEM with glutamate, which was added 3 min prior to the 5-HT stimulation, prevented the enhancement of 5-HT-stimulated Ca mobilization induced by 100nM dexamethasone, while other excitatory amino acids such as aspartate did not.

These results are suggesting that there is an interaction between glutamate and dexamethasone-induced enhancement of 5-HT-2 receptor function in C6 cells.

637.6

ANTAGONISM OF MK212-INDUCED INCREASE IN NOREPINEPHRINE (NE) TURNOVER IN RAT HYPOTHALAMUS BY $5HT_{1C/2}$ RECEPTOR ANTAGONISTS SERGOLEXOLE (SE, LY281067), AMESERGIDE (AM, LY237733) AND LY53857 (LY). D.T.Wong*, D.A.Mayle, R.D.Marsh and P.G.Threlkeld. Lilly Research Labs., Lilly Corp. Center, Indianapolis, IN 46285

SE, AM and LY, ergoline $5HT_2$ antagonists (Cohen et al, JPET 235:319, 1985; 251:1006, 1989; Misner et al, J.Med.Chem. 33: 652, 1990), exhibited higher affinities for $5HT_{1C}$ receptors labeled by [^{3}H]-mesulergine in membranes of bovine choroid plexus (pKi = 8.19, 8.57, 8.47) than for $5HT_2$ receptors labeled by [^{3}H]-ketanserin in membranes of rat cerebral cortex (pKi = 7.97, 8.11, 7.77). Thus, SE, AM and LY had 1.7, 3 and 5 ($p < 0.001$) times higher affinity for $5HT_{1C}$ sites than for $5HT_2$ sites. MK212, a $5HT_{1C/2}$ agonist, at 5 mg/kg i.p., increased hypothalamic levels of catecholamine metabolites, 3,4-dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA) and 3-methoxy-4-hydroxy-phenylglycol sulfate (MHPG-SO4) (Mayle et al, 21st Meeting Soc. Neurosci. 1991, p. 90), and that increase in DOPAC was antagonized most potently with LY, followed by AM and SE (ED_{50}s: 0.7, 1, 3 mg/kg). The MK212-induced increases of HVA and MHPG-SO_4 were also antagonized , while the ergolines alone had no effect. These data show that the antagonism of MK212-induced increase of NE turnover in hypothalamus by the ergolines correlates better with their affinity of $5HT_{1C}$ receptors than of $5HT_2$ receptors.

637.7

CHARACTERIZATION OF POTASSIUM CONDUCTANCE INCREASED BY SEROTONIN IN AREA CA3 OF HIPPOCAMPAL SLICES D. Okuhara*, K. Choi and S.G. Beck, Department of Pharmacology, Loyola University Chicago Stritch School of Medicine, Maywood, Il 60153.

The hippocampus receives extensive 5-hydroxytryptamine (5-HT) innervation from the median and dorsal raphe. 5-HT elicits a pronounced hyperpolarization in area CA3 hippocampal pyramidal cells through activation of a $5\text{-}HT_{1A}$ receptor. The characteristics of the $5\text{-}HT_{1A}$ mediated hyperpolarization in areas CA1 and CA3 differ in many respects. This study was designed to compare the potassium conductance increased by $5\text{-}HT_{1A}$ activation in areas CA1 and CA3. Standard intracellular recording techniques for current and voltage clamp were used. The hyperpolarization in area CA3 was not altered when either potassium chloride or potassium methylsulphate electrodes were used, but was blocked with cesium chloride filled electrodes. Under voltage clamp 5-HT elicited an outward current with a reversal potential of approximately -105 mV in 3 mM KCl artificial cerebrospinal fluid. The reversal potential shifted when the extracellular potassium concentration was changed to 5 or 10 mM KCl. The maximal response in area CA3 (approximately 600 pA) was three times larger than the amount of current elicited by $5\text{-}HT_{1A}$ activation in area CA1. The voltage dependency of this potassium conductance is currently under investigation. These results indicate that $5\text{-}HT_{1A}$ receptor activation increases potassium conductance in both CA1 and CA3. Supported by KO2 MH00880 and NS28512.

637.8

ANALYSIS OF THE ROLE OF 5-HT AND 5-HT RECEPTOR SUBTYPES IN MEDIATION OF THE PERISTALTIC REFLEX OF THE GUINEA PIG DISTAL COLON P. R. Wade*, G. Joseph, R. Chouinard, and M. D. Gershon Dept. of Anatomy and Cell Biology, Columbia Univ. P & S, New York, NY.

The peristaltic reflex, a coordinated propulsive wave of intestinal motility, is evoked in the guinea pig distal colon *in vitro* by insertion of an artificial fecal pellet. This activity occurs at reproducible rate that is maintained for hours. We tested the hypothesis that 5-HT plays an essential role in mediating this reflex. Propulsion of artifical fecal pellets in the distal colon *in vitro* was found to be blocked by tetrodotoxin (0.1 μM) and diminished, but not abolished, by hexamethonium (0.1 mM). The reflex is thus nerve-mediated and involves nicotinic cholinergic synapses; however, a non-cholinergic parallel pathway also exists. Propulsion was eliminated by desensitization of 5-HT receptors with 5-HT (1-10 μM), and by antagonists at $5\text{-}HT_{1P}$ (N-acetyl-5-hydroxytryptophyl-5-hydroxytryptophan amide [50 μM]) and $5\text{-}HT_4$ receptors (tropisetron [>1 μM]). In contrast, $5\text{-}HT_3$ antagonists (granisetron [10 μM] or tropisetron [< 1 μM]) had no effect. Other compounds that affected the $5\text{-}HT_{1P}$-mediated slow EPSPs evoked in ileal myenteric neurons and/or $5\text{-}HT_4$ receptors (including substituted benzamides such as renzapride [> 1μM] and zacopride [> 1μM]) all inhibited propulsion. These data show that 5-HT participates in the peristaltic reflex in the guinea pig distal colon and that both $5\text{-}HT_{1P}$ and $5\text{-}HT_4$, but not $5\text{-}HT_3$ receptors are involved. Supported by NIH grant NS 12969.

637.9

5-HT INCREASES cAMP IN GANGLIA ISOLATED FROM THE GUINEA PIG SMALL INTESTINE: MEDIATION BY A NOVEL 5-HT RECEPTOR. E. Fiorica-Howells and M.D. Gershon*. Dept. of Anat. & Cell Biol., Columbia Univ. P & S, New York, N.Y. 10032.

The slow depolarization evoked in enteric neurons by 5-HT is mimicked by elevation of intracellular cAMP. We therefore tested the hypothesis that 5-HT increases cAMP in neurons of the myenteric plexus of the guinea pig small intestine. Ganglia were isolated by differential filtration from collagenase digests of dissected preparations of longitudinal muscle with adherent myenteric plexus. The isolated ganglia (trapped on filters) were incubated with putative agonists for 10 min at 37° C in the presence of isobutylmethyl xanthine (10 μM; IBMX) and/or preincubated with putative antagonists for 10 min. cAMP was measured by radioimmunoassay. 5-HT induced a concentration-dependent increase in cAMP (ED_{50} = 0.3 μM). This effect was not shared by the $5\text{-}HT_{1P}$ agonist, 5-hydroxyindalpine (10 μM), or blocked by the $5\text{-}HT_{1P}$ antagonist, N-acetyl-5-hydroxytryptophyl-5-hydroxytryptophan amide (5-HTP-DP; 0.1 mM), which mimic or antagonize the 5-HT-evoked slow depolarization of myenteric neurons that is also elicited by raising cAMP. It is thus unlikely that the slow depolarization evoked by 5-HT is mediated by cAMP. Compounds that raised cAMP in isolated ganglia included: (±)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI), 5-carboxyamidotryptamine, 5-methoxytryptamine, and renzapride. Antagonists (at 10 μM) at $5\text{-}HT_1$, $5\text{-}HT_2$, $5\text{-}HT_3$, and $5\text{-}HT_4$ receptors, including methiothepin, methysergide, spiperone, tropisetron, DAU 6285, R58639, and R88226 all failed to prevent the rise in cAMP in response to 5-HT or other agonists. The response was inhibited by a high concentration of ketanserin (10 μM); however, mRNA encoding the $5\text{-}HT_2$ receptor could not be detected in isolated ganglia by Northern analysis. The elevation of cAMP induced in isolated myenteric ganglia by 5-HT thus cannot be attributed to mediation by a known subtype of 5-HT receptor and thus must be mediated by a novel 5-HT receptor subtype. Supported by NIH: NS 12969 and NS22637.

637.10

CHARACTERIZATION OF THE SEROTONIN UPTAKE SITE AND THE 5-HT1C RECEPTOR IN THE FAWN-HOODED RAT. B.A.Hulihan-Giblin*, Y.D. Park, C.S.Aulakh and D. Goldman. Laboratory of Neurogenetics, NIAAA Bethesda, MD 20892

The Fawn-Hooded (FH) rat strain possesses a platelet storage pool deficiency. In addition to the reduced peripheral accumulation of serotonin (5-HT), there is considerable evidence that central serotonergic function is altered in the FH rat. There is substantial behavioral and pharmacological data to indicate that $5\text{-}HT_{1C}$ receptors are altered in the FH strain relative to Sprague-Dawley (SD) and Wistar rats. Earlier reports have suggested diminished [^{3}H]imipramine binding to platelets and in brain tissue of FH rats, but these results have not been replicated. In the study presented here, three rat strains, FH, SD and Wistar were compared for differences in both the $5\text{-}HT_{1C}$ receptor and the serotonin (5-HT) uptake site. [^{3}H]Mesulergine was used to label $5\text{-}HT_{1C}$ brain receptors in four brain regions. In the hippocampus, hypothalamus and striatum there were no significant differences in either the Bmax or kD values among the three strains. However, the Bmax values for [^{3}H]mesulergine binding in the cortex were significantly greater in FH as compared to SD and Wistar, while affinity constants (kD) were significantly lower. [^{3}H]Paroxetine, was used because of its selectivity in labelling the 5-HT uptake site. In the cortex, the Bmax values for the FH strain were significantly greater than SD or Wistar, while in the hippocampus the FH Bmax values were significantly greater than SD, but not Wistar. However, the Bmax values for [^{3}H]paroxetine binding in the hypothalamus were significantly less than those of the SD and Wistar rats. Preliminary studies did not reveal any kD differences in the 5-HT uptake site among the three strains. The regional serotonergic differences found in the FH strain, relative to SD and Wistar, provide some support for the use of the FH rat as a genetic model for disorders such as alcohol abuse, anxiety and depression; which have been linked to serotonin dysfunction.

637.11

SEROTONIN-INDUCED POTASSIUM INCREASE IN THE RAT CEREBROSPINAL FLUID AS MEASURED WITH AN ION-SELECTIVE ELECTRODE. T. R. Yu and L. Yu*. Dept. of Medical & Molecular Genetics, Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Serotonin (5-HT) exerts diverse physiological effects in the central and peripheral nervous systems and in smooth muscle by interacting with pharmacologically distinct 5-HT receptor subtypes. The 5-HT_{1C} receptor is found in many brain regions, and is particularly enriched on the epithelial cells of the choroid plexus. To investigate physiological functions that the 5-HT_{1C} receptor may mediate, the level of potassium in the cerebrospinal fluid (CSF) was measured by an ion-selective electrode upon serotonin stimulation of the rat choroid plexus. Anesthetized rats were placed on a stereotaxic unit, and a potassium-selective electrode was positioned in the right lateral ventricle. Infusion of 10 μl of serotonin solution into the left lateral ventricle consistently produced a small but detectable increase in the CSF potassium level. The increase could be detected within 1-3 min of serotonin infusion, and lasted between 5-10 min. These data suggest that the effect may be a result of the activation of the 5-HT_{1C} receptor on the choroid plexus upon its exposure to CSF-borne serotonin, which produces a modulation in the rate of potassium filtration across the choroid plexus.

637.12

MODULATION OF THE ELECTRICALLY-EVOKED RELEASE OF [^{3}H]5-HT IN THE GUINEA PIG BRAIN BY 5-HT_3 RECEPTORS. P. Blier* and C. Bouchard. Neurobiological Psychiatry Unit, Dept. of Psychiatry, McGill University, Montréal, Québec, Canada H3A 1A1.

5-HT_3 receptors have been shown to modulate the release of noradrenaline, acetylcholine, dopamine, and cholecystokinin in the brain. We have recently reported on the capacity of 5-HT_3 receptors to modulate the electrically-evoked release of [^{3}H]5-HT in preloaded slices of the guinea pig hypothalamus (Eur. J. Pharmacol. 211:365,1992). The present study was undertaken to determine whether these 5-HT_3 receptors are also present in other regions of the limbic system and to assess their physiological relevance. The selective 5-HT_3 agonist 2-methyl-5-HT (0.1-3 μM) enhanced in a concentration-dependent manner the electrically-evoked release of [^{3}H]5-HT from preloaded slices of frontal cortex, hippocampus, and hypothalamus when added to the superfusate 8 min before the stimulation, without affecting the basal outflow of radioactivity. At 10 μM, 2-methyl-5-HT increased the basal outflow of radioactivity but this effect did not occur when using a calcium-free superfusate. The enhancing effect of 2-methyl-5-HT (1 and 3 μM) on the evoked release of [^{3}H]5-HT was blocked by the 5-HT_3 antagonists zacopride, MDL 72222, BRL 24924, ICS 205-930, ondansetron, BRL 46470A, quipazine, and mCPP. TFMPP and (+)tubocurarine were ineffective. When 2-methyl-5-HT was introduced 20 min before the stimulation, it did not alter the evoked release of [^{3}H]5-HT, suggesting that these 5-HT_3 receptors desensitize rapidly. The enhancing effect of 2-methyl-5-HT was not present when a calcium-independent release of [^{3}H]5-HT was elicited with fenfluramine. The 5-HT reuptake blocker paroxetine enhanced the overflow of [^{3}H]5-HT when introduced 8 min before the stimulation; this effect of paroxetine was blocked by ICS 205-930. These 5-HT_3 receptors can therefore be activated by synaptic 5-HT.

α_2 MEDIATED CONTROL OF 5-HT NEURONAL FIRING IN GUINEA-PIG DORSAL RAPHE NUCLEUS. M.K.Mundey*, C.A.Marsden* & A.Fletcher[1]* (SPON: Brain Research Association). Dept. Physiol. & Pharmacol, Q.M.C. Nottingham. NG7 2UH, U.K. [1]Wyeth Research Ltd. Huntercombe Lane South, Taplow, Maidenhead, Berkshire. SL6 OPH, U.K.

The selective 5-HT_{1A} agonist 8-hydroxy-2-(di-n-propylamino)tetralin (8-OHDPAT) produces a reversible inhibition of the firing of serotonergic neurones in the rat dorsal raphe nucleus (DRN) an effect also demonstrated in the guinea-pig DRN. Previous studies in the rat have demonstrated that the α_2 antagonist idazoxan increases the firing of identified 5-HT units in the DRN. The present study investigates the effects of idazoxan on 5-HT neuronal firing in the guinea-pig DRN. Male Dunkin-Hartley guinea-pigs (280-350g) were anaesthetised with urethane (1.3g/kg i.p.) and the jugular vein cannulated for i.v. administration of drugs. Single barrelled glass electrodes, filled with 2M NaCl containing 2% pontamine sky blue, were implanted into the DRN using stereotaxic coordinates taken from lambda (A +0.7-1.0; L 0.0; V -6.5-7.5mm). 5-HT neurones were identified by their slow, regular, firing pattern (0.5-4.0 spikes/sec) and their reversible inhibition by 8-OHDPAT (10μg/kg). The α_2 antagonist idazoxan (10μg/kg) significantly increased the firing rate of neurones in the DRN sensitive to 8-OHDPAT and revealed that these neurones exibited one of two types of firing pattern. The first type consisted of a phasic bursting pattern; each cycle lasting between 60 and 130 secs with the rate oscillating from 4-8 spikes/sec at the beginning, to 20-32 spikes/sec at the end (n=7). This effect was not attenuated by 8-OHDPAT but the α_2 agonist clonidine (15μg/kg) significantly decreased the bursting activity with normal spontaneous activity returning within 8-20 mins. With the second type idazoxan also increased the firing rate (82±5%, n=16) of 8-OHDPAT sensitive cells but without producing a phasic firing pattern. These results suggest that there may be two types of serotonergic cells in the guinea-pig DRN responsive to idazoxan. Furthermore the activity of the 5-HT neurones in the DRN of the guinea pig are under an α_2 adrenergic inhibitory tone as in the rat DRN.

CHARACTERIZATION OF SEROTONIN (5-HT) RECEPTORS ON NEURONS OF THE DIAGONAL BAND OF BROCA OF THE RAT. Wai Ling Lee* and J.P.Gallagher, Dept. of Pharmacology & Toxicology, University of Texas Medical Branch, Galveston, TX 77550.

5-HT has different actions at neurons in the vertical versus horizontal limb of the diagonal band of Broca (vnDBB, hnDBB). The principle effect of 5-HT on neurons in the vnDBB was membrane depolarization (10 out of 14 neurons, 72%); two neurons (14%) did not respond, while two were hyperpolarized. On the other hand, in the hnDBB (n=46) the majority (70%) of neurons were hyperpolarized by 5-HT, 10% did not respond, 10% exhibited a transient or biphasic membrane potential change, and 10% were depolarized by 5-HT.

In an attempt to classify the sub-type of 5-HT receptor responsible for membrane hyperpolarization of neurons in the hnDBB, agonist activity and antagonist efficacy were determined. 5-HT (1-30 μM) induced primarily a concentration dependent membrane potential hyperpolarization which was associated with a reduction of cell input resistance. This hyperpolarizing action was mimicked by the following 5-HT_{1A} agonists: 5-CT (nM), ipsapirone (μM), and 8-OH-DPAT (μM). The putative 5-HT_{1A} antagonist, BMY 7378 (2-10 μM) was effective, while NAN-190 (10-100 μM) was ineffective.

Our results demonstrate the presence of different 5-HT receptors on vnDD vs. hnDBB. Furthermore, our data with antagonists suggest that a different sub-type of inhibitory 5-HT_{1A} receptor is present on hnDBB neurons.

SEROTONIN: PHARMACOLOGY I

638.1

BEHAVIORAL, NEUROCHEMICAL AND ANATOMICAL EFFECTS OF NEONATAL 5,7-DIHYDROXYTRYPTAMINE (5,7-DHT) TREATMENT IN RATS. M. Mercugliano *, H.Q. Nguyen, S. Djali and I. Lucki. Children's Seashore House and Depts. of Pediatrics, Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA. 19104.

The consequences of the loss of serotonin (5-HT) neurons during early postnatal development were examined in rats after administration of the neurotoxin 5,7-DHT (100 μg i.c.v.) on postnatal day 1. Analysis of 5-HT content in separate groups of 4- and 8-week old rats indicated extensive depletion of 5-HT in the striatum and cortex, but not in the brainstem. Immunohistochemistry for 5-HT in 8-week old littermates revealed a 73% reduction in number of neurons in the dorsal raphe nucleus with relative sparing (27% depletion) of 5-HT neurons in the median raphe nucleus. Neonatal lesions of the 5-HT system were associated with residual changes in behavior in the forced swimming test at 4 and 8 weeks of age. Rats treated with 5,7-DHT showed decreased mobility during a 15-min forced swimming test as compared with vehicle-treated controls, which may relate to an altered response to stress. These results suggest a regionally heterogenous effect of the lesion on 5-HT content, with decreases in terminal regions and preservation in the brainstem, in spite of significant neuronal loss in the dorsal raphe. Furthermore, lesions of the 5-HT system induced during the neonatal period were associated with long-term behavioral changes which may be associated with the role of 5-HT in psychiatric conditions.

p-CHLOROAMPHETAMINE (PCA)-INDUCED MONOAMINERGIC NEUROPATHOLOGY IN MICE: PROTECTIVE EFFECT OF MK-801. P.K. Sonsalla* and L. Manzino. Neurology Dept., UMDNJ-RWJ Med.Sch., Piscataway, N.J. 08854.

The neurotoxic effect of various amphetamines in rats differ in selectivity for dopaminergic (DA) or serotonergic (5HT) neurons. Furthermore, the neurotoxic profile of the various amphetamines differ among species. For example, methamphetamine, which produces toxicity to both DA and 5HT neurons in rats has little effect on 5HT neurons in mice. PCA, which is a potent and selective 5HT neurotoxin in rats, has been reported to be neurotoxic to 5HT neurons in mice at high doses and with continuous infusion. One goal of the present study was to investigate if other dosing paradigms for PCA would produce neurotoxicity in mice and to determine whether this toxicity was selective for 5HT neurons. Furthermore, it has been demonstrated that the NMDA receptor antagonist MK 801 attenuates or prevents both the DA and the 5HT neuropathology produced by methamphetamine in rats but fails to prevent PCA-induced 5HT toxicity in rats. A second goal was to evaluate the protective effect of MK 801 in PCA-induced neurotoxicity in mice. Two injections of PCA (50 mg/kg, i.p.) administered 6 h apart produced a 50% depletion in neostriatal serotonin and 5-hydroxyindoleacetic acid 5 days after treatment. Surprisingly, neostriatal tyrosine hydroxylase activity and dopamine content in these mice were reduced by 38% and 62%, respectively. MK 801 (2.5 mg/kg, i.p., administered 30 min before each PCA injection) completely prevented the PCA-induced changes. These results indicate that PCA is not a selective serotonergic neurotoxin in mice and that NMDA receptors appear to be involved in mediating its neurotoxic actions, at least within the mouse neostriatum.

638.3

PARA-METHYLTHIOAMPHETAMINE (MTA), A New *p*-CHLOROAMPHETAMINE (PCA) ANALOGUE, DEVOID OF SEROTONIN NEUROTOXICITY. Xuemei Huang, Danuta Marona-Lewicka and David E. Nichols*. Depts. of Pharmacology and Toxicology, and Medicinal Chemistry and Pharmacognosy, Purdue University, W. Lafayette, IN 47907.

Para-Methylthioamphetamine (MTA), an analogue of *p*-chloroamphetamine (PCA), was compared to PCA in a number of pharmacological assays. MTA was about 2-fold more potent than PCA at inhibiting synaptosomal uptake of [^{3}H]-5-HT, and about 7-fold and 10-fold less potent than PCA at inhibiting synaptosomal uptake of [^{3}H]-DA and [^{3}H]-NE. In drug discrimination assays, MTA was nearly equipotent to PCA in animals trained to discriminate saline from 3,4-methylenedioxymethamphetamine (MDMA), or two related analogues *S*-MBDB or MMAI. Superfusion experiments in brain slices show that MTA causes dose-dependent increases of tritium efflux from rat frontal cortex slices preloaded with [^{3}H]5-HT. The degree of tritium efflux induced by 10 μM MTA was comparable to that induced by an equal molar concentration of PCA. The potential neurotoxicity of MTA was examined by measuring monoamine and metabolite levels at one week following an acute dose. A 10 mg/kg dose of PCA caused a 70-90% decrease of cortical, hippocampal and striatal 5-HT and 5-HIAA levels, while twice the molar dose of MTA (21.3 mg/kg) had no effect on 5-HT and 5-HIAA levels. Thus, substitution of the *p*-chlorine atom of PCA with a methylthio yielded a potent, selective, serotonin releaser, apparently lacking serotonin neurotoxic effects. This work also supports the idea that catecholamine systems may play a critical role in the neurotoxicity of PCA-like compounds.

638.4

CHRONIC FLUOXETINE ALTERS SEROTONIN-MEDIATED HORMONE SECRETION Q. Li*, M.S. Brownfield†, G. Battaglia, T.M. Cabrera, A.D. Levy, P.A. Rittenhouse, L.D.Van de Kar. Dept. Pharmacol. Loyola Univ. Chicago, Sch. Med. Maywood, IL 60153, †Univ. Wisconsin, Sch. Vet. Med., Madison, WI 53706.

The endocrine responses to serotonin (5-HT) agonists were used to assess the state of serotonergic function after chronic treatment with antidepressants. Fluoxetine (10 mg/kg), a 5-HT uptake blocker, was compared with the norepinephrine uptake blocker, desipramine (DMI 5 mg/kg). Both were injected (i.p) once a day for 21 days. MK-212 (5-HT$_{1-2}$ agonist 0-20 mg/kg i.p), RU 24969 (5-HT$_{1A/1B}$ agonist 0-10 mg/kg i.p) and DOI (5-HT$_{1C/2}$ agonist 0-5 mg/kg i.p) were administered 18 hrs after the final antidepressant injection and 30 min before decapitation. Fluoxetine potentiated the MK-212 and DOI-induced increase of plasma corticosterone, and the MK-212-induced increase of plasma ACTH level. DMI only potentiated the effect of MK-212 on plasma ACTH and corticosterone concentration. Both fluoxetine and DMI increased the effect of RU 24969 and DOI on plasma prolactin levels. Both fluoxetine and DMI potentiated the effect of DOI and the high dose of MK-212 on plasma oxytocin levels. Only MK-212 increased vasopressin levels and this effect was potentiated by fluoxetine. Fluoxetine decreased, but DMI increased, the effect of high dose MK-212 on plasma renin concentration. Neither fluoxetine nor DMI influenced the B_{max} or K_d of 5-HT$_1$ or 5-HT$_2$ receptors measured. The results suggest that fluoxetine influences 5-HT$_{1C/2}$ mediated ACTH and corticosterone release, but DMI does not. Also, both fluoxetine and DMI might influence 5-HT$_{1B}$ and/or 5-HT$_{1C/2}$ mediated prolactin secretion and 5-HT$_{1C/2}$ mediated oxytocin release. It is difficult to asses the influence of antidepressants on vasopressin secretion, because only MK-212 increased its secretion. Overall, the antidepressants potentiated most hormonal responses to 5-HT agonists. Since none of the 5-HT receptors measured were changed by treatment with fluoxetine or DMI, the influence of fluoxetine or DMI on the hormone responses to 5-HT agonists may not happen at the receptor level, but possibly at the second messenger level. (Supported by MH 45812).

ALTERATIONS IN RAPHE AND FRONTAL CORTEX SEROTONIN OVERFLOW FOLLOWING FOCAL AND SYSTEMIC ADMINISTRATION OF FLUOXETINE. K. Wozniak*, A. Pert and M. Linnoila. LCS/NIAAA and BPB/NIMH, Bld. 10, Rm 3C102, Bethesda, MD. 20892

Fluoxetine is an antidepressant drug that is a potent inhibitor of 5-hydroxytryptamine (5-HT) reuptake. This study describes in vivo assessment of this compound on serotonergic transmission in two brain regions. Male Sprague-Dawley rats were anaesthetized with chloral hydrate and stereotaxically implanted with concentric dialysis probes into frontal cortex and raphe nuclei. Microdialysis samples were collected and assayed for 5-HT content. After basal levels of 5-HT were attained in both areas, fluoxetine was applied either focally into one region or administered systemically. Focal fluoxetine (100μM) significantly increased local extracellular levels of 5-HT by approximately 400%. Both the frontal cortex and the raphe nuclei displayed similar sensitivity to fluoxetine perfusion. A concurrent decrease of 20% in 5-HT occurred in each normally perfused region following focally applied fluoxetine at the other site. Systemic fluoxetine (15mg/kg, i.p.) also significantly increased 5-HT by about 300% in the raphe nuclei, but in contrast there was a concurrent decrease in 5-HT (50%) in frontal cortex. This is an in vivo demonstration of opposite effects of systemic fluoxetine in two brain regions. Since reuptake blockade has similar effects on 5-HT in terminal as well as somatodendritic regions, it appears that the uptake sites have similar characteristics in both areas. A decrease in 5-HT overflow in the frontal cortex following application of fluoxetine to the raphe nuclei presumably reflects the activation of somatodendritic autoreceptors. The elevation of cortical 5-HT by focally applied fluoxetine on the other hand, probably activates feedback inhibitory pathways. The net effect of systemic fluoxetine appears to be determined predominantly by increased 5-HT in the somatodendritic regions which dramatically inhibits raphe neuron firing, resulting in a decrease in cortical release.

638.6

RECOVERY OF CENTRAL 5-HT AXONAL PROJECTIONS AFTER MDMA INJURY: OBSERVATIONS IN RODENTS C. Scanzello, G. Hatzidimitriou, A. Martello*, J. Katz, G. Ricaurte. Dept. of Neurology, Johns Hopkins School of Medicine and NIDA Addiction Res. Ctr., Baltimore, MD 21224.

Although the neurotoxic potential of the recreational drug, (±) 3,4-methylenedioxymethamphetamine (MDMA), has been well established, the fate of the damaged serotonin (5-HT) neurons remains uncertain. In MDMA-treated primates, there is evidence that 5-HT neuronal damage is persistent, and possibly permanent. The purpose of the present study was to determine if this was also true in MDMA-treated rodents. Rats were given MDMA (10 mg/kg; i.p) four times at 2 hour intervals. Two, 8, 16, 32 and 52 weeks later, groups (n = 8) of MDMA-treated rats, along with age-matched controls (n = 8), were analyzed for regional brain 5-HT, 5-HIAA, and [^{3}H]paroxetine-labelled 5-HT uptake sites. In addition, some animals were studied immunohistochemically using an antibody directed at 5-HT. Two weeks after MDMA treatment, there was a marked (42-82%) reduction in all presynaptic 5-HT neuronal markers, and in the density of 5-HT axons. By 16 weeks, 5-HT neuronal markers had partially recovered, and by 32 weeks, serotonergic recovery was largely complete. One year after MDMA treatment, there was evidence of sustained recovery in all brain regions. Detailed analysis of the group data revealed that while most MDMA-treated rats recovered, a few developed persistent 5-HT deficits. Immunocytochemical studies yielded results which corroborated the neurochemical findings. These results indicate that 5-HT axons in most (but not all) rats recover from MDMA injury, and argue against the notion that there is accelerated aging of brain 5-HT neurons following MDMA exposure. (Supported by NIDA grant DA05707)

638.7

DEXFENFLURAMINE NEUROTOXICITY: FURTHER PRECLINICAL STUDIES IN MICE AND MONKEYS. A. Ridenour, M. Martello, J. Katz and G. Ricaurte*. Dept. of Neurology, Johns Hopkins School of Medicine and NIDA Addiction Res. Ctr., Baltimore, MD 21224.

Recent findings indicate that dexfenfluramine, a drug prescribed for appetite suppression, damages central serotonin (5-HT) neurons in nonhuman primates (squirrel monkeys). Combined with similar observations in rodents (rats), these findings have raised concern that dexfenfluramine may damage 5-HT neurons in the human brain. The significance of the findings in squirrel monkeys and rats has been questioned on the grounds that: 1) the loss of presynaptic 5-HT neuronal markers has not been demonstrated to be permanent and 2) the only animal to have a metabolic ratio (ratio of plasma areas between dexfenfluramine and dexnorfenfluramine) similar to man is the mouse. We now report that serotonergic deficits in the dexfenfluramine-treated squirrel monkey last for at least one year after drug treatment. In addition, we report that 5-HT neurons in the mouse, like those in the rat and squirrel monkey, are damaged by dexfenfluramine. Notably, doses of dexfenfluramine which induced 5-HT deficits in the mouse did not produce significant weight loss. These results suggest that concerns over the possible health hazards of dexfenfluramine in man are well justified. Further, findings in the mouse suggest that the neurotoxic actions of dexfenfluramine are not mediated by its metabolite, dexnorfenfluramine, since only low levels of dexnorfenfluramine are found in the mouse brain. (Supported by NIDA grant DA06275)

638.8

PERSISTENT EFFECTS OF FENFLURAMINE ON DEVELOPING SEROTONIN (5-HT) AND DOPAMINE (DA) NEURONS IN REAGGREGATE TISSUE CULTURE. L. Woff, P.C. Hoffmann and A. Heller. Dept. of Pharmacol. and Physiol. Sciences, University of Chicago, Chicago, IL 60637.

Fenfluramine, an anorexic amphetamine derivative, depletes central 5-HT and DA levels in adult rats. Only the reductions in 5-HT however, are long-lasting. To study whether developing neurons would be similarly affected, reaggregate tissue cultures were prepared from neurons of mesencephalic tegmentum and corpus striatum of embryonic mice. Reaggregates were exposed to (±)-fenfluramine (10^{-7} to 10^{-4}M) between 15-22 days of culture and analyzed for monoamines. Fenfluramine decreased monoamine levels in a dose-dependent manner. Maximal reductions at 10^{-4}M fenfluramine were 79% for 5-HT, and 77% for DA. To determine whether the reductions in monoamine levels would persist, reaggregates were exposed to 10^{-5}M fenfluramine during days 15 to 22 of culture. Cultures were then allowed to recover in drug-free media for an additional 21 days. During the recovery period, samples of reaggregates were collected for analysis of monoamines. Following the 15-22d treatment period, DA and 5-HT levels in drug-treated cultures were significantly reduced from control levels. During the recovery period, an increase in monoamine levels was seen in both control and drug-treated cultures. However, the increase in monoamines in the treated groups was not sufficient to overcome the initial neurochemical insult produced by 7 days of fenfluramine exposure. The results indicate that, unlike in adult neurons, fenfluramine has marked and persistent effects on developing DA and 5-HT neurons. Supported by MH42134.

638.9

FENFLURAMINE INDUCED SEROTONIN DEPLETIONS ARE ENHANCED BY MK-801. K.E. Sabol*, J.B. Richards, C.S. Brent, L.S. Seiden. Dept. Pharm./Phys. Sci., University of Chicago, Chicago, IL

The effects of MK-801 (the non-competitive NMDA receptor antagonist) on dl-fenfluramine (FEN) induced serotonin depletions and *in vivo* release of serotonin were studied. Serotonin tissue concentrations were measured 2 wks after treatment with FEN or FEN+MK-801. FEN treated rats received either 1, 2, or 4 injections of 12.5 mg/kg DL-FEN at 1 hr intervals; FEN + MK-801 treated rats received the same FEN regimens with 2.5 mg/kg MK-801 administered 15 min before and 90 min after the first FEN injection (N=8 each gp). MK-801 did not alter FEN-induced serotonin depletions in frontal cortex and septum. MK-801 significantly enhanced FEN-induced serotonin depletions in striatum (1, 2, and 4 FEN injections), amygdala (1 and 4 FEN injections), somatosensory cortex (1 FEN injection), hippocampus (1 FEN injection), and hypothalamus (4 FEN injections). MK-801 alone significantly decreased serotonin depletions in striatum and amygdala. Serotonin release was measured in the striatum of awake rats using *in vivo* dialysis. FEN-induced serotonin release (a single injection of 12.5 mg/kg) was not altered by pretreatment (15 min) with 2.5 mg/kg MK-801.

MK-801 enhanced FEN-induced serotonin depletions in all regions except frontal cortex and septum. This result is in contrast to reports indicating that MK-801 blocks dopamine and serotonin depletions induced by methamphetamine. MK-801 did not enhance the FEN-induced serotonin release *in vivo*. This result indicates that the enhanced serotonin depletions with MK-801+FEN are not due to an enhanced increase in serotonin release. (Supported by NIDA DA-00085 & RSA10562 (L.S.Seiden).

638.10

TIANEPTINE (A 5-HT UPTAKE ENHANCER) INCREASES THE SECRETION OF CORTICOSTERONE AND RENIN BUT NOT PROLACTIN. L.D. Van de Kar*, Q. Li, A.D. Levy, P.A. Rittenhouse, and T.M. Cabrera. Dept. Pharmacology. Loyola Univ. Chicago, Stritch Sch. Medicine., Maywood, IL 60153.

Tianeptine is considered a selective serotonin (5-HT) uptake enhancer with antidepressant potential. We determined the acute neuroendocrine responses to injections of tianeptine (0-20 mg/kg, ip). Plasma prolactin was not altered by injections of tianeptine. In contrast, plasma corticosterone and renin concentrations were dose-dependently elevated. The maximal increase in plasma corticosterone was observed at a dose of 10 mg/kg, 15 minutes post-injection. Plasma corticosterone returned to normal levels within 30-60 minutes post-injection. Plasma renin concentration was elevated for a longer duration. At 2 hours post-injection, plasma renin concentration was still higher than saline injected rats. To determine whether 5-HT uptake sites mediate the neuroendocrine effects of tianeptine, rats were pretreated with the 5-HT uptake blocker fluoxetine (10 mg/kg ip) 3 hours before the injection of tianeptine (2-20 mg/kg ip). The rats were sacrificed 15 minutes after the tianeptine injection. Fluoxetine did not alter the effect of tianeptine on either plasma corticosterone or renin concentrations. The data suggest that the endocrine effects of tianeptine are mediated by a mechanism that is independent of the 5-HT uptake sites. Supported in part by MH45812 and DA04865.

UPTAKE INHIBITOR-INDUCED INCREASE IN SEROTONIN IN RAT HYPOTHALAMUS. J.J. Rutter* and S.B. Auerbach. Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855.

In vivo microdialysis was used to examine the effects of peripheral uptake inhibition on extracellular 5-HT and 5-HIAA in the hypothalamus of unanesthetized rats. Dialysis probes were perfused with aCSF, and samples were collected at 30 min intervals during the experiment. After stable baseline 5-HT was obtained, fluoxetine (10 mg/kg, i.p., n=5) was injected. Extracellular 5-HT was increased by 145 ± 24% within 30 min. Conversely, 5-HIAA was decreased by 20 ± 4% within 1.5 h. These alterations in 5-HT and 5-HIAA persisted for the entire 24 h observation period. To confirm the neuronal origin of the dialysate 5-HT, 8-OH-DPAT (500 ug/kg, s.c.) was administered 26 h after fluoxetine. This resulted in a 75% decrease in dialysate 5-HT.

In a similar experiment, sertraline (10 mg/kg, i.p.,n=3) resulted in a 110 ± 28% increase in 5-HT, and a 40 ± 15% decrease in 5-HIAA. These effects also lasted for 24 h post-injection. The 5-HT releaser fenfluramine (10 mg/kg, i.p.) was injected 26 h after sertraline to determine if the uptake site was still effectively blocked. This would appear to be the case, since fenfluramine only resulted in a 75% increase in 5-HT 1 day after sertraline, as compared to an 800% increase in 5-HT in control animals injected with fenfluramine.

In conclusion, selective uptake inhibitors produced a long-lasting change in 5-HT neurotransmission upon acute peripheral injection. Supported by NSF grant 9109662.

638.12

ARE THERE TWO SEROTONIN UPTAKE CARRIERS IN RAT BRAIN? S. Kongsamut*, C. Smith, J. Roehr & M. Szewczak. Neuroscience Strategic Business Unit, Hoechst-Roussel Pharmaceuticals, Somerville, NJ 08876

Molliver (see *J Clin Psychopharm* 7:3S;1987) proposed the idea of multiple serotonin (5HT) uptake carriers based on: (1) histochemical evidence that fine nerve endings from dorsal raphe serotonergic neurons (but not beaded endings from median raphe) are destroyed by p-Cl amphetamine (PCA) (2) PCA only enters these endings through a 5HT uptake carrier. We explored this using a pharmacological approach.

We first examined PCA selectivity for dorsal raphe neurons by measuring PCA-depletion of 5HT (measured by HPLC) in various brain regions. PCA (10 mg/kg) depleted 5HT equally well in the striatum (dorsal raphe input) and hippocampus (both dorsal and medial raphe).

We next examined inhibition of PCA-induced 5HT depletion by 5HT uptake blockers and found (as previously reported) that clomipramine had a shorter duration than expected. This discrepancy suggested that clomipramine might be selective for another uptake carrier. To test this, we treated rats with PCA (10 mg/kg, twice 24h apart) and allowed the PCA-sensitive neurons to degenerate over 7-10 days. The remaining [^{3}H]5HT uptake into synaptosomes from these rats (whole brain or selected brain regions) was still inhibited by the uptake blockers.

Finally, we injected rats i.p. with 5HT uptake blockers to examine any differential activity in various brain regions. Each drug inhibited [^{3}H]5HT uptake, more so in the hippocampus than in the striatum.

In summary, we find no conclusive evidence for the existence of multiple 5HT uptake carriers in the different brain regions.

638.13

EFFECT OF SERTRALINE ON MONOAMINE UPTAKE IN RATS AND MICE. Susan K. Hemrick-Luecke and Ray W. Fuller*. Lilly Research Laboratories, Lilly Corporate Center, Indianapolis, IN 46285

Sertraline (1S,4S-N-methyl-4-[3,4-dichlorophenyl]-1,2,3,4-tetra-hydro-1-naphthylamine) is a selective inhibitor of the serotonin (5HT) uptake carrier (Koe, et al., Eur. J. Pharmacol. 141:187-194, 1987). Sertraline blocked the depletion of brain serotonin by p-chloro-amphetamine (PCA), being more potent in rats (ED50 1.0 mg/kg, i.p.) than in mice (ED50 4.0 mg/kg, i.p.) when injected 1 hour before PCA. In rats, a 10 mg/kg i.p. dose of sertraline decreased brain 5-hydroxy-indoleacetic acid concentrations for as long as 24 hours, suggesting a long duration of uptake inhibition. Sertraline is metabolized to desmethylsertraline (DMS). At 8 hrs and longer times after sertraline injection into rats (10 mg/kg, i.p.), brain concentrations of DMS were higher than those of sertraline and may have contributed to 5HT uptake inhibition. Sixteen hours after sertraline injection, a time at which sertraline levels were only one-third those of DMS, the PCA-induced depletion of rat brain 5HT was antagonized with an ED50 of 7.0 mg/kg. In mice, 1-8 hour pretreatments with sertraline at 32 mg/kg had no effect on the 6-hydroxydopamine (6-OHDA)-induced depletion of heart norepinephrine (NE). Sertraline pretreatments shown to induce a decrease in the number of β-adrenoreceptors in rat brain (19.2 mg/kg, i.p., b.i.d. for 4 days), antagonized the 6-OHDA-induced depletion of rat hypothalamic NE and epinephrine (EPI). One hour after the last dose, brain levels of sertraline were 2 times and levels of DMS were 13 times those observed 1 hour after a single dose (19.2 mg/kg, i.p.) of sertraline, which had no effect on NE or EPI uptake in rat hypothalamus after 6-OHDA injection.

638.14

IN VIVO LABELING OF SEROTONIN UPTAKE SITES WITH [^{11}C]McN-5652. U.Scheffel*, M. Suehiro, R.F.Dannals, G.A.Ricaurte, H.T.Ravert, C. Steinert and M. Stathis. Departments of Radiology and Neurology, The Johns Hopkins Medical Institutions, Baltimore, MD 21205.

McN-5652 (1,2,3,5,6,10b-hexahydro-6-[4-(methyl thio) phenyl] pyrrolo-[2,1-a]-isoquinoline), a potent serotonin (5-HT) uptake blocker, was labeled with ^{11}C and evaluated in mice as a potential PET imaging agent for central serotonin (5-HT) uptake sites. Two resolved stereoisomers of [^{11}C] McN-5652, (+)McN-5652 and (-)McN-5652, and the racemate, (±)[^{11}C]McN-5652, were synthesized and studied *in vivo*. After i.v. injection, the (+) and (±) tracers accumulated rapidly and to a high degree in the mouse brain in 5-HT transporter-rich areas, whereas the inactive (-) isomer was cleared rapidly. At 60 min, hypothalamus/ cerebellar ratios were 3.9 for the (±) isomer, 5.9 for the (+) isomer and 1.3 for the (-) isomer. *In vivo* binding of the racemate was blocked in a dose-dependent manner by paroxetine and (+)McN-5652, but not by (-)McN-5652, GBR 12,909, desipramine or ketanserin. The data indicate that the *in vivo* binding of (+) and (±)[^{11}C]McN-5652 is saturable, selective and stereospecific and suggest that they may be promising radioligands for PET studies of 5-HT transporters. The labeled inactive isomer may permit an estimate of non-specific binding.

DISTRIBUTION OF SEROTONIN AXONS IN THE HYPOTHALAMUS AND HIPPOCAMPUS OF THE MOUSE. C.F. Phelix*, C. Cantu, R. Kaakaji, and M.J. Wayner, Division of Life Sciences, The University of Texas at San Antonio, TX 7249-0662

Serotonergic projections to the hypothalamus and hippocampus influence several known functions, i.e., neuroendocrine regulation, nociception, memory and anxiety. Coronal sections of the mouse forebrain were stained with the use of a rabbit anti-serotonin antibody using the unlabeled antibody peroxidase-antiperoxidase method, including a silver postintesification method. The stained tissue sections were projected onto white paper for cartography and semiquantitation. The regional distributions and relative density of serotonin axons for the mouse were compared with reports in the rat. The hypothalamus contained many, widely distributed axons with a density in the medial hypothalamus greater than the lateral hypothalamus. This pattern is reversed from the rat. The ventromedial hypothalamic nucleus displayed a reversed pattern compared to the rat. Other hypothalamic areas, e.g. paraventricular nucleus, contained moderate amounts of axons similar to the rat. In the hippocampus two major patterns were observed. A very high density of axons were present in the stratum lacunosum moleculare of the Ammon's horn. The lowest density was found in the dentate gyrus. The only pyramidal cells contacted by serotonin terminals were found in CA3. This distribution is consistent with reports in the rat but varies from reports of serotonin receptor densities in the hippocampus. Supported by UTSA-Faculty Research Award

SEROTONERGIC INNERVATION OF THE CORE AND SHELL OF THE NUCLEUS ACCUMBENS (ACB): NORMAL ULTRASTRUCTURE AND RELATIONSHIP TO CATECHOLAMINERGIC AFFERENTS. E. J. Van Bockstaele* and V. Pickel, Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, N.Y. 10021.

We examined the ultrastructural basis for known functional interactions between serotonin immunoreactive (5HT-ir) terminals, local neurons and catecholamine afferents in the core and shell of the Acb. These monoamines were identified in the same sections of tissue using the avidin-biotin immunoperoxidase method for a rabbit 5HT antiserum and silver intensified gold labeling for a mouse antibody against the catecholamine synthesizing enzyme, tyrosine hydroxylase (TH). By light microscopy, 5HT-ir processes appeared less dense and topographically more heterogeneous than the TH-ir varicosities throughout the Acb. Using electron microscopy, 5HT and TH-ir profiles included unmyelinated and a few myelinated axons and terminals. In the core, 5HT-ir terminals rarely formed synaptic junctions with neuronal targets but were more often found in apposition with other terminals most of which were not TH-ir. In fact, TH and 5HT-ir axons were usually separated by a distance of >0.5 μm in fields containing both labels. In the shell, 5HT-ir terminals (i) were larger in size (0.3-0.4 μm for shell vs. 0.1-0.2 μm for core), (ii) contained relatively more dense core vesicles, (iii) frequently formed symmetric and asymmetric contacts with dendrites and spines and (iv) were not often in contact with TH-ir axon terminals. The morphological differences suggest that 5HT terminals in the shell vs. core may be functionally distinct and may arise from different 5HT neurons. Moreover, the sparsity of direct appositions between TH and 5HT terminals suggest that release of dopamine by 5HT may occur through diffusion in extracellular space or may be indirectly mediated by targets of 5HT terminals. NICOTINE AND COCAINE INTERACT WITH SEROTONERGIC NEURONS. H. Tamir*, K.P. Liu, M. Adlersberg, H.S. Hsiung, P.R Wade, E.A. Nunez and M.D. Gershon, N.Y. State Psych. Inst. and Columbia U. N.Y.,N.Y. 10032.

The hypothesis was tested that synaptic vesicles, which are acidic, are targets for the action of nicotine and cocaine, each of which is a weak base. Secretion of 5-HT from synaptosomes and thyroid parafollicular (PF) cells was studied in the presence or absence of nicotine (50 μM) or cocaine (50 μM). In addition, the effects of these compounds on the actions of 5-HT on receptors in the enteric nervous system was also investigated. Cocaine, but not nicotine, increased the basal release of ^{3}H-5-HT from synaptosomes. Both cocaine and nicotine enhanced the veratridine- and K^+-stimulated release of ^{3}H-5-HT from synaptosomes, an affect that persisted when $[Ca^{2+}]_e$ was lowered. Neither cocaine, nor nicotine affected the basal release of 5-HT from PF cells; however both drugs inhibited the secretion of 5-HT from PF cells in response to TSH. Trapping of acridine orange confirmed that the acidity of the 5-HT-storing PF granules increased in response to stimulation of the cells with TSH; however, both cocaine and nicotine alkalinized these granules. Intracellular records from enteric neurons indicated that nicotine (5 μM) strongly potentiated the rapid depolarization mediated by 5-HT3 receptors; this action was manifest after the depolarizing phase of the response to nicotine itself. These data show that cocaine and nicotine can interact with serotonergic elements in a complex manner that may have both pre- and postsynaptic components. Differential serotonergic innervation of spinal somatic and parasympathetic motoneurons in rats. W. Wu*, M.W. Wessendorf and R. Elde Dept. Cell Biol. & Neuroanat., Univ. Minnesota, Minneapolis, MN 55455.

This study examined whether there might be differences in peptide coexistence between the serotonergic neurons innervating somatic and parasympathetic motoneurons. Somatic and parasympathetic motoneurons were retrogradely labeled in the spinal cord with hydroxystilbamidine (Fluoro-Gold) applied to either the sciatic or pelvic nerve, respectively. Ten μm sections containing labeled neurons were stained for either serotonin (5HT) and substance P (SP), or for 5HT and thyrotropin-releasing hormone (TRH) using 2-color immunofluorescence. When sections were examined, it was found that most retrogradely labeled profiles (99% of sciatic profiles and 91% of pelvic profiles) were apposed by 5HT varicosities. In tissue stained for 5HT and TRH, 104 out of the 106 sciatic profiles that were apposed by 5HT varicosities were apposed by 5HT/TRH varicosities, as were 111 out of 113 pelvic profiles. Similarly, in tissue stained for 5HT and SP, all sciatic nerve profiles that were apposed by 5HT varicosities were apposed by 5HT/SP varicosities (319 out of 319). However, almost none of the profiles labeled from the pelvic nerve were apposed by 5HT/SP varicosities (3 out of 168). These findings suggest that about 98% of somatic motoneuron profiles were innervated by 5HT varicosities containing both SP and TRH. In contrast, at most 2% of the profiles of parasympathetic preganglionic motoneurons were apposed by 5HT/SP/TRH varicosities with the great majority being apposed by 5HT varicosities containing TRH but not SP. Thus, we conclude that different populations of raphespinal serotonergic neurons modulate the activities of sciatic and pelvic neurons. Our earlier studies have demonstrated the expression of TRH and SP receptor mRNA in the spinal cord, suggesting that these peptides could exert direct actions on spinal neurons. IMMOBILIZATION OF TRYPTOPHAN HYDROXYLASE BY IMMUNE ADSORPTION: A METHOD TO STUDY REGULATION BY PROTEIN KINASES. P.A. Johansen*, I. Jennings[1], R.G.H. Cotton[1], and D.M. Kuhn. Lafayette Clinic & CCN Program, Wayne State Univ., Detroit, MI, and [1]The Murdoch Institute, Royal Children's Hosp., Melbourne, Australia.

Tryptophan hydroxylase (TPH) is the initial, rate-limiting enzyme in the biosynthesis of serotonin. TPH is an unstable enzyme, and detailed studies of its regulation have been limited by the lack of highly purified, active enzyme. We have utilized immunoprecipitation as a rapid, effective method to affinity purify TPH from brain. TPH was immobilized by adsorption to Pansorbin following binding to the monoclonal antibody PH8, and resuspended pellets were assayed for TPH activity. TPH could be completely immunoprecipitated from tegmental extracts in 1.5 hours, and the recovery of TPH activity using this method was 40%. Immobilized TPH (Im-TPH) displayed an apparent K_m for BH_4 of 84 ± 13 μM, and an apparent K_m for tryptophan of 44 ± 19 μM. The V_{max} values for Im-TPH were 33-50% of those observed for crude TPH. The thermo-stability of Im-TPH was nearly identical to that of soluble TPH. Like soluble TPH, Im-TPH was completely inhibited by the catechol compound apomorphine (IC_{50}=1.56 μM), while dopamine caused partial inhibition (54%). Im-TPH was much more sensitive to activation by phosphatidylserine than soluble TPH. Purified calcium/calmodulin-dependent protein kinase produced a 2-fold activation of Im-TPH, while purified PKA failed to produce activation. Using this method it was also demonstrated that PKA phosphorylates Im-TPH, supporting our previous results with soluble TPH that phosphorylation of TPH by PKA does not activate the enzyme. These results indicate that Im-TPH retains the characteristics of the soluble enzyme and can be used to study regulation by protein kinases.

MORPHINE-INDUCED INCREASE IN SEROTONIN IN RAT DIENCEPHALON. R. Tao, S.M. Grauer, and S.B. Auerbach*. Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855.

Increased 5-HT release may mediate some effects of opioids. Thus, we have studied the effect of morphine on 5-HT and 5-HIAA in the diencephalon of unanesthetized rats. Dialysis probes were perfused with aCSF (140 mM NaCl, 3 mM KCl, 1.5 mM $CaCl_2$, 1 mM $MgCl_2$, 1.2 mM Na_2HPO_4, 0.27 mM NaH_2PO_4). After stable baseline 5-HT was obtained (1.38±0.18 pg n=13), morphine (20 mg/kg, s.c.) was injected. Extracellular 5-HT was increased about 30% between 30 to 60 min, and returned to baseline 2 hr after morphine. This increase represents an average of values from 5 rats that showed no increase in 5-HT and 8 rats with increases between 30 to 100%. In contrast, for all rats, 5-HIAA levels increased steadily to a maximum of about 60% above baseline, 3 hr after injection. Intracellular breakdown of 5-HT to 5-HIAA may have limited the magnitude and time course of the effect of morphine. To test this, 1.0 mM pargyline was added to aCSF for 12 h before morphine injection. With MAO inhibited, basal 5-HT was 6.78±1.38 pg (n=5), and morphine then led to a reliable increase in 5-HT of about 65% lasting more than 3 hr. In conclusion, morphine produced a short-lasting increase in extracellular 5-HT that appeared to be limited in time and magnitude by intracellular breakdown of 5-HT to 5-HIAA. Regulation of MAO activity or access of intracellular pools of 5-HT to MAO could play a role in the extent of opioid-induced 5-HT release. Supported by NSF grant 9109662.

EFFECTS OF PROLONGED EXERCISE TO FATIGUE ON BRAIN MONOAMINES IN THE RAT. S.P. Bailey, J.M. Davis*, S.J. Kelly and E.N. Alborn. Depts. of Exercise Science and Psychology. Univ. of South Carolina, Columbia, SC 29208

The effects of prolonged exercise to fatigue on brain monoamines has yet to be described. The purpose of this experiment was to describe changes in brain monoamine concentrations in discrete brain areas following prolonged moderate intensity exercise to fatigue. Twenty-four (3 groups;n=8 each) treadmill accommodated male Wistar rats were sacrificed by decapitation at rest, following 1 hr of treadmill running, and after exhaustive treadmill running (20 $m \cdot min^{-1}$ & 5% grade). After sacrifice, brains were removed and midbrain (MB), striatal (ST), hippocampal (HI), and hypothalamic (HY) tissue were dissected, sonicated in 0.2 M PCA, and stored at -80 °C until analysis. In each brain area, norepinephrine (NE), dopamine (DA), DOPAC, 5-hydroxytryptamine (5-HT), and 5-HIAA were measured by HPLC-EC. 5-HT and 5-HIAA were elevated ($p<.05$) in all brain regions following 1 HR of exercise and at exhaustion as compared to rest. 5-HIAA was greater at exhaustion than following 1 HR of exercise in MB and ST. NE, DA, and DOPAC concentrations were elevated approximately 2-fold ($p<.05$) in MB, ST, and HY following 1 HR of exercise versus rest. However, at exhaustion NE, DA, and DOPAC concentrations in MB, ST, and HY were reduced to levels similar to rest. No differences in NE, DA, and DOPAC were found in HI. The results of this study indicate that prolonged exercise is associated with enhanced brain 5-HT and dopamine metabolism during the initial 1 HR; whereas at fatigue 5-HT metabolism is further heightened and dopamine metabolism is attenuated.

SEROTONIN RELEASE IN THE HYPOGLOSSAL (XII) NUCLEUS REGION UNDER CONDITIONS OF SUPPRESSED RAPHE SYSTEM ACTIVITY. L. Kubin*, H. Tojima, O. Taguchi, C. Reignier, A.I. Pack and R.O. Davies. University of Pennsylvania, Philadelphia, PA. 19104-4283.

Serotonin (5HT) may play an important role in controlling the excitability of XII motoneurons as both 5HT terminals and receptors are present within the XII nucleus. Previously, we found (Neurosci.Lett.136,1992) that methysergide, a non-selective 5HT receptor antagonist, depressed and 5HT increased the spontaneous activity of XII motoneurons when microinjected into the XII nucleus in decerebrate cats. In the present experiments, we studied the endogenous 5HT release in the XII nucleus region under experimental conditions associated with a suppression of activity in 5HT-containing raphe neurons. In decerebrate, paralyzed and artificially ventilated cats, the activities of the phrenic, XII and cervical motor nerves were recorded. The procedures used were: pontine microinjections of carbachol which produce a depression of cervical, XII and raphe neuronal activity similar to that occurring during REM sleep (5 cats); and injections of 8-OH-DPAT, a $5HT_{1A}$ receptor agonist, which also powerfully depresses the activity of raphe neurons (0.5 mg,s.c., 4 cats). A microdialysis probe was placed in the region of XII nucleus and perfused with artificial CSF. 5HT was electrochemically detected in successive 20 min/10 μl samples with a detection limit of 0.25 pg 5HT/5 μl. After a 3 h stabilization period, the resting 5HT level was 1.3±0.5(SE) pg/5μl for probes having *in vitro* recovery rates of 9.5-12.5%. During the carbachol-induced motor suppression, 5HT was reduced to 78±5%(SE) of control; after the recovery from the motor suppression, it increased to 109±12%(SE). Subsequent injection of 8-OH-DPAT reduced 5HT to 47±7%(SE). These data are consistent with the presence of a serotonergic drive to XII motoneurons that originates in the raphe system. During REM sleep this drive is likely to be reduced, thus contributing to the reduced tone in upper airway muscles. Supported by NIH SCOR grant HL-42236.

EFFECT OF DORSAL RAPHE NUCLEUS STIMULATION ON SOMATOSENSORY EVOKED RESPONSES IN RAT. W. Liu*, F.M. Sessler and B.D. Waterhouse. Dept. Physiol & Biophys. Hahnemann U., Phila., PA 19102

The neocortex is a major target of serotonergic axons emanating from the brainstem dorsal raphe nucleus (DRN). Despite the well documented anatomy of these projections, the potential impact of serotonin (5-HT) on the function of neocortical circuits remains unclear. In previous in vitro studies, we have observed a prominent depressant action of 5-HT on synaptically evoked excitatory postsynaptic potentials (EPSPs) and spiking activity in neurons recorded from the barrelfield region of the rat somatosensory cortex. In order to compare these actions of 5-HT with those produced by endogenous 5-HT release within a sensory cortical circuit, we examined the effects of DRN stimulation on somatosensory neuronal responses to activation of afferent sensory pathways in anesthetized rats. Recordings were made from neurons in the barrelfield region of the somatosensory cortex. Single unit responses were evoked by mechanical displacement of individual vibrissa. The spontaneous firing rate of recorded neurons ranged from 0.4 to 30.4Hz with an average of 9.1±6.5Hz. Whisker stimulation produced excitatory responses with instantaneous firing frequency of 47.1±25.8Hz (ranging from 14.0 to 122.5Hz). The effects of DRN stimulation (0.5-4Hz, 0.2ms) on these two parameters varied with stimulus intensities. Evoked responses were reduced at stimulus currents between 50-100uA and increased at currents above 200uA. Spontaneous discharge of cortical neurons was decreased at current 50uA and increased at stimulus currents above 100uA. Our results indicate that DRN stimulation with low current causes suppression of spontaneous discharge as well as unit responses to whisker stimulation. The depressant actions of DRN could be mediated by 5-HT, the major transmitter of this nucleus. While the transmitter responsible for such depressant effects cannot be identified on the basis of these experiments, the data are consistent with our in vitro observation that synaptically evoked activity of somatosensory cortical neurons can be supressed by 5-HT. Our in vitro and in vivo data support the hypothesis that serotonergic afferents to the neocortex may play a role in regulating the flow of sensory information through local sensory circuits by way of an action on synaptic transmission. ORGANIZATION OF THE RAT DORSAL RAPHE(DR): INPUT/OUTPUT RELATIONSHIPS OF SELECTED SUBREGIONS WITHIN THE NUCLEUS. M.L. Kirifides*, M.A.L. Nicolelis, R.C.S. Lin and B.D. Waterhouse, Dept. of Physiol. and Biophys. Hahnemann Univ., Phila., PA 19102.

Previous studies have demonstrated the existence of a crude topographic organization of the dorsal raphe (DR) nucleus with respect to selected efferent targets in the forebrain and brainstem. Furthermore, other investigators have identified the lateral habenula, cortex, substantia nigra and the hypothalamus as major sources of input to the DR. The relationship between DR afferents and subregions of the nucleus which have specific efferent targets has not been the subject of a detailed investigation. The goal of the present study was to use retrograde fluorescent tracers to determine the sources of inputs to different subregions of the DR. Adult Long Evans hooded rats (300gms) received injections of fluorogold (.5 ul) or rhodamine microspheres (.3 ul) in the midline (p 7.0 - 9.0, l 0.0, d 6.1) or "lateral wing" (p 8.0, l .5, d 5.5) regions of the DR nucleus. Coronal sections (80 um) through the DR were examined using fluorescence microscopy. Prominent inputs to the rostral portion of the midline DR originate in the lateral habenula, lateral hypothalamus, prefrontal cortex, and substantia nigra. In contrast to the midline DR, the lateral wing region of the nucleus receives inputs from a more restricted medial zone of the lateral habenula. In addition, the lateral wings receive inputs from the dorsomedial hypothalamus and neocortex but not the substantia nigra. Overall, these data suggest that activity within medial and lateral portions of the DR may be subject to regulation by different regions of the forebrain. (Supported by NIDA DA 05117 to BDW)

SEROTONIN (5-H T) DECREASES INSPIRATORY-MODULATED SYNAPTIC CURRENT IN NEONATAL RAT PHRENIC MOTONEURONS. A.D. Lindsay* & J.L. Feldman. Systems Neurobiology Lab., Dept. of Physiological Science, UCLA, Los Angeles, CA, 90024-1527.

Spinal respiratory motoneurons typically respond to exogenously applied 5-HT with an increase in inspiratory-modulated firing and little or no increase in firing during expiration. The effect on the underlying inspiratory drive is not known. We studied the effect of 5-HT on phrenic motoneurones (PMNs) in the isolated brainstem and spinal cord preparation from neonatal rats. PMN activity was recorded intracellularly under current and voltage clamp conditions. 5-HT was applied to the phrenic nucleus via pressure ejection from micropipettes positioned over the PMN pool. The effect of 5-HT on exogenously applied glutamate was also studied. Local application of 1 mM 5-HT (pH 7.4) decreased peak inspiratory-modulated synaptic current (I_{insp}) by 23 ± 6%. As observed by others, there was a concurrent increase in PMN excitability. This included a depolarization accompanied by a tonic inward current and increased input resistance, and a leftward shift in the *fI* relationship. The 5-HT_2 antagonist ketanserin selectively blocked the increase in excitability without blocking the decrease in I_{insp} produced by 5-HT. The 5-HT_2 agonist 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane HCl mimicked the increase in excitability but did not decrease I_{insp}. Under current-clamp conditions firing produced by local application of 10 mM glutamate was enhanced by 5-HT, but the underlying membrane current produced by glutamate was unaffected. Therefore, a presynaptic mechanism via 5-HT_1 receptors is suggested for the 5-HT-induced decrease in I_{insp}. Supported by NIH Grant NS24742 and a Muscular Dystrophy Fellowship to ADL.

ACUTE EFFECT OF 2,4,5-TRIHYDROXYMETHAMPHETAMINE ON THE HIPPOCAMPAL SEROTONERGIC SYSTEM. M. Johnson*, H.-K. Lim, R.L. Foltz, G.R. Hanson and J.W. Gibb. Dept. Pharmacology and Toxicology and Center for Human Toxicology, University of Utah, Salt Lake City, UT 84112.

3,4-Methylenedioxymethamphetamine (MDMA) decreases tryptophan hydroxylase (TPH) activity of the rat brain shortly after administration. TPH activity is recovered after incubation under nitrogen gas and dithiothreitol, indicating that oxidation of sulfhydryl sites on the enzyme causes the inhibition. 2,4,5-Trihydroxymethamphetamine (THM) was identified as a product of MDMA metabolism and induces a long-term decline in central tyrosine hydroxylase (TH) and TPH. The purpose of this study was to determine if THM can produce a rapid decline in TPH activity similar to MDMA. Male Sprague-Dawley rats (180-250 g) were injected i.c.v. with 1 µmole THM and killed 3 h later. In vitro TPH activity was measured using HPLC-EC; TH activity was determined with a radioisotopic method. THM failed to alter cortical TPH activity but reduced striatal and hippocampal TPH activity to 86% and 54% of control, respectively. Striatal TH activity remained unaltered. 6-Hydroxydopamine (1 µmole), a structural analogue of THM, failed to reduce hippocampal TPH activity but 1 µmole of 5,6-dihydroxytryptamine (5,6-DHT), a serotonergic neurotoxin, reduced TPH activity to 5% of control. This suggests that THM cyclizes to a 5,6-DHT-like compound to induce a rapid decrease in TPH activity. Since in vitro reducing conditions failed to reverse the effects of THM and 5,6-DHT, the loss in TPH activity may differ from the changes induced by MDMA. (Supported by USPHS grants DA 00869, DA 04222 and DA 05860)

639.9

2,4,5-TRIHYDROXYAMPHETAMINE, A METABOLITE OF MDMA, DECREASES TRYPTOPHAN HYDROXYLASE ACTIVITY *IN VITRO*. I.M. Elayan, M. Johnson, H.K. Lim, G.R. Hanson, R.L. Foltz and J.W. Gibb*. Dept. Pharmacology and Toxicology and Center for Human Toxicology, University of Utah, Salt Lake City, UT 84112.

3,4-Methylenedioxymethamphetamine (MDMA) induces a rapid decline in brain tryptophan hydroxylase (TPH) activity that is reversed by incubating TPH under nitrogen gas and dithiothreitol. Intracerebroventricular injection of 2,4,5-trihydroxyamphetamine (THA), a metabolite of MDMA, also induces a rapid decline in TPH activity suggesting that the metabolite may be responsible for the MDMA-induced changes. The purpose of this study was to determine if this rapid decline in TPH activity can be reproduced by THA *in vitro*. The hippocampus and striatum from male Sprague-Dawley rats were incubated in different concentrations of THA. Contralateral tissues were used as controls. After a 1-h incubation at 37 °C under a flow of 95% O_2 and 5% CO_2, hippocampal TPH activity was decreased to 3%, 47%, 68%, 71% and 83% of control after exposure to 5, 0.5, 0.1, 0.01 and 0.001 mM THA, respectively. Striatal TPH activity was reduced to 17%, 54%, 70%, 95% and 98% of control, respectively. Incubation of TPH under nitrogen gas and dithiothreitol failed to return the enzymatic activity to control levels. In contrast to MDMA, these results demonstrate that THA decreases TPH activity *in vitro*. However, this loss in enzymatic activity is different than the rapid decline in TPH activity induced *in vivo* by MDMA since this change in activity is irreversible. (Supported by USPHS grants DA 00869, DA 04222 and DA 05860)

***IN VITRO* ELECTROPHYSIOLOGIC ASSESSMENT OF AGE-RELATED SEROTONIN AUTORECEPTOR FUNCTION.**

H. Zheng* and J.M. Lakoski. Dept. Pharmacology and Toxicology, Univ. Texas Med. Br., Galveston, TX 77555-1031.

The alteration of hormonal and neuronal receptor function have emerged as an etiology common to many age-related diseases, including decline of the female reproductive axis. Aging of serotonin (5-HT) systems has been identified to include changes in cellular physiological responses mediated by a 5-HT_{1A} autoreceptor in the dorsal raphe nucleus (DRN) as recorded *in vivo* in the reproductively middle-aged and senescent rat. Using an *in vitro* preparation of the DRN, we have addressed the pattern of age-related decline in 5-HT receptor function in this brain region.

Electrophysiologic recordings were conducted in 400µm thick slices containing the DRN from female Fischer 344 rats (6, 12, 18, 26 mo); all animals were at diestrous or constant diestrous at time of sacrifice. In slices continually perfused with 10 µM phenylephrine to activate cell firing, no significant decline in baseline spontaneous activity was observed between 12 and 26 mo groups. However, a marked age-related decline in sensitivity to 5-HT was apparent; 30 µM 5-HT produced an average of 40% vs 3% decline in cell firing in middle-aged vs old groups, respectively. Application of selective 5-HT_{1A} antagonists NAN-190 or BMY-7378 did not attenuate 5-HT responses but, rather, produced only agonist-like inhibition of cell firing (2.5-10 µM). In summary, marked age-related decline in 5-HT receptor function is apparent in the *in vitro* DRN of the female rat.

CHANGES IN MONOAMINE LEVELS AND TURNOVER INDUCED BY SHORT-TERM FLUOXETINE TREATMENT. C.R. McKittrick*, V. Luine†, J. Marrast-Host†, and M. Frankfurt. Lab. of Neuroendocrinology, The Rockefeller University, New York, NY 10021 and †Dept. of Psychology, Hunter College, New York, NY 10021.

Fluoxetine, a clinically active antidepressant, is believed to act by inhibiting serotonin (5-HT) uptake in the brain, thus increasing 5-HT availability at the synapse. We tested the effects of short-term fluoxetine administration on monoamine levels and turnover in regions of the brain involved in affective states. Fluoxetine (10mg/kg) was administered i.p. to male rats daily for 4 days. The monoamine oxidase inhibitor, pargyline, was used to assess the rate of 5-HT accumulation. Monoamine levels in discrete brain regions were determined by HPLC. In the ventromedial hypothalamic nucleus (VMN), fluoxetine treatment significantly increased 5-HT (↑46%) while decreasing levels of 5-HIAA (↓44%), the major metabolite of 5-HT. 5-HT turnover was also decreased in the VMN (↓52%). Fluoxetine reduced 5-HIAA in the CA1 region of hippocampus (↓49%). Norepinephrine (NE) content in the dorsal raphe was significantly increased (↑99%), although 5-HT and 5-HIAA remained unchanged. No changes in monoamine content were observed in the medial preoptic area. This study shows regional variation in the effects of fluoxetine on the brain 5-HT system. Furthermore, our data indicate that, following its initial effects on 5-HT uptake, the mechanism of action of fluoxetine may involve alterations in the metabolism of both 5-HT and NE neurons.

SEROTONIN (5-HT) INHIBITS GASTRIC ACID SECRETION BY NONLUMINAL, VAGAL INDEPENDENT MECHANISMS. K.J. LePard and R.L. Stephens, Jr.*, Department of Physiology, The Ohio State University, Columbus, Ohio 43210.

Vagal stimulation increases luminal and portal 5-HT release. Previous studies suggest that released 5-HT produces an inhibitory tone on stimulated acid secretion. The mechanism of 5-HT-induced inhibition on stimulated acid secretion was investigated. In urethan-anesthetized rats with gastric and portal cannula, luminal and whole blood 5-HT levels were measured in response to the vagal stimulant RX77368. Basal luminal and portal 5-HT levels were elevated 1100% and 25%, respectively after intracisternal RX77368. Luminal perfusion of 5-HT (10, 30, 370 ng/10 min) had no effect on pentagastrin-stimulated acid secretion. However, systemic 5-HT (5 mg/kg,i.p.) inhibited pentagastrin-stimulated acid secretion by 67%. Bilateral cervical vagotomy did not reverse 5-HT-induced inhibition of carbachol (1 mg/kg)-stimulated acid secretion. The results suggest that 5-HT acts either through local mechanisms or splanchnic afferents to produce an inhibition in stimulated acid secretion. Supported by NIH DK 42880.

GENDER AND ESTROUS CYCLE EFFECTS OF 8-OH-DPAT ON HYPOTHALAMIC SEROTONIN. S. Maswood*, G. Stewart and L. Uphouse. Department of Biology and Department of Chemistry, Texas Woman's University, Denton, Texas, 76204

The effects of 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) on the synthesis, utilization and turnover of 5-HT has been studied primarily in males. However gender as well as estrous cycle differences in 8-OH DPAT-induced behaviors have been recently reported. The present research was initiated to study the effects of 8-OH DPAT on the levels of 5-HT and 5-HIAA in female rodents and to compare the findings to males. A dose of 0.25 mg/kg of 8-OH-DPAT was injected i.p. to estrous or diestrous females and age-matched males. Thirty minutes later they were decapitated and the hypothalamus collected for HPLC analysis. Males showed the greatest change in 5-HT, 5-HIAA and the 5-HIAA/5-HT ratio. In females the effect of 8-OH-DPAT was greater in diestrous than in estrous females. These findings are consistent with previous gender and estrous cycle differences in the behavioral effects of 8-OH-DPAT.

CO-EXPRESSION OF SEROTONERGIC AND GLUTAMATERGIC PROPERTIES BY SINGLE RAPHE NEURONS IN VITRO. M.D. Johnson*. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115.

Immunocytochemical studies suggest that serotonergic neurons of the pontomesencephalic raphe nuclei may contain other transmitters, including glutamate, GABA, and neuropeptides. However, direct electrophysiological evidence for co-release of these transmitters has been lacking. To investigate this matter further, dissociated pontomesencephalic raphe neurons from neonatal Long Evans rats were grown in microcultures and their synaptic interactions were studied using intracellular recording techniques. Serotonergic neurons were identified by the presence of serotonin-like immunoreactivity, tryptophan hydroxylase-like immunoreactivity, or high affinity uptake of the auto-fluorescent serotonin analogue, 5,7-dihydroxytryptamine. When stimulated with a single intracellular current pulse, approximately 3% of the neurons possessing serotonergic markers evoked slow inhibitory postsynaptic potentials (ipsp's) in themselves or in other neurons; another 50% of these neurons evoked fast excitatory postsynaptic potentials (epsp's), 17% evoked biphasic fast epsp/slow ipsp responses, and 30% failed to evoke an electrogenic postsynaptic effect. Fast epsp's were observed in microcultures containing solitary, cytochemically-identified serotonergic neurons. Glutamate receptor antagonists such as kynurenate, APV and CNQX blocked the fast epsp's, while $5HT_{1A}$ receptor antagonists such as propranolol and spiperone blocked the slow ipsp's. These data indicate that single pontomesencephalic raphe neurons possess both serotonergic and glutamatergic properties under these conditions, and raise the possibility that some raphe neurons release both serotonin and glutamate in vivo. THE EFFECT OF TRYPTOPHAN DEPLETION ON THE ACOUSTIC STARTLE RESPONSE IN DEPRESSED SUBJECTS H. L. Miller*, C. A. Morgan III, P. L. Delgado, L. Karper, M. Davis, D. S. Charney. West Haven VAMC and Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508.

Acoustic startle is a reflex with a well-characterized neural pathway that is useful as a model system to investigate effects of drugs on sensorimotor reactivity. Preclinical data indicate that the startle reflex is modulated by serotonin. Brain serotonin can be reduced by depleting plasma TRP by dietary manipulations. TRP depletion increases the startle reflex in rats. As part of a research program assessing the role of serotonin in depression, startle might provided a sensitive measure to ascertain whether TRP depletion was having central effects. **METHOD**: 14 depressed patients participated in two tests, one week apart. Each test involved 24 hrs. of a low TRP diet followed by a 15 amino acid drink. During one test, TRP was added to the diet and drink (control); during the other test TRP was not added (depletion). Eyeblink response to 36 tones of 5 different intensities was measured 5 hrs. after subjects received the depleting drink or the control drink. **RESULTS**: Plasma TRP was depleted by 70 to 90% 5 hrs. after the amino acid drink. The amplitude of the startle response was significantly increased after TRP depletion compared to control test ($p < .04$). **IMPLICATIONS**: These findings suggest that plasma TRP depletion has central effects, and, consistent with the preclinical literature, that the startle reflex is modulated by serotonin in humans.

DIFFERENTIAL EFFECTS OF RAPHE GRAFTS IN THE HIPPOCAMPUS, AMYGDALA OR THE HYPOTHALAMUS. G. Richter-Levin* and M. Segal. Dept. Neurobiol., The Weizmann Inst., Rehovot 76100, Israel.

Serotonin depletion in rats affected spatial memory ability, body weight and thermoregulation. In an attempt to localize these functions, we studied the behavioral and physiological effects of raphe graft-induced differential restoration of the serotonergic innervation of the hippocampus, amygdala and the hypothalamus, in serotonin depleted rats. Control (n=8), serotonin depleted (5,7-DHT, 200 ug, icv) (DHT, n=8), and DHT rats with raphe grafts in the hippocampus (HG, n=7), amygdala (AG, n=8), and hypothalamus (HTG, n=9), were tested in the Morris water-maze (+ atropine, 40 mg/kg, ip). All lesioned groups, with the exception of the HG rats, performed significantly worse than controls. There was a significant reduction in body weight in all the lesioned groups including the HG rats. Exposure of the rats to 3 min ice cold water, led to a significantly greater reduction in body temperature in all lesioned groups, except for the HTG rats which were not different from controls. These results indicate that the effects of the serotonergic lesion on spatial memory are not due to its effects on body weight or thermoregulation. The graft can thus be used as a tool for studying local serotonergic functions in the brain.

SEROTONIN1A AGONIST REDUCED CONDITIONED FREEZING BEHAVIOR. T.Inoue*, T.Koyama and I.Yamashita. Dept. of Psychiat. and Neurol., Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

We have found that conditioned fear stress (CFS) increased serotonin (5-HT) metabolism in the medial prefrontal cortex with an induction of freezing behavior. These results could support the 5-HT hypothesis of anxiety. In the present study, the effects of various serotonergic agents and diazepam on shock-induced freezing behavior were examined using time-sampling procedure. Various doses of diazepam (0.1-5mg/kg), ipsapirone (0.1-10mg/kg), ICI169,369 (5-20mg/kg), DOI (0.1-1mg/kg) or mCPP (0.1-10mg/kg) were administered subcutaneously to rats 24 hours after the last session of repeated footshock for 5 days. Rats were again placed in the shock chamber without shocks 20 min after treatment and observed. Diazepam (1mg/kg), ipsapirone (0.5-10mg/kg), DOI (0.1-1mg/kg) and mCPP (0.5-10mg/kg) significantly reduced freezing behavior. ICI169,369 failed to change freezing behavior. In conclusion, these results suggest an anxiolytic potential of 5-HT1A agonist and a possible role of 5-HT1C and 5-HT2 agonist in the treatment of anxiety.

640.1

DIFFERENTIAL EFFECT OF α_1-ADRENERGIC RECEPTOR ACTIVATION ON ADENOSINE A_2 AND β_2-ADRENERGIC RECEPTOR DESENSITIZATION. H.L. Wiener*, G.P. Thalody, J.M. Murray, R. Osman, J. Goldfarb, and S. Maayani. Dept. Pharm. Sci., Coll. Pharm., St. John's Univ., Jamaica, NY 11439, and Depts. Anesthesiol., Physiol. and Biophys., and Pharmacol., Mt. Sinai Sch. Med., CUNY, New York, NY 10029.

The contractile response mediated by α_1-adrenergic receptors and the relaxation responses mediated by either adenosine A_2 or β_2-adrenergic receptors in the isolated adventitia- and endothelium-denuded rabbit thoracic aorta were selected as a model to study functional antagonism between simultaneously activated membrane-bound receptors. The present study focused on the effect of α_1-adrenergic receptor activation on the desensitization of the response mediated by adenosine A_2 or β_2-adrenergic receptors. Neither adenosine nor isoproterenol altered basal tissue tension in naive rings. Prior incubation with adenosine or isoproterenol (10 min) had minimal effect on the concentration-response curve to phenylephrine suggesting that both receptors have fully desensitized in the absence of the α_1-adrenergic stimulus. Adenosine and isoproterenol rapidly relaxed phenylephrine precontracted rings in a concentration-dependent and saturable manner. The relaxation response to adenosine was monotonic and stable for over 30 min. In contrast the relaxation response to isoproterenol was biphasic, consisting of a rapid relaxation and partial regaining of tissue tension. In rings preincubated with low concentrations of phenylephrine and relaxed with adenosine, concentration-response curves to higher concentrations of phenylephrine were shifted dextrally. Taken together, these results suggest that while the adenosine A_2 receptor and the β_2-adrenergic receptor desensitize in the presence of their respective agonists, their desensitization is differentially attenuated by prior α_1-adrenergic receptor activation: the desensitization of the adenosine A_2 receptor is prevented while that of the β_2-adrenergic receptor is not. USPHS GM34852.

SYMPATHETIC INNERVATION OF THE BULLFROG AORTA BY 2 CO-TRANSMITTING SYNAPSES IN SERIES. JP Horn*, WD Stofer and R Thorne Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

We seek to understand the integrative significance of slow synaptic potentials in sympathetic ganglia. Our strategy has been to develop an isolated preparation containing ganglia and an end-organ. Here we describe a preparation made from a bilateral dissection of paravertebral ganglia 7-10 and the abdominal aorta. It has 2 co-transmitting synapses in series and is suitable for observing the transformation between controlled patterns of preganglionic activity and vascular contractions.

Anatomically, the lumbar ganglia innervate the aorta. In addition to the rami between each ganglion and its corresponding spinal nerve, smaller accessory nerves connect each lumbar ganglion to the aorta. From dissection it is clear that some axons project to the kidneys and gonads. However, tracing with DiI reveals that other axons in the accessory nerves enter the wall of the aorta where they form a fine plexus. When stained as a wholemount for neuropeptide Y, the aorta contains a dense plexus of immunoreactive axons and varicosities. This anatomy suggests that C-type sympathetic neurons innervate the aorta.

Nerve-evoked contractions can be recorded for many hours after coupling a 1 cm length of the aorta to a tension transducer. Stimulation of the preganglionic C, but not the B, pathway causes contraction. The aorta is bilaterally innervated. Nerve cuts show that ganglia 9 & 10 provide at least 90% of the innervation to the caudal aorta. Blockers of nicotinic and α-adrenergic receptors antagonize the evoked aortic contractions. Evidence for synaptic gain is presented in the companion paper. Supported by NIH grants NS21065, NS01427 and HD07343.

640.3

HOMOSYNAPTIC AND HETEROSYNAPTIC GAIN MODULATION AT CO-TRANSMITTING SYNAPSES IN THE BULLFROG SYMPATHETIC VASOMOTOR C SYSTEM. R Thorne* and JP Horn Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Based on their known actions in the bullfrog, luteinizing hormone releasing hormone (LHRH) and neuropeptide Y (NPY) are capable of endowing the vasomotor sympathetic system with use-dependent synaptic gain. To test this possibility, we studied the relation between patterns of preganglionic stimuli and arterial contractions in an isolated preparation of sympathetic ganglia and the aorta (see companion paper).

Short stimulus trains (<50) evoke contractions whose amplitudes saturate in a frequency-dependent manner at 1-5 Hz. Such responses are blocked by curare and phentolamine. However, small contractions return with longer stimulus trains. This suggests that co-transmitters can overide the blockade of primary transmitters. When trains are lengthened in the absence of drugs, contractions do not saturate but continue to grow. In 1 case, the growth in contractions was logrithmic between 2 and 1000 stimuli. These results suggest that co-transmitters produce homosynaptic gain modulation in this circuit.

Because the aorta is bilaterally innervated, one can test for interactions between separate pools of ganglionic C neurons. Using one side to evoke a test contraction and the other for conditioning, we found that long conditioning trains can potentiate the amplitude of subsequent test responses. This demonstrates that interactions occur between postganglionic synapses and is most simply described in terms of enhanced heterosynaptic gain.

CHARACTERIZATION OF POLYAMINE UPTAKE AND RELEASE IN CHICK RETINA CELLS IN CULTURE. A.L.M.Ventura* and R.B.S.Pedro. Dept. Neurobiologia, Univ. Fed. Fluminense, Niterói, Brasil.

Putrescine is an abundant polyamine that may serve as an alternative precursor for GABA synthesis in the CNS. In this work we show that retina cells in culture are able to incorporate and release (^{3}H)-putrescine. Two types of cul tures were used: cultures containing predominantly neurons and mixed, containing neurons and glia. Both types were able to incorporate radioactivity in a manner dependent on temperature and pH of the medium but independent on the presence of extracellular Na^+ions. Nipecotic acid, a potent inhibitor of GABA uptake, did not interfere with the uptake of (^{3}H)-putrescine, suggesting that the me chanisms of polyamine uptake is distinct of the mechanisms of GABA uptake. In mixed cultures, KCl 50 mM was able to induce the release of radioactivity in a calcium dependent manner. In cultures containing predominantly neurons, both KCl 50 mM and Veratridine 100uM released radioactivity, the effects also being Ca^{++} dependent. Glutamate, a com pound that releases GABA in the retina, did not induce the release of radioactivity in neuronal cultures, suggesting that the radioactivity released did not represent GABA. Our results suggest that polyamines, although participa ting in the synthesis of GABA, may have a neuromodulatory role in the retina.

GLUTAMATE MODULATED RELEASE OF 3H-GABA FROM RAT OLFACTORY BULB. E.H. Jaffé* and I. García, Laboratorio Neuroquímica, Instituto Venezolano de Investigaciones Científicas, Apartado 21827, Caracas 1020-A, Venezuela.

We studied the possible neurotransmitter involved in the modulation of GABA release from granule cells of the olfactory bulb. The GABAergic granule cell has been well characterized. However the neurotransmitter of the mitral cell, which establishes reciprocal synapsis with the granule cell controversial. A strong candidate is glutamate. In previous work (Jaffé, Vaello 1989, J. Neurochem. 52, 1766-1774) we observed that glutamate had only a week response on the release of GABA and was only seen after a previous K depolarization. This effect of Glutamate was indirect since it was inhibited by TTX. We further characterized the effect using continous superfusion of olfactory bulb slices prelabled with 3H-GABA. Nipecotic acid a GABA uptake inhibitor enhanced the GABA releasing effect of Glutamate, Kainate and AMPA. The effect of NMDA was only seen after a previous depolarization of the tissue with K or Kainate. The effect of Kainate and AMPA was inhibited by CNQX but not by AP7. TTX inhibited Glu and Kainate effect. The exitatory amino - acid, cysteinsulphinic acid was able to induce GABA release. At the level of the olfactory bulb several glutamate receptors are able to induce GABA release through a polysynaptic mechanism.

THE EFFECT OF CHRONIC HALOPERIDOL ADMINISTRATION ON GABA-IMMUNOREACTIVE AXON TERMINALS IN RAT MEDIAL PREFRONTAL CORTEX. E. Adamec*, S.L. Vincent, I. Sorensen and F.M. Benes. Department of Anesthesia, Massachusetts General Hospital, Boston, MA; Department of Psychiatry and Program in Neuroscience, Harvard Medical School; Mailman Research Center, McLean Hospital, Belmont, MA.

Several reports provide evidence that chronic haloperidol treatment induces ultrastructural changes in synapses of substantia nigra, corpus striatum and medial prefrontal cortex (mPFC). Recent studies suggesting that there is a loss of GABAergic cells in anterior cingulate cortex of schizophrenic subjects have prompted interest in the question of whether dopamine blocking agents can influence this transmitter system. This study provides a quantitative light microscopic analysis of GABA-immunostained axosomatic terminals in mPFC of rats treated with haloperidol decanoate (0.5 mg/kg/day i.m., McNeal Labs). GABAergic terminals were visualized with an immunoperoxidase method for localizing anti-GABA antibodies developed in rabbits (Incstar) using the avidin-biotin procedure. Computer-assisted image processing was used to determine the total number of pixels occupied by the reaction product in GABA-positive axosomatic terminals on individual neuronal cell bodies in various layers of mPFC. Drug-treated animals showed a significant increase in the number of GABA-positive pixels in layers 2, 3, 5 and 6 (93%, 63%, 31% 43%, respectively). These data suggest that chronic haloperidol administration induces a significant increase in the amount of GABA in rat mPFC. The fact that neurons in layer 2 showed the largest increase in GABA-immunoreactive terminals parallels the losses of interneurons and the up-regulation of GABA-A receptor binding observed in the same lamina of anterior cingulate cortex in schizophrenic patients. 640.7

EFFECTS OF TYPICAL AND ATYPICAL ANTIPSYCHOTIC DRUGS ON EXTRACELLULAR GABA LEVELS IN THE PREFRONTAL CORTEX. D. Cameron*, A. J. Bourdelais, and A. Y. Deutch. Department of Psychiatry, Yale University School of Medicine, New Haven, CT 06508, and VA Medical Center, West Haven, CT 06516.

Dopamine (DA) afferents to the prefrontal cortex (PFC) inhibit cortical pyramidal neurons through both direct and indirect means. Direct symmetric synapses between DA terminals and pyramidal neurons are present. DA indirectly inhibits pyramidal cell activity by enhancing GABA release from interneurons. We have used *in vivo* microdialysis to characterize the effects of typical and atypical antipsychotic drugs (APDs) on extracellular GABA levels in the PFC. Animals were implanted with chronic indwelling guide cannulae, and one week later a dialysis probe placed in the PFC. The freely-moving rats were then perfused with dialysis buffer until a stable baseline was obtained, and then either the typical APD haloperidol or the atypical APD clozapine was injected subcutaneously. Haloperidol resulted in a marked decrease in extracellular GABA levels as compared to vehicle control. In contrast, CLZ did not significantly reduce extracellular GABA levels in the PFC compared to its vehicle. Previous reports have indicated that clozapine results in a greater enhancement of DA release in the PFC than does haloperidol; coupled with the lower affinity of clozapine for the D_2 receptor, clozapine may not block postsynaptic activity of DA as much as haloperidol. The present data suggest that the atypical APD clozapine may act on negative symptoms by not enhancing GABA-induced inhibition over cortical pyramidal neurons. Supported by MH-45124 and VA National Center for Schizophrenia Research to the West Haven, CT VA Medical Center.

640.8

EFFECTS OF TYPICAL AND ATYPICAL ANTIPSYCHOTIC DRUGS ON GLUTAMIC ACID DECARBOXYLASE GENE EXPRESSION. P.Z. Gallipoli* and A. Y. Deutch. Department of Psychiatry, Yale University School of Medicine, New Haven, CT 06508 and VA Medical Center, West Haven, CT 06516.

Dopamine (DA) appears to regulate the activity of GABAergic neurons in both the striatum (CP) and in the prefrontal cortex (PFC). We have therefore examined the regulation of glutamic acid decarboxylase (GAD) gene expression in the PFC following chronic (21 day) administration of antipsychotic drugs (APDs); these include the typical APDs haloperidol and raclopride, the atypical APD clozapine, and the putative atypical APD remoxipride. Preliminary data suggest that haloperidol and raclopride increased expression of both GAD_{65} and GAD_{67}; remoxipride only marginally increased GAD_{67} expression, but appeared to more robustly increase GAD_{65} expression. The effects of haloperidol and raclopride on GAD mRNAs appeared to be more pronounced on GAD_{67} mRNA. These data suggest that APDs increase GAD gene expression in the striatum, but that there may be differences between two typical APDs (haloperidol and raclopride) and remoxipride, a putative atypical APD.

Partial Characterization of Excitatory Amino Acid-Evoked Striatal GABA Release in vivo: Comparison of Kainate and NMDA. T.N. Ferraro*, D.P. Carrozza, G.T. Golden, P.F. Reyes and T.A. Hare. Thomas Jefferson University, Philadelphia, PA and VAMC, Coatesville, PA.

Excitatory amino acid (EAA) receptors in the mammalian CNS are involved in a number of aspects of neuronal function. We have investigated the effects of intrastriatal (i.s.) administration of kainate (KA) and NMDA on GABA release using intracerebral microdialysis in freely-moving rats. An in vivo standardization procedure involving a brief (10 min, i.s.) perfusion with a Ringer's solution containing 100mM potassium (Brain Res. 543:69, 1991) was utilized to quantitate GABA release for a dose of KA or NMDA given subsequently. Doses of KA and NMDA were manipulated by varying the time (up to 10 min) that the drugs (12.5mM in normal Ringer's) were perfused through the microdialysis probe. Probes were of concentric design with tip parameters of 4 mm x 0.2 mm; perfusion flow rate was 2.75 ul/min with 15 min sampling intervals. Microdialyzate GABA levels were measured using an ion-exchange HPLC/fluorometric method. Results showed that KA and NMDA mediate dose-dependent striatal GABA release of a similar magnitude. KA-evoked GABA release was not affected by pretreatment with cadmium (1.0mM, up to 45 min) but was partially inhibited by pretreatment with kynurenic acid (1.0mM, 10 min). NMDA-evoked GABA release was partially inhibited by pretreatment with cadmium, dextromethorphan (1.0mM, 5 or 15 min) and "low" doses (0.04mM, 5 min) of aminophosphonovalerate (APV). Pretreatment with "high" doses (1.0mM, 5 min) of APV potentiated NMDA-evoked GABA release. Results suggest that KA and NMDA mediate striatal GABA release via distinct mechanisms and/or from distinct pools. Observed differences may be related to the striatal distribution of receptors which respond to these two EAAs. The ability of the higher dose of APV to potentiate NMDA-evoked GABA release may be explained by a mechanism involving relief of an NMDA receptor-regulated interneuronal negative feedback circuit. Supported in part by the Veterans Administration.

SEROTONIN-DOPAMINE INTERACTIONS IN THE REGULATION OF NEOSTRIATAL GENE EXPRESSION J. G. Capodilupo* & P. D. Walker, Department of Anatomy & Cell Biology, Wayne State University School of Medicine, Detroit, MI 48201.

Serotonin (5-HT) manipulation alters tachykinin biosynthesis in the neostriatum (Walker et al., Brain Res., 546 [1991] 33-39). However, the influence of 5-HT on neostriatal gene expression may ultimately be controlled via dopamine pathways (Walker et al., Brain Res., 557 [1991] 31-36). To further investigate possible 5-HT/dopamine co-regulation, we tested the ability of quinpirole, a dopamine D2 agonist, to regulate neostriatal gene expression during pharmacological inhibition of 5-HT synthesis.

Daily injections of *p*-chlorophenylalanine, *p*CPA, (100mg/kg/day i.p. for 7 days) blocked acute (single 1 mg/kg i.p.) but not chronic (7 daily 1 mg/kg i.p.) quinpirole-induced increases in neostriatal preprotachykinin (PPT) mRNA detected within hours of the last daily injection. Alone, *p*CPA did not influence PPT mRNA at this time. However, in another series of animals, *p*CPA significantly lowered PPT mRNA levels 1 week after the end of 7 daily injections. Such delayed effects were observed in additional *p*CPA experiments where increases in the length of *p*CPA treatment shifted the mRNA response to later periods. Therefore, later examination following combined quinpirole/*p*CPA administration may uncover the ability of *p*CPA to block the chronic effects of quinpirole.

These results provide further evidence for co-dependence between 5-HT and dopamine in the regulation of neostriatal gene expression. However, since 5-HT appears to influence glutamic acid decarboxylase (GAD) mRNA levels in a manner opposite to that of dopamine, further analysis is required to tease apart independent influences of these monoamines on basal ganglia neurotransmission. SIGMA RECEPTOR LIGANDS REGULATE N-METHYL-D-ASPARTATE (NMDA)-STIMULATED [^{3}H]DOPAMINE ([^{3}H]DA) RELEASE FROM RAT STRIATAL TISSUE. **G.M. Gonzalez* and L.L. Werling, Dept. Pharmacology, The George Washington University Medical Ctr., Washington, D.C. 20037.**

We have previously reported inhibition of NMDA-stimulated [^{3}H]DA release in rat striatal slices by sigma receptor agonists (+)pentazocine and (+)SKF10,047. We have investigated several potential sigma antagonists in this system.

Striata were dissected, chopped, and washed in Mg^{++}-free modified Krebs-HEPES buffer, then incubated with 15 nM [^{3}H]DA for 30 min. Slices were loaded into a superfusion apparatus and superfused with buffer to establish a low, stable baseline release. Tissue was stimulated to release [^{3}H]DA by a 2 min exposure to 25 µM NMDA. Inflow was returned to non-stimulating buffer, with or without potential inhibitor of release, for 10 min. Tissue was stimulated a second time (S2) for 2 min in the presence or absence of a potential inhibitor.

Both (+) and (-) isomers of SKF10,047 and pentazocine inhibited NMDA-stimulated [^{3}H]DA release from rat striatal slices in a naloxone-insensitive manner. In contrast, the sigma antagonist haloperidol and PRE084, a novel, selective sigma ligand, reversed the inhibition by (+)-pentazocine. BMY14802, an experimental antipsychotic drug, and NPC16377, another novel sigma ligand, not only reversed (+)pentazocine-induced inhibition, but potentiated NMDA-stimulated [^{3}H]DA release as well. Sigma ligands DTG, 3-(+)-PPP, and ifenprodil did not antagonize (+)pentazocine-induced inhibition. In addition, (+) pentazocine (10 µM) also inhibited NMDA-stimulated [^{3}H]DA release from rat striatal synaptosomes, suggesting that sigma receptors are located on dopaminergic nerve terminals. These data suggest a potential involvement of sigma receptors in the regulation of DA release from striatum. (Supported by a grant from NIDA to LLW and by NIGMS predoctoral fellowship to GMG.)

INTRAMEMBRANE INTERACTIONS BETWEEN CHOLECYSTOKININ (CCK) AND DOPAMINE (DA) RECEPTOR SUBTYPES IN THE RAT STRIATUM. X-M. Li, P.B. Hedlund, G. von Euler, F. Benfenati*, L. F. Agnati and K. Fuxe. Dept. of Histology & Neurobiology, Karolinska Institute, Stockholm, Sweden.

The interactions between CCK and DA receptors have been analyzed in the rat striatal membrane preparations. CCK-8 (0.1 and 1 nM) reduced the affinity of striatal D_2 agonist ^{3}H-N-propylnorapo-morphine (^{3}H-NPA) binding sites by about 25% without altering the B_{max} values (n=8). A kinetic analysis (n=8) indicated that this action was related to a reduction of the association rate constant for the radioligand. In contrast, 0.1, 1 (peak effect) and 10 nM of CCK-8 decreased the K_H and K_L values of DA for the D_2 antagonist ^{3}H-raclopride (^{3}H-RAC) binding sites by 40-57% (n=22). This action was completely antagonized by the D_1 antagonist SCH23390 (200 nM), which by itself significantly increased the K_H and K_L values of DA for ^{3}H-RAC binding sites (n=6) without directly affecting the D_2 receptors (IC_{50}=3516±279 nM). CCK-8 (1 nM) did not affect the K_H and K_L values of DA for ^{3}H-SCH23390 binding sites (n=7). All the effects of CCK-8 on D_2 receptors were blocked by the CCK_B antagonist PD134308 (100 nM). The results suggest the possibility that CCK-8 via CCK_B receptors produces its neuroleptic activity by reducing the affinity and possibly the transduction of D_2 receptors. However, when D_1 and D_2 receptors are coactivated CCK-8 may instead increase D_2 receptor activity leading to a synergistic interaction with D_2 receptors.

ACTH INPUT TO MIDBRAIN DOPAMINERGIC NEURONS: LIGHT AND ELECTRON MICROSCOPIC EXAMINATION. C.-L. Liang, G.P. Kozlowski, S.A. Joseph and D.C. German*. Depts. of Psychiatry and Physiology, UT Southwestern Med. Cntr., Dallas, TX 75235, and The Neuroendocrine Unit, Univ. of Rochester Med. Sch., Rochester, N.Y. 14642.

Stress activates the mesocorticolimbic dopaminergic (DA) neurons (Thierry et al., Nature **263**: 242, 1976). The present study sought to determine whether the stress-related peptide, adrenocorticotropin (ACTH), makes synaptic contacts with mesocorticolimbic DA neurons. Single- and double-labeling immunocytochemical staining procedures were used to examine the relationship between ACTH-containing nerve terminals, and DA neurons in the rat midbrain. ACTH nerve terminals were found extensively in regions occupied by the mesocorticolimbic DA neurons, such as in the interfascicular n., paranigral n. and central linear n. (CLi). In the CLi, ACTH axon terminals made both symmetric and asymmetric synaptic contacts with DA dendrites, and putative axo-axonic contacts with unlabeled axon terminals which, in turn, made contacts with DA dendrites. The ACTH-DA synapses may play a role in stress-induced changes in mesocorticolimbic DA neuronal activity. Supported by grant DA-05314.

EFFECT OF 6-HYDROXYDOPAMINE (6-OHDA) LESIONS IN NEONATE RATS ON mRNA LEVELS ENCODING THE ENZYME GLUTAMATE-DECARBOXYLASE (GAD) AND THE DOPAMINE D2 RECEPTOR. J-J Soghomonian*. Centre de Rech. en Neurobiologie, Univ. Laval, Québec, (Qc) Canada G1K 7P4.

6-OHDA lesions of dopamine neurons in adult rats increase mRNA levels encoding the dopamine D2 receptor and GAD enzyme in projection neurons of the striatum. When dopamine neurons are lesioned in neonates, adults exhibit specific behavioral and neurochemical features not observed after adult lesions. In this study, we determined if 6-OHDA injections (intraventricular; 150µg) in neonate Sprague-Dawley rats induce changes in mRNA levels encoding the enzyme GAD (Mrs 67,000) and the dopamine D2 receptor at adulthood. Brain sections were processed for in situ hybridization histochemistry with 35S-labeled probes. Labeling was visualized by X-ray film radioautography and measured by computerized densitometry. In agreement with previous studies, we found increased and decreased levels of mRNAs encoding the peptides enkephalin and substance P, respectively, in sections of the striatum. Adjacent sections of 6-OHDA-treated rats exhibited an increased labeling when processed with the dopamine D2 receptor probe (+114% as compared to controls) or with the GAD(Mrs 67,000) probe (+119% and +135% as compared to controls for stereotaxic levels IA 10 and 10.6, respectively). Both D2 and GAD mRNA increases appeared homogeneously distributed in the dorsal-ventral and lateral-medial portions of the striatum. The results indicate that injection of 6-OHDA in neonate rodents can modify the level of expression of GAD and dopamine D2 receptor mRNAs in a direction similar to that observed after adult lesions. UNCONDITIONED BEHAVIORAL EFFECTS OF SELECTIVE DOPAMINE D_1 AND D_2 AGONISTS IN SQUIRREL MONKEYS. I. Bergman*, P. Hesterberg, and S. Rosenzweig-Lipson. Harvard Medical School/NERPRC, Southborough, MA 01772.

Recent evidence suggests that the behavioral effects of high- and limited-efficacy D_1 agonists may differ in primates. In the present study, the unconditioned behavioral effects of the high-efficacy D_1 agonists SKF 81297 and SKF 82958, the limited-efficacy D_1 agonists R-SKF 38393 and SKF 75670, and the D_2 agonists (+)-PHNO and quinpirole were compared by videotaping unconditioned behavior of squirrel monkeys in their home cages following the administration of drug or vehicle. Videotapes were scored by at least 2 observers for different behaviors using a continuous observation procedure. The high-efficacy D_1 agonists SKF 81297 (0.1 - 3.0 mg/kg) and SKF 82958 (0.03 - 1.0 mg/kg) produced dose-dependent increases in the frequency of visual scanning and had no effect on either huddling or scratching. The limited-efficacy D_1 agonists R-SKF 38393 (0.1 - 1.0 mg/kg) and SKF 75670 (0.1 - 1.0 mg/kg) produced dose-dependent increases in the duration of huddling and had no effect on visual scanning or scratching. The D_2 agonists (+)-PHNO (0.0003 - 0.01 mg/kg) and quinpirole (0.003 - 0.3 mg/kg) produced dose-dependent increases in the frequency of scratching and had no effect on visual scanning or huddling. The present results indicate that the unconditioned behavioral effects of high- and limited-efficacy D_1 agonists differ in primates and that the unconditioned behavioral effects of D_2 agonists differ from those of D_1 agonists. Supported by USPHS Grants DA03774, DA00499, MH07658, and RR00168.

Intra-striatal injections of kainic acid induces contralateral rotation in rats. I.D. Smith* and R.J. Beninger, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The role of striatal kainate receptors in the control of locomotor activity was investigated with intra-caudate injections of kainic acid (KA). Kainate was injected in three concentrations (5 µM (0.53 ng), 50 µM (5.3 ng), 250 µM (26.6 ng) dissolved in 0.5 µl saline) into the dorsal striatum of 15 rats. A significant increase in contralateral turning was observed after 250 µM ($p<.05$) and 50 µM KA ($p<.05$) whereas the 5 µM dose had no effect. In addition, 250 µM KA resulted in an increase in the number of rotations exhibited during the observation period ($p<.05$). Behavioral evidence of seizure activity was not observed at any dose level.

Excitatory corticostriatal projections have been shown to depolarize striatal output neurons via a non-NMDA glutamate receptor subtype. Thus a KA receptor-mediated increase in striatal cell firing may underlie the activation of motor systems, resulting in rotation. Striatal glutamate receptor activation also stimulates the release of neurotransmitters such as dopamine (DA). Since rats with imbalances in striatal DA receptor stimulation tend to rotate away from the side of higher DA, it is possible that the contralateral turning resulted also from a KA-induced increase in extracellular DA levels. Additional experiments using systemic amphetamine injections will examine the involvement of an interaction between glutamate and dopamine receptor stimulation in the observed behavior. Blockade of S_2 receptors in rats enhances D1-mediated repetitive jaw movements (RJM) induced by SKF 38393. H.Rosengarten*, J.W. Schweitzer and A.J.Friedhoff
Millhauser Laboratories NYU School of Medicine
Department of Psychiatry , New York ,NY 10016

We have previously demonstrated that the D_1 dopamine system mediates behavior we have named (RJM) repetitive jaw movements in rats.This behavior can be induced by the D1 agonist SKF 38393 and inhibited by the D_2 agonist,LY171555, or enhanced by blockade or inactivation of D_2 dopamine receptors(Rosengarten et al. 1983, 1986,1988). In the present study we explored the effect of inactivation or bockade of S_2 serotonin receptors with cyproheptadine on this behavior. We found that inactivation or blockade of S_2 receptors greatly augmented SKF 38393 - inducible RJM.The present findings demonstrate that the S_2 system inhibits D_1 mediated RJM. These finding would provide a mechanism underlying the clinical use of serot nin-enhancing drugs such as fluoxetine in the treatment of tardive dyskinesia.

THE EFFECTS OF DOPAMINE AGONISTS AND ANTAGONISTS IN MICE PRETREATED WITH RESERPINE. M.J. Piesla, E.A. Muth*, and K.L. Marquis, Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

Typical stereotypy (sniffing-licking-biting) and climbing in normal rodents can be induced only by stimulation of both D-1 and D-2 receptors (Braun and Chase, 1986; Moore and Axton, 1988). However, either D-1 or D-2 agonists can reverse reserpine-induced akinesia, as measured by an increase in locomotor activity, in mice (Rubinstein et al., 1988). Therefore, the effect of dopamine agonists and antagonists on stereotypy (S) and climbing (C) in mice with supersensitive receptors (produced by 20-24 hour pretreatment with 5.0 mg/kg sc reserpine) was determined. The mixed D-1/D-2 agonist, apomorphine, dose-dependently increased S and C in supersensitive mice (S-ED50=0.05 and C-ED50=0.09 mg/kg sc). Quinpirole, the full D-2 agonist, significantly increased S and C (S-ED50=0.2 and C-ED50=0.3 mg/kg ip) in mice. SKF 38393, the full D-1 agonist, had a slight effect on C, but produced no S. However, mice treated with a fixed dose of SKF 38393 (10.0 mg/kg ip) and varying doses of quinpirole displayed S and C similar to that produced by apomorphine (S-ED50=0.09 and C-ED50=0.05 mg/kg ip). In antagonism studies, the selective D-1 antagonist, SCH 23390, failed to antagonize apomorphine-induced (1.0 mg/kg sc) S and C. Conversely, the selective D-2 antagonist, raclopride, reduced C, but not significantly, and dose-dependently blocked S (ED50=1.2 mg/kg ip). Partial dopamine agonists were also evaluated in this paradigm. For example, (+)3PPP induced these behaviors (S-ED50=2.5 and C-ED50=1.9 mg/kg sc) to a greater extent than (-)3PPP (S-ED50=9.0 and C-ED50=10.0 mg/kg sc). The very weak D-2 agonist, OPC 4392, failed to have any effect on these behaviors. Also, the putative D-2 agonist, Lu 22-106-C, produced both behaviors (S-ED50=0.7 and C-ED50=2.4 mg/kg ip) while the enantiomer Lu 22-105-C, a putative D-2 weak partial agonist/antagonist, had no effect. Thus, these data demonstrate the prevalent role for D-2 agonism in producing S and C through supersensitive receptors in mice. In addition, the level of intrinsic activity can be inferred from this model.

641.5

LOCOMOTOR ACTIVITY IN CONTROL AND CHRONIC CAFFEINE-TREATED MICE: INTERACTIONS OF ADENOSINE ANALOGS, CHOLINERGIC AND DOPAMIN-ERGIC AGENTS AND XANTHINES. O. Nikodijevic, K. A. Jacobson, and J. W. Daly,* NIDDK/NIH, Bethesda MD 20892.

Chronic caffeine ingestion (CCI) by NIH Swiss male mice results in a prolonged reduction in locomotor activity and alterations in response to caffeine, other xanthines, adenosine analogs, and nicotinic and muscarinic agents. Caffeine (IP) and an A_2-selective xanthine (3,7-dimethyl-1-propargylxanthine) remain stimulatory, and the typical bell-shaped locomotor dose-response curve to caffeine is left-shifted after CCI. Mice became more sensitive to depressant effects of A_1 and A_2 agonists. Depressant effects of xanthines that are potent PDE inhibitors are either blunted or enhanced by CCI. Depressant effects of nicotine are abolished. Responses to muscarinic agents are either little affected (oxotremorine, agonist) or right-shifted (scopolamine, antagonist). Depressant effects of the mixed A_1/A_2 agonist NECA, either alone or in combination with caffeine or other xanthines, are altered after CCI. Depressant effects of NECA in the presence of scopolamine or amphetamine, are similar in controls and after CCI. The depressant effects of a low dose of NECA in the presence of cocaine are reduced after CCI. The results suggest complex effects of CCI on adenosine-, dopaminergic-, and cholinergic-mediated behaviors.

641.6

EFFECTS OF DOPAMINE D1 AND D2 RECEPTOR INACTIVATION ON LOCOMOTOR ACTIVITY AND SNIFFING IN 11- AND 17-DAY-OLD RATS. M. Mestlin and S.A. McDougall*. Dept. of Psychology, CSUSB, San Bernardino, CA 92376.

Behavioral effects of dopamine (DA) receptors were assessed in 11- and 17-day-old rat pups using the irreversible DA antagonist, EEDQ. In Experiment 1, the locomotor activity and sniffing of 11- and 17-day-olds was assessed after treatment with the nonselective DA receptor agonist, R-propylnorapomorphine (NPA; 0.00, 0.01, 0.1, 1.0, and 5.0 mg/kg). Behaviors were assessed during a 20-min testing session which began 5-min after NPA treatment. Testing occurred across four days using a 25 X 25 X 18 cm grey heated chamber. Sniffing was recorded every 20-sec using a time-sampling technique. In Experiment 2, 10- and 16-day-old rat pups received a single dose of EEDQ (7.5 mg/kg) or vehicle after DA receptors were left either unprotected or protected using a combination of sulpiride (100.0 mg/kg) and SCH 23390 (1.0 mg/kg). NPA (0.00, 0.01, or 5.0) was then administered to rat pups 24, 48, and 96 hours after EEDQ treatment. Results from Experiment 1 suggest that NPA did not increase activity in 11-day-old pups; whereas, 17-day-olds showed an increase in activity, with 0.01 mg/kg NPA producing the greatest effect. NPA produced a dose-dependent increase in sniffing in both aged pups. In Experiment 2, EEDQ did not affect the locomotor activity or sniffing of either 11- or 17-day-old pups. Results indicate that the response of preweanling and adult rats to EEDQ is fundamentally different and may reflect a drug-induced change in receptor affinity.

641.7

THE NUCLEUS ACCUMBENS AND CAUDATE AS NEURAL MEDIATORS OF AMPHETAMINE-INDUCED LOCOMOTOR STEREOTYPY. D.E. Krug*and K. Mueller. Dept. of Psychology, Texas Christian University, Fort Worth, TX 76129.

Amphetamine-induced behaviors in rats include focused stereotypy, hyper-locomotion, and locomotor stereotypy (patterned locomotion). The mechanisms controlling hyper-locomotion (nucleus accumbens [NAC]) and focused stereotypy (anterior caudate [CAUD]) are well understood, but how locomotor stereotypy is produced is not well understood. Two experiments examined the CAUD and NAC for the production of locomotor stereotypy as measured by the gammahat procedure. In experiment 1, fluphenazine [FLU] (0.0, 1.25, or 2.50 µg) was infused into either the NAC or CAUD prior to systemic amphetamine (2 mg/Kg). In the NAC, both doses of FLU reduced hyper-locomotion and locomotor stereotypy. In the CAUD, neither dose affected hyper-locomotion, but the lower FLU dose was more effective than the higher dose at reducing locomotor stereotypy. In experiment 2, 100 µg amphetamine was infused into either the NAC or CAUD. In the NAC, amphetamine produced hyper-locomotion but did not produce locomotor stereotypy. Amphetamine in the CAUD produced focused stereotypy without producing locomotor stereotypy. These results suggest the involvement of both the NAC and CAUD in the production of amphetamine-induced locomotor stereotypy.

APPARENT MEDIATION OF THE STIMULUS PROPERTIES OF A LOW DOSE OF QUINPIROLE BY DOPAMINERGIC AUTORECEPTORS. D.V. Widzowski* and D.A. Cory-Slechta. Environ. Health Sci. Ctr., Univ. Rochester Med. School, Rochester, NY 14642.

Drug discrimination (DD) studies have established that the stimulus properties of quinpirole (QUIN) are mediated by dopaminergic (DA) D2-type receptors, although the involvement of autoreceptors vs postsynaptic D2 receptors in such effects remains to be established. This study examined the contention that the stimulus properties of QUIN were mediated via autoreceptors, engendering a decline in DA release and consequent decrease in postsynaptic stimulation. Thus pharmacological treatments which engender a decline in postsynaptic DA availability should result in QUIN-appropriate responding, while those that activate postsynaptic DA receptors either directly or indirectly should result in saline-appropriate responding. To test this hypothesis, pharmacological treatments which either ultimately produce or decrease postsynaptic DA receptor stimulation were examined in rats trained to discriminate QUIN (0.05 mg/kg) from saline. At the training dose, QUIN maintained levels of responding on the drug lever of about 90%, and a dose-related decline in QUIN responding was observed in the presence of doses of QUIN below the training dose. Two other D2 agonists which have been reported to primarily stimulate autoreceptors at low doses (apomorphine (APO), 0.04-0.167 mg/kg, and n-propylnorapomorphine,0.04-0.12 mg/kg) produced a dose-related increase in QUIN lever responding to levels of 70 and 90%, respectively. The DA-synthesis blocker and DA depleter alpha-methyl-p-tyrosine (AMPT, 25-75 mg/kg) substituted for QUIN when given alone and potentiated QUIN stimulus properties when coadministered (75 mg/kg) with QUIN, shifting the QUIN dose-effect curve to the left. Treatments known to stimulate postsynaptic DA receptors, including the D1 agonist SKF38393 (6-12 mg/kg) and d-amphetamine (1-6 mg/kg), resulted in saline responding when given alone and antagonized QUIN stimulus properties when coadministered with QUIN. In addition, a very high dose of APO (0.5 mg/kg), i.e., one known to stimulate postsynaptic D1 and D2 receptors, resulted in saline responding. Taken together, these findings are consistent with the contention that the stimulus properties of 0.05 mg/kg QUIN are primarily mediated by D2-type presynaptic autoreceptors, and that these stimulus properties involve a decline in DA release and consequent decrease in postsynaptic stimulation. ES05017, ES05093.

641.9

CHOLINERGIC, GLUTAMATERGIC AND OPIOID INDUCTION OF DOPAMINE (DA) RELEASE: IMPACT ON THE STIMULUS PROPERTIES OF D1 AND D2 DA AGONISTS. R.A. Fox, S.C. Johnson and D.A. Cory-Slechta. Environ. Health Sci. Ctr. and Interdepartmental Neuroscience Program, Univ. Rochester Med. School, Rochester, NY 14642.

It has become increasingly clear in recent years that neurotransmitter systems do not operate in isolation, but are interactive, regulating aspects of each other's function. Non-competitive NMDA receptor antagonists, mu opiate agonists and muscarinic cholinergic agonists have all been reported to increase DA release, as measured by in vivo microdialysis. To determine whether this DA release has functional or behavioral properties, the ability of these compounds to substitute for DA agonists in a drug discrimination (DD) paradigm was examined. Rats were trained to discriminate either the D1 agonist SKF38393 (6.0 mg/kg) or the D2-type agonist quinpirole (0.5 mg/kg) from saline using a standard two-lever operant food-reinforced DD paradigm. Following acqusition of the discriminations, the ability of the non-competitive NMDA antagonist MK-801 (0.05-0.3 mg/kg), the mu opiate agonists morphine (3.0-10.0 mg/kg) and fentanyl (0.025-0.3 mg/kg), and the muscarinic cholinergic agonist arecholine (1.75-3.5 mg/kg) to substitute for the DA agonist training drugs was examined and compared to non-DA releasing compounds such as pentobarbital (5.0-10.0 mg/kg) and the kappa opiate agonist U50488 (2.0-4.0 mg/kg). The peak level of drug lever responding across the range of doses was averaged across individual rats, since dose-effect curves were not always lineraly dose-related. Under those conditions, both quinpirole and SKF38393 resulted in peak levels of drug lever responding of about 90%. Mu opioid agonists evoked peak levels of drug lever responding averaging 70-80% in D2-trained rats, but only 45-55% in D1-trained rats. MK-801 and arecoline evoked peak levels of drug lever responding of about 50-60% in both the D1- and D2-trained groups. In contrast, compounds not inducing DA release (pentobarbital) or known to decrease DA release (U50488) provoked levels of drug lever responding of 34% and 15% in D2-trained and 42% and 23% in D1-trained rats, respectively. Taken together, these data suggest that some behavioral properties of compounds that act directly on glutamatergic, opioid or cholinergic neurotransmitter systems and lead to DA release, may be at least partially mediated by DA systems. In particular, behavioral effects of mu opioid agonists may include DA D2 mediation. ES05017, ES05093.

SENSITIZATION AND TOLERANCE TO HALOPERIDOL'S EFFECTS ON OPERANT BEHAVIOR. S.C. Fowler* and J.-R. Liou. Depts. of Psychol. and Pharm., Univ. of Miss., University, MS 38677

Each of 5 groups of male rats received a different daily dose of haloperidol (0, 20, 40, 80, or 120 ug/kg) 45 min before a water-rewarded operant session for 21 days. All haloperidol groups exhibited across session decrements in response rate, with rates in the two lower dose groups reaching a minimum about day 10. By day 21, rate for the two lower dose groups only substantially recovered. Operant response duration also displayed progressive slowing across the first 10 days of dosing, but unlike the case for rate, little tolerance to the maximal duration effect was observed in any haloperidol group. At the higher doses, muzzle entry into the reward well persisted in the absence of operant responding. Thus whether tolerance follows sensitization depends on dose, length of treatment, and type of behavioral measurement. Neither haloperidol accumulation in brain nor dopamine receptor supersensitivity fully account for these effects. Supported by MH43429.

641.11

DOPAMINE D1 AND D2 MEDIATION OF THE DISCRIMINATIVE STIMULUS PROPERTIES OF TRIADIMEFON. A.N. Perkins* and D.A. Eckerman. Dept. Of Psychology, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC 27599

Triadimefon (TDF), a triazole fungicide has been found to increase motor activity and to induce stereotypy, behavioral effects that are characteristic of the psychomotor stimulants. Triadimefon was also found to function as a discriminative stimulus, and its stimulus properties were found to be qualitatively similar to those produced by the psychomotor stimulant, methylphenidate.

A variety of evidence suggests that dopamine (DA) may be important in mediating the behavioral effects of TDF. The purpose of the present study was to address the role of DA in the discriminative stimulus effects of TDF. Rats (N=6) were trained to discriminate an i.p. injection of 40 mg/kg TDF from vehicle under an FR-20 schedule of milk reinforcement. Haloperidol, a D2 antagonist, in combination with TDF was found to antagonize the TDF stimulus in the absence of marked rate-decreasing effects. The D2 agonist quinpirole substituted for the TDF stimulus, whereas the D1 agonist dihydrexidine at dosages of up to 4 mg/kg did not substitute for the TDF stimulus. These preliminary data suggest a role for the involvement of the DA receptor in the discriminative stimulus properties of TDF.

SENSITIZATION OF HALOPERIDOL-INDUCED HYPOPHAGIA: ROLE OF INTERDOSE INTERVAL AND BEHAVIORAL EXPERIENCE. D. L. Wolgin*, J. Moore and L. Dalzell. Dept. of Psychology, Florida Atlantic Univ., Boca Raton, FL 33431.

Two experiments were conducted to elucidate the variables that control the development of sensitization to the hypophagic effects of haloperidol (HAL). In the first experiment, groups of rats were given chronic injections of either HAL (0.62 mg/kg) or saline at interdose intervals (IDIs) of 1, 2, 7, or 14 d. Following each injection, sweetened milk was presented for 30 min. HAL given at IDIs of 1 or 2 d produced neither tolerance nor sensitization to the initial hypophagic effect of the drug, whereas at IDIs of 7 or 14 d, sensitization developed. In the second experiment, groups of rats were given injections of HAL (0.31 mg/kg) at 7-day intervals either before (Before Group) or after (After Group) access to sweetened milk. Control groups were given injections of saline prior to milk access. After sensitization developed in the Before Group, all groups received a single injection of HAL (0.15 mg/kg) before access to milk. On this final test, only the Before Group showed sensitization of hypophagia. The After Group ingested as much as the control groups. These results demonstrate that sensitization of HAL-induced hypophagia develops at IDIs greater than 2d and is contingent on access to milk while in the drugged state.

REINFORCING EFFECTS OF THE D1 DOPAMINE AGONIST SKF 81297 IN RHESUS MONKEYS. M. R. Weed, K. E. Vanover and W. L. Woolverton.* Drug Abuse Research Center, The University of Chicago, Chicago, IL. 60637

The partial D1 agonist SKF 38393 has previously been found not to function as a positive reinforcer in rhesus monkeys (Woolverton et al., JPET 230: 678, 1984). The present experiment was designed to evaluate the reinforcing effect of the full D1 agonist SKF 81297 under similar conditions. Two rhesus monkeys were prepared with chronic intravenous catheters and lever pressing was maintained by cocaine (0.03 mg/kg/inj, FR10, 1 hr/day) under baseline conditions. When responding was stable (+/- 10% of 3 day mean), saline was substituted for cocaine. Responding declined to low levels (<10 inj/hr) within 4-6 sessions. Doses of SKF 81297 (SKF; 0.003-0.3 mg/kg/inj) were then made available for at least 4-6 sessions or until responding was stable. Baseline conditions were reinstated between SKF doses. Responding was maintained above saline levels at least at two doses in both monkeys. Injections of the D1 antagonist SCH 39166 (SCH; 0.003-0.03 mg/kg, i.m., 30 min pre-session) were administered before alternate sessions over the last several sessions of availability of the lowest SKF dose self-administered (0.01 mg/kg/inj). SCH decreased responding maintained by SKF in a dose-related manner in both monkeys. At the highest SCH doses, rate and pattern of responding were similar to that seen when saline was available for self-administration. Thus, the D1 agonist SKF functioned as a positive reinforcer and its reinforcing effect appeared to be blocked by the D1 antagonist SCH. These results further implicate D1 receptors in the reinforcing effects of drugs which increase dopamine neurotransmission. (Supported by NIDA grants DA-00250, DA-00161 and NIGMS grant GM-07151).

THE HIGHLY SELECTIVE α2-ADRENOCEPTOR ANTAGONIST RX811059 PRODUCES A CENTRALLY MEDIATED DISCRIMINABLE CUE IN RAT DRUG DISCRIMINATION STUDIES. S. Jordan, †H. C. Jackson, †D. J. Nutt, †R.B. Holman* and S. L. Handley. Pharm. Sci. Inst., Aston Univ., Birmingham. B4 7EA . UK. †Reckitt & Colman Psychoph. Unit, Bristol. BS8 1TD. UK.

Idazoxan is the most selective α2-adrenoceptor antagonist to date which produces an interoceptive discriminative stimulus or 'cue' in rat drug discrimination (DD) studies (Sanger et al, 1989, Psychopharm. 99, 117-121). However, this drug also binds with high affinity to the non-adrenoceptor idazoxan binding site (NAIBS, Michel & Insel,1989, Trends Pharmacol. Sci. 10, 342-344). The 2-ethoxy analogue of idazoxan, RX811059 is a highly selective α2-adrenoceptor antagonist with minimal NAIBS affinity (Mallard et al, 1991, Br. J. Pharmacol. 102, 221P).

The purpose of this study was to examine the ability of RX811059 to produce a discriminable cue in rats. A group of male Lister-Hooded rats (n = 6) learned to discriminate RX811059 (2.5 mg/kg, IP) from saline in a fixed ratio (FR = 10) DD schedule. A series of α2-adrenoceptor antagonists were tested for their ability to generalise to (i.e. mimic) the RX811059-induced cue.

RX811059 itself dose-dependently mimicked the RX811059-induced cue (i.e. >80% total responses were RX811059 associated), as did the α2-adrenoceptor antagonists idazoxan, fluparoxan and 1-(2-pyrimidinyl)-piperazine (1-PP), using doses up to 2.5, 10, 3 and 3 mg/kg respectively. However, the peripherally acting α2-adrenoceptor antagonist L659,066 (Clineschmidt et al, 1988, J. Pharmacol. Exp. Ther. 245, 32-40) failed to generalise to the RX811059-induced cue (i.e. <10% total responses were RX811059 associated) as did clonidine, an α2-adrenoceptor agonist, using doses up to 8 and 0.04 mg/kg respectively.

Thus the highly selctive α2-adrenoceptor antagonist, RX811059 produces a discriminable cue in rats which appears to be central in origin.

641.15

THE INVOLVEMENT OF β-ADRENERGIC MECHANISMS IN STRESS-RELATED BEHAVIORAL CHANGES.

A. Laurel Gorman and Adrian J. Dunn*. Dept of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Substantial evidence suggests that noradrenergic systems are involved in stress-like behavioral responses. Previous studies showed that α_1-adrenergic agonists induced defensive withdrawal in rats (Yang *et al.*, 1990) and decreased mean stimulus-contact times in mice tested in the multicompartment chamber (MCC: Berridge & Dunn, 1989). Because the α_1-agonist-induced behaviors were attenuated by pretreatment with the CRF antagonist, alpha-helical CRF_{9-41}, these responses may have resulted from α_1-adrenergic stimulation of CRF release. However, β-antagonists exhibit anxiolytic properties in defensive withdrawal, suggesting that noradrenergic systems play additional roles in anxiety-like responses. L-Propranolol (2.5-5 mg/kg ip) decreased defensive withdrawal in naive rats and reversed that induced by restraint or icv CRF (Yang *et al.*, 1990). We now show that propranolol also reversed restraint-induced changes in the behavior of mice in the MCC and the elevated plus-maze.

To investigate further the role of central noradrenergic systems in defensive withdrawal behavior, the effects of β-adrenergic stimulation were assessed using the β-agonist isoproterenol. Isoproterenol (1-10 μg icv) produced a dose-dependent increase in defensive withdrawal, significant at the 10 μg dose. L-Propranolol (0.1-3 mg/kg ip) reversed isoproterenol-induced defensive withdrawal, suggesting that the response to isoproterenol resulted from the activation of β-adrenergic receptors. These results support earlier data indicating the involvement of central β-adrenergic receptors in stress-related behavioral responses (Yang & Dunn, 1990).

INTERACTION OF GEPIRONE AND HOMOCYSTEIC ACID ON ULTRASONIC VOCALIZATIONS AND OTHER FEAR-RELATED BEHAVIORS IN ADULT RATS. D.J.Knapp, D.Benjamin, Y.Ahmad, J.Stern,* & L.A. Pohorecky. Center of Alcohol Studies and Department of Psychology, Rutgers University, Piscataway, NJ 08855-0969.

Previous experiments in this laboratory have found that the administration of 1-3 air puffs to rats elicits robust 22 kHz ultrasonic vocalizations (USVs) which continue, without further stimulation, for up to 20 minutes. In the present experiments, the ability of pharmacological agents to modify ultrasonic vocalizations (USVs) and other fear or anxiety related behaviors was studied in male Long-Evans rats. Previous investigators reported that the 5-HT1A agonist, 8-OH-DPAT, could reverse fear-inducing effects of the excitatory amino acid, D,L-homocysteic acid (DLH), administered to the dorsal periaqueductal gray (DPAG). In our investigations, the peripheral administration of the 5HT1A agonist, gepirone, potently reduced air-puff induced USVs. Intra-DPAG DLH (5 nmol/250 nL) induced a range of fear-like behaviors including USVs. Lower doses (1 nmol) or administrations of DLH onto the DPAG induced a behavioral response characterized primarily by immobility and USVs which were gepirone reversible (30 nmol/250 nL), while more dorsal administrations induced contralateral rotations or no response. Higher doses (3-5 nmol) or administrations more ventral or ventrolateral resulted in violent defensive reactions or running fits which were apparently incompatible with USVs and irreversible with gepirone (30 nmol/250 nL). Furthermore, administration of air puffs to these rats did not elicit USVs during or after this robust behavioral response to DLH. These data in part corroborate previous findings of anti-aversive 5-HT1A effects on excitatory amino acid stimulation in the central gray, and expand this interaction to include USVs. Rat USVs may serve as a useful model of human panic anxiety or fear.

OPERANT RESPONSE SUPPRESSION (RS) INDUCED WITH SYSTEMIC ADMINISTRATION OF 5-HYDROXYTRYPTOPHAN (5-HTP) IS CENTRALLY MEDIATED. E.A. Engleman*, J.M. Murphy, F.C. Zhou, M.H. Aprison, and J.N. Hingtgen. Depts Psychiat; Biochem; Anat; Psychol; Prog Med Neurobiol; Inst Psychiat Res; Indiana U Sch Med; Purdue Sch Sci; Indianapolis, IN 46202-4887

Systemic administration of 5-HTP produces behavioral disruptions in animals performing food reinforced operant tasks. Previous studies have demonstrated that these effects are likely mediated through serotonin 5-HT_2 and/or 5-HT_{1C} receptors. In the current study, intracerebroventricular (ICV) administration of LY53857, a potent and selective 5-HT_2 and 5-HT_{1C} receptor antagonist, was used to test the hypothesis that 5-HTP induced RS is centrally mediated. Male Wistar rats trained to lever press for milk reinforcement were stereotaxically implanted unilaterally with chronic 22 ga guide cannulae just above a lateral ventricle. DL-5-HTP (25mg/kg,IP) given 15 min. into a VI 1' operant session produced a baseline period of RS. ICV injections (1.0, 3.75, or 7.5ug in 5ul) of LY53857 immediately prior to systemic 5-HTP (25mg/kg) sessions, dose dependently reduced the period of RS. These results provide additional evidence that 5-HTP induced RS is centrally mediated through 5-HT_2 and/or 5-HT_{1C} receptors. (Indiana Dept. Mental Health, IUPUI Res. Invest. Fund, AA08553, Assn. Adv. of Mental Health Res and Edu. Inc.)

5-HT_{1A} RECEPTOR AGONIST AND ANTAGONIST EFFECTS ON SUPPRESSION OF RESPONDING IN A MODEL OF DEPRESSION. T.A. Lovell, E.A. Engleman, M.H. Aprison, J.N. Hingtgen* and J.M. Murphy. Dept. Psychology, Purdue Sch. Sci.; Prog. Med. Neurobiol., Inst. Psychiat. Res., Dept. Psychiatry, Indiana U. Sch. Med., IUPUI, Indianapolis, IN 46202-4887.

Previous studies have indicated the involvement of 5-HT_2 and/or 5-HT_{1C} receptors in 5-HTP-induced operant response suppression. This study tested whether 5-HT_{1A} receptors are also involved in the response suppression effects of 5-HT agents. Male Wistar rats (n=8), maintained at 80-85% of free-feeding weight, were trained to bar press for sweetened milk on a VI-60" reinforcement schedule. The 180-min sessions were given every other day, 3 days/week. After responding stabilized, rats received IP injections of saline or drug 15 min into at least one of 3 weekly sessions. Suppression of responding averaged 34±6 min after IP injection of L-5-HTP and 45±7 min after 8-OH-DPAT (1 mg/kg). Propranolol (5 mg/kg), which has 5-HT_{1A} antagonist properties, did not significantly block the 5-HTP-induced suppression, but it did significantly ($p<0.05$) attenuate the 8-OH-DPAT-induced response suppression by approximately 75%. 5-HT_{1A} receptors may partially mediate suppression seen after injection of some 5-HT agents in this pharmacological model of depression. RECEPTOR MODULATION, UP AND DOWN REGULATION IV

642.1

THE EFFECT OF CONTINUOUS AND INTERMITTENT LEVODOPA ADMINISTRATION ON STRIATAL DOPAMINE METABOLISM: A MICRODIALYSIS STUDY. J.L. Juncos*, M.S. Hooks, J.B. Justice, Jr., Departments of Neurology and Chemistry, Emory University, Atlanta, GA 30322.

Behavioral and biochemical indices of dopaminergic function are affected differentially by continuous and periodic levodopa administration. To elucidate the mechanisms of this differential effect, male SD rats were treated for 7 days with levodopa methylester (LDME, 100 mg/kg/d), a soluble form of levodopa, either continuously (ALZA® minipump) or intermittently (i.p., b.i.d.). Control rats received saline. Following a 24 hour washout, all groups were challenged with i.p. injections of either a dopamine receptor blocker (haloperidol, 1 mg/kg), or a dopamine transporter blocker (GBR-12909, 20 mg/kg). Outcome measures included locomotor activity, catalepsy scores, and dopamine concentration in the caudate-putamen using in-vivo microdialysis and HPLC.

During the 7 days of treatment there were no differences in locomotor activity; after the 24 hour washout there were no differences in baseline dopamine levels. Following haloperidol challenge there was a time-dependent threefold increase catalepsy scores ($p<0.05$) in all LDME-treated rats compared to the saline-treated rats. Haloperidol-induced elevations in dopamine levels were 55% higher in the continuously-treated group compared to the other two groups ($p>0.01$) which did not differ from each other. This difference consisted of plateau of dopamine levels evident in the 60-180 minute interval post challenge. GBR-12909-induced elevations in dopamine levels were 2-4 times higher than those induced by haloperidol. The saline- and continuous LDME-treated rats exhibited plateau responses comparable to the above, but in contrast, the saline group reached levels that were 55% higher than those in the continuous group ($p<0.01$). During the plateau the intermittent LDME-treated rats exhibited a biphasic response with high levels at 45-90 minutes and lower levels at 90-180 minutes ($p<0.0025$). The results suggest that continuous and periodic levodopa administration have a differential and probably reciprocal effect on extracellular dopamine modulation by the dopamine autoreceptor and the dopamine transporter.

642.2

AUTO-RECEPTOR (autoR) SUPERSENSITIVITY (SS) IS ASSOCIATED WITH PERMANENT, BUT NOT TRANSIENT, DA RECEPTOR (DAr) SUPERSENSITIVITY. JZ Fields-, GE Drucker, R Song & JH Gordon. Res Svce 151, VA Hosp, Hines IL 60141.

Female rats on chronic neuroleptics show a transient increase in postsynaptic D2 DAr density (TRANS rats). In contrast, in ovariectomized (OVX) rats on neuroleptics, the D2 upregulation is permanent (PERM rats). We hypothesized that an upregulation of presynaptic autoR occurs in PERM but not TRANS rats. This autoR SS should lead to lower DA levels in the synaptic cleft. This would then attenuate the normal ability of DA to downregulate D2 DAr and restore homeostasis. Testing PERM and TRANS rats, we evaluated nigrostriatal D2 autoR by 3 independent methods: i) apomorphine (APO) inhibition of in vivo DA synthesis in gamma-butyrolactone pretreated rats; ii) hypolocomotion induced by low dose APO; iii) in vitro APO inhibition of efflux of [3H]DA from superfused striatal slices. Our data show a significant increase in APO potency at autoR in PERM rats. We interpret these data as an autoR SS associated with decreased cleft DA levels. Our proposed mechanism for the permanence of the DAr upregulation in PERM rats thus involves autoR SS and decreased cleft DA levels which potentiate the D2 DAr SS; this leads to a vicious cycle that maintains upregulation of both pre- and post-synaptic DAr in PERM rats. The lack of an autoR SS in TRANS rats suggests that they retain the ability to compensate by increasing DA release. The PERM rat may be useful for modelling permanent DAr changes such as occur in tardive dyskinesia and schizophrenia. (Supported by VA Med Res & RoINS26449)

642.3

MODULATORY EFFECT OF SEROTONIN ON HALOPERIDOL-INDUCED UP-REGULATION OF DOPAMINE D-2 RECEPTORS. S.Matsubara*, R.Matsubara, T.Koyama, A.Ishikane and I.Yamashita. Dept. of Psychiatry Hokkaido Univ. School of Med., Sapporo, Hokkaido 060, Japan

Chronic treatment of rats with haloperidol (HAL,0.25-1mg/kg,3wks) increased the number of D-2 receptors in the striatum, while no increase was obseved by that with risperidone (1mg/kg), an atypical antipsychotic drug which has high affinity at serotonin(5-HT)2 receptor sites with lower affinity at D-2 sites. Chronic treatment with MK-212, a nonselective 5-HT agonist (2.5mg/kg), or with citalopram, a 5-HT reuptake inhibitor (10mg/Kg), both of which had no effect on the number of D-2 receptor sites by themselves, potentiated the up-regulation of D-2 receptor sites when coadministrated with HLA (0.5mg/kg). Coadministration of ritanserin, a 5-HT2/5-HT1c antagonist (1mg/kg), on the other hand, had no influence on the HAL-induced increase of D-2 receptor sites. These results suggest that serotonergic activity may have a complex modulatory influence on the up-regulation of D-2 receptor sites by HAL. Study on the effect of another manipulation of serotonergic activites is ongoing.

642.4

DENERVATION OF MOUSE STRIATUM DECREASES D_1 RECEPTOR mRNA AND THE RATE OF SYNTHESIS OF D_1 RECEPTORS AND INCREASES D_2 RECEPTOR mRNA AND THE RATE OF SYNTHESIS OF D_2 RECEPTORS. Z.H. Qin, J.F. Chen and B. Weiss*. Div. of Neuropsychopharmacology, Dept. of Pharmacology, Medical College of PA, Philadelphia, PA 19129.

To study the effects of dopaminergic input to the corpus striatum on the expression of D_1 and D_2 dopamine receptors, mice were unilaterally lesioned with 6-hydroxydopamine and then injected with a single dose of N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) which irreversibly inactivates both D_1 and D_2 receptor sites. D_1 and D_2 receptors and D_1 and D_2 receptor mRNAs were analyzed at various times after EEDQ treatment. D_1 and D_2 receptors were analyzed in situ by receptor autoradiography, using [^{3}H]-SCH23390 and [^{3}H]-raclopride for D_1 and D_2 receptors, respectively. D_1 and D_2 receptor mRNAs were analyzed by in situ hybridization histochemistry, using radiolabeled oligodeoxynucleotide probes. The results showed that 4 hr after EEDQ treatment, more than 90% of the D_1 and D_2 receptors were inactivated. The rate of recovery of D_1 receptors following inactivation by EEDQ was lower in the lesioned striatum than in the unlesioned striatum while the rate of recovery of D_2 receptors was higher in the lesioned striatum than in the unlesioned striatum. Denervated striata showed small but significant decreases in D_1 receptor mRNA and increases in D_2 receptor mRNA. In both cases, the largest percentage changes were seen in the lateral striatum. These studies suggest that dopaminergic denervation results in a decreased synthesis of D_1 receptors and an increased synthesis of D_2 receptors and that these changes are due to alterations in the levels of the respective mRNAs for the D_1 and D_2 receptors. (Supported by MH42148).

642.5

MODULATION OF DOPAMINE D1 RECEPTOR mRNA IN THE STRIATUM AND NUCLEUS ACCUMBENS OF RAT DURING THE ESTROUS CYCLE BY IN SITU HYBRIDIZATION. M. Morissette*, P. Falardeau and T. Di Paolo. Mol. Endocinol., CHUL Res. Centre, G1V 4G2 and Sch. Pharm., Laval Univ., G1K 7P4, Québec, CANADA.

Dopamine (DA) D1 receptor density was previously shown to increase after chronic estradiol treatment and to fluctuate during the estrous cycle. In order to investigate the mechanism of the hormonal modulation of D1 DA receptors, the present study investigated brain D1 receptor mRNA changes during the estrous cycle. The level of DA D1 mRNA in the rat striatum and nucleus accumbens was evaluated by *in situ* hybridization during the estrous cycle and compared to ovariectomized (OVX) rats. During the estrous cycle, rats in the morning of estrus, diestrus I, diestrus II, and proestrus (PAM) were studied as well as rats in the afternoon of proestrus. A groups of rats was OVX and killed 14 days after their surgery. A fragment from the rat striatal D1 receptor cDNA corresponding to the carboxy terminal tail of the receptor +2300bp of the 3' untranslated area was subcloned into pBluescript. ^{35}S-labelled antisense- or sense-strand RNA probes were prepared by *in vitro* transcription and hybridized with 4% paraformaldehyde-fixed adjacent coronal rat brain sections (10 µm). In OVX rats, a high level of DA D1 receptor mRNA was observed in striatum, nucleus accumbens and olfactory tubercle whereas no signal was detectable in the substantia nigra. During the estrous cycle, the levels of D1 mRNA in the striatum and in the nucleus accumbens were decreased in PAM as compared to rats in the other stages of the cycle and to OVX rats, the levels of D1 mRNA being similar in the latters. Fluctuation of striatal D1 DA receptors showing a peak in diestrus and of striatal D1 receptor mRNA during the estrous cycle probably reflected a different mechanism of action of steroid hormones on these dopaminergic components. Supported by a MRC of Canada grant to T.D.P..

642.6

DOPAMINE RECEPTORS AND BEHAVIOR: MODIFICATION BY DOPAMINERGIC LESIONS AND INTRASTRIATAL FETAL CELL GRAFTS. **L. Pundt*, L. Fisher†, F. Gage†, N. Narang and J.K. Wamsley**. Dept. of Pharm. Sci., NDSU and Neuropsych. Res. Ins., Fargo, ND 58103; †Dept. of Neurosci., UCSD.

Studies were undertaken to investigate alterations in dopamine receptors (D_1 and D_2), D_2 message, and dopamine uptake sites in the striatum of 6-hydroxydopamine (6-OHDA) lesioned rats after intrastriatal fetal cell transplantation. Attempts were made to determine the relationship between these alterations and behavior (amphetamine-induced rotations). It was observed that D_2 receptor binding on the ipsilateral (grafted) side was most highly correlated with the degree of behavioral recovery observed. Recovery was also found to be significantly related to the alterations of dopamine uptake sites on the ipsilateral side, but not on the contralateral side. There were no significant correlations between behavior and D_1 receptors or D_2 message. This study suggests that alterations in D_2 receptor binding and dopamine uptake sites on the ipsilateral side of a lesioned and subsequently grafted brain have the most influence on behavioral recovery.

642.7

BILATERAL INTERDEPENDENCE OF DA SYSTEMS IN THE BASAL GANGLIA. **N. Narang*, L. Pundt, M.E. Hunt, M.E. Alburges and J.K. Wamsley. Neuropsychiatric Res. Institute, 700 1st Ave. S., Fargo, ND 58103.**

Changes in dopamine (DA) receptors in basal ganglia result from many movement disorders. Injection of ibotenic acid (IA) in the caudate-putamen (CPU) of the rat has been proposed as an animal model for Huntington's disease. We examined the effect of unilateral IA lesions on D_2 receptor binding and message on both sides of the CPU. One group of male LE rats was stereotaxically injected with saline and the second group with IA (20 µg/2 µl) in the CPU. After 2 weeks, in situ hybridization and D_2 receptor binding were performed using [^{35}S]ATP radiolabeled DA D_2 receptor oligonucleotide probe and [^{3}H]raclopride. A significant increase in D_2 receptor mRNA (113%) with no change in D_2 receptor binding, was found in the CPU on the contralateral side when compared to saline injected animals. These results suggest that compensatory changes may be occurring on the unlesioned side of the brain which involve regulation of D_2 receptor transcription. This observation of bilateral interdependence in the DA system may be of importance in understanding movement disorders.

642.8

DOPAMINERGIC CHARACTERISTICS IN NEUROBLASTOMA CELL LINES FOLLOWING DIFFERENTIATION WITH RETINOIC ACID. D. R. NEW, H. A. GELBARD*, and M. F. D. NOTTER, Department of Neurobiology and Anatomy and Department of Pediatric Neurology, University of Rochester Medical Center, Rochester, N.Y. 14642.

The neuroblastoma originates from a solid tumor of the primitive cells of the neural crest, specifically from embryonic autonomic neuroblasts. Neuroblastoma cell lines are a commonly used model to study neuronal development and the influence of growth modulators on neural differentiation. The neuroblastoma cell lines, SK-N-AS and SK-N-SH, have been found to have functional D-2 dopamine subtype receptors. A functional D-1 dopamine subtype receptor that tightly couples to adenylate cyclase has been identified in the SK-N-MC cell line that is similar to striatal D-1 receptors. Studies on intracellular dopamine content in the LA-N-1 cell line have found that dopamine can be increased, while norepinephrine content decreases following differentiation with the morphogen retinoic acid.

Our studies utilized the neuroblastoma cell lines SK-N-MC and LA-N-1 to characterize the D-1 and D-2 dopamine subtype receptor expression following treatment of these cell lines with retinoic acid. Our preliminary results revealed that both cell lines can be morphologically differentiated with retinoic acid consistent with observations reported by others. While D-1 and D-2 receptor subtypes cannot be enhanced with retinoic acid in the SK-N-MC cell line. The LA-N-1 cell line has been found to contain a D-2 dopamine subtype receptor that can be upregulated with retinoic acid, with the appearance of two binding sites with two different affinities. Studies on the D-1 subtype receptor are in progress at this time. These results suggest that the LA-N-1 cell line can be upregulated with retinoic acid to express two different classes of the D-2 dopamine subtype receptor.

642.9

INDUCTION OF EXPRESSION OF ENDOGENOUS D2 DOPAMINE RECEPTOR IN GH4C1 CELL. S. Allard, M. Labbé and P.Falardeau*, Génétique Moléculaire, CHUL, and School of Pharmacy, Laval Univ., Québec, Canada, G1V 4G2

GH4C1 cells are subclone of the GH3 cells (a prolactin-secreting cell line) which do not respond to dopamine agonists. In contrast with GH3 cells (Missale et al, J.Biol. Chem., 266: 23392, 1991), native GH4C1 do not show any D2 receptors when assessed by PCR for mRNA levels or by [3H]spiperone binding. After transfection of pRSVNeo, a plasmid which procure neomycin resistance, all selected colonies expressing neomycin resistance gene showed the presence of both dopamine D2 receptor mRNA and [3H]spiperone binding. cDNA of this D2 receptor was amplified and sequenced. No difference was observed in the coding region of this receptor when compared with the cloned rat D2 dopamine receptor. In the transfected cells, level of binding for D2 receptor range between 150-500 fmol/mg of protein. Moreover, selective D2 agonist such as quinpirole can inhibit forskolin- as well as VIP-stimulated cAMP formation by up to 90% in a dose related fashion. Cells grown in presence of 0.25mg/ml Geneticin (G418 sulfate) for 3 weeks lead to a two fold increase in the amount of [3H]spiperone binding. The precise mechanisms associated with the induction of D2 dopamine receptor in these cells are still not well understand. However this model can be used to study gene regulation of D2 dopamine receptor. (Supported by MRC grant)

642.10

REPRESSION OR ACTIVATION OF REGULATORY (RI-RII) SUBUNITS OF cAMP DEPENDENT KINASE mRNA LEVELS FOLLOWING CHRONIC BLOCKADE OF D1 OR D2 DOPAMINE (DA) RECEPTORS IN RAT STRIATUM

G. Schettini*, C. Ventra, A. Porcellino ^, M. Grimaldi and E. Avvedimento ^. Dip. di Farmacologia, and ^ Dip. di Biol e Patol. Mol. e Cell, II Facolta'di Medicina, Universita'di Napoli, Italy.

We studied the modulation of RI and RII regulatory subunits of cAMP-dependent kinase mRNA expression in the development of DA receptors supersensitivity. We found both genes expressed in the striatum. The blockade of D1 receptor by SCH 23390 for 1, 3, 7, 14, and 21 days, likely lowering striatal cAMP levels, reduced RII mRNA content, measured 1 h after the last injection. This effect occurred after 7 days, lasted till the 21st day, and was no more detectable 72 h after the last injection. No apparent changes of RI mRNA content were observed. The blockade of D2 receptors by haloperidol, likely increasing striatal cAMP content, enhanced both RI and RII mRNA levels. Such changes occurred very rapidly. We suggest that high cAMP levels specifically increase RI and RII striatal mRNA, while low cAMP concentrations suppress RII mRNA.

642.11

REGULATION OF THE ALPHA-2C ADRENERGIC AND 5-HT_{1B} SEROTONERGIC RECEPTORS BY DEXAMETHASONE IN AN OPOSSUM KIDNEY (OK) CELL LINE. H.S. Blaxall,* R.C. Pleus, D.R. Cerutis, N.A. Hass and D.B. Bylund, Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198-6260.

Previous pharmacological studies from our laboratory have characterized the alpha-2 adrenergic receptor expressed by the OK cell line as the alpha-2C subtype and the serotonergic receptor expressed as the 5-HT_{1B} subtype. Both of these receptors are down-regulated by treatment with their respective agonists, norepinephrine and serotonin.

To further investigate the regulation of these receptors OK cells were treated with dexamethasone. Cells were grown in serum free, steroid free media (Ultroser SF, Sepracor, Columbia, MD) in the presence and absence of 100 nM dexamethasone. After 72 hours, control and treated OK cells were harvested and membranes were prepared for saturation binding assays. The B_{max} values were determined for the alpha-2C adrenergic receptor using [^{3}H]rauwolscine and for the 5-HT_{1B} serotonergic receptor using [^{125}I]iodocyanopindolol. The alpha-2C receptor number was decreased by ~ 30% and the 5-HT_{1B} receptor number was increased by ~ 55% with dexamethasone treatment. Thus, it appears that in OK cells dexamethasone causes a down-regulation of alpha-2C receptors and an up-regulation of 5-HT_{1B} receptors. (Supported by NIH grants GM40784 and MH47354).

REGULATION OF A2 ADENOSINE RECEPTOR mRNA BY PHORBOL ESTERS IN THE PC12 CELL LINE. JS Fink* and R A Peterfreund, Depts. of Anesthesia and Neurology, Massachusetts General Hospital, Boston, MA 02114

A rat cDNA which encodes a high affinity A2 adenosine receptor (A2R) was recently cloned and expressed in our laboratory (Mol Br Res, 1992, *in press*). PC12 cells, a clonal rat cell line known to express functional high affinity A2Rs (J. Neurochem. **37**, 1431: 1981) were found to produce high levels of mRNA which specifically hybridized to a rat A2R cDNA probe. Activation of the protein kinase C (PKC) second messenger system is known to regulate mRNA levels for other G protein-linked receptors. We asked if activation of the PKC second messenger system regulates A2R mRNA levels in PC12 cells.

Treatment with tetradecanoyl phorbol acetate (TPA), which activates PKC, reduced the levels of A2R specific mRNA by 50-75% in two different subclones of PC12 cells. The effect was dose dependent; inhibition was observed for doses greater than 10 nM. A reduction in A2R mRNA levels was first detected after 2 hours and was maximal by 5-6 hours. Structural analogs of TPA known to have reduced efficacy to activate PKC were less effective in reducing A2R mRNA levels. Cells treated with TPA and allowed to recover overnight exhibited an increase in A2R mRNA levels. The A2R is believed to exert its intracellular effects by a signal transduction pathway involving activation of adenylate cyclase and production of cAMP, but not through activation of PKC. Our results are consistent with heterologous regulation of transcription or stability of A2R mRNA by PKC activation.

642.13

THE G PROTEIN βγ SUBUNIT ACTIVATES AGONIST-DEPENDENT PHOSPHORYLATION OF β ADRENERGIC AND MUSCARINIC RECEPTORS by β ADRENERGIC RECEPTOR KINASE 1 AND MUSCARINIC RECEPTOR KINASE. Kimihiko Kameyama, Kazuko Haga, and Tatsuya Haga*. Dept. Biochem., Inst. Brain Res., Fac. Med., Univ. Tokyo, Hongo, Tokyo 113, Japan

We have previously shown that the βγ subunit of G proteins stimulates the agonist- or light-dependent phosphorylation of muscarinic receptors (mAChRs) and rhodopsin by a protein kinase (mAChR kinase) partially purified from porcine cerebrum (J.BiolChem.,267,2222 (1992)).The light dependent phosphorylation of rhodopsin by rhodopsin kinase, however, is not stimulated by the βγ subunit, and it is not known if the agonist-dependent phosphorylation of β adrenergic receptor (βAR) by βAR kinase is stimulated by the βγ subunit. We report here that the βγ subunit also stimulates the agonist-dependent phosphorylation of bovine lung βARs by the mAChR kinase and the agonist-dependent phosphorylation of mAChRs (m2 subtype) by recombinant βAR kinase 1 extracted from cos-7 cells. These results suggest that the βAR kinase 1 is the same as or very similar to the mAChR kinase but is distinguished from the rhodopsin kinase with respect to activation by the βγ subunit. We hypothesize that the βγ subunit activates the βAR kinase thereby facilitating the desensitization of phosphorylated receptors. The cDNA for βAR kinase 1 was kindly provided by Dr. R.J. Lefkowitz.

DIFFERENTIAL EFFECTS OF PHORBOL ESTER ON THE FUNCTIONAL COUPLING OF THE RAT MUSCARINIC M_1 AND M_2 RECEPTORS. S.W. Ma, W.R. Roeske, H.I. Yamamura and J. Lai*. Departments of Pharmacology and Internal Medicine, The University of Arizona Health Sciences Center, Tucson, AZ 85724.

Carbachol (CCh) mediated a stimulation of [^{3}H]IP_1 accumulation in transfected B82 cells expressing the M_1 receptors with an EC_{50} value of 22.6 μM and a maximal stimulation of 22 fold above basal level. Pretreatment of these cells for 60 min at 37°C with phorbol 12-myristate, 13-acetate (PMA) resulted in a rapid desensitization of the M_1 receptors with an IC_{50} value of 9.1 nM and a maximal inhibition of 84% of the effect of 100 μM CCh. PMA (0.1 μM) pretreatment had no effect on the multiple affinities of CCh for the M_1 receptors in intact cells or membrane preparations (K_H = 2.85 μM; K_L = 389 μM), contrasted with a single low affinity of 124 μM for CCh in the presence of 100 μM GTP-γ-S. Treated cells showed a reduction in total M_1 receptor density (67.4 ± 6.6 % of [^{3}H](-)QNB binding in control cells) as well as the number of receptors on the cell surface (76.7 ± 3.3 % of [^{3}H](-)MQNB binding in control cells). The affinity of the antagonists was not affected ($p>0.05$). The M_2 receptors expressed in B82 cells were coupled to an inhibition of cAMP formation and a small stimulation of [^{3}H]IP_1 accumulation. Neither of these functions nor the density of the M_2 receptors was altered by 0.1 μM PMA pretreatment. These data demonstrate clearly a differential sensitivity of the M_1 and M_2 receptors to PMA in their functional coupling. The rapid desensitization of the M_1 receptors may be due to a PMA-induced uncoupling of phospholipase C from the G-proteins. Supported by AHA and NIMH.

G PROTEIN LEVELS AND EXPERIMENTAL ASTHMA J.Y. Lee#+*, Y. Uchida+, T. Sakamoto+, A. Nomura+ and F. Hirata#+. #Dept. of EHS, The Johns Hopkins Univ., Baltimore, MD 21205, and +Depts. of Pharm. Sci., and Pharmacol., and Inst. of Chem. Tox., Wayne State Univ., Detroit, MI 48202

Asthma is characterized by the hyperresponsiveness to constrictors and hyporesponsiveness to relaxants. Since most, if not all, receptors for constrictors and relaxants are members of "G protein coupled receptor" family, we hypothesized that an altered expression of G proteins is responsible for such receptor dysfunctions. Mild (acute) and severe (chronic) asthma were produced in previously sensitized guinea pigs by a single or multiple challenges with aerosolized immunogen, ovalbumin. Levels of Gq_α and Gi_α but not of Gs_α and G_β increased as a function of time when measured at 0, 12 and 24 hr postimmunochallenge. Guinea pigs with severe asthma had larger increases in Gq_α and Gi_α than animals with mild asthma. The in vitro assay of isolated tracheas showed that the hyperreactivity to cholinergic agents takes place only in the animals with severe asthma immediately after the challenge, while the hyporeactivity to isoproterenol progressed in both of the animals with mild and severe asthma. Our results suggest that an altered expression of Gq and Gi proteins in airway smooth muscle is partly, if not totally, responsible for receptor dysfunctions observed in asthma.

642.16

SEROTONIN 1_A AND 1_B RECEPTOR BINDING IS INCREASED IN THE RAT HYPOTHALAMUS FOLLOWING ACUTE DENERVATION. M. Frankfurt*, S.D. Mendelson, C.R. McKittrick and B.S. McEwen. Neuroendocrinology Lab., The Rockefeller University, New York, NY 10021.

Alterations in serotonin (5-HT) receptor binding were assessed in male rats by quantitative autoradiography following intrahypothalamic injection of the serotonin neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT). [^{3}H]8-OH-DPAT binding was used to label 5-$HT1_A$ receptors and [^{125}I]-iodocyanopindolol binding in the presence of isoproterenol (to mask ß-adrenergic receptors) was used to label 5-$HT1_B$ receptors. Seven days after 5,7-DHT, when 5-HT levels are lowest, [^{3}H]8-OH-DPAT binding was increased in the ventromedial and dorsomedial hypothalamic nuclei (VMN, DMN). In the same animals, [^{125}I]-iodocyanopindolol binding was increased in the VMN, but unchanged in the DMN. No changes in 5-$HT1_A$ or 5-$HT1_B$ binding were observed in the lateral hypothalamic area, the dentate gyrus, or the CA1 region of the hippocampus, in spite of a large decrease in the binding of [^{3}H]paroxetine, which labels the presynaptic 5-HT transporter site. These results demonstrate differential regulation of 5-HT receptors in response to denervation and also suggest that some of the 5-$HT1_B$ receptors in the VMN are located post-synaptically. Studies in females are in progress to determine possible sex differences in the response of 5-HT receptors to 5,7-DHT. Supported by NS07080.

ANTISENSE OLIGODEOXYNUCLEOTIDE INHIBITION OF NEUROPEPTIDE Y (NPY) Y1-RECEPTOR EXPRESSION. F. Yee*, M. Heilig and C. Wahlestedt. Div. Neurobiol., Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021 and Dept. Neuropharmacol., Scripps Res. Inst., La Jolla, CA 92037.

The Y1-receptor mediates behavioral and vascular actions of NPY. Since specific Y1-receptor antagonists are not available, we have employed the antisense oligonucleotide approach to suppress Y1-receptor protein synthesis *in vitro* and *in vivo* (Heilig *et al.*, this meeting). Based on the recent cloning of human and rat NPY Y1-receptor (Larhammar et al., *J. Biol. Chem.*, in press), antisense and sense (control) oligodeoxynucleotides (D-oligos) corresponding to different regions of the receptor were synthesized. These D-oligos were then added to media of cultured cells, *e.g.* rat primary cortical neurons and human neuroblastoma cells (SK-N-MC), which we had previously found to express the Y1-receptor by RT-PCR and/or Northern analyses (*ibid*). In both these cell types, antisense D-oligos directed to regions immediately downstream of the initiation codon were found to reduce, by up to 90%, high affinity binding sites labeled by ^{125}I-peptide YY (PYY). D-oligo concentrations as low as 0.1-1 μM (maintained over 3-5 days) were sufficient for reducing ^{125}I-PYY binding sites in cortical neurons under serum-free conditions. In contrast, SK-N-MC cells, which were trypsinized prior to addition of D-oligos and grown in the presence of heat inactivated sera, required 10 μM concentrations for similar suppression. Comparable data (70% inhibition of full NPY response) were obtained when assessing the ability of NPY to reduce forskolin stimulated cAMP accumulation in SK-N-MC cells treated with the antisense D-oligo. No biochemical (protein content and LDH release) or morphological abnormalities were observed to be induced by the D-oligos at the above concentrations. The described antisense approach may thus be useful in attempts to specifically affect Y1-receptor synthesis and function, resulting in the reduction of NPY efficacy.

***IN VIVO* DOWNREGULATION OF NEUROPEPTIDE Y (NPY) Y1-RECEPTORS BY I.C.V. ANTISENSE OLIGODEOXYNUCLEOTIDE ADMINISTRATION IS ASSOCIATED WITH SIGNS OF ANXIETY IN RATS.** M. Heilig, E. Merlo Pich, G.F. Koob, F. Yee and C. Wahlestedt*. Dept. of Neuropharmacol., Scripps Res. Inst., La Jolla, CA 92037 and Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Central NPY transmission has been suggested to be altered in depressive illness, in which anxiety is a common symptom. In rats, centrally administered NPY produces anticonflict/antianxiety effects by activating NPY Y1-receptors. The importance of endogenous NPY for anxiety remains unclear due to the absence of specific Y1-receptor antagonists. We therefore designed an 18-mer antisense oligodeoxynucleotide (D-oligo) corresponding to the amino-terminus of the rat Y1-receptor (Larhammar et al., *J. Biol. Chem.*, in press); this D-oligo was tested *in vitro* (Yee et al., this meeting). In this study, the antisense D-oligo was injected twice daily for two days into the CSF of awake, freely moving rats. Control animals received the matching sense D-oligo or saline. On the third day, antisense D-oligo treated rats showed marked signs of anxiety in an established animal model of anxiety, the elevated plus-maze. Sense D-oligo treated animals did not differ from saline controls. No effects on feeding or locomotor activity were observed. In cerebral cortex of antisense D-oligo treated rats, there was a time dependent reduction of the density (B_{max}) of binding sites labeled by either ^{3}H-NPY or ^{125}I-PYY. Since the cortex contains both Y1- and Y2-type NPY receptors, we used a Y1/Y2 masking approach to determine that the downregulation involved Y1-receptors only. Using the described antisense approach, it was thus possible to selectively inhibit cortical synthesis of the Y1-receptor protein. Since this inhibition was accompanied by marked signs of anxiety, we suggest that the anxiolytic effects of exogenous NPY may represent a physiological function of this endogenous transmitter.

DEVELOPMENTAL EXPRESSION OF CANNABINOID RECEPTOR mRNA C.R. McLaughlin*, W.L. Dewey and M.E. Abood. Dept. of Pharm., Med. Coll. of Virginia, Virginia Commonwealth University Richmond, VA 23298.

The cloning of a putative cannabinoid receptor affords the opportunity to examine its developmental expression and distribution. Other receptor systems, notably those for the opioids, have been shown to have distinct developmental time frames. For the initial study, Sprague-Dawley rats from the following age groups were employed: postnatal days 2, 5 and adults. The brains were grossly dissected into cerebellum and forebrain, and total RNA was extracted by a modified acid-extraction method. Expression of cannabinoid receptor mRNA was analyzed by two methods: Northern blot analysis and polymerase chain reaction (PCR). The probe used in the Northern blot analysis was a full length cDNA corresponding to the rat cannabinoid receptor. The probe was cloned in our lab based on published sequence information. Oligonucleotide primers based on bp 1-21 and bp 824-843 on the opposite strand were chosen for use in the PCR. Preliminary results indicate that by postnatal day 2, the cannabinoid receptor mRNA can be detected in the brain. In addition, spinal cords from 13 day old rats were analyzed. Cannabinoid receptor message was present, but at low levels, consistent with published receptor autoradiographic data from adult animals.

HEPARIN INHIBITS HIGH-AFFINITY BINDING OF [^{125}I]MELATONIN IN CHICK BRAIN. C.Harjivan, L.P. Niles, A. Nanji and E.S. Werstiuk*. Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

It is now known that high-affinity binding sites for melatonin exist in diverse regions of the chick brain. Moreover, these sites are present on receptors which are coupled to inhibition of adenylate cyclase activity via a pertussis toxin-sensitive G protein. Recently, heparin was found to decrease the affinity of the α_2-adrenoceptor and to block adrenaline-induced inhibition of adenylate cyclase in human platelet membranes. Therefore, we have examined the effects of heparin on the G protein-coupled melatonin receptor in chick brain.

Heparin caused a dose-dependent inhibition of [^{125}I]MEL binding in chick brain synaptosomal membranes. In the presence of 100 units/ml heparin, binding was inhibited by about 50-75%. Typical biphasic agonist inhibition curves, which exhibit high- and low-affinity binding, were shifted to the right with loss of the high-affinity state in the presence of heparin. As previously observed for sodium, lithium inhibited high-affinity binding of [^{125}I]melatonin in chick brain membranes. A combination of maximally effective concentrations of sodium and lithium did not produce additional inhibition of binding. However, a combination of heparin and lithium resulted in an additive suppression of binding, indicating that these agents act on different sites on the receptor - G protein complex. The ability of heparin to abolish the high-affinity state of the melatonin receptor in chick brain, supports earlier evidence that this receptor is coupled to a G_i protein.

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: STRESS

643.1

FORCED AMBULATION IN AN EXTREME POSTURE INCREASES TONIC CORTICOSTERONE BUT NOT ACTH LEVELS IN RATS. J. Hulse-Neufeld*, L. Breen, and R. Hauger. VA Medical Center (151), San Diego, CA 92161.

An animal model of low back dysfunction has been described (1991 meeting #120.4). Now tonic serum levels of corticosterone (B) and ACTH after six weeks of forced ambulation are reported so as to assess the degree of stress between groups of rats. Three groups of rats were compared: rats forced to ambulate on a flat surface (normal posture), rats forced to ambulate in rotating cylinders (extreme posture), and rats not forced to ambulate. After six weeks, rats forced to ambulate in cylinders and rats not forced to ambulate had higher tonic levels of B than rats forced to ambulate on a flat surface. The relationships of tonic levels of ACTH to B were different between the rats forced to ambulate in cylinders and on a flat surface. It is suggested from the results that forced ambulation in a normal posture lowers tonic levels of B, and forced ambulation in an extreme posture is more stressful than in a normal posture. Since the adaptation to exercise stress was associated with higher B levels when exercise was performed in an extreme posture, the voluntary assumption of an extreme posture in the low back is stressful in exercising (forced ambulation) rats.

GLUCOCORTICOID REGULATION OF THE ADRENOMEDULLARY CATECHOLAMINERGIC SYSTEM FOLLOWING A MILD ACUTE STRESSOR. P. Boksa*, K. Betito, S. Bhatnagar, J.B. Mitchell, J. Diorio & M.J.Meaney. McGill University, Depts. of Psychiatry, Pharmacology, and Neurology & Neurosurgery, Douglas Hospital Research Center, Montreal, Quebec H4H 1R3, Canada.

Adrenal medullary enzymes are regulated both by splanchnic innervation and by glucocorticoids (GCs). Phenylethanolamine N-methyltransferase (PNMT), the final enzyme in the catecholamine biosynthetic pathway, is predominantly regulated by GCs. Changes in the activity of PNMT in rats have been observed following a variety of chronic stressors, as well as with more acute stressors, such as an intermittent 2h swim stress or a 2.5h immobilization stress. We have previously shown that bovine adrenomedullary cells respond to a pulse of GCs as short as 15 min by increasing PNMT 2d later (Betito et al, 1992, J. Neurochem 58, 1853). In the present study, we looked at the adrenomedullary response of male rats to a more moderate acute stressor, 20 min restraint stress, where the increase in plasma corticosterone (CORT) is relatively short (1h). A significant increase in PNMT activity was observed only at 18h (17%) and 24h (14%) following restraint, but not before. Adrenaline and noradrenaline content of the adrenal increased significantly at 18h with no increase in tyrosine hydroxylase (TH). Splanchnic nerve transection did not alter basal PNMT and TH activities (as previously shown) and did not prevent an increase in PNMT activity following restraint. Inhibition of CORT synthesis by metyrapone (100 mg/kg, injections 24h and 2h prior to stress) prevented a stress-induced increase in PNMT activity at 24h. Suppression of CORT release by dexamethasone (DEX; 100 μg/kg injection 3h prior to stress) did not affect basal levels of PNMT, however the stress-induced increase in PNMT activity was prevented at 24h. These results demonstrate that a relatively short moderate stressor, which elevates GCs for only 1h, can elevate the activity of PNMT following a period of 18-24h. The regulation of this activity appears to be independent of neural input and dependent on the release of CORT during the period of stress.

643.3

REGULATION OF ACTH CO-SECRETAGOGUES DURING THE ESTROUS CYCLE IN THE RAT. V.Viau* & M.J.Meaney. Douglas Hospital Research Ctr., Depts. of Psychiatry and Neurology/Neurosurgery, McGill Univ., Montreal H4H 1R3, Canada

We have previously shown that the HPA axis in the female rat is most sensitive to stress during the proestrous phase of the estrous cycle (Viau and Meaney, Endocrinology, 1991). This suggests that high, physiological levels of estrogen secreted during proestrous could regulate ACTH co-secretagogues. We examined median eminence CRH and AVP content during the estrous cycle and in ovariectomized-estrogen replaced females. CRH and AVP content was higher in tissue obtained under basal conditions from females during proestrous and estrous compared to diestrous: CRH=11.1 $\pm$ 2.3, 7.2 $\pm$ 1.3, and 5.3 $\pm$ 0.4 pg/μg protein, respectively; AVP= 47.5 $\pm$ 10.0, 49.8 $\pm$ 14.1, and 30.9 $\pm$ 7.7 pg/μg, respectively. No differences were observed in median eminence content for either CRH or AVP between OVX and OVX-E2 replaced females, suggesting a concerted role for both estrogen and progesterone in the regulation of these peptides. AVP content, but not CRH, was higher in tissue obtained from OVX-E2 replaced animals following 20 min of restraint stress.

Plasma ACTH levels 5 min following icv administration of the α-1 adrenoreceptor agonist phenylephrine (50 μg) were significantly higher in rats during proestrous compared to diestrous; 1060 $\pm$ 130 vs 646 $\pm$ 175 pg/ml, respectively. Consistent with these data, AVP has been previously shown to mediate α-1 adrenergic stimulation of ACTH secretion (Al-Damluji et al, Endocrinology, 1990). Taken together, these results suggest that estrogen enhances the HPA response to stress during proestrous by enhancing the synthesis/release of CRH and, possibly to a greater extent AVP via an α-1 adrenergic receptor mediated mechanism.

EFFECTS OF ACUTE RESTRAINT STRESS ON CORTICOSTERONE, ACTH, CRH, AND VASOPRESSIN DIFFER ACROSS SEX AND STRAIN. S.L. Cummings,*[1] A.C. Griffin,[2] and C.C. Whitacre[2]. University of California Davis, CA 95616 and The Ohio State University, Columbus, OH 43210.

Experimental autoimmune encephalomyelitis (EAE), a model for the human demyelinating disease multiple sclerosis, is frequently studied in the highly susceptible Lewis (LEW) strain of rat. We and others have reported that restraint stress delays the onset and decreases the severity of EAE, particularly in the LEW female. The hypothalamic-pituitary-adrenal axis (HPA) has been hypothesized to play a role in the innate as well as stress-induced resistance to various autoimmune diseases, including rheumatoid arthritis and EAE. Therefore, we have examined corticosterone (CORT), adrenocorticotropic hormone (ACTH), corticotropin releasing hormone (CRH) and vasopressin (VP) levels in response to restraint in both sexes of 4 rat strains with varying susceptibility to inflammatory disease (LEW, Lewis Resistant, Brown Norway, and Fischer (F344). Plasma CORT and ACTH levels were determined by radioimmunoassay, and expression of CRH and VP mRNA in the hypothalamic paraventricular nucleus (PVN) was examined using in situ hybridization histochemistry. CRH and VP levels in the median eminence (ME) were visualized immunohistochemically. Levels of CRH and VP mRNA within the PVN were similar across strains in non-stressed animals, though steady state peptide levels within the ME of the highly resistant F344's consistently were higher than in the susceptible LEW. In response to 30 min of restraint stress, CORT and ACTH levels increased in both sexes of all strains, but to a greater degree in F344's than LEW's. CORT increased to higher levels in females than males, regardless of strain. After 30 min of stress, small increases in CRH and VP mRNA already were evident in the PVN of F344's, but not LEW animals. Taken together, these data suggest that susceptibility of EAE and other inflammatory diseases may be related to differential genomic regulation within the HPA axis.USPHS:MH44660

643.5

PITUITARY-ADRENOCORTICAL AND ADRENOMEDULLARY RESPONSES TO A NOVEL STRESS IN CHRONICALLY COLD STRESSED RATS. K. Betito*, S. Bhatnagar, J.B.Mitchell, P. Boksa., & M.J. Meaney. McGill University, Depts. of Pharmacology, Neurology & Neurosurgery, and Psychiatry, Douglas Hospital Research Center, Montreal, Canada H4H 1R3.

Chronically stressed rats exhibit an adaptation of hypothalamic-pituitary adrenocortical and adrenomedullary systems when reexposed to the chronic stressor. Basal levels of adrenomedullary enzymes (phenylethanolamine N-methyltransferase, PNMT; tyrosine hydroxylase, TH), catecholamines (epinephrine, E; norepinephrine, NE), and pituitary-adrenocortical hormones may or may not be elevated depending on the chronic stress. However, these systems hyperrespond when challenged with a novel stressor. In the present study, we have exposed male rats to 3 week intermittent cold stress (4°C, 4h/d; CHR rats) and present a comprehensive endocrine profile. Adrenomedullary measures following chronic cold stress show an increase in adrenal NE and E content, and in basal TH but not in PNMT activities (as previously shown). Similar levels of free and total levels of plasma corticosterone (CORT) were seen in control and CHR rats, whereas an increase in ACTH was observed in CHR rats, suggesting loss of adrenocortical sensitivity in these animals. Exposure to a novel stressor (20 min restraint) tended to increase TH activity and adrenal catecholamines in both CHR and control rats, whereas little increase in PNMT activity was observed. However, CHR rats exposed to restraint had higher levels of plasma CORT compared to control rats exposed to restraint, suggesting a hyperresponsiveness of the CHR rats to the novel stressor. ACTH levels following restraint were similar in both groups, suggesting increased adrenal sensitivity in CHR rats. Therefore, adrenal medullary and adrenal cortical systems may not respond uniformly to chronic stress or to exposure to a novel stressor, but may be responding to particular physiological/metabolic requirements that are specific to this stressor. Alterations in the central regulation of both these systems following chronic cold stress and exposure to heterotypic stress are currently being studied.

643.6

HYPOTHALAMIC-PITUITARY-ADRENAL DYSREGULATION ASSOCIATED WITH A HIGH FAT DIET. B.M. Tannenbaum*, D.N Brindley, M.F. Dallman, M.J. Meaney. Douglas Hosp. Res. Ctr., McGill Univ., Montreal, Canada H4H 1R3; Dept. of Biochemistry, Univ of Alberta, Edmonton, Canada, T6G 2C2; Dept of Physiology, UCSF., San Francisco, CA, 94143

Current models of stress-induced pathology often lack the most serious factors which have been identified in human pathology. High-fat intake is an excellent case in point. Increased fat intake leads to insulin resistance; subsequently this results in a high cost metabolic strategy which includes increased secretion of glucocorticoids and free fatty acids as well as altered hepatic production rates and clearance of high-and low-density lipoproteins. Alone, this regimen presents a health risk; however, because of the hormonal adaptations to diet an additional risk lies in altered responses to acute, superimposed stress. We have begun a series of longitudinal, epidemiological studies in rats to explore the consequences of acute stress imposed on a common maladaptive nutritional state seen in man. Plasma corticosterone levels were examined before, during and following a 20 min restraint stress after 1 week exposure to either a high fat (23%) or control (3%) diet. Basal plasma corticosterone levels were slightly elevated in high-fat rats. Sixty min after the end of restraint, high-fat rats still had significantly elevated corticosterone levels (22±7 vs. 6±2 ug/dl in control). In a parallel set of rats, adrenalectomized one day earlier, glucocorticoid receptor binding measured in the hypothalamus was significantly reduced in rats on high-fat diets compared with controls; no differences in binding were observed in hippocampus, frontal cortex or pituitary. A decrease in brain corticosteroid receptors has been frequently associated with decreased inhibition of the hypothalamic-pituitary-adrenal (HPA) axis and chronically increased glucocorticoid secretion. Thus, these studies show that even short term (1 week) exposure to a high fat diet can augment the HPA axis response to acute stress. The augmented HPA axis response to acute stress should serve to worsen the insulin sensitivity imposed by the diet, and repeated acute stressors may result in provoking the capacity for metabolic adjustments to its limits.

643.7

MODEST INCREASE IN NADIR CORTICOSTERONE (B) SECRETION IN OBESE (fa/fa) ZUCKER RATS ALTERS FEEDBACK SENSITIVITY ON BASAL ACTH RELEASE. C-D. Walker, J.S. Stern, L.S. Myers*, M.F. Dallman. Dept of Physiology, UCSF; Dept of Nutrition UCD, Dept of Psychology, CSU Stanislaus, CA 94143.

Genetically obese Zucker (fa/fa) rats exhibit a number of metabolic and endocrine disorders, most of which can be reversed by adrenalectomy (ADX). We studied basal adrenocortical activity in intact lean (Fa/Fa) and obese (fa/fa) rats and the ability of B to affect ACTH and insulin secretion and fat deposition in both phenotypes. The effects of ADX with various B pellets replacements (15-120%B) over 5 days were measured on basal nadir (AM) and stress-induced ACTH secretion. Intact obese rats showed a modest increase in basal B secretion in the AM, despite no changes in ACTH secretion or ACTH responses to stress. The chronic increase in B in obese rats was evidenced by decreased thymus and increased adrenal weights and PNMT activity. The ability of B to suppress basal ACTH was diminished in obese (IC50=4.17+0.7) vs lean (IC50=3.16+0.5) rats. After stress, similar suppression by B was observed in both phenotypes. Hyperinsulinemic obese rats did not show greater increases in insulin secretion with increasing B than lean rats. Fat deposition slightly increased with B in obese, but not in lean rats. Like many models of chronic stress, small increases in nadir B secretion in obese rats are associated with a decline in feedback sensitivity on basal ACTH secretion and subtle changes in the central regulation of ACTH secretion occur to maintain adequate responses to stressful stimuli. Supported by Swiss NRF (CDW), DK28172 (MFD), DK18899 (JSS).

ADRENALECTOMY-INDUCED FOS-LIKE IMMUNOREACTIVITY (FLI) IN THE PVN OF STRESS-HYPORESPONSIVE RATS **N. Wintrip, D. M. Nance and M. Wilkinson* Depts. of Obst. and Gynecol., Physiol. and Biophys., and Anatomy, Dalhousie U., Halifax, N.S., B3H 4H7, and Dept. of Pathology, U. of Manitoba, Winnipeg, Manitoba, R3E 0W3, Canada**

Adrenalectomy (ADX) is reported to induce the appearance of FLI in the rat PVN (Jacobson et al, Endocr., 128:1709). However, we have observed FLI in the PVN of adult Sprague-Dawley rats 2h and 4h following ADX, unilateral ADX, sham ADX, OVX, sham OVX, and a number of other stressful challenges (antibody: Cambridge Res. Biochem.).

We have sought to dissociate the induction of FLI which results from generalized stress from that specifically due to ADX. A stress-hyporesponsive period is reported to occur in neonatal rat pups (approx. day 4 to day 15) (Endocr., 110:1676). At postnatal day 11, FLI was observed in the PVN 4h after ADX or unilateral ADX but not following sham ADX or other stress. However, at postnatal day 18, sham ADX or other stress did elicit FLI in the PVN. Lightman and Young (Endocr., 124:2358) have also reported an association between lactation and a stress-hyporesponsive period. We have found an increase in FLI in the PVN of lactating rats at 4h following ADX but not following anaesthetic stress. This phenomenon appears to be restricted to the immediate perinatal period.

In conclusion, during early postnatal life, the c-fos response to stressors other than ADX appears to be attenuated in both mothers and pups. **Supported by Can. MRC (M.W. and D.M.N.)**

PATTERN OF IMMEDIATE EARLY GENE ACTIVATION IN RAT BRAIN FOLLOWING ACUTE STRESS. [1]W.E. Cullinan*, [2] J.P. Herman, and [1]S.J. Watson [1]University of Michigan, Mental Health Research Institute, Ann Arbor, MI, 48109-0720, and [2]University of Kentucky Medical Center, Dept. Anatomy and Neurobiology, Lexington, KY, 40536-0084.

In an effort to produce a functional map of the neural circuitry related to activation of the hypothalamic-pituitary-adrenal axis, we examined the pattern of induction of the immediate early gene c-fos in rat brain at 0, 30, 60 and 120 min. following acute immobilization stress. A radiolabelled cRNA probe was used to detect c-fos mRNA using *in situ* hybridization histochemistry. Results indicated regionally specific patterns of c-fos expression. Prior to stress c-fos was undetectable in most brain areas, and was markedly induced at 30 min. post-stress in the cingulate, infralimbic and orbitofrontal cortices, the piriform cortex, and in several neocortical areas including frontal and parietal regions. Also prominently labelled at 30 min. were the lateral septal nucleus, portions of the lateral hypothalamus, the hypothalamic paraventricular nucleus, the mammillary hypothalamic region, the medial and cortical amygdaloid nuclei, as well as a number of thalamic and brainstem regions. In the majority of these regions message levels were reduced at 60 min., and generally undetectable at 120 min. Exceptions included the piriform and parietal cortices, which exhibited a slower rate of decline, remaining detectable at 120 min post-stress. We are currently examining the induction c-fos in these regions at earlier and intermediate time points, and have begun characterization of c-fos and other immediate early genes (c-jun, zif/268) with respect to chemically defined neuronal populations.

INVOLVEMENT OF THE VENTRAL HIPPOCAMPUS IN REGULATION OF THE HYPOTHALAMO-PITUITARY-ADRENOCORTICAL AXIS. J.P. Herman*, W.E. Cullinan, M.J. Morano and S.J. Watson, Univ. Kentucky Med. Ctr., Lexington, KY 40536 and Univ. Michigan, Ann Arbor, MI 48109.

The present studies were designed to address the hypothesis that ventral hippocampal structures play a role in modulation of hypothalamo-pituitary-adrenocortical (HPA) function. Male Sprague-Dawley rats received stereotaxic injections of ibotenic acid or saline (SAL) into the ventral subiculum (VSUB)/ventral hippocampus (VHIPP). An additional group remained unhandled (CON). Seven days after surgery rats were subjected to acute restraint stress and blood collected 0, 30 and 120 m after stress induction. Animals were sacrificed 4 d later and brains harvested for in situ hybridization analysis of paraventricular nucleus (PVN) corticotropin releasing hormone (CRH) mRNA levels. There were no differences among the groups in basal CORT secretion. The VSUB group did not differ from SAL or CON rats at either the 30 m or 120 m post-stress time points. However, animals with damage confined to the VHIPP (including portions of CA1, CA3 and the dentate gyrus, but *excluding* the subiculum) showed significantly increased CORT levels at 30 and 120 m post-stress. The decay in plasma CORT from 30-120 m showed a similar time-course in all four groups, suggesting that VHIPP lesions alter amplitude but not duration of HPA stress response. CRH mRNA levels were tonically increased (30-80%) in the medial parvocellular PVN in both the VSUB and VHIPP groups relative to SAL and CON rats, indicating tonic up-regulation of these important hypophysiotrophic neurons. The data suggest the existence of distinct hippocampal pathways involved in tonic regulation of the HPA axis and in modulation of the magnitude of the stress response.

HABITUATION OF THE CORTICOSTERONE STRESS RESPONSE TO REPEATED RESTRAINT STRESS IN SPRAGUE-DAWLEY, FISCHER, AND LEWIS RATS. F. S. Dhabhar*, R. L. Spencer, and B. S. McEwen, Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

We have examined the corticosterone (CORT) response to repeated restraint stress in three related strains of rats: Sprague-Dawley, Fischer 344, and Lewis. These strains are known to differ in their CORT response to acute stress. Here we describe how they also differ in their response to repeated stress. Rats were subjected to 1 h restraint stress daily for 10 days. Blood (tail clip) was sampled on days 1, 5, and 10. Four samples: basal (0 min), stress (30 & 60 min), and recovery (120 min) were collected for RIA determination of plasma CORT. Fischers had significantly higher stress CORT levels than Sprague and Lewis rats on all test days. Sprague and Lewis rats showed both within session and across session habituation. Fischers showed only across session habituation, and the magnitude of this habituation was much smaller than that shown by the other strains. On day 5, the decreases in peak CORT levels (compared to peak at day 1) were: Fischer (10 %), Sprague (13 %) and Lewis (42 %). On day 10, the decreases in peak CORT were: Fischer (13 %), Sprague (27 %), and Lewis (41 %). Stressed animals from all three strains showed a smaller percent increase in body weight compared to controls. Stressed Fischers showed adrenal hypertrophy whereas Spragues and Lewis did not. Repeated stress had no effect either on thymus and spleen weights, or on plasma corticosterone binding globulin levels. Our results suggest that these strains differ considerably in their reactivity to repeated stress. Comparisons between these strains provide an attractive model for studying the mechanisms underlying the processing of, and adaptation to, stressful information. (MH 41256)

643.12

AN INTEGRATIVE ROLE OF NGF IN CNS MECHANISMS OF STRESS. L. Angelucci*, G. Cigliana, P.J. Foreman[1], L.A.A. Muscolo, R. Nicolai, J.R. Perez-Polo[1], A. Porcu, S. Scaccianoce, G. Taglialatela[1]. Institute of Pharmacology II, La Sapienza Univ. of Rome, Italy; [1]Human Biochemistry Dept., Texas University at Galveston.

The increase in plasma corticosterone (B) by exogenous NGF (Otten et al., 1979) is abolished in hypothalamus (HY)-blocked rats but not by the CRH antagonist alpha-Helical CRH (9-41) indicating that the main releaser of ACTH is a non-CRH factor. In vitro NGF while inactive on pituitary and adrenal, stimulates the release from and the synthesis in the HY of CRFs. Cold stress reduces ^{125} I-NGF binding and increases the levels of NGF and NGF-mRNA in the hippocampus (HI) as well of p75 ^{NGFR} in the basal forebrain; these actions are not mimicked by exogenously produced equivalent increases in plasma B, nor abolished by adrenalectomy. Considering that NGF concentration in blood can be increased by aggression (Aloe et al., 1986) and that NGF can be exogenously increased in HI, a structure involved by its glucocorticoid receptor in the regulation of the HPAA, we conclude that NGF has a role in the mechanisms of stress activation, possibly integrating HI and HY activities.

HIPPOCAMPAL REGULATION OF THE PITUITARY-ADRENAL AXIS IN MONKEYS. H. Uno,* A. Sakai, S. Shelton and S. Eisele, Regional Primate Res. Ctr. and Psychiat. Res. Inst., Univ. of Wisconsin, Madison, WI 53706

Our previous studies revealed that prenatal administration of dexamethasone to pregnant rhesus monkeys at 132 and 133 gestation days caused degeneration of the CA3 pyramidal neurons and retarded growth of the dentate granular neurons in the hippocampuses of neonates. Three juveniles treated with prenatal dexamethasone (DEX) showed normal physical development compared to two vehicle-treated, sex- and age-matched animals. MRI of the hippocampal gyrus examined at 9 months of age showed no striking difference between the DEX and the vehicle group. However, the serum concentration of cortisol showed higher base line and post-stress levels in the DEX-treated animals. For the stress study, the infants were isolated from their mothers and kept in a restraining cage for 30 min. The average levels of cortisol were: DEX group: AM=34, PM=25, Post-isolation=52, 1 hr after =48, 2 hr=28; Vehicle group: AM=19, PM=14, Post-isolation=39, 1 hr=20, 2 hr=20 μg/dl). ACTH in the DEX group became elevated to 138 after isolation from 19 pg/ml. Developmental deficiency of the hippocampal neurons caused hypercortisolemia in both base line and post-stress conditions. These results suggest that the hippocampus appears to be a suprahypothalamic site for regulation of the pituitary-adrenal axis. (Supported by NIH RR00167.)

ALTERED CORTISOL RESPONSE TO STRESS AFTER FOUR MONTHS' PRACTICE OF THE TRANSCENDENTAL MEDITATION PROGRAM. C.R.K. MacLean, K.G. Walton*, S.R. Wenneberg, D.K. Levitsky, J.V. Mandarino, R. Waziri[1] and R.H. Schneider, Depts. of Physiology and Chemistry, Maharishi International University, Fairfield, IA 52556 and [1]University of Iowa, Iowa City, IA 52242.

Recent studies on the wild baboon suggest that low basal cortisol levels and high cortisol response to stressors is a more stable, more adaptive profile than its opposite. Previous research on the Transcendental Meditation (TM) technique has reported decreased basal cortisol levels both acutely with the practice and longitudinally. Using a random-assignment, pre-post design, the present research examined before and after the effects of four month's of TM or stress education class (SEC) on basal cortisol levels and the dynamic response of plasma cortisol to laboratory stressors. Twenty-nine healthy Caucasian males (ages 18-32) were randomly assigned to TM or SEC. Plasma for cortisol was sampled using a continuous withdrawal pump (Dakmed) during a one-hour laboratory stress session (which included three 5 minute tasks) . Samples were assayed for cortisol by RIA (DPC) and statistically analyzed by t-test and ANCOVA.

The decrease in basal cortisol from pretest to posttest was significant for the TM group when compared to the SEC group ($t(2,15) = 2.21$, $p = 0.043$). In addition, the TM group exhibited higher cumulative magnitude of the cortisol values relative to baseline ($F(2,26) = 4.814$ $p = 0.038$) and increased range of cortisol secretion during the session ($F(2,27) = 4.825$, $p = 0.037$). These results suggest that practice of the TM technique is associated with lower baseline cortisol and increased cortisol response to stressors. Such alterations are proposed to result from changes in neural modulation of the hypothalamic-pituitary-adrenal axis by TM practice. ADRENOCORTICAL FUNCTION IN PTSD

Michele Murburg M.D.* University of Washington, VAMC Seattle

Patients with Post-traumatic Stress Disorder (PTSD) have been found to have lower 24-hour urinary free cortisol levels than do controls. To test whether PTSD patients have less cortisol available for release in response to maximal stimulation by ACTH, we administered the ACTH analog Cosyntropin to healthy, medication-free male patients with PTSD and controls. On the study day, i.v. catheters were inserted and 45 minutes later 3 basal blood samples for cortisol were drawn 10 minutes apart. Cosyntropin 0.25 mg. was given i.v., and then cortisol levels were drawn at 15, 30, 60, 90, 120, 150, 180 and 210 minutes. T-tests revealed no differences in RIA-determined basal plasma cortisol (7.8+1.9 vs. 10.5+2.7 mg/dl), or area under the cortisol response curve (4373+366 vs 3265+1197 mgxmin/dl) for PTSD (N=6) or control subjects (N=4) (mean+SD). With the small N tested thus far, there is no evidence for a smaller cortisol response to maximal stimulation with ACTH in PTSD.

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS: DEVELOPMENT AND PLASTICITY

644.1

DEVELOPMENT OF METABOLIC ACTIVITY PATTERNS IN THE VENTROBASAL THALAMUS AND SOMATOSENSORY CORTEX OF THE NORMAL AND BASAL-FOREBRAIN-LESIONED MOUSE. S. Noctor[1], D. Eslin[2], C. Hohmann[3], S. Juliano[1,2]*. Depts. of [2]Anatomy and [1]Neuroscience, USUHS, Bethesda., MD, & [3]Kennedy Krieger Research Inst., Baltimore, MD.

Although a wealth of knowledge exists regarding the morphologic development of the barrel cortex and thalamocortical relations, very little is known about the development of functional activity in these regions. In order to further understand mechanisms that participate in development of the barrel field, mice (ages 1 wk to 6 mos) that were either normal or unilaterally basal-forebrain-lesioned (BFL) at birth underwent a 2-deoxyglucose (2DG) experiment. Following the 2DG injection, each mouse was either returned to its cage with whiskers intact, or received bilateral stimulation to a single whisker. At one wk of age, for both normal and BFL mice, although barrels were fully formed as indicated by cytochrome oxidase staining, above background stimulus-evoked 2DG activity was difficult to visualize in the barrel field. At this age the label was distinctly different from the pattern evoked in the adult and occurred in layer 4, the supragranular layers, and layer 6, with a distinct activity gap in layer 5. Activity specifically elicited by stimulation of single vibrissae was smaller in dimension than comparable activity evoked in the adult. At 2 wks of age, the whisker-stimulated activity was greater than that observed in the 1 wk animals, but was not close to the adult pattern until 4 wks of age. In contrast to weak activity observed in the barrel field, the ventrobasal thalamus demonstrated a remarkably high level of 2DG uptake, which was significantly stronger in the 1-2 wk old animals compared to the 4 wk old animals. At early developmental ages 2DG uptake in the somatosensory cortex ipsilateral to the BFL did not significantly differ from the contralateral or normal hemispheres. Supported by RO7064.

DEVELOPMENT OF NON-NMDA GLUTAMATE RECEPTORS IN RAT BARREL FIELD CORTEX. M.E. Blue*, M.Fotuhi, T.M. Dawson, S.H. Snyder and M.V. Johnston. Kennedy Krieger Research Institute and Depts. of Neuroscience and Neurology, The Johns Hopkins Univ. Sch. of Med. Baltimore, MD 21205.

The ontogeny of ionotropic (AMPA) and metabotropic (mGluR) glutamate receptors in barrel field cortex was studied in rats between postnatal ages P4 and P17 and in adults. To examine mGluR sites, flattened sections of cortex were labeled using ^{3}H-glutamate with AMPA and NMDA displacers. Autoradiographically labeled mGluR sites form a vibrissa-related map at P4, with higher densities of receptors in barrel centers than in barrel septa or surrounding tissue. Densities of mGluR sites in barrels reach their highest levels on P10 and then decline. Over time, the difference in density between barrel centers and surrounding tissue becomes less striking. At P10, the difference in density between barrels and surrounding cortex is 42% (2.94 versus 2.34 pmol/μg protein), in the adult, it is only 13% (1.69 versus 1.50 pmol/μg protein). The ontogeny of mGluR sites also was examined using an affinity purified antibody to the mGluR1 receptor which recognizes both α and β isoforms. Staining of mGluR receptors is enhanced in the immature brain, with greater concentrations of mGluR1 immunoreactivity in barrel centers than in septa and surrounding cortex. Within barrel centers, numerous varicose processes (presumably axonal) are stained. Relatively few neurons within the barrels are stained compared to surrounding cortex; these immunoreactive cells are predominantly located in barrel walls and are often contacted by immunoreactive boutons. In the adult, the relatively low density of staining in barrels contrasts with that in surrounding cortex; many fewer neurons and processes are stained. Ionotropic sites, labeled with ^{3}H-AMPA, show a contrasting developmental pattern of expression to that of mGluR sites. At all ages examined, barrel centers contain fewer AMPA sites than barrel septa or surrounding cortex. The density of AMPA sites increases to its highest value at P17 (1.95 pmol/mg protein) and then declines slightly to the adult value (1.76 pmol/μg protein). These results show a differential ontogeny of AMPA and mGluR receptors. Based on distribution and timecourse, the mGluR sites appear more likely to influence the process of barrel formation. Supported by NIH grants NS28208 and NS29167.

644.3

DEVELOPMENT OF CORTICO-CORTICAL CONNECTIONS IN THE PRIMARY SOMATOSENSORY CORTEX OF KITTENS. R. Sonty, R.A. Code*, S.L. Juliano. Dept. of Anatomy, Cell Biology, and Neuroscience, USUHS, Bethesda, MD 20814.

Stimulus-evoked metabolic activity in the primary somatosensory cortex (SI) of kittens is initially more diffuse and less distinctly patch-like than in adults, but becomes patchy and nearly adult-like by 5 weeks of age. To examine a possible anatomical substrate underlying these metabolic changes, we studied the development of SI cortico-cortical connections using DiI. Crystals of DiI were implanted in post-mortem, fixed SI of kittens yielding typical injection sites of about 1250 μm. Tissue was examined using confocal microscopy, fluorescence microscopy, and Nissl staining. At 3 days of age, there was a single, dense, continuous band of label in layer V, 750 μm deep to the cortical surface, spreading for long distances from the injection site. The label extended into the subplate where labelled cells were seen. At 6 days of age, the label was present as two distinct bands. A superficial, discontinuous, 400 μm thick band located in the cortical plate and a deep, continuous, 350 μm thick band located in layer V. A few labelled cells were seen in the subplate. At 9 days age, the label was present in two bands as given above, but fewer labelled cells were found in the subplate. At all ages, many cells with large nuclei, of varied morphology (including pyramidal and fusiform), and with complex dendritic branching were seen. The transformation of the diffuse, horizontally connected SI cells into discretely connected, patch-like clusters may serve as a basis for the observed change in the pattern of evoked metabolic activity. In turn, both phenomena may be activity-dependent. Supported by NIH Grant NS24014.

THE LAMINAR DISTRIBUTION OF CHOLINE ACETYLTRANSFERASE IMMUNOREACTIVITY DURING POSTNATAL DEVELOPMENT IN THE PRIMARY SOMATOSENSORY CORTEX OF THE CAT. C.S. Heck[1] and P.A.McKinley[2]. [1]Department of Physical Therapy, The University of Western Ontario, London, Ontario N6G 1H1, and [2]School of Physical and Occupational Therapy, McGill, Montreal, Quebec H3G 1Y5.

Acetylcholine has been implicated as playing an important physiological role in the modulation of several brain functions. Since choline acetyltransferase (ChAT) is presently regarded as the most definitive and reliable marker for the localization of cholinergic neurons, we decided to investigate the changes that occur in laminar distribution of ChAT during the postnatal development of the primary somatosensory cortex (SI) in cats, and furthermore, to compare its distribution with that of acetylcholinesterase (AChE) during the same time period. The immunohistochemical demonstration of ChAT in the layers of SI cortex was carried out in cats at various ages between 4 and 144 days of postnatal age. Results indicated that immunolocalization over the developmental period studied could be characterized by 3 distinct phases: 1) restriction of stained cell processes to the interface of layers V and VI at 4 days, 2) by 14 days, immunoreactivity was detected in layers I, V and VI, and 3) from 28 days onwards, positively labelled structures were localized in layers I, interface between IV and V, and interface between V and VI. Furthermore, the co-localization of ChAT and AChE shows a high correlation during the developmental period studied. The time course of development of cholinergic innervation appears to relate well to that of overall maturation of cortical structure and function.

CHANGES IN CORPUS CALLOSUM INPUTS TO BARREL FIELD DURING POSTNATAL DEVELOPMENT IN ALBINO RATS REVEALED BY DiI. L. Zhang*[1], A.J. Elberger[1] and N.G.F. Cooper[2]. [1]Dept. of Anatomy and Neurobiology, University of Tennessee, Memphis TN 38163; [2]Dept. of Anatomical Sciences and Neurobiology, University of Louisville, Louisville KY 40292.

In adult albino and pigmented rat SI cortex, the corpus callosum (CC) inputs to the barrel field in layer IV were shown to fill the septae outlining the barrels (Koralek et al., J. Comp. Neurol. 1990). The developing CC projections to rat SI cortex have not been examined in tangential sections. Studies of the development of thalamocortical (TC) inputs to the barrel field of albino and pigmented rats have shown that TC inputs fill the hollow core of the barrel from postnatal day (PND) 2 (day of birth=PND 1) to adult (e.g., Zhang and Cooper, Ann. NY Acad. Sci. 1991). In the present study we have examined the development of CC inputs to the barrel field by placing crystals of the carbocyanine dye, DiI, in the mid-sagittal CC in aldehyde-fixed tissue from PND 1 to adult in albino rats. Tangential sections 100 μm thick were examined with epifluorescence using a standard rhodamine filter set.

The CC inputs do not form a detectable barrel pattern until after PND 5. By PND 9 the CC input takes the form of filled hollows throughout the barrel field. At PND 14 and 17 the CC inputs are in a state of transition, with filled hollows in the anterolateral 2/3 and filled septi in the posteromedial 1/3 of the barrel field. At PND 24, 27 and adult the CC barrel field input is restricted to filled septae. Thus, the CC input to the barrel field in albino rats changes substantially during development; results from pigmented rats will be compared. Supported by NIH grants EY08466 (AJE) and EY02708 (NGFC).

α_1 ADRENOCEPTOR DISTRIBUTION IN THE BARREL CORTEX AND THE EFFECTS OF VIBRISSECTOMY AND NOREPINEPHRINE DEPLETION. A. Dunn-Meynell* and B.E.Levin, Neurol. Svc., VA Med. Ctr., Tremont Ave., E. Orange, NJ 07018

α_1 adrenoceptors (α_1AR) modulate neuronal firing and therefore may be involved in the metabolic plasticity seen in adult rat barrel cortex following vibrissectomy. α_1AR distribution in the adult rat barrel cortex was assessed autoradiographically using 1 nM ^{3}H prazosin with nonspecific binding defined in the presence of 100 μM phentolamine. In coronal sections, a discontinuous band of high prazosin binding was seen in layer IV of the somatosensory cortex. In tangentially sectioned cortices, the pattern of barrels was defined by the contrast between higher levels of binding in barrel septae (267±10 fmol/mg protein) than in the barrel centers (229±11 fmol/mg protein). Chronic (2 mo) total vibrissectomy with sparing of the C3 whisker produced no apparent change in α_1-AR density or distribution. However, 2 months after cortical norepinephrine depletion by unilateral locus coeruleus lesioning with 6-hydroxydopamine, specific binding was increased 16.4% over the unlesioned side, P=.057). Results therefore suggest an upregulation of α_1AR in layer IV of the barrel cortex but show little effect of spared C3 vibrissectomy on α_1AR regulation in the adult. Supported by the Research Service of the Department of Veterans Affairs.

THE EFFECT OF CORTICAL ACETYLCHOLINE DEPLETION ON SENSORY PROCESSING IN RATS. S.E. Jacobs[1]* and S.L. Juliano[1,2], Dept. Anat.[1] and Dept. Neurosci.[2], USUHS, Bethesda, MD

A number of studies have proposed a role for acetylcholine (ACh) in learning and memory, yet almost no research has explored its impact on sensory discriminative behavior. We studied the role of ACh on a rat's ability to perform a task of tactile sensory perception. Rats were trained in a T-maze to discriminate between a deflection of the vibrissae and a sham deflection. When a pre-determined level of performance was achieved, rats received either a sham lesion (SL) or an excitotoxic lesion of the basal forebrain (BFL). Behavioral testing continued until pre-lesion criteria were again met. All SL rats were immediately able to perform at pre-lesion levels. All BFL rats experienced difficulty with the pre-learned task. In addition, there was a strong correlation between the number of sessions it took the BFL rats to re-achieve criteria and the degree of cortical ACh depletion. A terminal 2-deoxyglucose (2-DG) experiment conducted on all rats allowed us to compare functional activity evoked by whisker stimulation in the somatosensory cortex with the behavioral performance. While all BFL rats returned to pre-lesion criteria, their 2-DG maps showed continued reduction of somatosensory cortical activity. This pattern of 2-DG activity is similar to that found in earlier studies from our lab where the animals sustained relatively short-term ACh depletion. Supported by RO7064.

PARALLEL DISTRIBUTED PROCESSING IN SOMATOSENSORY CORTEX: EFFECTS OF SII INACTIVATION ON SI RESPONSES IN CAT. A.B. Turman*†, J.W. Morley and M.J. Rowe. School of Physiology and Pharmacology, Univ. of NSW, and †Dept. of Biol. Sci., Faculty of Health Sciences, Univ. of Sydney, NSW, Australia.

The first and second cortical somatosensory areas (SI and SII) in primates appear to be organized in a serial scheme in which tactile information is conveyed from the thalamus to SI and thence to SII. However, in the cat, the SII responses are largely independent of SI although some facilitation appears to be exerted by SI on a small proportion (20 %) of SII neurons. In the present study we have used a very rapid, reversible procedure based on cooling to inactivate the forelimb SII area in order to extend previous investigations (Burton and Robinson, Somatosen. Res. 4, 1987) on whether responses in the SI area of the anesthetized cat are independent of the SII area. The distal forelimb areas in SI and SII were initially mapped by recording surface evoked potentials and a circular metal cooling block (6 mm diameter) equipped with a Peltier thermal cooling device was positioned over the distal forelimb focus of SII. Inactivation of SII by cooling, usually to 8-13°C, left SI evoked potentials intact in half the experiments or reduced in amplitude in the other half. The effects of SII inactivation on the responsiveness of single SI neurons activated by tactile stimulation of the glabrous or hairy skin of the forelimb were investigated before, during and after SII inactivation. The response level (impulses/s) remained unchanged in half the SI neurons studied, while there was a reduction in response in the other half. These results suggest that in the cat, the responsiveness of SI neurons to tactile stimulation depends to some extent on the functional integrity of SII. (Supported by NH&MRC and ARC).

EVIDENCE FOR RAPID CHANGES IN THE RECEPTIVE FIELD ORGANIZATION OF SI CORTEX IN SQUIRREL MONKEY: AN INTRACELLULAR RECORDING STUDY COMBINED WITH REVERSIBLE DEAFFERENTATION. R.S. Waters*, C.X. Li. Dept. of Anatomy and Neurobiology, UT, Memphis, Col. of Medicine, Memphis, TN 38163.

The ability of the cortex to rapidly reorganize following peripheral nerve injury suggests the unmasking of previously undetected inputs. We examined intracellularly recorded evoked responses in SI cortex following reversible deafferentation of the ulnar nerve and then re-examined SI cortex for changes in receptive field organization. We report that removal of peripheral nerve input from a single nerve alters the responsiveness of SI neurons and that the effect is reversible.

Adult squirrel monkeys were anesthetized with Ketamine (35mg/kg), the head and left arm were stabilized in custom made holders, and the ulnar nerve was exposed and placed on a pair of cuff-stimulating/recording electrodes; the nerve was also placed upon a modified cooling device. Following forepaw preparation, the contralateral SI cortex was exposed, and an acrylic recording chamber was fashioned on the surrounding bone. Carbon fiber electrodes were used to record evoked responses elicited by mechanical and/or hand held stimulators, and the forepaw region of SI cortex was identified and mapped. An intracellular electrode was then inserted into the forepaw representation in SI and the receptive field of the recorded neuron was identified in terms of suprathreshold and subthreshold components. The mechanical stimulator was then fixed to stimulate either component on the skin surface, the ulnar nerve was reversibly deafferented, and the receptive field was reexamined. Using these techniques the following result is noteworthy:

1. Following deafferentation, subthreshold responses may be altered and/or elevated to suprathreshold firing levels. These results bear directly on the unmasking process.

RADIAL NERVE INPUT TO THE MEDIAN NERVE REPRESENTATION IN MONKEY AREA 3B. *C.E. Schroeder *, S. Seto, M. Steinschneider, J.C. Arezzo and P.E. Garraghty. Depts. Neurosci. & Neurol., Albert Einstein Coll. Med., and Dept. Psychology, Indiana Univ.*

The pattern of reorganization in Area 3b of adult primates after median nerve section suggests that somatic afferents carried by the radial nerve have preferential access to median nerve territory. A likely mechanism underlying preferential access is pre-existing, but silent, radial nerve inputs. We tested this by comparing effects of electrical stimulation (100μsec, 4-6mA, 2/sec) of median versus radial nerve, on responses in the median nerve representation of Area 3b. Laminar current source density and multiunit activity profiles were recorded with linear array multicontact electrodes spanning the laminae of Area 3b. Isolation of peripheral nerve stimulation was confirmed by simultaneous recording of EMG from appropriate distal muscles. Repeated sampling of one site was obtained with an implanted electrode in a squirrel monkey anesthetized during recording. Subsequent sampling was conducted during acute penetrations in an awake (conditioned) macaque. In both monkeys, compared to colocated median nerve responses, radial nerve responses typically had longer latencies (by 11-16 msec), lower amplitude, longer duration, more variability and different laminar distribution. Since median and radial nerve primary cortical responses differ by only 1.8 ms: 1) the latency difference is not due to differences in median and radial nerve conduction times to cortex; 2) the "delayed" radial nerve response is not due to a trivial cause such as volume conduction. Rather, it may reflect indirect or extralemniscal input. (MH06723 and DC00657).

644.11

THE EXTENT OF CORTICAL REORGANIZATION AFTER NERVE INJURY IS LIMITED BY THE CONTENT OF THE DEPRIVATION. P.E. Garraghty*[1,2], D.P. Hanes[2], S.L. Florence[2] and J.H. Kaas[2]. [1]Dept. of Psychology, Indiana Univ., Bloomington, IN 47405 and [2]Dept. of Psychology, Vanderbilt Univ., Nashville, TN 37240.

When multiple digits are amputated in adult monkeys [JCN, 224 (1984) 591], cortical reorganization is incomplete. Yet when a much larger area of cortex is deprived by transection of the median and ulnar nerves, deafferenting the entire volar surface of the hand [PNAS, 88 (1991) 6976], apparently complete reorganization ensues, with the dorsum of the hand and digits expanding their representations. Is it possible that incomplete reorganization follows multiple digit amputation because both the dominant and preferred latent set of inputs have been removed (i.e., the glabrous and hairy surface of given digits). We report here on squirrel monkeys in which the ulnar and radial nerves were transected and ligated. This manipulation completely eliminates both glabrous and hairy surface inputs from D5, ulnar D4, and the ulnar hand. Yet the total amount of cortex deprived is less than with median and ulnar nerve cut. We find in these animals, as in monkeys with multiple digit amputations, that cortical reorganization in areas 3b and 1 is incomplete. Large sectors of deprived cortex are unresponsive to cutaneous stimulation, though noncutaneous stimulation can frequently drive responses. Thus, the specific pattern of peripheral deafferentation and not the absolute amount of deprived cortex limits the extent of reorganization that is possible. (Supported by N.I.H. NS16446 and HD15052.)

644.12

THE ORGANIZATION OF SOMATOSENSORY AREA 3A IN THE NEOCORTEX OF THE FLYING FOX (*PTEROPUS POLIOCEPHALUS*). S. Finnigan, L. Krubitzer*, J. C. Clarey, and M. Calford. VTHRC, Department of Physiology and Pharmacology. University of Queensland, Australia 4072.

Although there is some evidence for the existence of a deep representation rostral to 3b in a number of mammals, there are no descriptions of the overall organization of this deep rostral field, area 3a, in any mammal. Because neurons in 3a respond to joint manipulation and hard taps to the body surface, it is believed to be involved in proprioception and motor control. Thus, how this field is organized and interconnected with cutaneous representations and motor cortex is of great interest. The flying fox was chosen to study the organization of area 3a for several reasons. First, as an archontan, the flying fox shares a close phylogenetic relationship with primates, and information gained on the somatosensory cortex of the flying fox may be applicable to all archontans, including primates. Second, much is already known about the organization and connections of somatosensory cortex in the flying fox. Finally, the flying fox has a smooth neocortex and most of 3a is on the dorsolateral surface. In many primates, 3a is inaccessible because it is located on the fundus of the central sulcus. Using microelectrode recording procedures, receptive fields were obtained for single neurons and neuron clusters at a number of closely spaced sites across the cortex, and detailed maps of area 3a were obtained. In these same animals, the myeloarchitecture of 3a was matched to recording sites and architectonic borders were added to physiological maps. Most neurons in 3a responded to light pressure and joint manipulation, although some neurons responded to cutaneous stimulation as well. Receptive field sizes for neurons in 3a varied from very small (located just on distal digit 1), to very large (located on the trunk and portions of the forelimb). Mediolaterally, the topographic organization of 3a mirrored that of 3b, although 3a appeared to be less topographically precise than 3b. In cortex that has been stained for myelin, 3a stains very lightly relative to 3b caudally and motor cortex rostrally.

644.13

INTERHEMISPHERIC CONNECTIONS OF SOMATOSENSORY CORTEX IN THE FLYING FOX (*Pteropus poliocephalus*). L. Krubitzer, R. Tweedale, J. C. Clarey, and M. Calford*. VTHRC, Department of Physiology. and Pharmacology, University of Queensland, Australia 4072.

The precise role of the corpus callosum in connecting the two cerebral hemispheres is unknown. However, we do know that cutting the corpus callosum in humans results in unique impairments in coordinating opposite sides of the body. One theory is that the corpus callosum fuses midline representations in the somatosensory and visual systems so that an integrated sense of the body and visual world is formed in the neocortex. In the present investigation we examined the connections of area 3b, 1/2, SII and PV with the opposite hemisphere in the flying fox. Using microelectrode recording procedures, the area of interest was mapped in detail and anatomical tracers were restricted to that area. Cortex was flattened and cut parallel to the cortical surface so that areal patterns of connections could be observed. Alternate sections were processed for anatomical tracers or stained for myelin, and a comprehensive reconstruction based on electrophysiological mapping, cortical connections, and myeloarchitecture was obtained. Injections in 3b resulted in very sparse connections with 3b in the opposite hemisphere regardless of the body part injected. Most connections were with the lightly myelinated area 1/2 interspersed within 3b. Connections of area 1/2 were moderate to dense with area 1/2 in the opposite hemisphere. Injections in SII resulted in dense label in the contralateral SII, and sparse label in VS and area 1/2 in representations similar to those injected. Finally, injections in PV resulted in moderate to dense transported tracer in PV, SII and VS in the opposite hemisphere, in representations similar to those injected. Our results indicate that midline body part representations are not preferentially interconnected. Another interesting finding was that anterior parietal areas , 3b and 1/2, were only sparsely to moderately interconnected between hemispheres, while lateral parietal fields such as SII and PV were more densely interconnected.

644.14

PATHWAYS OF INTERHEMISPHERIC TRANSFER OF DYNAMIC PLASTICITY REVEALED BY FOCAL COOLING OF SOMATOSENSORY CORTEX. J. C. Clarey*, R. Tweedale, and M. Calford, Vision, Touch, and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, Australia 4072.

A small denervation in the periphery results in an immediate expansion of the neuronal receptive field representing the affected body area in primary somatosensory cortex (area 3b) in *both* hemispheres (Calford & Tweedale, Science 249: 805, 1990). This expansion is explicable in terms of a rapid unmasking of existing but normally inhibited inputs, and is termed dynamic plasticity here. Since each half of the body is represented in the contralateral hemisphere only, it is likely that these plastic changes are transferred to the ipsilateral hemisphere via the corpus callosum. However, in the animal under study (flying foxes), the callosal connections of area 3b are sparse, while those of an adjacent and interconnected somatotopically-organised field (area 1/2) are relatively dense (see Krubitzer et al., this meeting). To uncover the pathway(s) responsible for the interhemispheric transfer of dynamic plasticity, focal cortical cooling experiments were performed in adult, ketamine-anaesthetised flying foxes (*Pteropus scapulatus*). Cooling the forelimb digit 1 (D1) representation of area 3b, until neural activity beneath the cooling probe decreased, resulted in an expansion (of approximately 2-4 times in area) of a D1 receptive field (RF) recorded from an extracellular microelectrode in area 3b of the opposite hemisphere (n=8). The RF rapidly contracted to its original dimensions when the cortex was rewarmed to normal temperatures. Expansion and contraction of D1 RFs in area 3b of *both* hemispheres was also obtained when the D1 representation of area 1/2 in one hemisphere was cooled and rewarmed (n=2). In two other animals, this effect was observed only in the area 3b RF ipsilateral to the cooling probe. These results suggest that blocking the callosal pathway(s) produces a disinhibition that allows unmasking of large RFs and is probably mediated by the interhemispheric connections of area 1/2 via its intracortical connections with area 3b.

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS: PSYCHOPHYSICS AND NETWORKS

645.1

BODY SITE DIFFERENCES IN SENSITIVITY TO HEAT PAIN AND COOLNESS. J.D. Greenspan* and D.J. Taylor, Depts. of Neurosurgery and Physiology, SUNY Health Science Center, Syracuse, NY 13210

Thresholds for 1) slight heat pain, 2) moderate heat pain, and 3) coolness were determined for 32 subjects at four body sites, bilaterally: thenar eminence, dorso-lateral forearm, lateral calf, and plantar surface of the foot. A multiple staircase procedure was used to assess all three thresholds within the same session.

Heat pain thresholds (both slight and moderate) were significantly higher on glabrous skin sites than on hairy skin sites (ANOVA $F=37.64$, $p<0.001$). In contrast, cool thresholds were lowest on the hand, intermediate on the forearm, and highest on the leg and foot (ANOVA $F=19.94$, $p<0.001$). Heat pain thresholds were slightly higher on the dominant side of the body (mean difference for slight pain = 0.3°C; ANOVA $F=5.72$, $p<0.05$). Cool thresholds were also slightly higher on the dominant side of the body, but not at a statistically significant level (mean difference = 0.4°C; ANOVA $F=1.76$, $p>0.05$). There was a significant trend for heat pain thresholds to increase with repeated testing. Over a 2-3 week period, slight heat pain thresholds increased an average of 0.8°C. In contrast, cool thresholds decreased an average of 0.8°C. over the same time period.

There are highly significant differences in heat pain and cool sensitivity at various body sites. However, dissimilar factors appear to be responsible for the regional variation of these two sensory systems.

INDIVIDUAL MAGNITUDE ESTIMATES CORRELATE WITH NEURAL INTENSITY CHARACTERISTICS. S.J. Bolanowski, G.A. Gescheider* and R.T. Verrillo, Institute for Sensory Research, Syracuse University, Syracuse, NY 13244.

Four distinct channels of information can combine to signal the mechanical aspects of touch (Bolanowski, et al, 1988), the particular combination of channels mediating a given tactile sensation being dependent upon stimulus conditions. For example, a 250 Hz vibratory stimulus of large size (2.9 cm^2) and of low and moderate intensities is signaled only by the Pacinian (P) channel, while stimuli at higher intensities are signaled by both the P and the non-Pacinian II (NPII) channels. Additionally, the P channel includes Pacinian corpuscle (PC) fibers that display entrainment plateaus in their intensity characteristics as obtained with sinusoidal stimuli, while the SA II fibers of the NP II channel do not. Lastly, a psychophysical correlate of neural intensity characteristics are the magnitude estimation (ME) functions which for results averaged across observers approximate power functions. We performed absolute ME experiments on observers [n=5; stimulus frequency, 250 Hz and noise (175-350 Hz); location, thenar eminence; contactor size, 2.9 cm^2 and 0.008 cm^2] to determine if breaks in the individual functions occur since: a) crossing from one information channel (e.g., P) to another (e.g., NP II) should result in a break in the overall function; b) PCs entrain while SA IIs do not and c) averaging data across observers may obscure ideosyncratic relationships. The individual functions obtained were scalloped in shape, as predicted, with breaks correlated with the P/NPII crossover and PC entrainment levels. The breaks correlating with the P channel were eliminated with the noise stimuli, also as predicted and consistent with the fact that noise precludes PC entrainment. Supported by NIH grants DC00380 and DC00098.

DOES PERFORMANCE OF TACTUAL TEXTURE DISCRIMINATION DEPEND ON SCANNING VELOCITY?

Ehud Ahissar[1] and Merav Ahissar[2], *
[1]Dept. of Neurobiology, Brain Research Building, The Weizmann Institute, Rehovot, Israel. [2] Dept. of Neurobiology, Institute of Life Sciences, The Hebrew University, Jerusalem, Israel.

The ability of humans to tactually recognize or discriminate between different textures improves when they are allowed to move their fingers across these surfaces. Several research groups have claimed that the velocity of movement is irrelevant to the subject's performance. Yet, this claim was not tested for naive subjects that were free to utilize their own scanning strategies. Previously, we suggested a model (the "PLL model") predicting that when the task becomes difficult, requiring subjects to reach optimal performance, scanning velocity (V) will depend on the spatial frequency (SF) of the texture (Ahissar and Vaadia (1990) *Proc. Natl. Acad. Sci. USA* **87** (22): 8935-8939). The model further predicts that scanning velocity will change in a way that will keep the resulting temporal frequency (f = V * SF) as close as possible to a preferred value. Three such preferred values were suggested, as expected from the tri-modal distribution (0-15 Hz, 15-50 Hz and 80-250 Hz) of the oscillating frequencies of cortical local oscillators found in the second somatosensory cortex of the monkey. This distribution corresponds also to the distribution of the best frequencies for activating mechanoreceptors in the finger tips of humans and monkeys.

Naive human subjects were tested for tactile recognition and discrimination tasks. The subjects were allowed to choose their own scanning strategies. The locations of the scanning fingers of both hands were sampled in 20 ms time resolution and 0.1 mm spatial resolution by an infra-red, ultra-sonic location detector. The analysis of scanning strategies revealed that when the task became difficult subjects adjusted their finger velocities according to the spatial frequencies, as predicted by the PLL model.

645.4

ROBOTIC TACTILE STIMULATOR FOR NEUROBEHAVIOR EXPERIMENTS WITH PRIMATES. H. Burton* and R.J.Sinclair, Dept. Anatomy & Neurobiology, Washington University Sch. Med., St. Louis, MO 63110

We developed a tactile stimulator for passive stimulus presentation paradigms using mostly "off-the shelf" products. The device provides controlled mechanical stimulation across an extensive range of stimulus patterns with a degree of flexibility previously available only with visual or auditory stimuli. The stimulator automatically positions and moves one of 11 different Nyloprint etched surface strips (20x100mm) linearly against a fingertip with controlled force and velocity. Force resolution is 1 gm and ranges to 1 Kg. Velocity resolution is <5mm/sec and ranges from 10-180mm/sec. Hydraulic pistons damp vibrations during strokes whose maximum length is 280mm. Commercial software integrates stimulator controls with simultaneous recordings from single neuron electrodes. Simple programs present surface strips in any sequence. Different sets of stimulus patterns interchange within seconds, permitting uninterrupted study with varied tactile stimuli. Stimulation is possible with any object by attaching it to the movable, magnetized tablet. Initial observations from neurons in primary somatosensory cortex of *M. mulatta* show ascending, monotonic response functions to differences in groove width of gratings rubbed along the fingertip at different velocities. (Supported by McDonnell Ctr. for Studies of Higher Brain Funct. & NIDCD 00096)

645.5

CONTEXT DEPENDENT MODULATION IN MONKEY SECOND SOMATOSENSORY AREA (SII) DURING ACTIVE TOUCH OF TEXTURED SURFACES. R.J. Sinclair* and H. Burton. Dept. Anatomy & Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Two *M. mulatta* stroked their fingertips over pairs of horizontal gratings and discriminated differences in their groove widths. Hand position and downward applied force were measured. We recorded from 127 single units and compared response periods with similar average force (1) before, (2) during, and (3) after strokes. The hand was stationary in 1 & 3. Task dependent modulation was seen in 6 cells with suppressed activity levels during contact with gratings. Firing rates decreased approximately 150ms prior to hand movement, but increased after movement ended. Comparable modulation was seen in 3 other cells with vigorous responses during strokes over gratings. Firing rates were higher during the hold time before movement began compared to the period following stroke termination. Thus, in both cell types responses depended on behavioral context of the task; either pre or post movement. This resembles sensory "gating" during locomotion or ballistic reaching. Activity changes in condition 1 could reflect anticipating hand motion. Facilitation or inhibition may relate to task relevance or attention. Changed responsivity after strokes (condition 3) may result from altered task requirements. Recordings from VPL and SI neurons in the same animals performing this task showed no similar response modulation. (Supported by NIDCD 00096)

645.6

THE EFFECT OF ATTENTION ON SPATIAL FORM PROCESSING IN THE FIRST AND SECOND SOMATOSENSORY CORTICES. S.S. Hsiao*, D.M. O'Shaughnessy, and K.O. Johnson, Phillip Bard Laboratories of Neurophysiology, Dept. of Neuroscience, The Johns Hopkins University Sch. of Medicine, Baltimore, MD. 21205.

The effect of selective attention on the responses of neurons in the primary (SI) and secondary (SII) somatosensory cortex were studied in a Macaque monkey trained to perform a tactile letter discrimination and a visual light detection task. Embossed letters of the alphabet were scanned continuously across each neuron's receptive field while the animal's focus of attention was switched between the tactile and visual tasks. In the tactile task the animal was rewarded for responding when the letter scanning across its finger matched the letter on the video screen. In the visual task the animal was rewarded for responding when one of 3 illuminated squares dimmed slightly. Because the same tactile stimulus patterns were presented continuously during both tasks differences in the neural responses can be attributed to differences in the animal's focus of attention.

A total of 104 neurons in SI cortex and 158 neurons in SII cortex were studied for attentional effects. The results show that attentional focus plays a major role in somatosensory form processing. Approximately 10% of neurons in SI cortex (3/55 in area 3b and 8/49 in area 1) and 40% of neurons in SII cortex (65/158) were affected. The effects were expressed not simply as an overall change in neuronal excitability but as specific modifications in the patterns of neuronal responses. Two main kinds of attentional effects were observed. The first was a modification of the discharge pattern that occurred before or during the stimuli. These effects were particularly prominent for the target letters. The second was a change in the evoked neural activity between relevant and irrelevant letters. For example, letters following target letter often evoked reduced responses perhaps because the animal had learned that target letters never occurred twice in a row in our design. The first effect may reflect enhanced signal processing for critical stimuli. The second may reflect a variation in signal processing related to the animal's expectation. Supported by NIH R01 NS18787.

645.7

TACTILE RECOGNITION THROUGH INTERMEDIATE SURFACES.

A.J. Brisben, S.S. Hsiao, F. Looft*& K.O. Johnson, Bard Laboratories, Dept. Neuroscience, The Johns Hopkins University School of Medicine, 725 N. Wolfe St., Baltimore MD 21205

The effects of placing an intermediate surface between the fingertip and a tactile stimulus were studied in combined neurophysiological and psychophysical experiments. This investigation had two purposes. The first was to develop the use of intermediates as a method of immobilizing the skin during somatosensory experiments. The second was to study how intermediates, such as gloves, alter somatosensory perception, and how the alterations affect the responses of slowly-adapting (SA) and rapidly-adapting (RA) afferents.

Psychophysical letter recognition experiments were performed on 33 human subjects using various intermediate surfaces, such as paper, different types of tape and surgical gloves. Subjects were asked to identify randomly presented embossed letters with a bare finger, which is the control condition, or with an intermediate between the letter and the finger. Overall, subjects' performance was 60% correct with the bare finger, 58-65% for a range of surgical gloves, and 35-44% for other intermediates, i.e tapes and paper. Mechanical tests performed on the skin with and without intermediates provide a potential explanation for these results. Surgical gloves increased the stiffness of the finger by a factor of 2 or less, permitting the skin to conform to the embossed surface, whereas the other materials increased the stiffness by 2.5-10 times, preventing the skin from conforming to the letters.

Neurophysiological recordings were made from the peripheral nerve of macaque monkeys to study the effects of surgical glove rubber on the spatial and temporal responses of the afferent fibers. The surgical glove rubber produced a significant decrease in RA mean firing rate but had relatively little effect on the response properties of SA fibers. Since the glove intermediate did not diminish perceptual performance, the differential effects on SA and RA responses support the notion that the SA afferents are critical for spatial form perception and the RA afferents encode other aspects of tactile perception.

645.8

A QUANTITATIVE STUDY OF THE CODING OF DIRECTION AND MOTION IN THE SOMATIC SENSORY CORTEX OF AWAKE MONKEYS. S. Ruiz, P. Crespo and R. Romo*. Instituto de Fisiología Celular, Universidad Nacional Autónoma de México. 04510 México D.F.

A first step in the study of the representation of tactile signals in the somatosensory cortex, is to see whether in the neuronal responses there is information regarding the physical properties of the stimuli. We studied the responses of single neurons of areas 3b and 1 in the primary somatic cortex of awake monkeys, to a single 1 mm probe scanned across their receptive field in eight different directions, variable speeds, and constant traverse distance and force. The mean discharge rate of 129 of 178 neurons changed as a function of the speed. No differences were encountered between areas and submodalities, suggesting that neurons in both areas 3b and 1 can encode motion across the skin of the hand. An analysis of variance (ANOVA, F test, $p < 0.05$) detected 129 neurons that varied significantly with the direction of the stimulus. A linear regression model was used to test whether the mean discharge rate varied orderly with the direction of movement. Sixty seven neurons showed good fits to the model, ($p < 0.05$, $r > 0.7$). These observations suggest that single neurons in areas 3b and 1 possess radially tuned functions and that there is a relationship between the directional properties and the speed of the stimulus. It is hypothesized that the direction of the stimulus is encoded across a neuronal population distributed in primary somatic cortex in the form of a neuronal population vector. The research of R. Romo was supported in part by an International Research Scholar Award from the Howard Hughes Medical Institute, DGPAPA-UNAM (Proyecto IN206491) and CONACyT (Proyectos D111-903556 and F0006). R. Romo is a fellow of the Guggenheim Foundation.

645.9

ACTIVITY OF PARIETAL CORTICAL AREA 7B NEURONES DURING ACTIVE AND PASSIVE TOUCH. F. Tremblay*, S.A. Ageranioti-Bélanger, I. Zompa, C.E. Chapman. Centre de recherche en sciences neurologiques, Université de Montréal, Québec, Canada, H3C 3J7.

While it is known that lateral area 7 (7b) in the monkey contains cells with complex somatic and somatomotor response properties, the function of such cells, particularly those related to active hand movements, is at present unclear. In the present study, we were interested in determining if such cells play any role in a task requiring active scanning of textured surfaces. Recordings were performed in 3 monkeys (*macaca mulatta*) trained to discriminate textured surfaces (smooth vs smooth/rough) using either active touch (surface actively explored with digit tips) or passive touch (surface passively displaced under digit tips). The animal indicated the texture of the surface explored by pulling or pushing a lever with the opposite hand. Out of a total of 194 neurones, 45 had a somatic receptive field (RF; 32, somatic only; 13, somatic and visual) while 52 had no somatic RF (28 discharged specifically with Active Hand Movements, AHM units). While modulation was often observed in active (70%) or passive touch (50%), only a few cells signalled differences in texture (6%); such responses were not specific to the active task and no AHM units showed any relation to texture. The results suggest that neurones in area 7b do not play an important role in these relatively simple tasks of texture discrimination, although a role in the analysis of more complex tactile stimuli cannot be discounted. (Supported by MRC-Canada and FRSQ).

SOMATOSENSORY RESPONSES TO HUMAN PARIETAL LOBE STIMULATION. F. Richer*, M. Martinez, M. Robert, J.M. Saint-Hilaire. Serv. Neurologie, Hôpital Notre-Dame, Montréal, QC, H2L-4M1.

We investigated the somatosensory perceptions evoked by stimulation of peri-rolandic as well as lateral and medial parietal cortex in 50 epileptic patients undergoing a presurgical evaluation with intracerebral electrodes. Bipolar stimulation trains were delivered in an incremental sequence at medial and/or lateral contact pairs of stereotaxically-implanted multilead electrodes, while monitoring afterdischarge propagation with electrodes in frontal and temporal lobes. Lateral stimulation evoked: 1) contralateral sensations in rolandic sites, 2) sensations on either or both sides in the opercular region, 3) mostly contralateral sensations in posterior parietal regions. Medially we evoked: 4) ipsilateral sensations in cingulate sulcus (around medial area 5), 5) contralateral sensations in posterior cingulate gyrus, and 6) bilateral sensations of changes in body position (levitation) in the region of the subparietal sulcus. These observations suggest the presence of distinct somatosensory regions in the human parietal cortex, some of which may show some correspondence to those identified in the macaque, such as PE, PEci, and PGm medially and PF and PFop laterally (Pandya & Seltzer, 1982).

645.11

AUTOMATED DETECTION OF 2DG/IMMUNOSTAINED NEURONS IN BARREL CORTEX. *L.S. Hibbard*, J.S. McCasland, and T.A. Woolsey, Departments of Neurology and Neurological Surgery, and Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.*

With detailed immunohistochemical and metabolic maps of the barrel cortex, we expect to see a new picture of barrel function in the patterns of neuronal excitation/inhibition and energy use. These maps are montages of contiguous fields (125^2 μm, using a 40X objective with high NA) of immunostained sections and the corresponding autoradiograms, digitized under computer control. To detect neurons in GAD–stained sections, we correlate templates (averaged images of obvious GAD+ and GAD– cells) with the digitized fields. Potential cell locations in the field–images correspond to maxima in the 2–D correlation function $R = F^{-1}\{F(a)F(b)^*\}$, where a and b are the image and template, and F is the Fourier transform operation. Detection is confirmed for features having high–valued normalized correlation coefficients with the templates. By inspection, false positive and false negative detections in GAD–stained sections are <2% of the detected cells. For each section, image collection (1280 digital fields, 320 Mbytes) and cell detection (>10^4 cells per image set) take 5 hours, running unattended under software control. This system can gather vast amounts of data quickly, and apply analyses to it which are both quantitative and exhaustive. By adjusting the templates, this method may be generalized for other histology preparations.

645.12

CELLULAR MAPS OF METABOLIC ACTIVITY IN ANTIGENICALLY IDENTIFIED NEURONS: A 2-DEOXYGLUCOSE/IMMUNOSTAINING APPROACH TO BARREL FIELD CIRCUITRY. *J.S. McCasland*, L.S. Hibbard, S. Kalmbach and T.A. Woolsey. Department of Neurology and Neurological Surgery, Washington University School of Medicine, Saint Louis, MO. 63110.*

Local circuit axons in barrel cortex do not develop normally without input from the whiskers via the infraorbital nerve (PNAS **89**:1832-1836). This and other evidence suggests that the pattern of connections within and between barrel columns is sculpted by activity, and we reason that the characteristic patterns of metabolic activation in normal behavior (Somat. Mot. Res. **8**:111-116) reflect a dynamic equilibrium disrupted by experimental manipulation. We have developed a new approach to examine cellular patterns of metabolic activation by combining a high resolution 2-deoxyglucose (2DG) technique, glutamate decarboxylase (GAD) immunostaining, and an automated cell detection algorithm (see companion abstract by Hibbard et al.). We compared 2DG labeling densities over GAD+ (presumably inhibitory) and GAD- (mostly spiny stellate and pyramidal) neurons of the awake behaving hamster. GAD+ neurons are heavily 2DG-labeled in every lamina of barrel cortex, more so in layer IV and less in layers II-III. Our data indicate that the ratio of 2DG labeling for GAD+ and GAD- neurons is approximately 2.0 in layer IV, 1.5 in layers V and VI, and 1.3 in superficial layers. These ratios are strongly correlated with overall labeling in their respective laminae, suggesting a dynamic matching between degree of local inhibition and local metabolic activation such that inhibitory influences become more predominant in heavily activated zones. Changes in the pattern of antigenically identified cellular 2DG labeling patterns in the barrel field with different combinations of stimulated whiskers will be evaluated in behaving animals.

Supported by NIH grant NS17763.

OPTICAL INTRINSIC SIGNAL IMAGING OF SOMATOSENSORY CORTEX IN THE RODENT.

S. Narayan*, E.M. Santori, J.Burton and A.W.Toga , Laboratory of Neuro Imaging, Dept of Neurology, UCLA, Los Angeles CA 90024.

The detection of optical intrinsic signals enables the visualization of dynamic functional architecture in mammalian brain cortex. The response is known to be species and modality specific. Here we demonstrate the application of this method to functional mapping of whisker barrel cortex in the rat.

Male Sprague-Dawley rats were anesthetized (inhaled halothane, followed by urethane 1g/kg i.v.) and stereotactically mounted. Prefabricated brass wells were cemented to the skull, centered over the posteromedial barrel subfield (PMBSF). The cortex was exposed, the well filled with artificial cerebrospinal fluid and sealed with a glass window. Contralateral vibrissae A4 to E4 were pulled for 2 seconds at 4Hz. Synchronized digital images were acquired at 640 nm illumination with a slow scan cooled CCD camera. Stimulated images were divided by control images for timepoints post stimulation, and averaged over 20 to 100 trials. Optical intrinsic signals were observed as a focal decrease in reflectance (magnitude 10^{-3} of control) over stereotactically determined PMBSF cortex. The signal has two distinct spatiotemporal components. The first (diffuse) component begins 1.5-2.0 secs after stimulus onset, peaks at 2.5-3.0 secs, falls away by 4.5-5.0 secs, then exhibits an undershoot lasting approximately 3 secs. The second component (coincident with local vessels) begins at 2-2.5 secs, peaks at 4-4.5 secs and dissipates by 5.5-6 secs.

This work demonstrates that optical intrinsic signals may be used to study functional cortical activity in the rat.

645.14

MAPPING FUNCTIONAL PLASTICITY OF RODENT WHISKER BARREL CORTEX USING OPTICAL INTRINSIC SIGNAL IMAGING

A.W. Toga*, S. Narayan, E.M. Santori, & J. Burton, Laboratory of Neuro Imaging, Dept of Neurology, UCLA School of Medicine, Los Angeles, CA.

The functional anatomy of rat whisker barrel cortex was imaged using optical intrinsic signals. Mechanical and electrical stimulation of the vibrissae or upper lip were varied in intensity, frequency, duration and location to determine the plasticity and robustness of the response. A cranial window was created over the contralateral posteromedial barrel subfield, the cortex illuminated with white light and signals digitized and averaged at 640 nm, 550 nm and 850 nm. Stereotactic measurements were made and bony landmarks identified for subsequent mapping and correlation with 2DG studies and histologically defined 3D digital atlases. The pattern within the focal response was not tightly coupled with the cytochrome oxidase patterns observed in this area. However, its location changed in response to stimulation of different vibrissae. The magnitude and shape of the reflectance change was influenced by stimulus characteristics, anesthetic state of the animal, and integrity of the cranial window. The intrinsic signal response could be divided into separate temporal components, lasting up to 6 secs post-stimulation. The latter half contained changes that included reflectance changes in blood vessels. The vascular component of this response may be influenced by the proximity of functionally active sites to one of two blood vessels. Somatosensory cortex is supplied by the middle cerebral artery and venous drainage is accomplished by the parietal and parietal-temporal branches of the superior cerebral vein.

INTRINSIC SIGNAL OPTICAL IMAGING IN RAT SOMATOSENSORY CORTEX
J. J. Gelfand, P. M. Gochin, P. Bedenbaugh, C. G. Gross* and G. L. Gerstein, Dept. of Psychology, Princeton University, Princeton NJ 08544

The responses of somatosensory cortex to tactile stimulation of the forepaw were assessed by intrinsic signal optical imaging. The tips of digits 2 or 5 were repeatedly touched with mechanical tappers while CCD photographs were taken of S1 illuminated by an 800 nm light source. The resulting images showed two highlighted areas about 300 μm in diameter and 500 μm apart. Electrical recording in the areas highlighted during stimulation yielded receptive fields appropriate for the stimulated digit and and not the other digit. Penetrations between the highlighted areas had receptive fields on intervening digits. These results demonstrate that intrinsic signal optical images are obtainable in S1 and confirm the functional somatotopy previously reported using electrical recording. Furthermore, the short time required to produce the images and the spatial resolution suggest that optical recording could be used for the study of cortical reorganization in this brain region. Attempts to image activity from the hindpaw, and from adjacent digits of the forepaw yielded only weak and inconsistent signals. Furthermore, we have also been unable to detect acoustic activation of rat auditory cortex although we have replicated results of others in the cat [Frostig et al. 1990], demonstrating orientation stripes in visual cortex. These observations may foreshadow limitations, or at least difficulties which may be encountered in the use of the optical imaging method.

645.16

COMPUTER SIMULATION OF THE DYNAMICS AND PLASTICITY OF SOMATOSENSORY CORTEX
J.Xing* & G.L.Gerstein, Dept. of Physiology, Univ. of Pennsylvania, Philadelphia PA 19104

Recent experimental evidence has clearly demonstrated the functional plasticity of somatosensory cortex in adult animals. A computer model is set up to understand the activity of somatosensory cortex and the fundamental mechanism of the plasticity. The model is a 3-layered feedforward neural network, corresponding to skin, subcortex and cortex. In addition to receiving the input from thalamus, cortical neurons can also be stimulated directly mimicking microstimulation. There are both excitatory and inhibitory lateral connections among cortex neurons. Neuronal activity in the network is simulated by MacGregor's PTNRN10, which produces action potentials and in so doing causes post-synaptic potentials. The excitatory connective strengths are modifiable by general Hebbian rule. Repeated stimulation of the skin layer resulted in the formation of neuronal groups, as has been reported by Pearson. (1987, J. Neurosci.). The sizes of groups are determined by the underlying excitatory connection, irrespective of the training stimuli. The sharpness of groups is largely dependent on the balance between total lateral excitation and inhibition in the cortical network. Groups can not be formed in the absence of distant inhibition. The receptive fields of neurons in the same group have similar locations, but their sizes vary dramatically. Both intensive stimulation of a restricted skin area and simulated cortical microstimulation can result in "regrouping" in the cortex and the subsequent changes in receptive field sizes and locations. However these changes occur at different time scales for the two manipulations. Individual neuron firing patterns and measures of assembly organization are changed by training. NIH-MH46248.

REFLEX FUNCTION II

646.1

DISRUPTION OF SENSORIMOTOR GATING OF THE STARTLE RESPONSE BY RU24969 AND DOI.
T.A. Sipes* and M.A. Geyer. Department of Neuroscience, UCSD, La Jolla Ca 92093.

Prepulse Inhibition (PPI) refers to the attenuation of the startle response (SR) due to the prior presentation of a subthreshold prestimulus and is presumed to reflect sensorimotor gating mechanisms. Sensorimotor gating deficits in schizophrenics can be mimicked in rats with manipulations of a variety of neurotransmitters, including dopaminergic, glutamatergic, GABAergic and cholinergic systems. Based on the report of a disruption of PPI by 8-OH-DPAT (8-hydroxy-2(di-n-propylamino)tetralin), a selective agonist for the 5HT1A receptor, the present studies determined the effects of other selective serotonin agonists on PPI. Male Sprague-Dawley rats were received RU24969 (0.3 - 1.2 mg/kg. s.c.) or DOI (2,5-dimethoxy-4-iodoamphetamine) (0.125 - 0.5 mg/kg, s.c.) 10 min prior to testing with a series of high and low pulse (105, 120dB) and prepulse (75, 85dB) intensities and air puffs (50 psi). RU24969, a 5HT1B/1A agonist, disrupted acoustic-acoustic but not acoustic-tactile PPI, while increasing tactile startle. DOI, a 5HT2/1C agonist, also disrupted PPI, primarily at the lowest prepulse intensities. These findings further implicate a role for serotonin in sensorimotor gating mechanisms.

646.2

SYNAPSES IN VENTROLATERAL PONS (VLP) AND RETICULARIS PONTIS CAUDALIS (RPC) MEDIATE ELECTRICALLY EVOKED STARTLE.
P.W. Frankland* and J.S. Yeomans, Dept. of Psychology, University of Toronto, Toronto M5S 1A1, Canada.

Circuits for the acoustic startle reflex were analyzed by measuring hindlimb EMG latencies, and testing for collision in hindbrain sites in chloral hydrate anaesthetized rats. In medulla and caudal RPC sites, latencies recorded in posterior biceps femoris had a mean value of 4.5 ms and varied by less than 0.2 ms, when two 0.1 ms pulses were delivered at a 1.0 ms interpulse interval at currents 2.5 times threshold. Latencies in other hindlimb muscles were also reliable, but latencies between muscles varied by up to 2.5 ms. The shortest observed latency following medulla stimulation was 3.0 ms in anterior biceps femoris.

As electrodes moved into rostral RPC and VLP, latencies increased by 0.3-0.4 ms. Collision tests between medulla and rostral RPC or VLP resulted in asymmetry with 0.3-0.4 ms collision intervals, suggesting a monosynaptic connection in RPC (Hempel et al., 1990). Between rostral RPC and VLP sites, or between medulla and caudal RPC sites, symmetric collision was observed suggesting connections by axons. Another increase in latency of 0.3-0.4 ms was observed in rostral VLP sites, along with a second increase in collision interval of 0.3-0.4 ms, suggesting that a second monosynaptic connection in rostral VLP near the rostral periolivary area mediates the startle reflex.

(Supported by NSERCC grant A7077 to J.S. Yeomans).

646.3

RELATIONSHIPS BETWEEN THE MODIFICATION OF ACOUSTIC STARTLE REFLEX BEHAVIOR AND VARIATION IN ITS BASELINE STRENGTH IN RODENTS.
G.P. Bowen, J.A. Barlow & J.R. Ison*. Department of Psychology, University of Rochester, Rochester, NY 14627.

The vigor of the acoustic startle reflex is suppressed if weak irrelevant stimuli occur just prior to the moment of reflex elicitation. Here we show how variation in baseline reflex strength, produced by various manipulations, may influence the degree of suppression. When reflex strength is increased because of an increase in the intensity of the eliciting stimulus, then (1) the initial stimulus has a proportionately reduced effect when expressed relative to baseline strength, but (2) a constant absolute effect, measured by subtracting its effect from the amplitude of the baseline response. In contrast, if reflex strength varies because of other factors, namely (a) age of the animal; (b) diurnal rhythmicity; (c) individual differences; or (d) habituation, then the initial stimulus has a constant proportionate effect when expressed as a ratio of the baseline response, and a greater absolute effect, as more is subtracted from large compared to small responses. These data have implications for understanding the theoretical relations between the levels at which these manipulations may be processed, and practical import for interpreting experiments concerned with sensory function. Calculating the impact of a particular test stimulus on startle responses of different strength has become a contentious exercise, and we suggest that relative measures of response suppression are more useful indices of sensory ability.

646.4

ANATOMICAL CONNECTIONS MEDIATING THE PINNA COMPONENT OF THE ACOUSTIC STARTLE REFLEX IN THE RAT.
E. G. Meloni & M. Davis*. Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT.

The pinna component of the acoustic startle reflex involves an ipsilateral backward movement of the ear in response to an auditory stimulus. Previous studies have demonstrated that the pinna component of startle shows plasticity similar to that of whole body startle (Cassella & Davis, 1986). By identifying the neural circuit mediating the pinna response, it may be possible to isolate areas where plasticity takes place and eventually determine how these changes are brought about at the cellular level.

Fluoro-Gold injected into the posterior auricular nerve which innervates the muscles responsible for the pinna reflex labelled motoneurons located exclusively in the most medial and ventral division of the facial nucleus. Iontophoretic deposits of Fluoro-Gold in this region produced labelling in three major contralateral areas: (1) the ventral part of the nucleus reticularis pontis caudalis (RPC); (2) the ventrolateral tegmental nucleus (VLTg); and (3) the intermediate nucleus of the lateral lemniscus (ILL) and paralemniscal zone (PL). Afferent connections from each of these areas to the facial motor nucleus were confirmed with the anterograde tracer Fluoro-Ruby.

Electrical stimulation of the ventral RPC and VLTg areas produced a contralateral pinna movement whereas electrolytic lesions of these areas reduced the acoustic pinna reflex. No response occurred to stimulation of the ILL or PL regions and lesions of these areas did not diminish the pinna response.

We are currently recording single units in the facial nucleus in freely moving rats. Facial motor neurons that innervate pinna muscles respond to an acoustic stimulus within 5-7 ms. Further studies will record from other nuclei along the pinna reflex circuit.

CONDITIONAL FEEDBACK OF HUMAN MUSCLE SPINDLE AFFERENTS. S.E. Grill, Å. B. Vallbo, W.Z. Rymer* Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892; Univ Göteborg, Göteborg, Sweden; Rehab Institute of Chicago, Chicago, IL

The presence of parallel intrafusal/extrafusal activation may conceivably enable spindle afferents to function as a model reference system. If such a system were in effect, spindle afferent discharge would remain constant during commanded movements; changes in the feedback signal would be conditional upon an error. We evaluated whether there are situations in which spindle afferents display constancy of discharge during movement by recording microneurographically from single human muscle spindle afferents from finger extensor muscles. Subjects made slow (20 deg/sec) ramp movements against various-sized isotonic loads ranging from 2 to 17 % of maximum voluntary torque (MVT).

For most afferents, the discharge rate increased or decreased at the onset of the shortening movement in a step-like fashion. The rate changed little during the subsequent shortening movement (see fig). This was true for 4 of 5 afferents studied, for at least one isotonic load level ($p<.05$). It was not true, however, for all loads studied for each afferent. These findings suggest that conditional feedback may be operational during slow voluntary finger movements but only under certain loading conditions.

IMMOBILIZATION HAS A MINIMAL EFFECT ON MUSCLE AFFERENT RESPONSES TO STRETCH IN A CAT HINDLIMB MUSCLE. M.A. Nordstrom*[1,3], R.M. Enoka[1,2], R.M. Reinking[1], and D.G. Stuart[1]. Depts. of Physiology[1] and Exercise & Sport Sciences[2], Univ. of Arizona, Tucson AZ 85724, and Dept. of Physiology[3], University of Adelaide, Australia.

We studied muscle spindle and tendon organ afferents in cat tibialis posterior muscle after six weeks of right-hindlimb immobilization by splinting. The effects of this protocol on muscle force and fiber cross-sectional area have been reported previously (Nordstrom *et al.*, Neurosci. Abstr. 17:648, 1991; Callister *et al.*, Neurosci. Abstr. 17:649, 1991). Seventy-eight afferents (21 Ia, 34 sp II, 23 Ib) in 12 control and 9 splinted cats were recorded from dorsal-root filaments. Afferent responses were quantified using a ramp-and-hold stretch (3 mm at 5 mm/s with a 2s hold) beginning from two different initial muscle lengths (L_0, optimal for whole muscle twitch & L_0-2 mm). There were no significant effects (ANOVA) of immobilization on axonal conduction velocity, mean or variability of the resting firing rate, initial burst peak frequency, dynamic index or dynamic response. The significant effects of immobilization included: 1) an increased stretch sensitivity of sp II afferents (peak and mean discharge rates during the stretch were 144% and 135% of control, respectively); and 2) increased static length sensitivity of Ib afferents (the static index was 173% of control) and an increase in one index of dynamic sensitivity (148% of control). In all cases, significant differences were only seen with stretch from the shorter initial length. For Ia afferents, there were no significant immobilization effects in any variable. In summary, the effects of immobilization on muscle proprioceptive afferents were relatively minor, and would not appear to pose additional motor control problems for recovery other than the weakness associated with muscle atrophy. Supported by USPHS grants NS 20544, HL 07249, NS 25077, NS 07309 and RR 05675. M.A.N. was a C.J. Martin Fellow of the NH&MRC of Australia.

REFLEX RESPONSES TO UNEXPECTED LOSS OF FOOT SUPPORT IN INTACT AND CHRONIC SPINAL CATS

K.G.Pearson*, M.Gorassini, G.Hiebert and A.Prochazka.
Div. Neuroscience, University of Alberta, Edmonton, AB, CANADA

Adaptive responses to loss of ground contact during gait were compared in intact and spinalized cats. In normal cats, a walkway equipped with a trap door that opened just prior to hindlimb contact was used. Behavioural responses to this perturbation depended greatly on prior experience and the speed of locomotion. For example, in naive cats, the leg entering the hole remained extended for approximately 200 ms after entry whereas after a few trials, extension was aborted after 80 ms and the cat quickly flexed its leg out of the hole. When the cat trotted across the platform, the contralateral hindlimb commenced its swing phase at the time the ipsilateral foot entered the hole and as a result, this led to a prolonged extension into the hole. Spinalized cats whose forelimbs were supported and hindlimbs walking on a treadmill with a hole cut into one side of the belt exhibited responses to loss of ground contact similar to naive, intact cats. During spontaneous walking, latencies to initiation of flexion were > 200 ms and these responses did not change with repeated exposure to the hole. With concomitant perineal stimulation, however, the latencies to initiation of flexion were reduced, but not to the minimal values seen after a few stimulus presentations in intact cats. This indicates that the fast flexion responses in experienced intact animals are supraspinally initiated and dependent on anticipatory set.

A METHOD FOR ELICITING MONOSYNAPTIC REFLEXES IN THE NORMAL CAT. A. Prochazka*, P. Whelan, J.L. Taylor & K.G. Pearson
Div. Neuroscience., University of Alberta, Edmonton, AB, CANADA

H-reflex studies have provided valuable information on monosynaptic reflex (MR) gain during various locomotor tasks[1]. Potentially, MR testing in the cat could provide valuable information on reflex gain in a variety of normal and disordered movements, but so far it has been difficult to elicit stable MR's in the freely moving animal. Our method is derived from the classical work of Lloyd[2], who showed that MR's could be produced by stimulation of the dorsal root (DR) in acute spinal cats. We have found in 4 intact cats that short-latency responses can be evoked in various hindlimb muscles by stimulating at low amplitude via implanted DR electrodes[3]. In a decerebrate cat we found that amplitudes of DR-evoked MR's (DRMR's) rose and fell in parallel with MR's evoked by conventional LG-SOL nerve stimulation. Electrodes on the sciatic nerve and on the dura mater overlying the L5 dorsal spinal quadrant were used to monitor the afferent volleys. Latencies were consistent with monosynaptic transmission around the reflex arc. We conclude that low-threshold, DR-evoked responses at 5-6 ms latency are MR's and that this new approach will allow MR gain to be studied simultaneously in various muscles under a variety of normal and pathological conditions.

QUANTITATIVE ASSESSMENT OF INTERSEGMENTAL REFLEXES BETWEEN THE TAIL AND HINDLIMB IN THE AWAKE CAT. R. M. Friedman*, C. J. Vierck, Jr., and L. A. Ritz. Departments of Neuroscience and Neurosurgery, University of Florida College of Medicine, Gainesville, FL 32610.

We have previously investigated the hyperreflexia observed in segmental reflexes of the tail of cats after a chronic sacrocaudal transection (Friedman et al., 1990, 1991). Here we report on observations of intersegmental modulation of reflexes of the tail and hindlimb. Normal cats were conditioned to receive innocuous electrocutaneous stimulation to the tail and then the hindlimb (or visa-versa). Interstimulus intervals (ISIs) in the condition-test paradigm were 20, 50, 100, 250, 500, and 1000 msec. Quantitative assessments of reflex force were performed by tethering the tail and hindlimbs to strain gauges. At short ISIs we observed facilitation, while at intermediate intervals there was a decrease in amplitude of the test reflex. In addition, conditioning stimulation affected the amplitude of hindlimb reflexes greater than that of the tail. With this approach, we will be able to characterize segmental and intersegmental reflexes prior to and after specific lesions of spinal cord. Supported by grant NS27511.

IPSI- AND CONTRALATERAL AFFERENT INTERACTIONS IN CAT SACROCAUDAL MOTONEURONS. Louis A. Ritz* and Robert M. Friedman. Depts. of Neuroscience and Neurosurgery, University of Florida, Gainesville, Florida 32610

Anatomical evidence from our laboratory has demonstrated that tail Ia fibers project bilaterally and that sacrocaudal motoneurons have bilateral dendritic trees. Sacrocaudal motoneurons, innervating tail muscles, might receive monosynaptic input from contralateral dorsal roots. Intracellular recording techniques were used to investigate contralateral influences on sacrocaudal motoneurons.

In most cases, contralateral input was weakly excitatory, at a latency of 0.7-1 msec longer than that of ipsilateral input. When contralateral and ipsilateral input were combined, there was usually a late augmentation of the compound EPSP, compared to that produced by ipsilateral input alone; occasionally, there was a diminution of the compound EPSP at high stimulus rates. In other cases, the contralateral input inhibited ipsilateral responses at delays of 5 msec or longer. We have thus far found no conclusive physiological evidence for monosynaptic input from contralateral dorsal roots to sacrocaudal motoneurons. Supported by NS27511.

INHIBITORY INFLUENCES OF PERIPHERAL C FIBERS ON THE FLEXION WITHDRAWAL REFLEX IN SPINAL CATS. J.A. McMillan*, J.E. Quisno and J.L. Small. Biology Department and WAMI Program, Montana State Univ., Bozeman, MT 59717

We reported earlier (McMillan et al., 1989, Soc. Neurosci. Abs. 15:918) that the peripheral C fibers contribute little to the flexion reflex (FR) in spinal cats. We report here C fibers can in fact inhibit the reflex.

Experiments were performed on cats initially decerebrated under ketamine anesthesia. The FR, evoked by stimulating the left sciatic nerve at 10 Hz, was monitored by recording isometric tension from the left semitendinosis. To evaluated influences of myelinated vs unmyelinated fibers we added C fibers to, or removing them from, the afferent volleys by adjusting the intensity of the stimuli.

C fibers were consistently excitatory on the FR in the decerebrate state. After cutting the spinal cord (T12-L1), the C fibers typically had either an initial excitatory and subsequent inhibitory effect or just a pure inhibitory effect. In only 1 of 10 cats did C fibers have a pure excitatory effect in the spinal state.

These observations suggest a population of interneurons which are inhibitory on the FR. We propose a model in which these neurons (i) receive more excitatory inputs from C vs myelinated afferents and (ii) are more strongly inhibited by descending inputs than are the interneurons which have excitatory influences on the FR. THE STRENGTH OF RECURRENT INHIBITION BETWEEN LATERAL AND MEDIAL GASTROCNEMIUS MOTONEURONS IN THE CAT M.L. McCurdy* and T.M. Hamm. Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

The strength of recurrent inhibition is reported to be greatest between motor pools that innervate muscles with common periods of activity, within homonymous motor pools, and between motor pools or motoneurons in close proximity (Eccles et al.,1961; Hamm et al., 1987; Hamm, 1991; McCurdy and Hamm, 1991). We evaluated these findings by measuring the strength of recurrent inhibitory post synaptic potentials (RIPSPs) in ischemic decapitate cats by impaling pairs of homonymous or heteronymous motoneurons that innervated the medial (MG) or lateral gastrocnemius (LG) muscles, which are muscles with common activity patterns. RIPSPs were recorded in one motoneuron in response to stimulation of the other motoneuron by injecting brief current pulses.

Results indicate that proximity of these motoneurons was a stronger variable than motoneuron specie in determining the strength of recurrent inhibition of gastrocnemius motoneurons. RIPSPs recorded in homonymous LG, but not MG, pairs and those recorded in MG, but not LG, motoneurons of heteronymous pairs had significantly greater RIPSPs when motoneurons were separated by 1 mm or less than when separated by greater distances. Homonymous pairs of Mg and Lg motoneurons did not have significantly greater RIPSPs in comparison to heteronymous pairs. These results suggest that the pattern of recurrent inhibition within and between the MG and LG motor pools is not symmetric.

Additional analysis revealed that homonymous pairs of motoneurons innervating the muscle anterior-middle biceps femoris had significantly greater RIPSPs than homonymous pairs of MG, but not LG, motoneurons. This result suggests that the strength of recurrent inhibition in homonymous pools is not homogeneous for all species of motoneurons. Supported by NS22454, NS07309 and GM08400.

CONDUCTANCE CHANGES PRODUCED BY RECURRENT INHIBITION IN CAT SPINAL MOTONEURONS. T.M. Hamm* and M.L. McCurdy. Div. of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013.

Both the magnitude and location of changes in conductance during synaptic inhibition can be significant factors in the inhibitory effect (e.g., Rall, 1964; Koch et al., 1983). Previous studies have been unable to detect a conductance increase associated with recurrent inhibition of spinal motoneurons (Smith et al., 1967; Friedman et al., 1981). However, Lindsay and Binder (1991) demonstrated small changes in motoneuron input resistance during sustained recurrent inhibition. Since synapses from Renshaw cells to motoneurons are located on proximal dendrites of motoneurons (Burke et al., 1971; Fyffe, 1991), we thought it important to evaluate the conductance changes associated with recurrent inhibition using a method that determines not only conductance magnitude but also synaptic location. To do this, we have determined motoneuron impedance with and without recurrent inhibition produced by repetitive stimulation of muscle nerves. The preparation used has been the pentobarbital-anesthetized cat with sectioned dorsal roots. Intracellular recordings were made of the voltage response to the injection of a mixture of sinusoidal currents (2.5 - 500 Hz), which provides information on the location of the conductance change (Fox, 1985). Current injection and voltage recording were accomplished with a single glass microelectrode using a discontinuous current clamp. Sets of voltage and current records were then subjected to Fourier analysis to determine power spectra.

Our preliminary data show a small decrease in the voltage response in trials with recurrent inhibition, indicating an increased conductance. The change in the voltage response is greater at lower frequencies (< 300 Hz), consistent with the dendritic location of the synapses in this pathway. These results indicate that the inhibitory effects of recurrent inhibition are attributable to conductance changes in addition to hyperpolarization. Supported by NS22454, NS07309 and GM08400.

CUTANEOUS AFFERENT STIMULATION AND MOTONEURON RECRUITMENT IN THE MEDIAL GASTROCNEMIUS OF THE DECEREBRATE CAT. B.D. Clark*, S.M. Dacko and T.C. Cope. Dept. Physiol & Biophys, Hahnemann Univ., Phila. PA 19102

It is often suggested that Henneman's size principle of recruitment is violated by certain cutaneous inputs which can preferentially recruit large, fast-twitch (F) motor units over small, slow-twitch (S) motor units supplying the same muscle. In the cat, evidence for this view rests on a few cases described in a single study (K. Kanda et al., *Exp. Br. Res.* 29: 55) in which motor units were characterized only by their axonal conduction velocities. In contrast, in our previous report (Cope and Clark, *J. Neurophysiol.* 66: 1127) we found both stretch of the medial gastrocnemius (MG) and electrical stimulation of the caudal cutaneous sural nerve (CCS) to recruit motoneurons in accord with the size principle. The present study describes our attempt to resolve this disagreement. Using simultaneous intra-axonal recording from pairs of motoneurons, we assessed recruitment of physiologically characterized motor units in the MG under stimulation conditions that replicated as closely as possible those of Kanda et al. In agreement with our earlier findings, the relative excitability of the units in 27 out of 27 pairs (including 5 pairs containing one S and one F unit) was the same for the tonic vibration reflex (TVR), pinch of the skin overlying the ankle, or their combination. Furthermore, there was little evidence of inhibition of the firing of small motor units by cutaneous sources; only 1 of 9 type S units and 1 other unit of unknown type showed any slowing from skin pinch or electrical stimulation of the CCS delivered during TVR, regardless of whether electromyograms from the soleus showed that muscle to be excited or inhibited. For the two units that were slowed, this effect appeared only in some of the trials, lasted only for 100-400 msec, and was followed by an increase to firing rates equal to or greater than they exhibited for TVR alone. We conclude that differential activation of motor units by cutaneous afferents in this preparation is rare, variable and, when it occurs, transient. (Supported by NIH NS21023)

THE USE OF NATURAL SENSORY SIGNALS IN FUNCTIONAL ELECTRICAL STIMULATION (FES) SYSTEMS. M. Haugland*, T. Sinkjær, J.A. Hoffer, J. Haase. Department of Medical Informatics and Image Analysis, Aalborg University, Fredrik Bajersvej 7D, DK-9220 Aalborg, DENMARK.

In an experimental cat model, we have previously demonstrated that the tactile sensory information recorded from a whole nerve cuff electrode contains reproducible information about changes in a force applied on the skin. In conformity with the human precision grip, where updating of the motor program during a small slip is based on the triggered phasic activity in glabrous skin mechanoreceptors, an event-driven FES system automatically corrected the "motor" output to the controlled muscles, whenever an object started to slip.

The aim of the present study was to show that it is possible to extract signals from whole nerve cuff electrode recordings in a human cutaneous nerve which contains similar important information as demonstrated in the FES system of the animal model.

Whole nerve cuff electrodes were implanted on the sural nerve of three human subjects in general anaesthesia. All subjects gave their consents and the study was approved by the Local Ethical Committee. The dorsal and lateral parts of the foot were mechanically stimulated using a hand-held probe manipulated by the experimenter. The human sural nerve responses to perpendicular and lateral force input on the skin were nearly similar to the tibial nerve responses found in cat experiments. In both specimens, a large phasic response was detected when a step force was applied on the skin or when the probe slipped along the skin. These findings suggest that FES systems in paralysed humans can be controlled from the natural tactile sensory information in the same manner as shown in the cat experiments.

SELECTIVE RECRUITMENT WITHIN TRICEPS SURAE OF THE DECEREBRATE CAT ALTERS THE DIRECTION OF ANKLE TORQUE PROFILES. S.J. Bonasera, J.H. Lawrence, III, and T.R. Nichols*. Department of Physiology, Emory University Atlanta, GA 30322.

The feline gastrocnemius (G) inserts in a complex manner onto calcaneus. The lateral head (LG) forms a tendon whose insertion is parallel to the long axis of the foot. By contrast, a portion of the medial head (MG) tendon crosses the LG tendon to insert on the lateral aspect of calcaneus. Thus, differential activation of the heads of G can potentially generate torques in different directions. We placed a three-dimensional torque transducer at the ankle joint of unanesthetized decerebrate cats and employed peripheral nerve stimulation to evoke the flexion reflex, crossed-extension reflex (XER), and the sural nerve reflex (SNR). Muscle denervation and successive tenotomy isolated muscle groups of interest. XER and SNR both generated torques with large plantarflexion/toe-out components, but SNR generated torques with consistently higher proportions of toe-out compared to matched XER responses. These data are consistent with prior observations demonstrating selective recruitment of MG during SNR (Kanda et al., *Exp. Brain Res.* 29:57-74, 1977). We have already demonstrated that muscle nerve activation of MG produces larger toe-out torques compared with muscle nerve activations of LG and soleus (S). We conclude that there are interneuronal mechanisms subserving the control of three-dimensional ankle torque through differential activation of MG and LG. (Supported by NIH Grant NS20855).

COMPUTER SIMULATIONS OF FORCE-LENGTH-VELOCITY FUNCTIONS OF A HETEROGENEOUS POPULATION OF MOTOR UNITS. C.J. Heckman* and K. Paul, Physiology, Northwestern Univ. and VA, Lakeside Hospital, Chicago, IL 60611.

The Hill model of muscle is widely used for theoretical studies of limb movements. It assumes that the shapes of the muscle's force-length (FL) and force-velocity (FV) functions do not vary as a function of neural drive. To test whether the FL and FV functions of a heterogeneous population of motor units undergoing normal recruitment and rate modulation conform to this assumption, data on single motor unit FL and FV functions in the cat medial gastrocnemius (MG) muscle were coupled to realistic computer simulations of the steady-state recruitment and rate outputs of the MG motoneuron pool.

The simulation results showed that, at low to moderate input levels, the population FL and FV functions were both much steeper than predicted by the Hill model. The FL steepness was due to the net effects of rate-dependent shifts in optimal lengths of each of the single unit FL functions. The FV steepness occurred because the FV slopes of type S units were steeper than those of F units. These basic results were not sensitive to changes in the input organization to the motoneurons nor to nonlinear summation of motor unit forces.

In conclusion, neither the Hill model nor whole muscle analyses provide an accurate description of intrinsic muscle FL and FV functions. The simulations are being adapted to include steady-state reflex actions to study the contributions of intrinsic and reflex mechanisms underlying the equilibrium point hypothesis.

DIRECTIONAL SENSITIVITY OF DSCT RESPONSES TO HINDLIMB MOVEMENT IN THE CAT. G. Bosco, R. Poppele* Dept of Physiology, University of Minnesota, Minneapolis MN 55455

A large polysynaptic convergence of afferent input onto DSCT cells suggests they may encode information about the whole limb rather than single joints or muscles. We tested this possibility by recording from DSCT units during passive movements of the hindlimb in anesthetized cats.

From a normal standing position, limb configuration (length and sagittal orientation) was manipulated by passively displacing the foot. Spontaneous discharge rates depended on a specific configuration in 70% of the cells tested. There was a maximum discharge rate associated with a single configuration corresponding to a specific foot placement with respect to the normal position. Such tuning was observed for all placement directions except those oriented forward and upward.

Transient discharge patterns were observed during displacements in 95% of the cells and 76% of them exhibited a tuning for a single direction which was either forward and downward 30 deg from horizontal or opposite. Only half of the cells exhibiting both static and dynamic tuning showed the same directional sensitivity for both.

The results illustrate the capability of DSCT cells to encode the configuration of the whole limb and direction of movements.

CONTROL OF POSTURE AND MOVEMENT: ARM MOVEMENT II

647.1

MOVEMENTS TO APPARENT AND TRUE MOTION TARGETS. N.F. Port*, G. Pellizzer, and A.P. Georgopoulos. Brain Sciences Center, VAMC, Minneapolis, MN 55417; and The Graduate Program in Neuroscience, Univ. of Minnesota, Minneapolis, MN, 55455.

Apparent motion is a well known perceptual phenomenon in which visual objects appear to be moving when physically they are a series of still frames. Apparent and real motion were used to assess sensory-motor performance in intercepting targets. Normal human subjects were asked to intercept targets traveling in a square by moving a pointer from the center point to the midpoint of a target's path. In the true motion condition, subjects intercepted a target moving smoothly in a square around the center point. In the apparent motion condition, the target appeared only at the corner points of the square, but the subjects were required to intercept the midpoint of the "apparent moving" target. Target velocities were varied across blocks ranging from 1 deg/s to 9 deg/s.

Subjects successfully intercepted the target in both conditions. Interception of the apparent moving target was slightly but systematically worse than that of the real target. The error in interception increased in an approximately linear fashion with velocity for both types of motion. A similar increase was observed in the variance of the error. These results show that the motor system can successfully utilize information from apparent motion and that visual-motor performance is very similar under conditions of real or apparent motion. (Supported by 1-PSMH48185-01).

647.2

MOVING TO THE SYMMETRICAL DIRECTION FROM A VISUAL STIMULUS. G. Pellizzer[1]*, G. Léone[2], and A.P. Georgopoulos[1]. [1]Brain Sciences Center, VAMC, Minneapolis, MN 55417; Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455; and [2]Lab. de Physiologie Neurosensorielle, CNRS, 75270 Paris, France.

Bilateral symmetry was used to study perceptual mechanisms since the pioneer work of Mach nearly a century ago. Basically, the perception of bilateral symmetry is more salient when the axis of symmetry is vertical, less so when the axis is horizontal, and the least salient when the axis is oblique. We studied the processing of symmetry when the motor system is involved. For this purpose, normal human subjects were tested in a series of experiments in which the stimuli consisted of a red line (axis of symmetry) and a black line starting from the center of the red line and at an angle from it. The orientation of the axis and the angle of the black line were varied. Subjects were asked to make an arm movement (M) in the symmetric direction from the black line (B) relatively to the axis of symmetry (A). We measured the reaction time (RT) and the spatial accuracy. The perception of symmetry was tested in two additional psychophysical tasks. We found that movement RT increased with the angle of the black line. Moreover, the rate of increase varied with the orientation of the axis of symmetry, and was lowest when the axis was vertical. These results suggest that the intended movement direction is mentally rotated from the axis of symmetry toward the correct direction, and that the rate of rotation depends on the orientation of the axis of symmetry. Similar effects were obtained in the perceptual tasks. (Supported by NIH and HFSP).

ROLE OF PROPRIOCEPTIVE INPUT IN THE CONTROL OF INTERACTION TORQUES DURING MULTIJOINT ARM MOVEMENTS. R.L.Sainburg, M.F.Ghilardi, F.Ferraccl, H.Polzner, C.Ghez*. CMBN, Rutgers Univ., Newark, NJ, 07120; Ctr. for Neurobiol. & Behav., Columbia Univ. & NYS Psych. Inst., New York, NY 10032.

We have previously shown that deafferentation disrupts the temporal coordination of multijoint arm movements (Neurosci. Abs. 17:553). We now ask whether this disruption results from failure to control joint interaction torques that develop from motion of mechanically coupled limb segments. We studied horizontal movements in normal subjects and patients with large-fiber sensory neuropathy. Subjects were to trace a series of straight paths in different directions from a central starting position on a digitizing tablet. They were to make single overlapping outward and inward movements reversing direction without stopping. Elbow and shoulder angular displacement and EMGs of elbow flexors and extensors were recorded; hand paths and joint torques were calculated. Controls produced straight paths, with bell-shaped elbow and shoulder joint displacements which reversed direction simultaneously. The patterns of elbow muscle activity varied systematically with movement direction, acting to accelerate the limb or to counter the interaction torques produced by motion of the upper arm. The paths produced by deafferented patients were severely distorted; joint displacement profiles were assymetric and direction reversals at each joint were temporally decoupled.The distortions varied with the direction of movement and reflected the magnitudes of the interaction torques at each joint. Muscle activation patterns did not have a consistent temporal structure and were not matched to the differences in interaction torques. We conclude that proprioceptive input is critical to control the interaction torques which arise during multijoint movements. Supported by NS 227715, NS 25149, McKnight Fnd.

SELECTIVE EFFECTS OF MUSCIMOL MICROINJECTIONS INTO CEREBELLAR NUCLEI IN CATS PERFORMING BOTH A LOCOMOTOR AND A REACHING TASK. M.S. Milak*, V. Bracha, F. Kolb, J.D. McAlduff, J.R. Bloedel, Barrow Neurological Institute, Phoenix, AZ 85013.

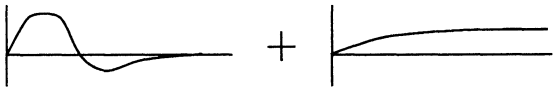
These experiments were designed to test the hypothesis that the individual cerebellar nuclei play different roles in regulating the performance of two different tasks. Each animal was trained to walk on a treadmill while avoiding a bar interjected into each swing phase and to perform a reaching task in which a manipulandum was moved through a grooved plexiglass template in a sequence of 2 straight movements. The effects of muscimol (400 ng) injected into individual cerebellar nuclei ipsilateral to the performing extremity were assessed during both tasks. The EMG was recorded from forelimb muscles, and the kinematics of the same extremity was assessed using an active LED system.

Microinjections in the dentate and fastigial nuclei affected the coordination of the locomotor cycle. Injections in the anterior interposed nucleus (AIN) resulted in an inability of the animal to perform a flexion adequate to avoid the bar, thereby forcing the animal to adapt a different strategy to avoid the perturbation. In the reaching task, dentate injections resulted in a distinct tremor before contact with the manipulandum and an apparent difficulty in smoothly directing the sequence of movements. Injections in the AIN caused marked ataxia before bar contact as well as changes in posture before the initial reach was performed. Even though movements were impaired following these injections, the movement sequences could still be performed and actually improved with practice. NIH Grant R01 NS21958.

647.5

MUSCLE ACTIVATION WAVEFORMS DURING ARM MOVEMENTS OF VARYING DISTANCE. C. Buneo*, J. F. Soechting, and M. Flanders. Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

We have previously shown that during arm movements of fixed distance and varying speed, the amplitude scaling of muscle activation waveforms can be described by a summation of two components: a phasic component that scales with speed (or movement time) and a tonic component that remains relatively constant. In the present study activation waveforms from 7-9 shoulder and /or elbow muscles were examined as human subjects made pointing movements of varying distance and speed to stationary targets aligned in the sagittal plane. All movements were made from a fixed initial position. Movement times ranged from 300-1500 ms.



Observation of the electromyographic (EMG) waveforms revealed that the amplitude of the tonic component was dependent upon the distance of the movement. The amplitude of the phasic component was related more to movement time than to the speed of movement: shorter movement times were associated with more phasic EMG waveforms.

CHARACTERISTICS OF ARM MOVEMENTS IN NORMAL SUBJECTS AND SUBJECTS WITH UNILATERAL BRAIN LESION

CA Giuliani *, P Genova, JL Purser. Motion Analysis Lab, Univ of North Carolina at Chapel Hill, Chapel Hill, NC 27499-7153

The purpose of this study was to characterize the motor control of arm movement during a tapping task in normal subjects and subjects with unilateral brain lesion. A method for analysis was developed to characterize differences between the groups. Data were analyzed from five normal subjects and five subjects with unilateral brain lesion. Subjects were instructed to tap vertically on a target with a stylus. Six trials were videotaped and three trials were digitized at 60 Hz. Variables calculated from the digitized data of a marker on the stylus were: number of tap cycles; mean latent, event, and cycle periods; vertical displacement and velocity. An FFT was performed for each trial, and vertical velocity/position phase planes were generated. Analysis of normal data revealed consistent cycle, event, and latent periods within and across trials with the greatest variability in the latent periods, and for the non-dominant arm. Latent period doublings were more common in the non-dominant arm than the dominant arm, and observed more frequently within the first few cycles of the trial. Analysis of the stroke data revealed increased variability of all variables within and across trials, increased cycle periods, decreased mean velocity, a broader distribution of the frequencies in the power spectrum, and an increased range of vertical amplitude for the hemiparetic limb compared to the contralateral limb. These analyses appear to be sensitive indicators of motor control differences between limbs and for deficits in subjects with unilateral brain lesion.

KINEMATIC ANALYSIS OF PLANAR TWO-JOINT ARM MOVEMENTS IN HEMIPARETIC STROKE. R.F. Beer*, J.P.A. Dewald and W.Z. Rymer. Depts. of Biomedical Engineering and Physiology, Northwestern University, Chicago, IL 60611

There have been relatively few quantitative studies of the disturbed motor performance associated with hemiparetic stroke. Accordingly, we have conducted a preliminary investigation of the kinematics associated with performance of planar two-joint arm movements by a number of moderately impaired subjects.

Subjects were seated in a dental chair in front of a horizontal surface upon which thirteen targets were indicated - 12 located equidistantly along the circumference of a circle and one central marker which served as the beginning point for all movements. A set of straps were used to immobilize the torso and shoulder girdle while the wrist and finger joints were immobilized using a fiberglass cast. Subjects were instructed to move as fast as possible from the central starting point to a designated target without regard to movement accuracy. The OPTOTRAK/3010 motion analysis system was used to track the position of an IRED located distally on the hand. EMGs were recorded from the major flexors and extensors of the elbow and shoulder using surface electrodes. Two sets of experiments were conducted. In the first set, subjects were required to actively generate the anti-gravity torques necessary to maintain the arm in a horizontal plane. In a second set of experiments the protocol was repeated with the upper limb passively supported.

For unsupported movements, trajectories were most disturbed in directions involving shoulder flexion and elbow extension, and hence, increased gravitational torques at the shoulder. Angular velocity profiles were distinctly asymmetric, with a prolonged deceleration phase. Most striking was the positive effect provided by arm support. Trajectories became nearly linear, velocity profiles bell-shaped, with as much as a 300% increase in peak joint velocities. Our results suggest that moderately impaired subjects retained a significant residual capacity to plan and execute goal-directed movements. We are currently examining various hypotheses that may explain the radical deterioration in movements requiring stabilization against gravitational loads.

THE CONTRIBUTION OF VISUAL AND EYE MOTION SIGNALS IN DIRECTING THE ARM TO MOVING TARGETS. P. van Donkelaar, R.G. Lee* and R.S. Gellman. Dept. of Clinical Neurosciences, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Normal human subjects were required to track a moving target with their extended index finger either (i) with full vision of the arm and unrestricted movement of the eyes, (ii) without vision of the arm, or (iii) while fixating a stationary target. The subject initially pointed at the target when it appeared at its starting position. After a variable delay the target started moving to the right and the subject was required to catch up to and follow it as accurately as possible. In each condition target velocity was varied randomly from trial to trial. Under normal conditions subjects were able to catch up to the target and match its velocity. Without vision of the arm subjects did not catch up to the target, but did match target velocity. However, when the arm was visible for the first 100-400 ms of the response the accuracy increased.

When subjects were required to fixate they caught up to the target, but then produced a steady-state hand velocity which was greater than target velocity. This is consistent with studies which demonstrate that target velocity is perceived as greater during fixation. Together these results suggest that extraretinal signals concerned with eye motion are needed to produce an appropriate hand velocity. However, one needs to see the position of the limb relative to the target to produce an appropriate hand position.

VELOCITY OF MOTION INFLUENCES THE PERCEPTION OF HAND TRAJECTORIES IN THE ABSENCE OF VISION. A.H.Fagg[1], S.I.Helms Tillery[2] and C.A.Terzuolo[2]*. [1] Center Neural Eng. Dept. Comp. Sci., Univ. Southern California, Los Angeles 90089 and [2]Dept. of Physiology, Univ. Minnesota, Minneapolis 55455

During naturally executed movements the radius of curvature of the trajectory (T) and the tangential velocity are related by a power law ($V_{(t)} = kR_{(t)}^{1/3}$). Thus one can ask if the recognition of curvilinear Ts can be altered by imposing different velocity profiles (vps). A robot arm was used to transport repetitively the hand along a circular T which engaged primarily shoulder and elbow joints. Three vps were used corresponding to a circle (C) or an ellipse with either an horizontal (B) or vertical (A) major axis. Data from 16 subjects show that vp significantly affects the identification of T as a circle ($F(2.45) = 22.1$, $p < .001$), a horizontal ellipse ($F(2.45) = 38.59$, $p < .001$) or a vertical ellipse ($F(2.45) = 118.19$, $p < .001$). In addition, perception of tilted ellipses was frequent for conditions A and B. This illusion, which during passive movements depends exclusively on kinesthetic inputs, is taken to suggest that $V_{(t)}$ contributes to the perception of curvilinear Ts also during self-initiated movements.

STRATEGY SELECTION TRIGGERS MOVEMENT SCALING. V. B. Brooks*[1], F. Hilperath[2], H.-G. Ross[3], M. Brooks[4] and H.-J. Freund[2]. Dept. of Physiology[1], Univ. of Western Ontario, London N6A 5C1, Canada. Dept. of Neurology[2]; Physiology[3], Heinrich Heine Univ. Düsseldorf, FRG. Inst. for Information Technology[4], National Res. Council of Canada, Ottawa K1A 0R6.

A novel paradigm for human subjects learning a task using goal-directed hand movements showed that a strategy: *what* to do, was learned first (phase 1); and then tactics: *how* to make it successful (phase 2). Phase 1 included cognition of the correct strategy: the movement pattern; and phase 2 consisted of calibration of strategy use by scaling movement amplitudes and timing. Some subjects could declare *that* they had found the right strategy after one or only a few trials, before they had achieved successful scaling.

The paradigm required subjects to guide a display cursor from a start-box to a target-box by moving a pen on a digitizing board. Hand positions modulated cursor velocities ('rate control'). Thus correct strategy was to start and stop the cursor with two oppositely directed hand movements; and correct tactics required their amplitudes to be close enough to each other to stop the cursor in target, within the time set by the paradigm. Sessions of 200 trials took 25 min.

Phase 1 began with naivety and ended with strategy selection [measured as task performance with no more than 2 consecutive non-strategy trials], attained by different subjects in up to 111 trials. End of phase 1 triggered phase 2, the highly visible movement rescaling, that ended with stable ratios of stop and start move amplitudes [ratios sufficiently close to 1 in 9 consecutive trials]. Rescaling (phase 2) was completed by seven subjects using the correct strategy in 7 to14 trials (in a total of 7 - 25 trials); and by three subjects with the strategy in 34 to 56 trials (in 44 - 61 total). The number of trials used to attain stable amplitudes for the correct pattern strategy is in the range of trials reported for adaptive scaling attributed to cerebellar function.

This simple kind of test with easy read-out could be used for recording and imaging brain activity during visuomotor learning.

COORDINATION OF SINGLE AND DOUBLE JOINT MUSCLES OF THE ELBOW. L.E. Sergio* and D.J. Ostry. McGill University, Montreal, PQ, Canada H3A 1B1

In previous work with A.G. Feldman and J.R. Flanagan we have suggested that central commands specify the equilibrium point in multi-joint movements by controlling many muscles in concert. In particular, for both arm and jaw movements we have proposed central commands which control motion in different degrees of freedom as well as the level of coactivation without motion. The basic problem is that since muscles do not - in general - act in individual degrees of freedom central commands must be coordinated to produce motions in separate degrees of freedom. In this paper we report an empirical study of the coordination of central control signals necessary to produce movements about the elbow involving flexion alone, supination alone, and combinations of the two. The work was carried out by examining the kinematic and electromyographic patterns associated with 3D arm movements. EMG was recorded from eight single and double joint elbow muscles as subjects made pronation / supination and flexion / extension movements of different magnitudes. Shoulder elevation and orientation were also varied. Kinematic patterns were recorded using WATSMART. The data presentation focuses on the relationships between kinematics and EMG activity associated with motion in more than one degree of freedom.

CONTROL STRATEGIES FOR AIMED ARM MOVEMENTS IN 3-DIMENSIONAL SPACE O.Bock and K.Arnold (SPON: European Neuroscience Assoc.). Human Perf. Lab, Inst. f. Space&Terrestrial Sci., York University, Downsview, Ont. M3J 1P3, CDN

When humans point without seeing their arm, successive errors tend to accummulate, which suggests that pointing is amplitude- rather than position- controlled[1]. We now compare trends for error accummulation and for error correction for movements with varying directions.

Six humans pointed, without seeing their arm, at mirror-viewed targets. The targets appeared sequentially in a frontal plane and required direction changes between successive movements of 0, 45, 90, 135 or 180 deg. Pointing accuracy was registered by the Watsmart® system, and we calculated the linear regression between successive pointing errors. Positive correlation R indicated error accummulation; the regression slope S indicated the relative roles of accumulation (S=1) and correction (S=0).

We found that R>0 throughout the sequences (mean: 0.53, $p<0.01$), and that R was significantly smaller for movements preceded by a direction change of more than 45 deg (0.37 versus 0.71, $p<0.01$). We also found that S>0 (mean: 0.60, $p<0.01$) and that S depended on direction changes in much the same way as R (0.42 versus 0.75, $p<0.01$)

We conclude that error accummulation persists, albeit reduced, across changes of movement direction, and that a complementary trend for error correction exists. Correction is probably due to proprioceptive feedback since it is absent in deafferented subjects[2].

TIMING AND AMPLITUDE CONTROL OF REACHING AND GRASPING. P. Cordo* and M. Schieppati. Institute of Human Physiology II, University of Milan, Italy

Reaching and grasping is a multijoint movement involving a sequence of actions that include transporting the arm, orienting the hand, and opening and closing the fingers. This movement sequence is controlled by many of the muscles of the shoulder, arm and hand. The purpose of the experiment reported here was to determine what principles underlie the coordination of activity in these muscles.

Normal human subjects, seated at a table, reached for an L-shaped handle located at 1 of 3 heights, with 1 of 3 orientations with respect to the vertical plane. Subjects grasped the handle with one of these 9 combinations of height and hand orientation in contiguous blocks of 10 repetitions. The movement time to the handle was constrained by playing a series of tones through headphones. We recorded the activity of up to 7 muscles with surface and wire electrodes: upper trapezius, anterior deltoid, biceps brachii, pronator teres, supinator, flexor digitorum communis, and extensor digitorum superficialis.

We made the following observations with these reaching and grasping movements: 1) different muscles are involved in the control of reaching height, hand orientation, and hand opening and closing, but some muscles can control more than one of these kinematic variables, 2) the control of a given variable can be via the *onset timing* of activity or via the *amplitude* of activity, and 3) changes in the level of muscle activity occur at discrete, periodic times during the movement.

FAST GOAL-DIRECTED ARM MOVEMENTS CAN BE PERFORMED WITHOUT THE PERFORMER'S KNOWLEDGE. A.C. Sittig and J.J. Denier van der Gon (SPON: European Neuroscience Association). University of Utrecht, Princetonplein 5, NL-3584 CC Utrecht, The Netherlands.

Muscle tendon vibration is known to excite muscle spindles, the primary source of information for the perception of limb position in the absence of vision. Vibration of the biceps of a stationary or slowly moving arm causes the perception of elbow position to be biased towards extension. During slow tracking tasks undue flexion of the elbow results. Contrarily, in fast step-tracking tasks correct positioning is achieved despite vibration, even if the arm was unduly flexed before the step as a result of matching arm and initial target position. We now asked if we could make subjects perform fast goal-directed movements when they thought their arm was already at the target position. Four subjects tracked slowly moving targets. A mirror covered the arm. The image of a light above the mirror formed the target such that the hand and the target moved in the same plane below the mirror. Biceps vibration induced undue flexion. At times subjects were asked to grab the target with their hand. All subjects then performed fast and often substantial elbow extension movements reaching the target and, when asked about this, claimed they had not made any such fast movements. Electromyograms recorded from biceps and triceps show that the muscles were activated as if the subject were performing a voluntary fast movement. We conclude that the programming of fast movements does not depend on the conscious decision to perform such a movement, and that the performance of a fast movement in itself does not give rise to the perception of movement.

A COMPUTATIONAL MODEL FOR OPTIMAL PLANNING AND CONTROL OF LIMB MOVEMENTS. N. Lan* and P. E. Crago. Applied Neural Control Lab, Dept. of Biomedical Engineering, Case Western Reserve Univ., Cleveland, OH 44106, and Center for Biomedical Engineering, University of Kentucky, Lexington, KY 40506.

In this abstract we present a computational model for generating limb movement trajectory, muscle control signals, and the associated joint stiffness and equilibrium states. The model includes a central planning algorithm derived from a minimum effort criterion, a spinal integration circuit involving reciprocal inhibition, as well as the musculoskeletal dynamics. The central nervous system (CNS) initiates the movement by issuing commands representing movement direction, amplitude and the height of an excitation pulse. Movement planning and control are eventually described as a dynamic optimization problem, minimizing the centrally perceived effort functional, and are solved by a numerical paradigm of nonlinear optimization.

Simulation results indicate that a movement may be performed with excitation pulses of a range of heights. The gain of reciprocal inhibition appears to modulate mainly the extent of reciprocal control of the antagonists, and has relatively less influence to movement kinematics, as compared with that of the pulse height. The stereotyped tri-phasic muscle control signals are shown to be characteristic of the minimum effort criterion. The joint stiffness increases during the movement as a consequence of the tri-phasic muscle control pattern. The equilibrium trajectory displays an "N" shaped alternating profile about the movement trajectory. It is shown that when the velocity profiles of movements are scaled with each other, invariant kinematic property emerges, and the height of the excitation pulses is well correlated to the speed of movements, suggesting a speed control strategy by pulse height modulation. The model is able to reconcile many lines of experimental findings about single joint voluntary movements. It can also be extended to multi-joint movements.

MIDLINE PLANE ATTRACTION IN THE LOCOMOTION OF NORMAL AND DOPAMINE STIMULANT TREATED RATS. I. Golani, H. Einat and P. Teitelbaum*. Dept. of Zoology, Tel Aviv University, Ramat Aviv, Israel and Dept. of Psychology, University of Florida, Gainesville, Florida, U.S.A.

In our work we search for "natural" frames of reference and collective variables, presumably used by the brain in the coordination of movement. The rat's midline plane, which divides body-related space into two symmetrical hemispheres, was used as a reference plane for the scoring of five measures of locomotor behavior. A comparison of the behavior of rats with saline and three dopamine stimulants revealed three distinct locomotor profiles which differed in the strength of attraction of the anterior body parts to the midline plane. With saline and apomorphine rats showed a similar rather strong attraction of the torso and the head to this plane. Quinpirole greatly enhanced and amphetamine first enhanced and then greatly reduced this attraction. This suggests that the midline plane is used by rats as a reference plane in the coordination of trunk movements. The head's angular displacement from this plane could be a collective variable used in the coordination of locomotor behavior.

RECIPROCAL INHIBITION (RI) DURING VOLUNTARY DORSIFLEXION OF THE ANKLE: A LINEAR RELATIONSHIP. L.E. TREMBLAY* OTTAWA UNIV. CANADA J.L. PÉPIN AND P.J. DELWAIDE AND LIEGE UNIVIERSITY, LIEGE 4000, BELGIUM.

RI is believed to play a crucial functional role in motor control with spinal inhibitory interneurons (IN 1a) being clearly implicated. Tanaka (1974) found that RI was scarcely detectable in normal subjects at rest. He has shown that the 1a inhibitory pathways to the triceps surale muscle become active during voluntary dorsiflexion of the ankle. The purpose of this study was to quantify the effect of voluntary isometric contraction in dorsiflexion on the H-soleus reflex. Twenty nine normal subjects (30 $\pm$ 8 years) were studied. Hoffman's H-reflexes in the soleus (S) was used to assess the changes in (RI) evaluated by electrical stimulation of the antagonist muscle (tibialis anterior) (TA) via the common peroneal nerve (CPN) using five condition levels; at rest, slight contraction, 1kg, 2kg and 4kg resistance in dorsiflexion. Subjects were given auditory and visual feedback of the EMG to help maintain a steady voluntary contraction of the TA muscle. The electrogoniometer was used to ensure the isometric condition. Stimulation of the CPN demonstrated a 9.2 $\pm$ 7% ($P < 0.01$) augmentation in RI in (S) at rest and 26.6 $\pm$ 17%, 46 $\pm$ 16%, 61% $\pm$ 10% and 58 $\pm$ 12.5% respectively for slight contraction, 1, 2, 4kg respectively. The relationship is linear until 4kg. The regression curve is $y = 1.2x + 11.96$ ($r=.94$). A voluntary contraction of the TA muscle is one the best methods of RI reinforcement. The possible implications of Renshaw cell discharge and presynaptic inhibition will be discusssed.

EFFECTS OF ANKLE EXTENSOR CONTRACTIONS ON CAT LUMBAR MOTONEURONS . L. Jami*, D. Zytnicki, J. Lafleur and G. Horcholle-Bossavit CNRS URA 1448, Collège de France, Paris, France.

The effects of muscle afferent inputs generated by contractions of gastrocnemius medialis (GM) were recorded in ipsilateral lumbar motoneurons of chloralose-anaesthetized cats. Contractions were obtained by stimulating a cut branch of the muscle nerve.

In homonymous and synergic motoneurons, GM contraction evoked a quickly declining Ib inhibition in spite of a persistent Ib input (1). Recordings of contraction-induced PAD in Ib terminals suggested that pre-synaptic inhibition of Ib effects accounts for the decline of autogenetic Ib inhibition (2).

Declining inhibitions elicited by GM contractions were also observed in various other species of motoneurons. On repetitive electrical stimulation of GM nerve, the strength required to elicit declining inhibitions similar to those evoked by GM contraction in non-synergic motoneurons was 5-8 times group I threshold, recruiting group II in addition to group I fibers. These observations suggest a significant contribution of group II afferents to the effects elicited by GM contractions in non-synergic lumbar motoneurons. The mechanism causing the decline of the contraction-induced effects might involve pre-synaptic inhibition of group II fibers.

In addition to tendon organs and spindle primaries, group II muscle afferents also contribute information about ankle extensor contractions, in the form of a negative feedback distributed to a variety of lumbar motoneurons and quickly filtered out, leaving motor units available for recruitment as may be required by motor coordination.

OSCILLATIONS OF EMG BURST AMPLITUDE IN NORMAL AND SPINAL CATS DURING TREADMILL LOCOMOTION. J. A. Hodgson, R. R. Roy, C. P. de Guzman, R. de Leon, A. Garfinkel* and V. R. Edgerton. Brain Research Institute and Department of Physiological Science, UCLA, Los Angeles, CA 90024.

Recordings of EMG activity from locomoting spinal cats in our laboratory have indicated exaggerated levels of oscillations in amplitude of EMG bursts (Lovely et al. Brain Res 514:206, 1990). In most cases, the bursts were divided into short 'packets' of activity separated by periods of silence. This contrasts with examples of EMG bursts in spinal cats from other laboratories where such clear oscillations were not apparent (Barbeau and Rossignol Brain Res 412:84, 1987; Forssberg et al. Brain Res 50:184, 1973). One significant difference in our treatment of the animals was that they were left to recover for one month before locomotor training was initiated. In more recent experiments, we have initiated training one week after spinalization and found much less oscillation in the amplitude of EMG bursts following spinalization. This observation suggests that the timing of therapeutic interventions in the treatment of spinal injuries may affect the outcome of those therapies. We have also analyzed the frequencies of EMG oscillations in control and spinal cats and in two instances compared tremor before and after spinalization in the same animal. The frequency of EMG oscillation in all spinal cats was approximately 25 Hz, compared to 50 Hz in controls. Similar results were found in the two cats studied before and after spinalization. Together these data suggest that descending pathways influence the spinal circuitry involved in generating tremor. (Supported by NIH Grant NS16333)

GAIT ASSISTANCE WITH FES CONTROLLED BY THE CUTANEOUS ENG. K. Kallesøe[1], M. Haugland[2] and J.A. Hoffer[1]*. 1) School of Kinesiology, Simon Fraser University, Burnaby, B.C. V5A 1S6, Canada and 2) Department of Medical Informatics and Image Analysis, Aalborg University, Aalborg, Denmark.

The activity of skin mechanoceptors recorded by cuff electrodes implanted on sensory nerves can provide useful information on the forces applied on the skin. Last year we reported an application in an anesthetized animal model, in which the cutaneous electroneurogram (ENG) was used for closed-loop control of functional electrical stimulation (FES) of paralyzed muscles in order to restore a precision grip reflex (Hoffer & Haugland, SN Abstr. 17:1031). We now present an application in the conscious, walking animal, in which the cutaneous ENG was used to control FES in order to assist gait.

The cat hindlimb served as a model to test this application. A tripolar nerve cuff electrode (30 mm long, 2.5 mm ID) was implanted on the tibial nerve near the ankle, in order to record activity generated largely by footpad mechanoceptor afferents. Bipolar stimulating electrodes were implanted in each head of triceps and plantaris. For each muscle, a recruitment curve was determined under anesthesia by stimulating at 25 Hz with constant current pulses of variable duration ($\leq$255 µs). Pulse amplitude was set to the minimum value needed to obtain maximal force using 255 µs pulses.

The tibial ENG recorded during gait included a sharp burst at footfall and modulated activity during stance. A "ground contact" signal was derived from the rectified, filtered ENG and served as control signal for a 4-channel stimulator that activated each muscle at 25 Hz (100 Hz total) as long as the foot was in contact with the ground. A reliable control signal was obtained from the tibial ENG during walking, even in the presence of FES of muscles that surrounded the nerve cuff. An interleaved sampling method was used to reject simulation artifacts that contaminated the nerve signal. At low levels of stimulation (<30% of maximal), FES did not interfere with the cat's normal gait. At 30-40% of maximal, the cat occasionally shook the stimulated limb during the swing phase. At 40-75% of maximal stimulation, the paw shakes became more vigorous and the ENG signal during stance was more irregular. This caused discontinuities in the stimulation, but the cat continued to walk regularly, with no sign of pain or discomfort.

Since this approach is feasible in both anesthetized and normally active animals, it promises to be clinically applicable to paraplegic as well as to hemiplegic humans.

STRYCHNINE- INDUCED MODULATION OF EMG OF HINDLIMB FLEXORS AND EXTENSORS DURING STEPPING IN CHRONIC ADULT SPINAL CATS. C. P. de Guzman, J. A. Hodgson, R. D. de Leon, R. R. Roy and V. R. Edgerton*. Department of Physiological Science and Brain Research Institute, UCLA, Los Angeles, CA 90024.

Strychnine initiated full weight-bearing stepping in spinalized cats that were unable to walk and resulted in a more robust stepping pattern in those that were trained to walk (de Guzman et al. Soc Neurosci Abstr 17:1577, 1991). EMG activity of hindlimb flexors (semitendinosus, iliopsoas, tibialis anterior) and extensors (vastus lateralis, soleus-Sol, medial gastrocnemius) were examined in 4 adult spinalized cats (T12-T13) before and after the administration of 2 doses of strychnine (0.03 and 0.10 mg/kg, i.p.) to determine if the improvements in locomotion were a result of a direct effect of strychnine on motor pools or due to changes in other spinal mechanisms. Two cats were trained to walk on the treadmill at varying speeds (0.2-1.0 m/s) and 2 were trained to stand. Training (30 min/day, 5 days/week) began 1 week after spinalization. At 3 months post-spinalization the treadmill-trained cats walked at all speeds. Standing-trained cats rarely exhibited coordinated cyclic activity and were unable to walk at any speed throughout the entire training period. Averaged EMG waveforms for each muscle were generated from 5-12 steps. In treadmill-trained cats strychnine had only a minor influence on the EMG patterns observed after spinalization. Burst durations were similar before and after strychnine administration. Mean amplitudes in Sol increased slightly after strychnine and was dose-dependent. The standing-trained cats were able to walk after strychnine administration and higher doses increased the Sol mean amplitude in one of two cats. These data indicate a selective effect of strychnine on the amplitude of specific muscles and a maintenance of the EMG patterns in both flexors and extensors after spinalization suggesting that the major influence of strychnine is on premotoneuronal networks that generate cyclic activity in the spinal cord rather than a direct effect on motoneuronal pools. (Supported by NIH Grant NS16333)

648.7

EFFECTS OF SPINALIZATION ON EMG WAVEFORMS IN CAT FLEXOR AND EXTENSOR MUSCLES. R. D. de Leon, C. P. de Guzman, J. A. Hodgson, R. R. Roy, B. Jiang* and V. R. Edgerton. Department of Physiological Science and Brain Research Institute, UCLA, L.A., CA 90024.

Cats spinalized as adults can regain effective full weight-supported stepping of their hindlimbs when properly trained over a period of weeks to step on a treadmill (Lovely et al. Brain Res 514:206, 1990). Although it is known that the stepping pattern in these spinalized cats can accommodate varying speeds, loads and other sensory perturbations, details of the EMG during stepping that reflect supraspinal compared to spinal control has not been defined. In the present study, EMG from selected flexors and extensors in 4 adult cats were recorded during bipedal stepping before and 1 or 3 months following spinalization (T12-T13). Two spinal cats were trained to walk on a treadmill at speeds ranging from 0.2 to 1.0 m/sec and 2 cats were trained to stand. Each cat was trained for 30 min/day, 5 days/week. Training began 1 week after spinalization, at which time none of the cats was able to execute weight-supported stepping. The 2 cats trained to walk were able to step with full weight support after 3 weeks of training. The standing-trained cats were unable to walk throughout the entire training period. Following an acute administration of strychnine (0.03 mg/kg) 3 months after spinalization, however, these 2 cats could generate full weight-supported stepping (see accompanying poster, de Guzman et al.). Amplitudes within each burst of EMG activity were averaged over 5-15 consecutive step cycles. Double bursts per cycle were observed consistently in the semitendinosus and iliopsoas before spinalization while one of these bursts became much less prominent following spinalization. Packets of EMG bursts were observed frequently in the flexors, particularly in the tibialis anterior, after, but not before, spinalization. Generally, the EMG waveforms of extensors (vastus lateralis, soleus, medial gastrocnemius and gluteus medius) were similar pre- and postspinalization. These data suggest that the neural networks of the lumbar spinal cord that control the extensors can compensate more completely for the absence of supraspinal control or that in the absence of compensation, the flexor motor pools are more dependent on supraspinal control than extensors. (Supported by NIH Grant NS16333)

GENERATING HUMAN LOCOMOTOR ACTIVITY PATTERNS USING AN ARTIFICIAL NEURAL NETWORK MODEL.
S.D.Prentice* and A.E.Patla. Dept. of Kinesiology, Univ. of Waterloo, Waterloo, Ontario, Canada, N2L 3G1.

A neural network model was used to map out a relationship between desired locomotor trajectories and the necessary muscle activations. The proposed network incorporates a fully connected feed-forward model receiving twelve inputs, ten hidden units and four output units. The inputs include the vertical and horizontal displacement trajectories for the hip and toe, the hip and knee angles, and the time derivatives of these six inputs. The output consists of the muscle activation time histories of the major extensors and flexors of the lower limb - soleus, tibialis anterior, biceps femoris and rectus femoris. The bias values and connection weights of the network were learned using the back-propagation rule, using the NeuralWare software. A robust model must be able to control walking over uneven terrains. Therefore, data from subjects walking over obstacles of different heights were used to train and test the network. The test data set was presented at specific intervals during training to monitor the model's ability to generalize to novel data. The muscle activation patterns produced by the resulting model upon presentation of the training data closely matched those obtained experimentally. Presentation of the novel data also closely resembled the actual activation time histories. The performance of the model was quantified by calculating the correlation and root mean squared error between the actual and predicted curves. All muscles of the training data had correlations greater than 0.9 and RMS errors less than 0.1. Most of the muscles in the test data values had correlations greater than 0.8 and RMS errors less than 0.3.

DIFFERENTIAL EFFECTS IN PATHWAYS INTERCONNECTING KNEE AND ANKLE EXTENSORS IN MAN. R. Pelletier, R. Forget, D. Bourbonnais*. Centre de Recherche, Institut de Réadaptation de Montréal et l'Ecole de réadaptation, Faculté de Médecine, Université de Montréal.

To study the specificity in spinal pathways interconnecting heteronymous muscles a conditionning H-reflex technique was used to investigate, at rest, the pathways interposed between the soleus (SOL) and the vasto-crureus (VC) muscles. Fourteen normal human subjects (x=27 ± 1.37 years) participated in the study. Two experimental conditions were investigated: (1) conditioning stimulation applied to the femoral nerve (FN) and a test stimulation applied to the the posterior tibial nerve (PTN), and (2) conditionning stimulation applied to the PTN and a test stimulation applied to the FN. Under both experimental conditions the intensity of stimulation was adjusted so that conditionning stim. was at motor threshold and the test stim. at Hmax/2. The results for both experimental conditions was an initial short lasting facilitation (≈ 5 ms) followed by a relatively long lasting (≈ 50 ms) inhibition. However this inhibition was much stronger in the FN-sol experimental condition. In this situation (FN-SOL) the Conditionning-Test intervals (C-T int) had a significant effect on the conditionned H-reflex values (p=.0001) and these conditionned values were found to be significantly different from their control values (p=.0005). In the second experimental condition (PTN-VC), although the C-T int had an effect on the conditionned values (p=.004) no difference between the conditionned and control values were demonstrated (p=.8456). Different conditionning stimulation intensities of the FN were investigated at the C-T int where the strongest inhibition of the soleus muscle was present. The inhibition appeared with a stimulation strength of 1.0 x Reflex Threshold and increased in concordance with the amplitude of the H-reflex response in the conditionned muscle. Spinal mechanisms regulating inhibition between extensor muscles may facilitate the task of supraspinal structures in the regulation of heteronymous muscles important to maintain an erect posture in stance and gait. THE EFFECT OF EARLY LOCOMOTOR TRAINING WITH CLONIDINE ON THE RECOVERY OF LOCOMOTION IN ADULT SPINAL CATS.
C.W.M. Chau*, H. Barbeau, J. Provencher and S. Rossignol. Cntr for Res. in Neurol. Sci., Fac. of Med., U. de Montréal, Québec, Canada, H3C 3J7.

Our previous studies have shown that, after spinal transection at T13 in cats, locomotor recovery with plantar foot placement and weight support of the hindquarters takes between 2 to 3 weeks. We have also shown that injection of noradrenergic drugs (clonidine and L-Dopa) together with perineal stimulation can produce, in the first week post-transection, a coordinated locomotor pattern on the treadmill for several hours. We have taken advantage of this possibility to train cats on a treadmill after daily injection of clonidine (150 to 225 ug/kg i.p.) in the first post-transection week and study the effects of training (60-90 mins/day) on the recovery of spontaneous locomotion. Electromyographic (EMG) activity synchronized to video images of the hindlimbs were recorded before and after clonidine injection. From the 3rd to the 9th day post-transection, there was a gradual increase in the duration of the step cycle for the same treadmill speed accompanied by a corresponding gradual increase in the duration of extensor EMG activity and a gradual decrease in the duration of flexor muscles activity. The increase in total angular excursion of the hip, knee and ankle joints was also evident. Concomitant changes in kinematics included a brisk transition from swing to stance, hyperextension of the ankle during late stance, and synchronous flexion of hip, knee, and ankle during early swing. It is noticeable that, from the 3rd to the 7th day, the effect of clonidine given on one day was not carried over the next day i.e. the spontaneous locomotion before clonidine injection was not improved. The 3 cats were able to elicit a locomotor pattern without clonidine injection by the 8th, the 9th and the 11th day respectively. These observations suggest that early locomotor training with clonidine accelerates the recovery of locomotion after spinalization. (Supported by the NCE, the MRC and the FCAR).

EFFECTS OF MOVEMENT INITIATION CONDITIONS ON POSTURAL AND TASK EMG ACTIVITY DURING INITIATION OF RAPID SHOULDER FLEXION. L.D. Abraham, D. Kalakanis, and A.M. Baylor*. Kinesiology & Health Education and Institute for Neuroscience, University of Texas, Austin, TX 78712.

In order to study in detail the relationship between patterns of postural and voluntary muscle activation, kinematic, dynamic, and electromyographic data were collected from normal adult male subjects performing bilateral rapid shoulder flexions while freely standing. Experimental conditions varied temporal constraints on initiation by including self-paced (SP), reaction-time (RT), and coincidence-anticipation (CA) paradigms. Data were collected with a two-camera video system, a force plate, and twelve channels of surface EMG. The data were examined to identify variations in performance which could suggest the extent to which postural and task muscle activation patterns played a fixed role in execution of the task. We report here data from subjects who displayed consistent arm movement kinematics in all three conditions. RT data were clearly different from SP and CA data. Ankle muscles were less involved in movement initiation in the RT condition, evidenced by later and less consistent bursts of activity. Activation patterns of other muscles were also different in RT vs SP and CA conditions, though in subject-specific ways. These data suggest that patterns of anticipatory postural activity for similar arm movements may be highly sensitive to temporal constraints on movement initiation.

INFANT STEPPING: A LONGITUDINAL STUDY OF LOCOMOTOR DEVELOPMENT. **M.C. O'Sullivan*, E.L. Leonard, B.G. Farley and J.R. Bloedel. Dept. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.**

Studies were undertaken in 10 normal infants at ages 12, 18 and 24 weeks to investigate the characteristics of the early changes in the kinematics of stepping prior to the development of independent locomotion. Infants were supported over a treadmill moving at 0.06m/s and light emitting diodes were placed over critical points on the lower limb. Three classes of lower limb movements were identified: alternate steps, hops and jumps. The active phase of alternate steps was analyzed. Dependent variables included percentage of alternate steps, step duration, height, length, angular displacements of hip, knee and ankle, limb velocity and acceleration. With age, significantly increasing values were obtained for step length, step height, time of maximum ankle flexion and maximum velocity of the leg during gait with smoothing of the velocity profile. These data suggest that in preambulatory infants between 3 and 6 months of age, stepping acquires characteristics which contribute to the development of independent bipedal locomotion. **(Supported by Az Dis Res Cont Com and NIH RO1NS-21958).**

THE ROLE OF SOMATOSENSORY INFORMATION IN A CONSTRAINED LOCOMOTOR TASK. S.M. Henry, J.M. Held,* B.P. Vietje and J. Wells. Dept. of Anatomy and Neurobiology, Univ. of Vermont College of Medicine, Burlington, VT 05445.

Sensory information from the body is distributed and processed by different central nervous system structures which are involved in both sensory perception as well as motor activity. The present study examined the role of the dorsal column nuclei and the ventral posterolateral (VPL) nucleus of the thalamus in a constrained locomotor task. Rats were trained to traverse an elevated 1" bar for a reward. The time it took to run across the bar was used as a measure of goal directed behavior. The trajectory of the hindlimb during the swing cycle was quantified from videotape. The lesion groups were 1) right gracile nucleus, 2) bilateral gracile nucleus, 3) right gracile nucleus and left VPL and 4) bilateral VPL. The animals were tested on the bar running task for 50 days post-lesion and filmed periodically. Two measures of loss and recovery of function were used: 1) the running time and 2) the movement topology of the hindlimb swing cycle. Only the bilateral VPL lesioned animals were significantly impaired in run times during week 1 post-lesion. However, all groups demonstrated an impairment in movement topology even on the day they returned to their pre-lesion run times. This impairment in movement did not recover. This result is similar to sensorimotor cortex lesions and suggests that central processing of tactile information is important in constrained locomotion.

UNIQUE EMG PATTERNS FOR FDL AND EDL DURING FORWARD AND BACKWARD WALKING. T.V. Trank* and J.L. Smith, Dept. of Physiological Science, UCLA, Los Angeles, CA, 90024-1568.

We have previously described kinematics and related EMG of the hip, knee, and ankle joints during forward (FWD) and backward (BWD) treadmill walking. However, the action and muscle activity at the toe (metatarsophalangeal joint) was not addressed. Our methods for assessing EMG and kinematic data in the cat are published (Buford and Smith, *J Neurophysiol* 64:756-766, 1990).

The flexor hallicus longus (FHL) exhibited activity typical of an extensor muscle in both forms of walking, being active prior to paw contact (PC) and remaining active through 75% of stance. The extensor digitorium longus (EDL) tended to have a biphasic burst during swing. In FWD walking, the first burst was related to the F-E1 toe-joint reversal that occurred 30 ms after paw off (PO). The second EDL burst, coactive with the onset of FHL, was associated with deceleration of toe extension in preparation for PC. Overall, EDL activity appeared to control toe extension throughout swing. During BWD walking, the EDL also exhibited biphasic activity. However, the onset of the first burst occurred before PO and coincided with slight toe extension as the paw prepared for lift off. The second EDL burst centered around PC and was related to the F-E1 reversal at the end of swing. In FWD walking, the flexor digitorium longus (FDL) had a brief burst (15-45 ms) that occurred prior to PO; this burst preceded the onset of rapid toe flexion that ended 30 ms after PO. 'Facultative' activity during stance was evident in both forms of walking. In BWD walking both the swing burst and its associated toe flexion were absent. Instead, a brief burst unrelated to 'facultative' activity was occasionally recorded just after PC coincident with FHL activity.

Like previous muscles studied (Buford and Smith 1990), FHL and EDL maintained their basic flexor or extensor synergies. But for the first time, we have described a muscle that does not. Under fictive preparations, the CPG programs a short FDL burst coincident with the flexor synergy (Fleshman et al. 1984); this burst does not occur during backward walking and may be suppressed by supraspinal input or sensory feedback associated with BWD walking. Supported by NIH NS 19864.

648.15

MUTABLE ACTIVATION OF BIFUNCTIONAL THIGH MUSCLES DURING FORWARD AND BACKWARD WALKING. C.A. Pratt*, J.A. Buford and J.L. Smith. Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1586.

In contrast to unifunctional muscles, the bifunctional semitendinosus (ST) has a distinctly different EMG pattern during the swing phase of forward (FWD) and backward (BWD) walking, suggesting that the activity of bifunctional muscles may be more mutable and adjusted by proprioceptive feedback to match the different limb kinematics associated with the two forms of walking (Buford et al. II. *J. Neurophysiol.* 64, 1990). To explore this possibility, the activity of two hip flexor-knee *extensor* muscles (anterior sartorius, SAa, and rectus femoris, RF) and a hip flexor-knee *flexor* (medial sartorius, SAm) were recorded along with limb kinematics (ciné film) in 3 cats trained to walk FWD and BWD on a motorized treadmill.

Both of the hip flexor-knee extensors had significantly different EMG patterns during BWD as compared to FWD walking. The changes in pattern were different among the muscles and appeared to reflect relative differences in their actions at the hip and knee. The reversal from flexion to extension occurs *later* at the knee during BWD swing (0.22 of the normalized step cycle; paw off at 0.0) than in FWD swing (0.10), but *earlier* at the hip (BWD = 0.12, FWD = 0.30). During FWD swing, activity in all three muscles ended at 0.29 and, thus, appeared to be related to their *hip* flexor action. In contrast, during BWD swing, SAa and RF activity (EMG offset = 0.04) was related to hip flexion, but SAm activity ended at 0.29 and was more related to *knee* flexion. FWD and BWD walking also differ in that the hip flexes during BWD stance. Typically, SAm was not active during either FWD or BWD stance. SAa and RF were both active during late FWD stance (0.68-0.86), but the two knee extensors were differentially activated during BWD stance: RF was active throughout knee extension (0.22-0.98), but SAa was active just briefly (0.26-0.47) around paw contact (0.35). In both FWD and BWD stance, SAa activity coincided with the reversal of hip extension to flexion. The temporal shifts in SAa activity were linked to the timing of hip kinematics and allowed SAa to contribute to deceleration of hip extension in both FWD and BWD stance. Supported by NIH NS 19864.

EFFECT OF SURFACE CHARACTERISTICS ON GAIT MODIFICATION IN INDIVIDUALS WITH AGE-RELATED MACULAR DEGENERATION. S.J.Spaulding*, A.E.Patla, S.Rietdyk, J.Flanagan & D.Elliott, Kinesiology Dept. & Sch. of Optometry, U. of Waterloo, Waterloo, Ont., Canada, N2L 3G1.

The possible strategies used by individuals with reduced central vision for travel over various surfaces under different ambient light levels were examined. Age-related macular degeneration (ARMD) subjects (N=7) and age-matched controls (56-86 years) walked over different surfaces (uneven, compliant and shiny) imbedded halfway into a 12 meter walkway under high light (2300 lux) & low light (5 lux). Gait adaptations prior to the surfaces were characterized by changes in impulse parameters under the contralateral limb, ipsilateral limb (landing first on altered surface) muscle activity during functionally relevant phases, and ipsilateral kinematic changes. Differences between the two groups were as follows: Normal subjects used similar vertical braking impulses regardless of the surface, whereas the ARMD subjects used a greater braking impulse in the single support phase for the uneven and shiny surfaces; and ARMD subjects had lower heel and toe velocity and increased vertical displacement as the foot cleared the edge of the surface. Level of lighting had no effect on gait. The ARMD group used both contra and ipsilateral strategies to reduce foot velocity, prior to landing on the altered surface. Both groups proactively altered their gait; increased toe elevation over the surface, increased contralateral horizontal braking and increased contralateral stance time suggest that subjects perceived that more caution was required for approaching the uneven surfaces. Decreased head angle suggests that subjects were monitoring the altered surface. Changes in gait parameters from the first to the tenth trial within a surface suggests that subjects adapt relatively quickly to the altered terrain. Supported by NHRDP.

THE EFFECTS OF TERRAIN DIFFICULTY ON CHARACTERISTICS OF VOLUNTARY VISUAL SAMPLING OF THE ENVIRONMENT DURING LOCOMOTION. A.E. Patla*, C. Martin, R. Holden & Sa. Prentice. Dept. of Kinesiology, Univ. of Waterloo, Waterloo, Ontario, Canada, N2L 3G1.

Young subjects (N=16) were instructed to walk over travel paths (9.1 m long) of varying difficulties while wearing opaque liquid crystal eyeglasses, and pressing a switch to make the glasses transparent when they needed to sample the environment. Their movement time (MT) & following visual sampling characteristics were recorded: number of visual samples (#SAMP); total duration of visual samples (TDVIS); average (ADVIS) & variability of visual sample duration (SDVIS); average (AISI) & variability of intersample time (SISI). A 2 (straight or winding path) x 2 (even or uneven step length requirement) x 2 (one or two obstacles in path) repeated measures ANOVA revealed the following results. #SAMP decreased in presence of obstacles coupled with even step length (6.8 vs 7.7); TDVIS was higher for winding compared to straight path (3.68s vs 3.06s) & higher for uneven step length condition compared to even step length (3.46s vs 2.90s); SISI was higher when obstacles were present (0.43s vs 0.29s). When a hole was included in the travel path affecting the consequence of error in foot placement, #SAMP increased (8.3 vs 7.0) along with higher TDVIS (3.73s vs 2.83s), & AISI reduced (1.23s vs 1.46s). When subjects were not constrained to place their feet on specific location, TDVIS (2.45s to 0.88s) & #SAMP (5 to 1.4) reduced dramatically. MT was similar for all conditions (9.38s). Inclusion of a large barrier in the winding path to influence preview region increased MT (11.91s vs 9.34s), AISI (1.76s vs 1.36s), & SISI (0.57s vs 0.29s). These results provide insights into how intermittent visual sampling of the environment is normally used for navigation. (Supported by a grant from NSERC, Canada.)

EFFECT OF LESIONS OF THE DORSAL COLUMNS AND DORSOLATERAL FUNICULI ON LOCOMOTION IN ADULT CATS. W. Jiang* and T. Drew Dept. of Physiology, Université de Montréal, Canada, H3C 3J7.

Experiments to determine the relative importance of different descending systems for the adaptive control of locomotion were performed in two cats which were chronically implanted for recording electromyographic (EMG) activity from muscles of the fore- and hindlimbs. Following control studies, a bilateral lesion of the spinal cord was made under general anaesthesia at T13 which completely interrupted the dorsal columns (DC) and extended to differing degrees into the dorsolateral funiculi (DLF). In one cat, with a relatively small lesion of the DLF, locomotion recovered within one week, and the cat was readily able to adapt its locomotion to walk at different speeds and at different treadmill inclinations (both roll and tilt). In the other cat, with a larger DLF lesion, locomotion recovered more slowly over a period of 4-6 weeks, and even after this time there was often a tendency for the cat to place the hindpaw on its dorsal surface. Nevertheless, this cat could also walk at different speeds and adapt its locomotion to inclined planes. Both cats, however, showed long-lasting deficits in their capacity to modify their hindlimb gait in order to step over obstacles attached to a treadmill belt or to walk along a horizontal ladder. These preliminary results suggest that whereas pathways contained within the ventrolateral and ventral spinal cord are sufficient for normal locomotion, pathways within the DC and/or DLF seem to be essential for anticipatory control. DISCORDANT EXPRESSION OF ACETYLCHOLINESTERASE ACTIVITY AND mRNA LEVELS IN SINGLE NEUROMUSCULAR JUNCTIONS OF NORMAL MUSCLE. R.K. Lee, B.J. Jasmin and R.L. Rotundo*. Department of Cell Biology and Anatomy, University of Miami School of Medicine, Miami, FL 33101.

Acetylcholinesterase (AChE) is highly concentrated at the vertebrate neuromuscular synapse. Among the mechanisms that could account for this selective accumulation of AChE molecules is localized transcription of the AChE gene in postsynaptic sarcoplasmic nuclei. One prediction of this model is that AChE enzyme at the neuromuscular junction (NMJ) would mirror the levels of AChE transcripts. To examine this, we used a PCR-based assay to determine AChE mRNA copy number and a micro-assay for determining AChE activity in samples containing single isolated NMJs. AChE mRNA is an intermediate message at the NMJ compared to our internal standard used in competitive PCR assays (pACQNT) and to α-actin mRNA levels measured in the same samples. AChE message levels in non-innervated regions of the muscle fibers are either undetectable or very low, making the AChE mRNA a rare transcript in these fiber regions. Analysis of more than 50 individual NMJs shows that the AChE transcript levels are highly variable (more than 20 fold range) yet were detected in only 36% of our single NMJ samples. In contrast, analysis of AChE activity in single NMJs showed that enzyme levels were remarkably constant (12.23 ± 1.4 pmoles of ACh hydrolyzed/ min/NMJ; mean ± S.D.). These results show that AChE mRNA is compartmentalized at the NMJ and provide a mechanism for regulating the abundance of this synaptic protein at sites of nerve-muscle contact. Furthermore, the observed variability in AChE transcript levels compared to enzyme activity suggests that transcription of this synaptic protein gene may occur intermittently rather than constitutively possibly reflecting a regulated transcriptional control mechanism linked to muscle activity. Supported by NIH and MDA grants to R.L.R.

ACETYLCHOLINESTERASE mRNA LEVELS INCREASE IN PARALLEL WITH ENZYME ACTIVITY IN OVERLOADED SKELETAL MUSCLE. B.J. Jasmin*, R.K. Lee and R.L. Rotundo. Department of Cell Biology and Anatomy, University of Miami School of Medicine, Miami, FL 33101.

Normal expression of acetylcholinesterase (AChE) in vertebrate skeletal muscle depends upon the presence of the nerve as well as normal contractile activity. In general, denervation of skeletal muscles results in disappearance of the collagen-tailed AChE form whereas muscle overload induces significant increases in specific AChE oligomeric forms. These observations indicate that expression of AChE can be modulated according to the activity state of the muscle. As a first step towards studying the molecular mechanisms underlying the activity-induced AChE plasticity in muscle we subjected adult quails to an overload model that results in a dramatic enlargement of the anterior latissimus dorsi (ALD) muscle. Birds had a weight corresponding to 10% of their body mass attached to one wing, the contralateral side serving as control. Seven days later, control and overloaded ALD muscles were excised, weighed and, protein or RNA extracted. Overloaded ALD muscles showed an 80% increase in wet weight compared to contralateral muscles. Enlarged ALDs showed an average 130% increase in total AChE activity per muscle compared to controls. Sedimentation analyses revealed an increase in all AChE oligomeric forms with A12, G4, G2 and G1 displaying 32%, 122%, 230% and 210% increases, respectively. Quantitative RT-PCR and Northern blot analyses showed that AChE mRNA levels more than doubled over control values thereby paralleling the increase in AChE activity. These results indicate that regulation of transcript levels may play an important role in dictating AChE activity in skeletal muscle fibers. Furthermore, this overload model will prove useful for testing the proposal that AChE gene transcription occurs intermittently and is regulated by the functional demands placed upon the muscle. Supported by NIH and MDA grants to R.L.R.

COORDINATION OF MYOSIN HEAVY CHAIN AND SARCOPLASMIC RETICULUM CALCIUM ATPASE ISOFORMS IN CAT SOLEUS FIBERS SIX MONTHS AFTER SPINAL TRANSECTION. R.J. Talmadge, M. Wang, and R.R. Roy*. Department of Physiological Science and Brain Research Institute, UCLA, L.A., CA 90024.

The coordination of isoform expression of proteins responsible for both contraction (myosin heavy chain, MHC) and relaxation (sarcoplasmic reticulum ATPase, SR-ATPase) was evaluated in the soleus of cats undergoing a slow to fast transition, induced by spinal transection at T_{12}-T_{13}. Three groups of adult cats were used: 1) control ; 2) spinal transected (ST); and 3) spinal transected with daily weight support exercise (ST&WS). Serial cross sections were processed for immuno-histochemistry using monoclonal antibodies to MHC and SR-ATPase isoforms. Fibers with the following MHC compositions could be determined: Type I, I & IIa, IIa, IIb, and Embryonic/Neonatal (Emb/Neo). In controls, 98% of all fibers contained type I MHC exclusively. ST and ST&WS reduced the percentage of type I MHC fibers to 67% and 73%, respectively. Fibers co-expressing type I and IIa MHC accounted for 12% of all fibers in both ST groups vs. <1% in control. Fibers containing Emb/Neo MHC were observed rarely in the ST groups. Fibers containing slow (SSR), fast and slow (FSR&SSR) and fast (FSR) SR-ATPase could be identified. In controls, 98% of all fibers contained SSR exclusively. The number of SSR exclusive fibers was reduced to 67% in ST and 76% in ST&WS. Relatively few fibers (5% ST, 7% ST&WS) showed a complete transition to FSR compared to the number of fibers showing a complete transition to type II MHC (14% ST, 20% ST&WS). A relatively high percentage (8% ST and 10% ST&WS) of fibers showed dual expression of type I and II MHC and FSR&SSR isoforms. These results are consistent with a coordination of initiation of MHC and SR-ATPase protein transformation. The MHC transformation, however, appears to be more complete than the SR-ATPase. (Supported by NIH Grant NS16333 & NRSA (DE07212) from NIDR)

HISTOCHEMISTRY AND IMMUNOHISTOCHEMISTRY OF CAT TIBIALIS ANTERIOR MOTOR UNITS AFTER 6 MONTHS OF ELECTRICAL INACTIVITY. D.J. Pierotti*, R.R. Roy, and V.R. Edgerton. Brain Research Institute and Deptartment of Physiological Science, UCLA, LA, CA, 90024-1568.

The effects of chronic electrical inactivity on the myosin heavy chain (MHC) composition and succinic dehydrogenase (SDH), alpha glycerophosphate dehydrogenase (GPD), and myofibrillar ATPase activities of fibers in tibialis anterior (TA) motor units (MU) of adult cats were studied. Spinal cord isolation (SI) was used to produce inactivity in 10 cats. The cord was transected at T12-T13 and L7-S1 and a bilateral dorsal rhizotomy was performed between the two transection sites. Two 24-hr EMG recording sessions verified that the muscles in the lower limb were electrically silent. One MU from each hindlimb was isolated using ventral root isolation techniques, physiologically typed, and glycogen depleted (Bodine et al. *J Neurophysiol* 57 :1730, 1987). Optical density measurements from glycogen-stained frozen sections were used to classify fibers as depleted (unit) or non-depleted (non-unit). Myofibrillar ATPase activity was determined as described by Jiang et al. (*Muscle & Nerve* 13: 1037, 1990). SDH and GPD activities were determined as described by Martin et al. (*J Histochem Cytochem* 33 :1053, 1985). MHC composition was assessed using monoclonal antibodies specific for slow and fast MHCs (Donated by S.Schiaffino, Padova, Italy). A similar degree of variability in ATPase, SDH, and GPD activities was evident among fibers within a unit as well as among units as found in the normal TA. SDH activity decreased, GPD activity increased, and ATPase activity remained unchanged compared to control. No heterogeneity in the type of MHCs expressed was present among fibers of a MU or within a single fiber of a unit. The coordination of contraction time, force, and fatigability with metabolic properties was similar in SI and in control units. These data demonstrate that the coordination of expression of metabolic and contractile proteins, which in large part form the biochemical basis for physiological unit types, remains regulated at the MU level following chronic inactivity. (SUPPORTED BY NIH GRANT NS16333).

EMG/FORCE RATIO AS AN INDICATOR OF MUSCLE CELL DEATH FOLLOWING ECCENTRIC EXERCISE. J.N. Howell*, G. Chleboun, D. Karapondo and R. Conatser. Ohio University College of Osteopathic Medicine, Athens, OH 45701.

Following eccentric exercise to failure of the human elbow flexors under heavy load (90% of isometric max.; elbow angle = 90°), the integrated EMG amplitude during submaximal, isometric contractions (up to 20% of isometric max.) increased 2 to 3 fold (N=37). Associated with failure was a decrease in mean power frequency (MPF) of the EMG from about 60 Hz to less than 50 Hz. This decrease was less than the decrease in MPF associated with concentric exercise carried to failure, suggesting lesser metabolic fatigue. The increased EMG amplitude required to produce a given force after exercise indicates that at least some fibers, capable of generating action potentials, could generate little force, either because of fatigue or cellular injury. Maximum isometric force output of the eccentrically exercised muscles decreased by almost 50%. Recovery was slow, taking weeks in many subjects (50% recovery in 2 weeks; N=39). After concentric exercise, despite the greater downward shift in MPF, strength was far less compromised, recovering fully in 1-2 days. Thus the prolonged strength loss following eccentric exercise was related more to mechanical stress than to metabolic fatigue. Although strength returned slowly after eccentric exercise, the EMG amplitude required to produced submaximal contractions recovered in three days. It is likely that injured fibers, able to produce action potentials but little force after the exercise, subsequently lose their ability to produce action potentials and become inexcitable. The time course of recovery of the normal EMG/force ratio may indicate the time course of death of these cells, which must ultimately be replaced by the regeneration of new cells. The motor units involved must include those recruited during low level isometric contractions, <20% of isometric max. (Supported by the American Osteopathic Assn.)

649.6

FATIGABILITY OF CAT SOLEUS MOTOR UNITS ACTIVATED AT VARYING FORCE LEVELS. B.R. Botterman*, L.B. Graf, and K.E. Tansey. Dept. of Cell Bio. and Neurosci., Univ. of Texas Southwestern Med. Cent., Dallas, TX 75235.

The fatigue resistance of motor units in the soleus muscle has been appreciated for some time. Recently, however, it was shown that the relative fatigue resistance among these motor units can vary dramatically (*Cope et al., J. Neurophysiol. 66:1483, 1991*). The fatigue resistance of a motor unit was determined by noting the length of time (endurance time, E_t) it could maintain its tension output at 85% of maximum. Using computer feedback control, a unit's tension was clamped at the target level by altering the stimulation rate applied to its axon (maximum of 100 pps). E_t was found to be correlated with axonal conduction velocity (CV) but not with maximum tetanic tension (P_o).

In the present experiments, the same procedures were followed except that motor unit tension output was varied between 3 levels (50 - 70 - 90% of P_o) in ascending and descending order. The time at each level was held constant, although various step durations (10, 20 or 40 s) were selected at random for different units. A wide range of E_ts was found (~100x), regardless of the step duration used. In contrast to the earlier study, E_t was correlated with not only CV but also P_o. In addition, the relationship between stimulation frequency and tension output changed over time as a function of output level. The stimulation frequency necessary to maintain 50% and 70% of P_o remained fairly constant (~7 pps and ~10 pps respectively) or increased modestly throughout the endurance test, while the frequency necessary to maintain 90% of P_o increased steadily from ~30 pps to ~60 pps, after which it increased rapidly to 100 pps. Early in their endurance tests, some units showed a notable decrease in the stimulation rate required to clamp tension at 90% of P_o. This indicates that soleus motor units can undergo a form of potentiation which operates at relatively high tension output levels. Supported by NIH grant NS17863.

FATIGABILITY AND RELAXATION PROPERTIES OF THE HUMAN PARALYZED SOLEUS MUSCLE. R.K. Shields and C. Kukulka*. University of Iowa Hospitals and Clinics, Iowa City, Iowa 52242.

Spinalized animal models have been reported to show minimal changes in muscle fatigability as the result of reduced use. The fatigability of the human paralyzed soleus muscle was tested in both chronic (n=10) and acute (n=3) paralyzed individuals using a modified Burke fatigue protocol. In addition, the relaxation properties and electromyographic activity (emg) of the soleus muscle was determined during the fatigue protocol.

Plantarflexion torque was measured in both paralyzed groups from a seated position with the knee and ankle at 90 degree angles. A 20 Hz supramaximal stimulation was administered to the tibial nerve each second for 330 ms for a duration of four minutes.

Plantarflexion torque and the normalized maximum rate of relaxation (nMRR) were significantly reduced at two minutes of the fatigue protocol in the chronic group, but no significant changes were noted in the acute group. The emg (chronic) was significantly reduced at three minutes, but was minimally related to the changes in torque. The fatigability of the chronically paralyzed group is consistent with clinical reports of muscle fatigue during neuromuscular stimulation and contrary to the reports of unchanged muscle fatigability in long term spinalized animal models.

DIFFERENCES IN FATIGABILITY OF MOTOR UNITS OF THE SAME TYPE NOT RELATED TO DIFFERENCES IN ENERGY-METABOLISM. S. Sesodia*, R.J. Callister, P.M. Nemeth, R.M. Enoka, R.M.Reinking and D.G. Stuart. Dept. of Neurology, Wash. Univ. Med. Sch., St. Louis, MO 63110 and Dept. of Physiology, Univ. of Arizona, Tucson, AZ 85724

Earlier studies on muscle fatigue led to the recognition that resistance to fatigue of motor-units of different histochemical types was positively correlated to the levels of activity of energy-generating enzymes of the oxidative pathways. In this study we have examined the relationship between energy metabolism and fatigue in motor-units of the same histochemical type but of differing fatigabilities. Isolated single axons to rat EDL muscles were stimulated to fatigue fast-fatiguable (FF) motor-unit muscle fibers. After the fatigue test, the motor unit was continuously stimulated at 40 Hz for one hour to deplete its muscle fibers of their glycogen. Muscles were then rapidly dissected, snap frozen in liquid nitrogen and mounted on blocks for cross-sectioning. Series of thick (56 μm) and thin (14 μm) cross-sections were cut from the muscles with the thick sections being freeze-dried and then stored under vacuum at -70°C. Thin sections were stained for glycogen (Periodic acid-Schiff (PAS) reaction) and myosin adenosine triphosphatase. Glycogen depleted fibers as identified from the PAS-stained sections were dissected from the thick freeze-dried cross-sections. The fibers were divided into smaller pieces, weighed on quartz-fiber balance and assayed for activity of enzymes belonging to different metabolic pathways (i.e. glycolytic, oxidative and high energy phosphate). Our preliminary results show that while a difference in fatigue index (and hence fatigatiliby) exists, no correlatable difference exists in the activity of the enzymes of energy-generating pathways. However our data suggest that a relationship may exist between the ratio of certain energy-generating and energy-consuming enzymes and fatigability. We are presently examining this aspect in further detail.

IDENTIFICATION OF OPTIMAL INTERPULSE INTERVAL (IPI) PATTERNS FOR ACTIVATION OF FATIGUED HUMAN QUADRICEPS FEMORIS MUSCLE. S.A. Binder-Macleod* and Scott Baadte, School of Life and Health Sciences, Univ. of Delaware, Newark, DE, 19716.

This study attempted to identify the stimulation pattern during brief (10-pulse), subtetanic trains of pulses that produced the greatest force per pulse when the muscle was fatigueD by repetitive activation. Each train lasted ~600 ms; rest periods of ~600 ms separated each train. Subjects (N=8) participated in three experimental sessions. During the first session, each subject was stimulated with constant frequency trains (CFTs, all IPI durations = 70 ms) and five variable frequency trains (VFTs, first IPI duration = 5, 10, 15, 20 or 30 ms; the remaining 8 IPI durations = 70 ms). During the second experimental session, the second IPI duration was varied while the first IPI was kept at the interval that produced the greatest force during the first session. During the third session, the third IPI duration was varied. The sequencing of trains within each session was random, with each train repeated 30 times during each session (180 contractions). By the 120th contraction a stable level of fatigue was noted. The mean force produced during the last 10 contractions for each stimulation pattern was calculated to compare the response of the muscle to each stimulation pattern.

The results showed that one short IPI at the onset of the train produced 32% more force than the CFT, two short IPIs 64%, and three short IPIs 29%. Thus, two short IPIs produced marked force augmentation in a fatigued muscle compared to the CFTs and other VFTs ($F_{(2,14)}=9.411$, $P=0.003$). These results may have significant implications when electrical stimulation is used clinically to activate skeletal muscle repetitively. Such applications include stimulation of lower extremity muscles to assist spinal cord injured patients to ambulate and stimulation of the latissimus dorsi muscle to assist cardiac muscle function.

649.10

INNERVATION RATIO IS THE MAJOR DETERMINANT FOR THE WIDE RANGE OF MOTOR UNIT FORCE IN THE CAT MEDIAL GASTROCNEMIUS (MG) MUSCLE. V. Rafuse*, M.C. Pattullo and T. Gordon. Dept. of Pharmacology, Div. of Neuroscience, Univ. of Alberta, Edmonton, Alberta, Canada, T6G 2S2.

The extent to which motoneuron branching (innervation ratio; IR) determines the normal variation in motor unit (MU) force within a single muscle is a contentious issue. Determining the range of unit IRs in a large heterogenous muscle such as the cat MG muscle has been difficult due to 1) the wide range in muscle fiber cross-sectional areas (CSAs) between different MU types and 2) counting all muscle fibers by glycogen depletion is difficult due to the steep pinnation of muscle fibers. These problems for calculating the IR of MUs in the cat MG muscle have been overcome in recent experiments with long-term low-frequency electrical stimulation. Cat MG muscles were selectively stimulated (20Hz, 50% duty cycle) for 6 to 32 weeks via a MG nerve cuff electrode attached to a small portable stimulator fastened to the cat's back. In a final acute experiment the unit force distribution was determined by isolating and characterizing at least 14% of the MG MUs. The muscle fibers of a single MU were also depleted of glycogen by repetitive stimulation at a low frequency. The MG muscle was then removed and prepared for histochemical analysis. Following 19 $\pm$ 10 weeks of stimulation the normal 100- fold range in unit force was reduced to a 40- fold range. Concurrently, the range of CSAs for the whole muscle fiber population was similarly reduced from an 8 to 4- fold range. Normally, the range in muscle fiber CSAs within a single MU is 50% that of the whole muscle fiber population. Following stimulation the mean and range of muscle fiber CSAs within a single MU was the same as for the entire muscle. Since the mean muscle fiber CSA of all MUs became similar and IR is not changed by stimulation, these results provide strong evidence that the 40- fold range is IR of MG motoneurons. (Supported by MRC, AHFMR and NCE).

MOTOR UNIT HETEROGENEITY FOLLOWING FUNCTIONAL STIMULATION OF CAT AND HUMAN MUSCLES. M.C. Pattullo, V.F. Rafuse, D.J. Parry, J. Yang*, R.B. Stein and T. Gordon. Div. Neurosci., Univ. Alberta, Alta T6G 2S2 and Dept. Physiol., Univ. Ottawa, Ontario K1H 8M5, Canada

Although it is well recognized that whole muscle properties can be modulated by imposed activity, it is not known whether the predicted conversion to a homogeneous motor unit (MU) population occurs. In medial gastrocnemius (MG) in the cat and tibialis anterior (TA) in spinal injured patients, functional electrical stimulation (FES; 20Hz, 50% duty cycle for at least 2 hrs/day), caused a gradual increase in twitch conctraction time (CT) and fatigue resistance (Rafuse et al., Soc. Neurosci., 17: 256.4, 1991; Stein et al., J. Appl. Physiol. In press). We analyzed up to 14% of the total MU population in the cat MG at 6 weeks (short-term FES) and, in the rest, at 16-32 weeks after continuous FES (long-term FES). In both cat and human, increase in mean values of MU CT and fatigue indices corresponded with changes in whole muscle properties. However, the range of values was NOT greatly reduced and did not correspond to the range of the normal slow MU population. Immunohistochemical analysis of myosin heavy chain (MHC) isoforms in stimulated cat muscles showed that, at 6 weeks, muscles were heterogeneous in composition but long-term stimulated muscles were homogeneous in type I MHC composition with no evidence of hybrid fibers. The finding that all MUs become slower without reducing the range of CT in the MU population provides evidence that 1) factors other than MHC content which include Ca release and uptake rates, are rate limiting for CT and 2) that differences between fibers remain in stimulated muscles which account for the wide range of MU CTs, despite the change in gene expression of contractile proteins. (Supported by Canadian MRC and MDAC and AHFMR).

649.12

IMMUNOHISTOCHEMICAL ANALYSIS OF FIBER TYPES WITHIN PHYSIOLOGICALLY TYPED MOTOR UNITS OF RAT TIBIALIS ANTERIOR MUSCLE AFTER LONG-TERM CROSS-REINNERVATION. S. Fu, T. Gordon*, D.J. Parry and N. Tyreman. Dept. Pharmacology., Div. Neuroscience., Univ. of Alberta, Alta T6G 2S2, & Dept. Physiology. Univ. of Ottawa, Ont. K1H 8M5, Canada.

We have previously shown in the rat (Totosy de Zepetnek et al., Soc. Neurosci., 15: 65, 1989) and mouse (Parry & Wilkinson, Can. J. Physiol. Pharmacol. 68: 596-602, 1990) that the characteristic distribution of fiber types in the deep and superficial regions of Tibialis Anterior (TA) is also seen after self-reinnervation, under conditions in which nerves do not reinnervate their former muscle fibers. In this study, we have used antibodies to type I, IIa and IIb myosin heavy chains (MHCs) to investigate 1) the spatial distribution of fiber types 1 year after cross-reinnervation of rat TA by posterior tibial nerve and 2) the fiber type composition of characterized MUs. We found that the spatial distribution of fiber types was not statistically different from normal despite increased clumping of fiber types. Fibers which did not react with any of the 3 antibodies, presumably type IIx fibers, comprised up to 30% of the total, similar to the proportion of FI MUs in normal and self-reinnervated muscles (Totosy de Zepetnek et al., J. Neurophysiol., 67 #5, 1992). Within identified fast MUs, most fibers showed MHC expression which was congruent with the MU type (i.e. FF=IIB, FR= IIa). However, there was considerable variation in the intensity of staining and a significant proportion of fibers (>5%) in FF and FR MUs appeared to be type IIx. In FI MUs, 5-10% of fibers were IIb positive. These findings provide suggestive evidence for an intrinsic regulation of muscle fiber type which allows for the maintenance of the original spatial distribution and may account for the fiber heterogeneity within a single MU. (Supported by MDAC, MRC and AHFMR).

649.13

NEURAL REGULATION OF GLYCOGEN PHOSPHORYLASE EXPRESSION IN RAT SKELETAL MUSCLE C. C. Matthews and R. C. Carlsen*. Department of Human Physiology, School of Medicine. University of California, Davis 95616

Denervated skeletal muscle undergoes a series of metabolic changes, including a decrease in both the activity of glycogen phosphorylase and the content of muscle-specific glycogen phosphorylase (MGP) messenger RNA. We tested the hypothesis that the loss of neurotrophic substances following denervation is responsible for the decrease in MGP transcription. Several concentrations of vinblastine were used to block axonal transport in situ in the rat peroneal nerve. Nerve conduction velocities and tibialis anterior (TA) contractile properties were assessed at 7 days after initiation of the axonal transport block. MGP expression in the TA muscle was determined using standard Northern analysis procedures. The results show that axonal transport of acetylcholinesterase activity declined in nerves treated with 0.2% (w/v) and 0.4% vinblastine. There was also a dose-dependent decline in motor and sensory nerve conduction velocities one week after treatment with 0.2% or 0.4% vinblastine. The ability of the muscle to produce force likewise declined with the highest doses of vinblastine. The amount of MGP mRNA present 7 days after vinblastine treatment decreased substantially when the nerve was exposed to 0.4% vinblastine. A lesser decrease in MGP mRNA developed after treatment with 0.2% vinblastine. Lower concentrations of vinblastine produced no apparent change in the content of MGP mRNA. These results suggest that MGP transcription is under neurotrophic regulation, but by some means other than the release of an axonally transported diffusable substance.

IS MUSCLE LIKE PAINT? J.L.F. Weytjens* and J.A. Hoffer[1]. Dept. of Clinical Neurosciences, University of Calgary, Calgary, Alberta T2N 4N1, CANADA.

Hoffer et al. (Prog. Brain Res. 80: 75-85, 1989) found that the origin-to-insertion length of the cat medial gastrocnemius muscle (MG) and the length of its fibers do not vary in unison during locomotion: the maximum difference was 2 mm in stance and 5 mm in swing. In contrast, Elek et al. (J. Physiol. 429: 237-258, 1990), using the spindle-null method, estimated the length changes in the tendinous component of the muscle ("extramysial displacement") during simulated locomotion to be only 0.3 to 0.7 mm (stance). We have reassessed extramysial displacement during locomotion using direct measurements of muscle length and muscle fiber length in simulated locomotion with and without stimulation of the muscle.

In six chronically instrumented cats muscle force, muscle length, muscle fiber length, and the length of a small part of the ventral aponeurotic sheet were measured during treadmill locomotion. Locomotion was simulated in the same animals under anesthesia by matching muscle force and muscle fiber length (Weytjens and Hoffer, SN Abstr. 17: 648, 1991). Extramysial displacement was computed from the measurements made in the simulations, using simple assumptions about the structure of MG.

Tendon length and muscle force did not change in phase. After an initial increase in length more or less proportional to force, the rate of lengthening decreased abruptly. However, tendon length kept increasing (until after the last stimulus) even though muscle force declined. It shortened back to its original length only slowly, the last half of the shortening occurring in the absence of muscle force. The same pattern was observed in the measurements of aponeurotic sheet length. The mean maximum estimated change in tendon length was 2.53 mm.

These observations were most simply explained by assuming that muscle has paint-like, i.e., *thixotropic*, properties: that it "thins" when "stirred" by internal or external movement, and "thickens" when left "standing." On the basis of the same mechanism other hitherto unexplained muscle phenomena could also be explained: (1) the time course of force responses of passive muscle to stretch, (2) the shape of single motor unit force-velocity curves, and (3) movement-dependent motor unit force potentiation.

Muscle unit architecture and motor pool organization of the pectoralis muscle in pigeons. A. Sokoloff*, J. Ryan, E. Valerie, D. Wilson and G. E. Goslow Jr. Biology, Brown University, Providence, RI 02912.

The pectoralis muscle of the pigeon *(Columba livia)* is composed of fast oxidative glycolytic (FOG) and fast glycolytic (FG) fibers thought to be differentially recruited during take-off and steady flight. To assess the neuromuscular organization of FOG and FG motor units, pectoralis muscle unit architecture and motor pool organization were studied with glycogen depletion and retrograde axonal tracing techniques. Individual motor units were identified in ventral root filaments by the presence of a stable EMG and force trace during a 5-10 fold increase in voltage and were stimulated for 1-3 hours. The pectoralis muscle was sectioned and stained for glycogen to allow muscle unit reconstruction. Three FOG units were 2.4, 2.5 and 3.5 cm in length, and consisted of 100, 250 and 300 fibers respectively. A single FG unit was 3.5 cm in length and consisted of 170 fibers. None of the muscle units extended more than 30% of the origin-to-insertion whole muscle length. Following application of a 30-40% solution of HRP to cut pectoralis nerves (N=3), retrogradely labeled neurons were located in cervical segments 10 to 12. Motoneuron soma area ranged from 3000-18000 sq μm (x = 9000 sq μm). A few exceptionally large neurons (15000-18000 sq μm) were observed in each bird. These results 1) demonstrate that individual muscle units occupy a small portion of the pigeon pectoralis and do not extend from muscle origin to muscle insertion and 2) suggest that force transmission in the pectoralis proceeds through myo-myous and/or endomysial connections between the fibers of in-series muscle units. The presence of large motoneurons in the pectoralis motor pool suggests a possible correspondence between motoneuron size and muscle unit area and/or fiber type. Supported by NSF grant DCB-87-18727.

MORPHOLOGY OF MOTONEURONS INNERVATING TWO REGIONS OF RAT MEDIAL GASTROCNEMIUS MUSCLE WITH DIFFERING PHYSIOLOGIAL AND HISTOCHEMICAL PROPERTIES. S. Vanden Noven*, P.F. Gardiner and R.A. Turcotte. *School of Physical & Occupational Therapy, McGill University, (H3G 1Y5) & Sciences de l'activité physique, Université de Montréal, Montréal, Québec, H3C 3J7, Canada.

We studied the medial gastrocnemius (MG) motoneuron pool/muscle complex in Sprague-Dawley rats in which the MG nerve enters the muscle as two branches. In situ experiments showed that the muscle region innervated by the proximal MG nerve branch generated 25% of total muscle tetanic force and demonstrated slower twitches and higher fatigue resistance than that innervated by the distal branch. Glycogen depletion experiments showed the proximal branch to innervate the axial core of the muscle which contains the slow twitch and most of the fast twitch, high oxidative fibers. In separate experiments, proximal and distal nerve branch motoneurons were labeled with horseradish peroxidase (HRP). 'Proximal-branch' alpha-motoneurons were smaller and accounted for up to 44% of the total MG pool. A systematic variation in rostral-caudal location of motoneurons from the two nerve branches was present within the MG pool. Thus, the unique organization within the MG motoneuron pool/muscle complex will permit comparative studies on the adaptive properties of different motor unit types within a given complex.

FIBER TYPE DIVERSITY IN THE VIBRISSAL FACIAL MUSCLES OF RODENTS. L.E. Wineski*, S.A. Pitts and O.I. Weeks. Dept. Anatomy, Morehouse School of Medicine, Atlanta, GA 30310; Dept. Biological Sciences, Florida International University, Miami, FL 33199.

The golden hamster (Mesocricetus auratus), Norway rat (Rattus norvegicus), and guinea pig (Cavia porcellus) exhibit three types of exploratory behavior, as defined by the use of the mystacial vibrissae. The gross morphology of the superficial facial muscles that operate the vibrissae is very similar in the three species; however, the muscles may differ in their physiological characteristics. Preliminary enzyme histochemical tests indicate significant species differences. Myosin ATPase reactions show that the muscles that act to protract the vibrissae are composed predominantly of type IIa fibers in the whisking species (hamster, rat); those in the nonwhisking guinea pig are composed largely of types IIb and IIc fibers. The muscles involved in retraction are more heterogeneous in their composition: the hamster has predominantly type IIa fibers, the rat mainly types IIb and IM fibers, the guinea pig largely types IIc and IM fibers. NADH tetrazolium reductase reactions show that all vibrissal muscles in the hamster are composed entirely of highly oxidative fibers. Those in the rat and guinea pig contain large populations of intermediate-level fibers. In general, the vibrissal muscles are composed almost entirely of fast-twitch, fatigue-resistant fibers with minor populations of slow-twitch, fatigue-resistant fibers. However, there is great diversity in the subtype composition of the muscles. Supported by NIH S06-GM08248 and NIDR.

650.4

MUSCLE FIBER TYPE COMPOSITION AND SUCCINATE DEHYDROGENASE ACTIVITY OF SEXUALLY DIMORPHIC MUSCLES. G.C. Sieck*, C.F. Blanco, P. Popper and P.E. Micevych. Depts. of Physiology & Anesthesiology, Mayo Clinic, Rochester, MN 55905, and Dept. of Anatomy & Cell Biology, Laboratory of Neuroendocrinology, UCLA School of Medicine, Los Angeles, CA 90024.

The succinate dehydrogenase activity (SDH) of muscle fibers from the sexually dimorphic levator ani (LA) and bulbocavernosus (BC) muscles were determined using a quantitative histochemical technique from cryostat sections of fresh frozen tissues (Histochem. J. 20:230, 2988). The BC, LA and medial gastrocnemius (MG) muscles of male Long-Evans rats were excised and frozen in liquid nitrogen cooled isopentane. The MG muscle was included so that comparisons could be made with a non-sexually dimorphic muscle. All of the BC and LA muscle fibers were type IIb. Furthermore, the BC and LA muscle fiber populations were metabolically homogeneous. For type IIb fibers the mean SDH activity was greatest among fibers from the deep region of the MG followed in descending order by the superficial region of the MG, the BC, and the LA muscles. These results suggest that the BC and LA muscles are composed of highly fatigable fast-twitch muscle units. (Supported by grants HL 34817 and HL 37680.)

THE CATCH-LIKE PROPERTY OF TURTLE MUSCLE: EFFECT OF SHORTENING, LENGTHENING, AND FATIGUING ISOMETRIC CONTRACTIONS. R.J. Callister, D.H. Laidlaw, R.M. Reinking, and D.G. Stuart.*Department of Physiology, University of Arizona, Tucson AZ 85724.

We have shown previously in mammals (adult cat) that subtle changes in motor unit firing patterns can delay and reduce fatigue (Bevan *et al.*, J. Physiol. (Lond.) 449:85-108, 1992). To extend on these observations, we have recently changed our animal model from cat to turtle (*P. scripta*) as this species affords the unique opportunity, in vertebrates, to study segmental motor mechanisms in intact *(in vivo), in vitro* (slice) and cell-culture preparations. In this report, we examine the catch-like property in the whole external gastrocnemius muscle (EG; 27% SO, 39% FOG and 34 %Fg fibers) during shortening and lengthening contractions, and following fatiguing isometric contractions. Two different stimulation patterns, *constant-frequency* (10 pulses, 100 ms intervals) and *catch-inducing* (two additional 10 ms intervals inserted at the beginning of the constant-frequency pattern), were applied to the EG muscle nerve. The force-time integral attributable to each stimulus pattern was quantified. The catch-inducing pattern always produced greater force than the constant-frequency pattern. However, the magnitude of the increase depended on the type of contraction. A comparison of force enhancement, due to the catch-like property, prior to and during shortening (17% *vs.* 14%) and lengthening (20% *vs.* 16%) contractions did not reveal any significant differences. This contrasts with the marked difference (12% pre-fatigue *vs.* 37% post-fatigue) in force enhancement observed in muscles following a period of fatiguing (10 Hz trains, 10 p/train, 1 train/2 s for 4 mins) isometric contractions. It remains to be determined if a catch-inducing activation pattern becomes more important during dynamic contractions in fatiguing muscle, as is the case for isometric contractions. SARCOMERE LENGTH-JOINT ANGLE RELATIONSHIPS OF SEVEN FROG HINDLIMB MUSCLES. R. L. Lieber* and C. G. Brown. Department of Orthopaedics and Biomedical Sciences Graduate Group, *U.C. San Diego Medical School and VAMC*, San Diego, CA 92161

The sarcomere length-joint angle relationship was measured in seven different muscle-joint complexes (n=49 muscles) of the frog hindlimb (*Rana pipiens*). Muscles studied included the cruralis, iliacus internus, gastrocnemius, gluteus magnus, gracilis major, semimembranosus, and the semitendinosus. Muscle-joint complexes were mounted in a jig and submerged in chilled Ringer's solution. Joints were rotated throughout their range of motion while sarcomere length was measured by laser diffraction. Sarcomere length change per degree of joint rotation (i.e., $dL_S/d\theta$) ranged from a low of 3.7 nm/° for the cruralis muscle acting at the knee to a high of 12.5 nm/° for the semitendinosus muscle acting at the hip. $dL_S/d\theta$ values for muscles acting at the hip joint were significantly greater than those for muscles acting at the knee ($p<0.005$). $dL_S/d\theta$ was also negatively correlated with fiber length, suggesting a balance between fiber length and moment arm in most muscle-joint systems. Many exceptions to this generalization were noted. These data suggest that various muscle-joint combinations are "designed" for differential contribution of muscle force production to the joint torque profile.

ELECTROPHYSIOLOGICAL PROPERTIES AND CALCIUM ACTIVATED POTASSIUM CHANNELS IN RAT CEREBROVASCULAR SMOOTH MUSCLE CELLS. Y.Wang* and D.A.Mathers. Department of Physiology, University of British Columbia, Vancouver B.C., Canada V6T 1W5.

Patch clamp methods were used to study the electrophysiological properties and the calcium activated potassium channels of smooth muscle cells (SMCs) from the cerebral arteries of adult Wistar rats. Procedures were developed for the enzymatic dissociation of these cells. Dissociated cells were maintained at 4°C for 1-3 days prior to use. Whole cell and inside-out patch clamp recordings were made at 21°C using a List EPC-5 amplifier.

During whole-cell, current clamp recordings from these cells, the resting membrane potential was found to be -41 mV. Application of strong depolarizing stimuli evoked only small regenerative responses and full action potentials were not observed. When measured at zero applied current, the slope membrane resistance was 3.2 gigaohm. The average membrane time constant was 78 ms and cell capacitance was 24 pF.

Isolated, inside-out membrane patches excised from these cells displayed calcium activated potassium channels with intermediate single channel conductance (92 pS) in symmetrical 140 mM KCl solution. These channels were activated by both increasing intracellular free calcium and depolarization of the patch membrane. Tetraethylammonium caused a reversible, dose-dependent reduction in the amplitude of current in the channels, when applied to the cytoplasmic membrane face (K_d=0.31 mM).

CYTOARCHITECTURE OF THE NEUROMUSCULAR JUNCTION IN DIABETIC MUSCLE. K. M. Klueber* and S. Stansel. Department of Anatomical Sciences and Neurobiology, University of Louisville, School of Medicine, Louisville, KY 40292.

During the pathogenesis of diabetes, a peripheral neuropathy occurs in the C57Bl/KsJ-dbm diabetic mouse. Prior work indicated that neuromuscular remodelling occurs in this mouse (Klueber and Stahr, Neurosci. Abts.15:51, 1989). The objective of the present study was to evaluate the cytoarchitecture of these neuromuscular junctions (NMJ) to provide an index of remodelling. The extensor digitorum longus muscles from young (8wk) and old (20wk) female diabetic and control mice were examined electron microscopically: In the diabetic muscles, thirty percent of the NMJ's examined at both time points exhibited various degrees of degeneration. Remodelling was also observed as indicated by the presence of sprouts (4%). Reinnervation was indicated by NMJ's exhibiting secondary synaptic clefts which extended beyond the axon (10%, 8wk; 5%, 20wk) while others exhibited only limited shallow secondary cleft formation (13%, 8wk; 9% 20wk). Both of these profiles are characteristic of reinnervation following nerve section and are hypothesized to be stages in the maturation of regenerating NMJ's (Hansen-Smith, Anat. Rec. 207:55, 1983). Thus regeneration and remodelling of NMJ's is more frequent in young rather than old diabetic muscle and occurs to a greater degree in diabetic than in normal muscle. (Funded by DK41553).

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS—CONDITIONING I

651.1

DISRUPTING CEREBELLAR DEVELOPMENT IMPAIRS EYEBLINK CONDITIONING IN THE INFANT RAT. M.E. Stanton[*1,2] & J.H. Freeman, Jr.[2] [1]Neurotox. Div., US EPA, RTP, NC, 27711; [2]Psychology Dept., UNC, Chapel Hill, NC 27514

There is a dramatic increase in rate of eyeblink conditioning (EBC) between Postnatal Day 17 (PND17) and PND24 in the rat (Stanton, Freeman & Skelton, Behav. Neurosci., in press), which may reflect postnatal development of the cerebellum. To examine this possibility, we exposed pups neonatally to the antimitotic agent, methylazoxymethanol (MAM), a treatment that impairs the development of cerebellar cortex, while leaving most other brain structures intact (Chen & Hillman, 1986, Exp. Neurol., 94, 103).

On PND0 and PND1, rat pups were injected (s.c.) with saline or 20 mg/kg MAM. On PND21 or PND22, they were trained on spatial delayed alternation, a task that is sensitive to early limbic and prefrontal cortical damage (Freeman & Stanton, in press; 1991, Behav. Neurosci, 105, 386-395). On PND23 or 24, they were trained on EBC (see Stanton et al., in press). Pups exposed to MAM were not impaired on delayed alternation (suggesting no functional impairment of hippocampus or prefrontal cortex). In contrast, pups that showed MAM-induced cerebellar hypoplasia were impaired on acquisition of EBC. These findings suggest a role for cerebellar development in the ontogeny of EBC.

651.2

EARLY CEREBELLECTOMY IMPAIRS EYEBLINK CONDITIONING IN THE INFANT RAT. J.H. Freeman[*1] & M.E. Stanton[1,2] [1]Psychology Dept., UNC, Chapel Hill, NC 27514; [2]Neurotox. Div., US EPA, RTP, NC, 27711

Initial studies have demonstrated that associative eyeblink conditioning (EBC) can be established in the infant rat (Stanton, Freeman, & Skelton, Behav. Neurosci., in press). One purpose of this research is to develop a preparation for the neurobiological analysis of the ontogeny of learning. As a first step toward this end, we sought to determine whether the cerebellum was critical for EBC acquisition in the infant rat. In the adult rat, lesions of the cerebellar deep nuclei abolish EBC (Skelton, Behav. Neurosci, 1988). However, it is not known whether early cerebellar damage would affect acquisition of EBC in the infant rat.

Pups received either sham surgery or cerebellar removal by aspiration on Postnatal Day 10 (PND10). On PND25, all pups were trained on EBC (see Stanton et al., in press). Animals with complete cerebellar removal were dramatically impaired when compared with animals in the sham-surgery group.

This experiment extends and confirms the structure-function homology between neuranatomical substrates of EBC in the rat and rabbit. Moreover, the results suggest a role for the cerebellum in the ontogeny of EBC.

651.3

EVIDENCE THAT THE PRINCIPAL ABDUCENS NUCLEUS UNDERLIES THE *IN VITRO* CONDITIONED EYE-BLINK RESPONSE. J. Keifer*, Dept. of Physiology, Northwestern Univ. Medical School, 303 E. Chicago Ave., Chicago, IL 60611.

Two distinct populations of abducens motor neurons contribute to the eye-blink reflex: the principal and the accessory abducens nuclei. Accessory abducens sends its axons to the retractor bulbi muscle and receives afferents from the trigeminal nucleus and premotor blink areas. Principal abducens projects to the lateral rectus and retractor bulbi muscles, and receives inputs from nerve VIII, the reticular formation, and a minor input from the trigeminal nucleus. Thus, the pathways that undergo modification during conditioning may be different depending on the relative contribution of the abducens nuclei to the conditioned response (CR). Previously, we reported that the *in vitro* turtle brainstem-cerebellum was a useful model to study the conditioned eye-blink reflex. Using the activity-dependent dye sulforhodamine, evidence has been obtained suggesting that the principal abducens nucleus, rather than the accessory abducens, has a predominant role in producing the conditioned response.

Paired electrical stimuli to the posterior nerve VIII (CS) and the trigeminal nerve (UCS) were applied to the *in vitro* preparation while recording activity in the abducens nerve as described previously (*Soc. Neurosci. Abs.* 16: 763, 1990). Once a conditioned response had been acquired, sulforhodamine was added to the bath and the preparation was given CS-only stimuli. Hence, during dye application, only CR's were recorded. The results show that during expression of the CR, labeled neurons were found predominantly in the principal abducens nucleus as compared to the accessory abducens nucleus. Labeled neurons were also observed in the red nucleus and lateral cerebellar nucleus, areas which never label during the UCR. Purkinje cells, the reticular formation, trigeminal nucleus, and the cochlear nucleus also labeled with dye.

The results suggest that the principal abducens nucleus is in the modifiable pathway leading to the CR. This is intriguing since activity in this nucleus, but not in the accessory abducens, is mediated by NMDA. Although not traditionally considered, the principal abducens and trigeminal nuclei, both of which receive CS-US convergence, are postulated to be potential sites of learning. (NSF BNS-9109572)

PERFORMANCE OF UNCONDITIONED NICTITATING MEMBRANE RESPONSES IN THE INTACT RABBIT IS AFFECTED BY MUSCIMOL INACTIVATION OF THE NUCLEUS INTERPOSITUS. V. Bracha*, M.L. Webster, J.R. Bloedel, Barrow Neurological Institute, Phoenix, AZ 85013.

The purpose of this study was to examine the specificity of involvement of the anterior nucleus interpositus (AIN) in the control of nictitating membrane reflexes. Animals were trained in the standard delay paradigm using 450 ms sound as the conditioned stimulus and 100 ms unilateral corneal air-puff as the unconditioned stimulus (ISI=350 ms, ITI=17-23 s). The trained animals were injected with muscimol in the AIN ipsilateral to the trained eye and tested in experiments in which trials consisting of paired conditioned and unconditioned stimuli were alternated with trials containing the unconditioned stimulus alone.

The muscimol microinjections (200 ng) completely abolished the conditioned responding. Explicit testing of the unconditioned reflex before and after drug administration revealed that activation of GABA-a receptors significantly decreases the amplitude of the unconditioned nictitating membrane responses. The analysis of behavior in animals which developed bilateral conditioned responses indicate that the drug effect is mostly restricted to the ipsilateral eye.

The results of the present study do not support the notion that the AIN is involved exclusively in mediating the classically conditioned nictitating membrane reflex. The behavioral effects of the muscimol injections in the AIN suggest that this cerebellar nucleus participates in control of both conditioned and unconditioned nictitating membrane responses in intact rabbits . NIH Grant R01 NS21958

LIDOCAINE INFUSION IN A CRITICAL REGION OF CEREBELLUM COMPLETELY PREVENTS LEARNING OF THE CONDITIONED EYEBLINK RESPONSE. A.F. Nordholm*, J.K. Thompson, S. Standley, G.Tocco, C. Dersarkissian & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

New Zealand White rabbits were implanted with cannulae in the dorsal or ventral aspect of the anterior interpositus nucleus. Three days (and six days for some animals) of standard tone-airpuff training was given with continuous infusion (constant rate of 0.2 ul/min) of Lidocaine (2, 4, 8, 16%) or saline. All animals were then given three days of training with no infusion. The minimum dose (concentration) of Lidocaine necessary to abolish performance of the CR was then determined for every animal. Saline control animals learned to criterion during the three days of infusion training; Lidocaine animals with dorsal cannula locations and appropriate doses exhibited no CRs in the three (or six) days of infusion training and learned in the subsequent three days of no-infusion training as if naive, i.e. they exhibited no savings. Animals with ventral cannula locations and appropriate doses showed no CRs during Lidocaine infusion training but substantial savings in subsequent no-infusion training. Thus both acquisition and performance of the CR were completely abolished, depending on cannula location, in a dose dependent manner. These results strongly support the hypothesis that the essential memory trace for eyeblink conditioning is formed and stored in the cerebellum. (Supported by NSF and ONR grants to R.F.T.)

651.6

INACTIVATION OF CEREBELLUM WITH GABA AGONIST MUSCIMOL REVERSIBLY BLOCKS ACQUISITION AND RETENTION OF RABBIT'S CLASSICALLY CONDITIONED EYEBLINK RESPONSE D.J.Krupa*, J.K.Thompson, R.F.Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520

The GABA agonist muscimol was used to assess the cerebellum's role in eyeblink conditioning. In well trained rabbits, varying concentrations of muscimol were infused into the cerebellum through chronically implanted cannulae aimed at the ipsilateral interpositus nucleus. Conditioned responses (CRs) were completely blocked for up to 8 hours with no effect on unconditioned responses (URs). By 12 hours, CRs returned to pre infusion levels.

A group of naive rabbits (n=6) received 6 days of tone-airpuff conditioning. On the first 3 days, muscimol was infused into the cerebellum prior to training; no infusion was given on the last 3 days. A control group (n=5) received vehicle alone infusions on days 1-3 and no infusion on days 4-6.The muscimol group showed no learning on days 1-3 and no savings on day 4. These rabbits learned normally on subsequent days. Their rate of acquisition and average percent CRs on days 4-6 was identical to days 1-3 of controls. Controls were responding at a high percentage by day 3. Average UR amplitude on paired trials as well as airpuff alone trials was the same for both groups. Infusions of ^{3}H-muscimol following training and subsequent histology confirmed that the muscimol was localized to the dentate/interpositus nuclei and overlying cortical regions. Another group of rabbits (n=5) received infusions of muscimol into the red nucleus on days 1-3. These rabbits showed no CRs on those days but showed a significantly higher percent CRs on day 4 than the cerebellar group.

These results demonstrate that the cerebellum is required for acquisition and expression of eyeblink conditioning. The results also indicate that the cerebellum is a locus for storage of this memory. Supported by NSF, ONR, and McKnight grants to RFT.

Reversible Lesions of the Red Nucleus During Acquisition and Retention of a Classically Conditioned Behavior in Rabbits. Robert E. Clark* and David G. Lavond. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

We have previously shown that temporary cooling of the interpositus nucleus prevents acquisition of a classically conditioned eyeblink. In the present study we assess the role of the red nucleus during conditioning. A cooling probe was implanted lateral to the red nucleus. Recording electrodes were implanted in the right red nucleus and the left interpositus nucleus. Animals were trained for five days with the cooling probe activated. No behavioral conditioned responses (CR) developed and multiple unit recordings related to learning did not develop in the red nucleus. However, a learning related model did develop in the interpositus. Animals were then given five days of normal training (cooling probe inactive) to assess retention. Substantial savings were evident as CRs appeared quickly and multiple unit models were present in both red nucleus and interpositus nucleus. These results support the idea that the red nucleus is a necessary efferent for the memory trace formed in the cerebellum. Supported by NSF: BNS8906612.

TEMPORAL DISCRIMINATION AND PAVLOVIAN EYELID RESPONSES: CEREBELLAR VERSUS PRE-CEREBELLAR MECHANISMS. S. P. Perrett* and M. D. Mauk. University of Texas Medical School, Houston, TX 77225.

We previously reported (Perrett et al, **Neurosci. Abstr.** 115.1, 1990) that lesions of the cerebellar cortex disrupt the adaptive timing of conditioned eyelid responses in the rabbit. The retention of inappropriately timed conditioned responses (CRs) after the lesion suggests a) the temporal discrimination necessary for adaptive timing of CRs occurs in the cerebellar cortex or b) occurs afferent and is conveyed to the cerebellar cortex. To distinguish these possibilities we tested the ability of individual animals to acquire differently timed CRs using stimulation of mossy fibers in the middle cerebellar peduncle (MCP) as the conditioned stimulus (CS).

Rabbits are conditioned by pairing a stimulus train in the MCP coterminating with periocular eyeshock as the unconditioned stimulus (US). Differently timed responses are produced in an individual animal by training at one interstimulus interval (ISI) until a criterion of 90% responding is reached, extinguishing this CR, then training at a different ISI. All animals with electrode placements in the mossy fiber bundle learned at least three differently timed responses at criterion levels before degeneration of the electrode. Peak amplitude for all CRs occurs approximately when the US is presented. The animals' ability to produce differently timed responses when a constant set of mossy fibers in the MCP are activated, along with the lesion data, suggests that a temporal discrimination mechanism exists in the cerebellar cortex. To test this hypothesis further we trained rabbits with single pulse stimulation as the CS to preclude temporal summation as a mechanism to recruit different subsets of mossy fibers. While the ISI range that supports conditioning is much smaller with a single pulse CS, rabbits learn differently timed responses at criterion levels. We hypothesize that temporal discrimination occurs via the activation of different subsets of granule cells, rather than different subsets of mossy fibers, throughout the ISI. This may result from the dynamic interaction of granule cells and inhibitory Golgi cells in the cerebellar cortex. If the granule cell synapses active in a time window around a climbing fiber response decreased in strength (e.g. LTD), nuclei cells would be disinhibited when this subset of granule cells is subsequently active and an appropriately timed CR could be elicited.

EFFECTS OF REWARDING ELECTRICAL STIMULATION OF LATERAL HYPOTHALAMUS ON CONDITIONED NICTITATING MEMBRANE RESPONSE IN RABBITS J. Arikoski*, T. Korhonen, M. Penttonen, and T. Ruusuvirta. Dept. of Psychol., Univ. of Jyvaskyla, P.O. Box 35, SF-40351, Finland

Possible facilitation or retardation effect of rewarding brain stimulation of lateral hypothalamus (ESB) was studied in classical conditioning of nictitating membrane responses in rabbits. A 250 ms train of ESB pulses were applied 250 ms after the unconditioned stimulus (UCS, corneal airpuff, 150 ms, 2.1 N/cm^2). The conditioned stimulus (CS, tone 1000 Hz, 400 ms) preceded the UCS 250 ms. In the control group ESB preceded the CS-UCS pair by 250 ms. A tone CS was classically conditioned to an air-puff UCS followed by stimulation of the lateral hypothalamus. The rabbits showed increased orienting and activity to brain stimulation. Preliminary observations showed also that the airpuff UCS can act as a CS eliciting conditioned responses.

SUBICULAR AND CINGULATE CORTICAL COMBINED LESIONS AND LIMBIC THALAMIC UNIT ACTIVITY DURING LEARNING IN RABBITS. E. Kang* and M. Gabriel, Dept. of Psychol. and Beckman Inst., Univ. of Illinois, Urbana, IL 61801.

Separate bilateral electrolytic lesions in the dorso-posterior subicular complex or in posterior cingulate cortex (area 29) enhanced the magnitude of training-induced unit activity (TIA) exhibited by anterior ventral (AV) thalamic neurons comprising circuitry involved in discriminative avoidance conditioning. Rabbits acquired a conditioned response (CR, stepping in an activity wheel) to prevent foot-shock 5 sec. after presentation of a .5-sec. tone conditional stimulus (CS+), and they learned to ignore a different tone (CS-) which did not predict shock (Gabriel et al., Exp Br Res, 1987, 67, 131-152). These findings indicated subicular and cingulate cortical modulation of limbic thalamic TIA. One account of these findings states that subicular and area 29 efferents in intact rabbits suppress TIA in the AV nucleus. Lesions in either area thus enhance AV thalamic TIA. Alternatively, efferents of the two cortical areas may enhance AV thalamic TIA and mutually inhibit one another. Lesions in one area would thus disinhibit the other thereby enhancing AV thalamic TIA. Combined lesions (1.0 DC mA. for 20 sec. each) at 3 sites along the subicular septo-temporal axis and at 9 sites from bregma to 9.0 mm posterior in area 29 (N=8) enhanced AV and medial dorsal (MD) thalamic TIA relative to TIA in sham lesion controls (N=9). As after single lesions, TIA was maximally enhanced in asymptotically trained rabbits, but discharge enhancement also occurred before training, unlike the single-lesion case. These results support the first and rule out the second of the previously stated accounts. The combined lesions increased CR incidence in the first conditioning session, as did the single subicular lesions. CR loss found in well-trained rabbits with single area 29 lesions was not found here in the rabbits with combined lesions. Also, an increased latency and decreased duration of shock-elicited locomotion occurred in the rabbits with combined lesions. (Supported by an NIH grant to MG).

CINGULATE CORTICAL AND LIMBIC THALAMIC NEURONAL RESPONSES TO UNEXPECTED CUE AND CONTEXTUAL STIMULI DURING EXTINCTION OF DISCRIMINATIVE AVOIDANCE BEHAVIOR IN RABBITS. A. Poremba*, Y. Kubota, E. Kang and M. Gabriel. Dept. of Psychol. and Beckman Institute, Univ of Illinois, Urbana IL 61801.

Hippocampal formation lesions enhanced the training-induced neuronal activity (TIA) in the anterior ventral (AV) thalamic nucleus during discriminative avoidance training, wherein rabbits performed a locomotory conditioned response (CR) in an activity wheel to avoid a footshock signaled by a tone (CS+) 5 sec. before the shock, and they learned to ignore a tone (CS-) of different auditory frequency than the CS+, which did not predict shock (Gabriel et al., Exp Br Res, 1987, 67, 131-152). Unexpected training experiences such as extinction (CSs presented without shock to a trained subject) did not effectively suppress CR performance in rabbits with lesions, suggesting the hypothesis that CR suppression by unexpected events is due to TIA suppression in AV and possibly other limbic thalamic nuclei. Here, CRs were suppressed but anterior and medial dorsal (MD) thalamic and cingulate cortical TIA was **not** suppressed during initial trials of extinction with an unexpected context (altered background odor and illumination) or tone. These results disconfirm the hypothesis. TIA in anterior cingulate cortical area 24b, and in the anterior dorsal, magnocellular AV and MD thalamic nuclei was enhanced by the unexpected context (but not by the unexpected tone) during the first 20 extinction trials, relative to TIA during extinction trials without novelty. The novel context-induced AV thalamic TIA enhancement corroborated preliminary results of a study (Kang et al., Soc Neurosci Abst., 1990, 16, 264) which also showed loss of the enhancement in rabbits with lesions of Ammon's horn. These results suggest that hippocampal efferents mediate the enhanced TIA. The cortical and thalamic sites exhibiting the context-related enhancement of TIA may be part of a circuit involved in the immediate suppression of CRs and/or mnemonic encoding of novel information, but this circuit does not appear to be engaged by unexpected CSs. (Supported by NIH).

651.12

SUBICULAR AND CINGULATE CORTICAL LESIONS AND ANTERIOR THALAMIC NEURONAL RESPONSES TO UNEXPECTED CUE AND CONTEXTUAL STIMULI IN RABBITS. M. Gabriel* and E. Kang. Dept. of Psychol. and Beckman Institute, Univ of Illinois, Urbana IL 61801.

Anterior and medial dorsal thalamic neurons are essential for discriminative avoidance conditioning, wherein rabbits learn to avoid footshock by stepping in response to a tone (CS+), and to ignore a different tone (CS-) which does not predict shock. CR acquisition, blocked by limbic thalamic lesions, is accompanied in intact rabbits by training-induced neuronal activity (TIA, increased tone-elicited discharges and discrimination, i.e., greater discharges to CS+ than to CS-). Standard CSs presented to intact trained rabbits following the introduction of unexpected contextual stimuli (alteration of odor and illumination cues) increased anterior ventral (AV) thalamic TIA and suppressed CR incidence, an effect blocked by hippocampal lesions. Presentation of an unexpected tone stimulus in the standard training context also suppressed behavior but did not increase TIA (see abstract by Poremba et al, this volume, and Kang et al., Soc Neurosci Abst. 16, 1990, 264). These results suggested that hippocampal efferents in the presence of altered contextual stimuli induce: a) AV thalamic TIA enhancement; b) CR suppression. Ammon's horn efferents gain access to AV nucleus via subicular and cingulate cortical (area 29) synaptic relays. If true, then subicular/area 29 lesions should, as Ammon's horn lesions, diminish AV thalamic discharges elicited in the presence of unexpected contextual stimuli. Instead, AV thalamic novel-context-specific discharges were enhanced, relative to controls (N=11), in rabbits with the combined lesions (N=11). These results suggest that Ammon's horn neurons do not drive directly the AV thalamic discharges. Computations of interactive Ammon's horn and subicular circuitry may permissively allow the thalamic discharges (driven by as yet unknown afferents) to occur. Ammon's horn lesions may unbalance the permissive interactions, with the result that subicular/area 29 influences suppress the thalamic discharges. (Supported by an NIH grant to MG).

LESIONS OF THE CEREBELLAR FASTIGIAL NUCLEI FAIL TO AFFECT APPETITIVE PAVLOVIAN CONDITIONING OF JAW MOVEMENT (JM). C.M. Gibbs* and K.L. Watson. WJB Dorn Veterans' Hospital and University of South Carolina, Columbia, SC 29201.

We recently reported [Gibbs et al: Soc Neurosci Abstr 17(1991)870] that bilateral lesions of the cerebellar interpositus n. have no effect upon the acquisition of conditioned JM responses in rabbits with repeated pairings of tone (CS) and an intraoral pulse of water (US), though such lesions do disrupt circuitry associated with climbing fiber responses to intraoral stimulation. Since the vermal cortex receives gustatory information [Somana & Walberg: Neurosci Lett 11(1979)41-47], the present studies sought to determine whether bilateral lesions of its deep nuclear target, the fastigial n. (FA), influence JM conditioning.

To date, 4 animals with lesions of the rostral FA and 8 sham-operated animals have been subjected to 4 daily sessions of appetitive Pavlovian training (30 pairings/day of a 2-s, 1216-Hz tone with a 1-ml pulse of 0.5M sucrose solution). Evaluation of a variety of dependent measures indicated that lesioned and sham animals exhibited orderly and statistically indistinguishable JM CR acquisition functions, reaching levels of 84-90% CRs during training days 3-4. Moreover, FA lesions did not affect JM URs to unsignalled sucrose presentations. These data thus provide further evidence suggesting an extracerebellar substrate for appetitive JM conditioning. (Supported by VA Institutional Research funds and NSF Grant BNS 88-20379.)

CHANGES IN STIMULATION THRESHOLDS FOR DLPN-ELICITED EYEBLINKS REFLECT CR-BEHAVIOR IN THE RABBIT. J. Tracy*, D. J. Krupa, N. L. Bernasconi, J. S. Grethe & R. F. Thompson, Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Classical conditioning of the rabbit eyeblink response using paired presentations of dorso-lateral pontine nucleus (DLPN) stimulation as a CS, and corneal airpuff as an US, results in rapid acquisition. In order to better localize the plasticity associated with pontine/airpuff conditioning we measured the stimulation thresholds required to elicit eyeblinks, in both the DLPN and the interpositus nucleus (IPA), before and after training. New Zealand White rabbits (n=6) received paired presentations of DLPN stimulation (350 ms., 200 Hz.) and airpuff to the eye (100 ms., 3 psi). All CS stimulation intensities were calibrated to be well below the threshold required for eliciting any kind of motor activity. A second group of rabbits (n=6) received an equivalent number of unpaired presentations prior to training. After training all rabbits were extinguished with CS-alone presentations.

Paired training reliably lowers the DLPN stimulation threshold required for eliciting eyeblinks to well below the training intensity. Subsequent extinction brings the threshold back up to a level not statistically different from pre-training levels. Unpaired presentations of DLPN stimulation and airpuff do not change thresholds. Thresholds for eyelid movement from IPA stimulation do not change following paired, unpaired, or extinction training. Interpositus lesions following paired training abolish CR's elicited with pontine stimulation. These results strongly suggest that changes in neural activity due to conditioning are occurring efferent to the pons and provide further evidence of the critical role of the cerebellum in eyelid conditioning. Support:NSF(BNS-8117115) and ONR(N00014-88-K-0112) to RFT.

UNCONDITIONED STIMULUS (US) EFFECTS DURING AN INTRACEREBELLAR STIMULATION PARADIGM. R.A. Swain* & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

Intracerebellar stimulation of lobule HVI white matter as US produces robust classical conditioning when paired with either tone or intracerebellar stimulation CS. CS alone presentations produce extinction and reinstatement of paired trials produces rapid reacquisition. In addition, explicitly but not randomly unpaired presentations of the conditioning stimuli profoundly retard learning in subsequent acquisition trials (Swain, et al., 1992).

In the current experiment, we examined the nature of US elicitation of movement and any nonassociative effects of US preexposure on learning. Previous lesion results have underscored the essential role of the interpositus (IP) in the generation of movement in this paradigm (Swain et al., 1989; 1991). However, as HVI stimulation necessarily activates Purkinje cell, mossy fiber and climbing fiber afferents to IP, we sought to determine the relative contribution of these fibers to the IP's generation of movement. 108 US trials of varying stimulus durations (50-300 msec) were presented to 7 rabbits. Analyses indicated that IP is differentially sensitive to climbing and/or mossy fiber input. UR onset occurs within 100 msec of US onset eliminating the possibility that movement arises from rebound excitation of IP during Purkinje cell hyperpolarization. Maximum UR amplitude, however, always occurs 50-100 msec from US offset.

The nonassociative impact of US preexposure on learning was examined in these same rabbits by presenting up to 10 days of paired CS-US trials. Comparison with non-preexposed controls (N=9) indicated that US alone trials impair learning as measured by total number of trials to criterion and also by variability of CR performance from session to session.

INTRACEREBELLAR ELECTRICAL STIMULATION AS BOTH CS AND US IN CLASSICAL CONDITIONING OF DISCRETE MOTOR RESPONSES. P.G. Shinkman*, R.A. Swain, and R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

In earlier experiments we showed that electrical stimulation of cerebellar white matter elicits discrete motor responses of the facial and neck musculature; pairing a tone CS with the intracerebellar electrical US leads to the development of robust conditioned responses. The present experiment was designed to test for associative learning in a preparation in which both CS and US are delivered directly to the cerebellum. Chronic stimulating electrodes were implanted in rabbit cerebellum, providing an electrical CS activating cortical parallel fibers and thence Purkinje cells, and an electrical US activating underlying white matter and eliciting unconditioned responses. Paired CS-US presentations led reliably to the development of conditioned responses; also, increased local excitability was observed in cerebellar cortex. Pseudorandom unpaired presentation of CS and US did not produce any CRs, indicating that true associative learning, and not sensitization, is responsible for the observed results. Subsequent pilot data suggest that similar conditioning may occur when intracerebellar electrical CS and US are delivered via the same intracortical electrode, at different intensities. This preparation provides a model for the study of plastic neuronal interactions within cerebellar networks critically involved in associative learning. MOTOR CORTEX LESIONS DO NOT AFFECT ACQUISITION OR RETENTION OF THE CLASSICALLY CONDITIONED NICTITATING MEMBRANE RESPONSE IN RABBITS.

D. Ivkovich* and R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520

Rabbits were classically conditioned using the delay paradigm with a tone conditioned stimulus (CS; 350 ms, 1KHz, 85 dB) and an airpuff unconditioned stimulus (US; 100 ms, 3 psi, coterminating with the CS). Seven rabbits received bilateral motor cortex lesions prior to receiving 5 days of acquisition training. Another 7 rabbits received 5 days of acquisition followed by the lesion and 5 days of retention training. Each training session consisted of 12 blocks of 9 trials (1 CS-alone followed by 8 paired CS-US trials). Bilateral motor cortex lesions did not affect the acquisition or retention of the classically conditioned nictitating membrane response. The percentage of conditioned responses did not differ between lesioned and unlesioned animals during acquisition. Animals lesioned following acquisition showed no conditioned or unconditioned response deficits during subsequent training on any measure (percentage, amplitude, onset or peak latency, and amplitude-time area). Reflexive eyeblinks to 4 different US intensity levels (1, 2, 3, & 4 psi) measured over the course of training were unaffected by motor cortex lesions.

INTRA-OLIVARY INFUSIONS OF PICROTOXIN PREVENT "BLOCKING" OF RABBIT CONDITIONED EYEBLINK RESPONSE. J. J. Kim*, D. J. Krupa and R. F. Thompson. Neurosciences Program, USC, Los Angeles, CA 90089-2520.

This experiment investigated the effect of a GABA antagonist picrotoxin (PTX) on the phenomenon of "blocking" using the conditioned eyeblink response in the rabbit. Kamin's two-stage paradigm was employed. The blocking group received 7 days of tone-airpuff conditioning followed by 5 days of tone-light-airpuff compound conditioning. Half of the blocking animals received intra-olivary infusions of PTX (1 nM) during the compound conditioning phase, while the other half received artificial cerebrospinal fluid (CSF). The control group received 5 days of tone-light-airpuff compound conditioning only. Preliminary results indicate that the CSF animals that received tone-airpuff conditioning prior to the compound conditioning did not show any conditioned eyeblink responses to the light. Subsequent light-airpuff training in this group indicates that there was no *savings* to the light. Animals that received PTX, however, showed reliable conditioned responses to the light as well as a marked *savings*. These results support the view that the inferior olive provides the unconditioned stimulus information to the cerebellum for classical eyeblink conditioning.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS—CONDITIONING II

SEXUALLY DIMORPHIC EFFECTS OF DEXAMETHASONE ON ACTIVE AVOIDANCE LEARNING AND CENTRAL MUSCARINIC ACETYLCHOLINE RECEPTORS IN RATS. Ş.Pöğün*, L.Kanıt, S.Demirgören, F.Z.Kutay, B.Okur, H.Özkan, H.Semerci, M.Altınışık. Depts.of Physiol. and Biochem., Ege Univ. School of Med.,35100 İzmir, Turkey

Glucocorticoids have prominent roles in the modulation of behavior and the proposed psychoneuroendocrine interactions are sexually dimorphic. The present study was undertaken to study the effects of dexamethasone (DEX) on active avoidance learning and 3H-QNB binding in 8 brain regions. Male and female Sprague Dawley rats (4 months) were injected with either 1 mg DEX in sesame oil or only the vehicle at 8:00 and were given active avoidance learning trials at 10:00. Following 5 days of learning trials, the rats were decapitated, brains removed and dissected. Blood corticosterone levels were assayed. Receptor binding was determined in the cerebellum(cb), hypothalamus(hyp), corpus striatum(c.st), hippocampus(hip)and frontal(frn), parietal(par), temporal(tem) and occipital(occ) cortices. ANOVA revealed significant differences between the groups with regard to corticosterone levels($p<0.01$), learning performance at day 5 ($p<0.05$) and 3H-QNB binding in the cb, hip, frn and par cortices ($p<0.05$). There was a significant correlation between learning performance at day 5 and corticosterone levels ($p<0.001$), 3H-QNB binding in the hip, c.st, tem and occ cortices ($p<0.05$). Correlations were also observed between corticosterone levels and receptor binding in the hip, c.st and tem cortices ($p<0.05$). Our results show that DEX effects active avoidance learning in rats through the muscarinic cholinergic system and more prominently in males.

652.2

INVOLVEMENT OF THE LATERAL AMYGDALA AND PERIRHINAL CORTEX IN FEAR POTENTIATED STARTLE TO ACOUSTIC AND VISUAL CONDITIONED STIMULI S. Campeau* and M. Davis. Dept. of Psychology and Psychiatry, Yale Univ. Sch. of Med, 34 Park St., New Haven, Ct 06508.

Prior studies in our laboratory have indicated that post-training lesions of the lateral/basolateral complex of the amygdala or perirhinal cortex block fear-potentiated startle using a visual conditioned stimulus (CS). The goal of the present studies was to test the generality of the involvement of these nuclei in fear-potentiated startle using an acoustic CS. Anatomical data show that the medial geniculate nucleus of the thalamus, the source of all auditory information to the forebrain, projects subcortically to the lateral nucleus of the amygdala, and cortically to the auditory and perirhinal cortex. The auditory cortex projects to the lateral nucleus of the amygdala, via a relay in the perirhinal cortex.

Rats received 10 pairings of a 70-dB, 3.7-s noise centered at 2 kHz, mixed with 10 pairings of a 3.7-s fluorescent light, each coterminating with a 0.5-s, 0.6-mA footshock, presented at a variable intertrial interval of 2.5 min, on each of 2 consecutive days. To preoperatively match rats into groups with similar fear-potentiated startle to the noise and light CSs, a startle test consisting of 30 startle stimuli alone, or 5 startle stimuli 3.2 s after the onset of each noise or light CS was used. Twenty-four hr later, rats were given either electrolytic (n = 6), neuro-toxic NMDA (n = 8) or sham (n = 5) lesions of the lateral amygdala, or electrolytic (n = 8) or sham (n = 6) lesions of the perirhinal cortex. Ten days later, a startle test, similar to the pre-lesion test, revealed that specific and complete lesions of the lateral nucleus of the amygdala (electrolytic and neurotoxic) or anterior perirhinal cortex reliably blocked potentiated startle to the acoustic and visual CSs.

These post-training lesion results indicate that the lateral nucleus of the amygdala and the perirhinal cortex are relays along a pathway normally mediating the expression of visual as well as acoustic aversive memories. Experiments in progress are testing the effects of pre-training lesions of the lateral amygdala and perirhinal cortex on fear-potentiated startle.

652.3

A PRIMARY ACOUSTIC STARTLE CIRCUIT : LESION AND ANATOMICAL TRACING STUDIES. Y. Lee*& M. Davis. Dept of Psychology & Psychiatry, Yale Univ. Med. Sch., 34 Park St., New Haven, CT 06508.

The delineation of neural circuits that mediate behavior provides a foundation for determining where behavioral plasticity might occur, and how these changes might alter behavior. The acoustic startle reflex in the rat has proven to be extremely sensitive to a range of experimental manipulations and is currently being used as a model system to analyze behavioral plasticity in vertebrates.

Using a variety of techniques, our laboratory has proposed a primary acoustic startle circuit that consists of the auditory nerve, posteroventral cochlear nucleus (PVCN), an area including the ventral nucleus of the lateral lemniscus (VLL), paralemniscal zone (PLZ), and the rostroperiolivary nucleus (RPO), an area just dorsomedial to the lateral superior olive (LSO) in the nucleus reticularis pontis caudalis (RPC), and motor neurons in the spinal cord. (Davis et al 1982; Cassella & Davis 1986). While lesion and stimulation studies generally support this circuitry, some important details that are crucial for future electrophysiological studies remained to be found. For example, because the original studies used relatively large lesions in the vicinity of the VLL, it is not known which structure in this area is critical in relaying information from PVCN to RPC. The present studies attempted to identify more precisely the locus of this relay in the startle circuit.

Discrete, bilateral electrolytic lesions of the RPO region completely eliminated startle, while lesions of areas just lateral (VLL) and medial to the RPO (PLZ), showed a partial blockade of startle depending on the size, and the location of the lesions. Retrograde (Fluro-Gold) and anterograde (Fluro-Ruby) tracers deposited into the RPO clearly labeled cell bodies in the contralateral PVCN, and terminals in both ipsilateral and contralateral RPC, respectively.

To investigate the functional significance of these connections more definitively, currently we are using ibotenic acid to destroy cell bodies of each of these structures (VLL, PLZ, & RPO) without damaging fibers of passages. To be sure that the PVCN projects to the part of the RPO critical for startle, we are injecting retrograde tracerS into the RPO in combination with ibotenic acid lesions of the adjacent areas such as the VLL and the LSO, which are known to receive dense projections from PVCN (Lee & Davis unpublished observation; Thompson et al 1991).

VISUAL CORTEX ABLATIONS FAIL TO PREVENT EXTINCTION OF FEAR-POTENTIATED STARTLE USING A VISUAL CONDITIONED STIMULUS. W.A. Falls*& M. Davis. Depts. of Psychology & Psychiatry, Yale Univ. Med Sch., 34 Park St., New Haven, Ct. 06508.

Paired presentation of a neutral stimulus, such as a light, with an aversive stimulus, such as shock, leads to the acquisition of a variety of behavioral effects that are used to define a state of conditioned fear. If the same light is then presented in the absence of shock, it loses its ability to produce these behavioral effects. This reduction in conditioned fear is called experimental extinction and is thought to involve the acquisition of a new memory that may mask or inhibit the expression of the original conditioned fear. Several reports indicate that sensory cortex is not critically involved in the acquisition or expression of conditioned fear. However, it has been suggested that sensory cortex may be a component of a neural circuit that is responsible for inhibiting subcortically mediated conditioned fear (LeDoux et al., *J. Cog. Neurosci.*, 1989, 1, pp 238-243; Teich et al., *Brain Research*, 1989, 480, pp 210-218). Following the observation that sensory cortex ablations prevent extinction of conditioned fear, the present experiments sought to investigate the generality of this finding by examining whether visual cortex ablations would prevent the acquisition and/or expression of extinction of conditioned fear as assessed by fear-potentiated startle using a visual conditioned stimulus.

Rats underwent training in which a light was paired with footshock. Three to 5 days after training, the rats' intial level of fear-potentiated startle was assessed by measuring the amplitude of noise-elicited startle in the presence or absence of the light. On each of the next two days, the rats were given 30 light-alone extinction trials. Following this, fear potentiated startle was assessed again.

Visual cortex ablations *performed prior to fear conditioning* did not prevent the subsequent acquisition of extinction of fear-potentiated startle to a visual conditioned stimulus. Visual cortex ablations *performed following extinction* did not reverse pre-operatively established extinction as would be expected if visual cortex is a component of a neural circuit that is responsible for inhibiting subcortically mediated conditioned fear. Together these results indicate that sensory cortex is not required for the acquisition or expression of extinction of conditioned fear in all behavioral systems.

ELECTROLYTIC LESIONS OF THE AMYGDALA BLOCK ACQUISITION AND EXPRESSION OF CONDITIONED FEAR EVEN WITH EXTENSIVE TRANING, BUT DO NOT PREVENT REACQUISITION, AS ASSESSED BY FEAR-POTENTIATED STARTLE. M. Kim* & M. Davis. Dept. of Psychiatry, Yale University School of Medicine, 34 Park St., New Haven, CT 06508

The amygdala is well-known to be important for aversive conditioning. Lesions of the amygdala block the expression of fear-potentiated startle in which the amplitude of the acoustic startle reflex is elevated when elicited in the presence of a cue previously paired with footshock. However, it has not been determined how extensive training would alter this lesion effect.

In Exp.1, rats received 2 training trials (light CS paired with 0.6 mA footshock US) and 6 fear-potentiated startle test trials per day for 30 days, and either sham or electrolytic lesions aimed at the amygdala central nucleus (ACe) on day 32. The rats showed asymptotic performance by day 12 (after 22 training trials). ACe lesions totally abolished fear-potentiated startle, but did not prevent reacquisition of potentiated startle when the rats were retrained over the next 7 days. In Exp.2, rats were first sham- or ACe-lesioned, and then given 24 days of training. Shock intensity was always 0.6 mA for controls, but increased to 1 mA on day 15 for ACe-lesioned rats. The lesioned rats showed no acquisition at either shock intensity. In summary, ACe lesions given after extensive training abolished expression, but did not prevent reacquisition, of fear-potentiated startle. In contrast, ACe lesions given before training totally blocked acquisition.

These results suggest that the amygdala is normally involved in the expression of fear-potentiated startle regardless of the degree of learning. Also, the amygdala is necessary for the acquisition of fear-potentiated startle and other brain structures do not support this form of learning when training occurs without the amygdala. However, when learning occurs with an intact amygdala, other brain structures can reacquire conditioned fear after amygdala damage, suggesting that the amygdala may induce some functional change in those brain structures during original acquisition.

ROLE FOR THE AMYGDALA CENTRAL NUCLEUS IN ATTENTION. Michela Gallagher* and Peter Holland. Dept. Psychology, Univ. N. Carolina, Chapel Hill, NC 27599 and Dept. Experimental Psychology, Duke University, Durham, NC 27706.

Conditioning episodes can modify attentional processing of conditioned stimuli (CSs). Some of these changes can be characterized as incremental and others as decremental. Elsewhere we reported that neurotoxic lesions of the amygdala central nucleus (CN) in rats disrupt normal conditioning-dependent enhancement of orienting responses (OR) but do not affect the ability of a CS to elicit ORs prior to conditioning. This work examined whether CN damage alters selected CS processing functions.

Our results indicate that CN lesioned rats fail to exhibit conditioning that depends on increments in CS processing. This deficiency was evident in failures to show the enhanced associability of a CS that is normally observed when either an inconsistent predictive relation is arranged between that CS and another cue, or the reinforcement value of the unconditioned stimulus (US) is reduced in an unblocking procedure. In contrast to these impairments, CN damage did not affect the reduction in associability of a CS produced by CS preexposure (latent inhibition), blocking, or consistent reinforcement procedures. Thus the CN appears to be part of a neural system that regulates broadly-based increments in processing or attending to signals for biologically significant events, but is not critical for tuning out redundant or uninformative cues. POSTTRAINING INJECTIONS OF LIDOCAINE INTO THE LATERAL/ BASOLATERAL COMPLEX OF THE AMYGDALA IMPAIR RETENTION OF INHIBITORY AVOIDANCE. M.B. Parent* & J.L. McGaugh. Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717

The central nucleus (ACe) and the lateral/basolateral complex (LBL) are two areas within the amygdala that have been extensively implicated in learning and memory. The present experiment examined the role of the ACe and LBL in the retention of inhibitory avoidance by reversibly inactivating these regions after training. Male Sprague Dawley rats (175 - 200 g) were implanted bilaterally with cannulae aimed at the ACe (AP - 0.23; ML ± 0.4; DV - 0.5 cm) or the LBL (AP - 0.31; ML ± 0.51; DV -0.5 cm). One week after recovery, the rats were trained in a one-trial inhibitory avoidance task (0.45 mA footshock; 1 sec) followed immediately by injections of lidocaine hydrochloride (Sigma; 0.01 mg; 40 mg/ml; 0.25 µL/1 min) or phosphate buffer administered via the cannulae. On a retention test 48 hr later, the latency to enter the dark/shock compartment (maximum 600 sec) was recorded and used as an index of retention. Animals that received buffer in the ACe did not differ from those that received buffer in the LBL. However, in comparison with buffer controls and ACe-lidocaine animals, LBL-lidocaine animals had significantly shorter entrance latencies. This retrograde impairment produced by posttraining reversible inactivation of the LBL suggests that the LBL may be involved in regulating the consolidation of aversively-based memory. This interpretation is in agreement with the finding of Liang (1991), who reported that pre-retention test injections of lidocaine into the basolateral amygdala impair retention only when retention is tested 2 days after learning, but not 21 days later.

ACQUISITION OF NEGATIVE PATTERNING IN HIPPOCAMPAL LESIONED RATS. D.M. Skinner*, A. Bechara and D. van der Kooy. Dept. of Anatomy and Cell Biology, University of Toronto, Toronto, Ontario, M5S 1A8.

Hippocampal lesions do not impair acquisition of simple, Pavlovian associations, but more complex forms of learning do seem to be disrupted. We have previously shown that performance on complex, conditional tasks is not affected by hippocampal lesions when visceral cues (drug states and flavors) are used. We suggested that visceral cues were unique in that they can (unlike visual, auditory, and somatosensory cues) enter into configural associations independent of hippocampal processing. As a further test of this hypothesis we have designed a negative patterning task using visceral cues. In a negative patterning task each of two cues is followed by an unconditioned stimulus when presented singly, but the unconditioned stimulus is withheld when the two elements are presented together. We used a novel 0.1% saccharin solution and an injection of 5 mg/kg morphine sulfate as cues. Each of these cues alone signals an injection of 100 mg/kg lithium chloride. However, when presented together they signal the absence of lithium chloride. The acquisition performance of rats that had undergone aspiration lesions of the hippocampus was no different than control animals. Substituting contextual cues (visual and textural cues from a distinctive environment) for the morphine drug state made the task slightly more difficult, as evidenced by the need for a longer training period, but again lesioned and control animals performed at a similar level. The data provide further support for the idea that visceral cues can enter into configural associations in the absence of the hippocampus, whereas the same task employing visual and auditory cues does appear to depend on the hippocampus.

652.9

OPPOSITE ROLES OF VENTRAL AND DORSOLATERAL PERIAQUEDUCTAL GRAY IN CONDITIONAL FEAR-RELATED DEFENSIVE BEHAVIOR. J. Landeira-Fernandez*, M. S. Fanselow, & B. M. De Oca. Dept of Psychology, UCLA, L.A., CA 90024.

Lesions of the ventral portion of the periaqueductal gray (vPAG) reduce defensive freezing to conditional fear stimuli. The function of the more dorsal portions of this structure lateral to the aqueduct (dlPAG) on conditional freezing is unclear. In order to investigate the role of these regions of the PAG in mediating freezing, rats were given electrolytic lesions of either the vPAG or dlPAG. There were two types of controls (sham & superior colliculus lesioned). The rats were given electric footshock immediately after placement in a chamber for 3 consecutive days. This procedure does not provide the animal with ample time to appreciate the contextual cues prior to shock and therefore does not normally condition defensive behavior. However, rats with dlPAG lesions were unique in acquiring conditional freezing using this procedure. Following this treatment, all the rats received a shock after being given a 3 min period to explore the chamber. All rats, except those with vPAG lesions, evidenced a high level of conditional freezing . During several extinction tests, dlPAG lesioned animals showed enhanced, and vPAG lesioned animals showed reduced, freezing. Superior colliculus lesioned animals never differed from shams. These data suggest that the vPAG mediates conditional freezing while the dlPAG inhibits acquisition of this defensive behavior.

DORSOLATERAL PERIAQUEDUCTAL GRAY LESIONS AND BENZODIAZEPINE AGONISTS AND ANTAGONISTS DISSOCIATE ASSOCIATIVE AND NONASSOCIATIVE FEAR CONDITIONING. J. P. DeCola* & M. S. Fanselow, Dept. of Psychology, UCLA, Los Angeles, CA 90024.

Previously we demonstrated that administration of the NMDA antagonist APV, blocks associative fear conditioning but does not block the sensitization of conditional fear. The present experiments further dissociate associative and nonassociative fear conditioning. Sensitization of fear can be demonstrated behaviorally as an enhanced response to a conditional stimulus (CS) when conditioning is preceeded by exposure to unconditional stimuli (US). In our paradigm, the sensitization pretreatment is done by exposing rats to a series of footshocks in a distinct context the day prior to a single pairing of a novel contextual CS, and a single shock US. The sensitized animals exhibit enhanced fear to the novel context as compared to a nonsensitized group. Lesions of the dorsolateral periaqueductal gray (dlPAG) prior to the sensitization treatment resulted in an enhanced sensitization of fear to the novel context. Paradoxically, both the sensitization treatment and dlPAG lesions produced a reduction in unconditioned responding (activity) to the shock. Administration of the benzodiazepine (BZD) agonist tetrazepam (20 mg/kg, i.p.) prior to the sensitization treatment in the first context did not affect the sensitization of fear observed in the second novel context. However, it did block the acquisition of conditional fear to the first context where the pretreatment shocks were delivered. The BZD antagonist RO15-1788 (7mg/kg, i.p.) had no effect on conditional fear but tended to enhance the sensitization effect.

652.11

THE DORSAL HIPPOCAMPUS AND CONTEXTUAL FEAR CONDITIONING. S. L. Young*, M. S. Fanselow & D. L. Bohenek. Department of Psychology, University of California, Los Angeles, CA 90024.

Previously, we reported that electrolytic lesions of the dorsal hippocampus, made shortly after Pavlovian fear conditioning, eliminated the fear response to contextual stimuli associated with shock. The present studies sought to extend that finding to pre-conditioning elimination of cell bodies in that structure. We made excitotoxic lesions, which spare fibers of passage, prior to conditioning. Conditioning to contextual cues immediately after the first conditioning trial was not impaired in the lesioned animals. However, as training progressed, hippocampal animals showed markedly attenuated conditional responding. In a shock-free retention test given 24 hours later, hippocampal lesioned animals showed severe impairments in responding to contextual fear cues. This pattern of results closely parallels the effects of competitive NMDA antagonists on contextual fear conditioning. In conclusion, hippocampal lesions made either before or after training reduce contextual fear and this effect appears to depend on neurons intrinsic to the hippocampal formation.

BEHAVIORAL AND NEUROLOGICAL DIFFERENCES IN BXSB-Yaa AND BXSB-Yaa+ MICE L.M. Schrott*, G.F. Sherman, N.S. Waters G.D. Rosen, A.M. Galaburda and V.H. Denenberg Biobehavioral Science Graduate Degree Program, University of Connecticut, Storrs, CT 06269; and Beth Israel Hospital and Harvard Medical School Boston, MA 02215.

BXSB mice are autoimmune and have approximately a 50% incidence of cortical ectopias. Because of associations between immune disorders, ectopias and developmental learning disorders in humans, we have been investigating behavior in these mice. The autoimmunity in BXSB mice is not hormonally mediated and is more severe in males because of a Y-chromosome autoimmune accelerator gene. To determine the effect of this gene on behavior, BXSB mice with the autoimmune accelerator gene (BXSB-Yaa) were compared to BXSB mice lacking the gene (BXSB-Yaa+). The mice were tested on a behavioral battery, blood samples were obtained for immune analyses and their brains were examined for ectopias. Significant difference between the two genotypes were found for activity and learning measures. BXSB-Yaa were more active in a swimming rotation task, and performed better in discrimination learning and avoidance conditioning. BXSB-Yaa+ had better performance in water escape, the Lashley maze, and the Morris maze. Ectopias, in interaction with strain, sex, and paw preference, significantly affected learning measures. There was no difference in the incidence of ectopias between the two strains, although there was a significant sex difference with males having more ectopias (60%; and 40% for females).

Strain differences in males might be expected since they differed genetically. Strain differences between the two female groups are indicative of genetic drift. Therefore, it is unlikely that the males differ only with respect to the Yaa gene. The reason for the sex difference in ectopia incidence is not known, but is not due to the autoimmune accelerator gene, since a higher incidence was also seen in the non-accelerated strain. This work was supported in part by NIH grant HD 20806.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS—CONDITIONING III

653.1

EVIDENCE OF INTERACTION OF NEURAL PATHWAY SYSTEMS DURING ASSOCIATIVE LEARNING: UNCONDITIONED STIMULUS CAN MODIFY EVOKED SLOW POTENTIAL CHARACTERISTICS OF THE ALPHA RESPONSE. T.Korhonen* and M.Penttonen, Dept.of Psychol.,Univ.of Jyvaskyla,40100 Jyvaskyla, Finland.

General facilitation effect of the unconditioned stimulus (UCS) on the conditioned response has been reported in many studies. Here, more specific effect is shown: the time amplitude characteristics of evoked slow potential response in the conditioned stimulus (CS) period changed as a result of paired training similar to the waveform of the unconditioned response (UCR). A tone CS was given to one ear of the cat eliciting orienting head movements to the direction of the tone accompanied with evoked neural response in recorded brain sites. The brain stimulation UCS to the lateral hypothalamus elicited, in turn, a typical head movement and unconditioned evoked slow potential response pattern. Compared to the unpaired presentation of the CS and UCS a significant correlation (between .46 and .95) was found to emerge as a result of paired conditioning.Three alternative explanations were examined: first, the observed similarity between the evoked neural UCR and developing conditioned response during the interstimulus interval (ISI) might be results of a general, increased facilitation of the CS pathway, second, any strong stimulus such as an UCS might disclose some typical "maximum orienting response", specific to the CS pathway system measured, and third, the UCS may actually modify the CS-pathway system; it might leave a temporal "memory trace" on the time-amplitude course of the CS pathway system. The results presented here supported the "memory trace"-hypothesis.

653.2

FUNCTIONAL NEUROIMAGING OF CONDITIONED INHIBITION EFFECTS ON THE AUDITORY SYSTEM OF THE RAT: FLUORODEOXYGLUCOSE MAPPING AND STRUCTURAL MODELING. A.R. McIntosh* & F. Gonzalez-Lima, Dept of Psych and Inst of Neurosci, Univ of Texas, Austin, TX, 78712, USA.

[^{14}C(U)]2-fluoro-2-deoxyglucose (FDG) was used for functional neuroimaging of the auditory system processing an acoustic stimulus trained as either a conditioned excitor (A^+) or inhibitor (X-). Structural modeling (McIntosh & Gonzalez-Lima, *Brain Res.* 547, p. 295, 1991) used the mapping data to demonstrate interactions between auditory structures related to conditioning. Rats were trained in two phases. In the A^+ phase, a tone was paired with footshock for Group 1 and a light was paired with footshock for Group 2. In the X- phase, reinforced trials of A^+ were intermixed with nonreinforced trials of the tone-light compound (AX-). For Group 1, the tone was the excitor, for Group 2 the tone was the inhibitor. After conditioning, both groups were injected with FDG and presented with the same tone. Group 1 showed greater FDG uptake in the dorsal cochlear n. (DCN) and the external n. of the inferior colliculus. Structural models of the auditory system showed that effects through the direct lemniscal path were similar for both groups, but effects of lemniscal-adjunct paths were in opposite directions for the two groups. Extra-auditory influences on DCN were stronger for Group 2 suggesting that differentiation of the significance of the tone was a function of alterations in the interactions between parallel auditory pathways. These data indicate that auditory pathways can code both the physical parameters of stimuli and the behavioral significance acquired through learning. (Supported by NIMH grant RO1 43353).

653.3

SELECTIVE ACTIVATION OF THE CEREBRAL CORTEX OF RATS DURING CONDITIONED AND UNCONDITIONED STRESS - REVEALED BY THE IMMEDIATE EARLY GENE *C-FOS*. C. H. M. Beck* and H. C. Fibiger. Department of Psychology, University of Alberta, Edmonton, AB, T6G 2E9 and Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, Vancouver, BC, V6T 1Z3.

Male hooded rats were individually shocked acutely (1 session), shocked chronically (3 sessions), or were placed in the shock apparatus without being shocked. With the multiple cues of the shock box serving as contextual cues, the rats were assigned to groups (n=7) as unconditioned (shocked on the final session), conditioned (shocked previously but not on the final session), or control animals. Two hours after the beginning of the final session, the animals were terminated, perfused, and their brains removed. Following sectioning and immunohistochemistry, Fos-positive nuclei were counted on coronal sections of the cerebral cortex. Exposure to conditioned cues, compared to being placed in the box without shock, resulted in increased Fos counts in several allocortical (piriform, infralimbic, cingulate, retrosplenial, lateral orbital, perirhinal, and entorhinal) and isocortical structures (secondary occipital, frontal Area 2, forelimb, and hindlimb). Suprisingly, the unconditioned effect of acute shock appeared only in the retrosplenial cortex. The unconditioned effect of chronic shock was observed only in the insular, perirhinal, and hindlimb cortices. The relative unconditioned effects were small in part because of the large effect of simply exposing the rat to the apparatus.

653.4

FUNCTIONAL NEUROIMAGING OF DIFFERENTIAL CONDITIONING EFFECTS ON THE RAT AUDITORY SYSTEM: A FLUORODEOXYGLUCOSE WITHIN-SUBJECTS MAPPING STUDY. F. Gonzalez-Lima[1]* & J. Agudo[2]. [1]Dept Psych and Inst Neurosci, Univ of Texas, Austin, TX 78712; [2]Dept Cell Biol, Univ of Valladolid, Spain.

Autoradiography with [^{14}C(U)]2-fluoro-2-deoxyglucose (FDG) was used to functionally map the effects of a differential conditioning paradigm consisting of two tones of high and low frequencies, with one tone paired with water reward. Control rats were presented tones and water randomly or explicitly unpaired. This paradigm allowed direct comparison of the effects of the two tones within each auditory structure in the same subject, taking advantage of the separate tonotopic spatial maps for the two tones visualized with FDG. Differentially enhanced activity to the tone paired with the reinforcer was demonstrated within the cochlear nuclei, inferior colliculus, medial geniculate nucleus and auditory cortex. These effects were not simply a generalized increase in activity in the conditioned rats, but involved a frequency-dependent effect specific to the tone used to signal reward. Cortical tonotopic effects as revealed by FDG have never been obtained with the 2-DG method, suggesting that FDG is better suited for experiments where the goal is to map functional effects rather than calculation of glucose utilization. The FDG results provide a direct image within each auditory structure of the specific modification of the reinforced tone representation induced by the associative process, as opposed to the pure sensory effects of the tone. This supports previous studies showing that the auditory system is involved in associative learning of sounds signaling positive or negative reinforcers (Gonzalez-Lima & Agudo, Neuroreport 1, 161-4, 1990), and is not merely a feature detector system. (Supported by R01 MH43353).

653.5

CONDITIONAL CONTROL OF FLUID CONSUMPTION BY DISCRIMINATIVE CUES IS INDEPENDENT OF THEIR PAVLOVIAN ASSOCIATIONS. G.M. Martin, D.M. Skinner, A. Pridgar, and D. van der Kooy*. Dept. of Psychology, Memorial University, St. John's, Newfoundland, A1B 3X9. Dept of Anatomy and Cell Biology, University of Toronto, Toronto, Ontario, M5S 1A8.

Conditional associations involve discriminative cues that predict whether or not a target stimulus will be followed by a motivational event (the US). An important question in conditional associations is how much of the discriminative control is due to simple, Pavlovian associations between the discriminative cue and the US and how much is due to a more complex type of association among all three elements. In the first experiment, two groups of rats were trained using distinct contexts as cues (visual and textural stimuli from boxes). In the Pavlovian group a distinct, novel context was paired with an injection of lithium chloride (LiCl) while a second novel context was paired with injections of saline. In the Conditional group one novel context predicted that access to a saccharin solution would be followed by an injection of LiCl and the alternate context predicted that saccharin would be followed by saline injections. After conditioning, the Pavlovian group showed larger aversions to the context previously associated with LiCl than did the Conditional group. In contrast, the Conditional group showed greater suppression of consumption of saccharin and other novel fluids in the context associated with LiCl than did the Pavlovian group. These results suggest that the Conditional group learned something separate and different from the Pavlovian group. It might be possible to dissociate Pavlovian and conditional associations in the same animals. We predict that if the Conditional group were given unreinforced exposure to the distinctive environments this would result in the extinction of the mild place aversions seen in this group (presumably measuring the weak Pavlovian association) without abolishing the ability of the contexts to control saccharin consumption. Indeed, results from experiments using drug states or novel fluids as cues to predict when saccharin will be followed by LiCl suggest that extinction of the Pavlovian properties of the discriminative cue do not abolish the conditional control over fluid consumption. Thus, conditional suppression of saccharin consumption by various discriminative cues seems to result from complex, non-Pavlovian associations.

653.6

DOUBLE DISSOCIATION OF PASSIVE AVOIDANCE AND MILK MAZE DEFICITS WITH DISCRETE LESIONS OF THE SUBSTANTIA INNOMINATA OR GLOBUS PALLIDUS. R.C. Meyer* and G.D. Coover. Department of Psychology, Northern Illinois University, DeKalb, IL 60115.

We previously reported (Soc. Neurosci. Abstr., 17:480) that discrete electrolytic lesions along the rostrocaudal extent of the substantia innominata (SI) in the rat produced differential deficits in drinking passive avoidance (dPA), step-through PA (sPA), and milk maze (MM) performance. The present study examined the effects of bilateral lesions at three sites in the SI (placed relative to bregma): central (SI: A-1.4 mm, L±3.0, V-8.4), lateral (lSI: A-1.4, L±3.7, V-8.4), or rostral (rSI: A- 0.7, L±2.5, V-8.2). Also, lesions were placed in the globus pallidus: central (GP: A-1.4, L±3.2, V-7.2), or rostral (rGP: A-0.7, L±2.7, V-7.0).

Significant deficits in dPA were produced by SI and also lSI lesions, but not rSI, GP, or rGP lesions. The control group (CON) required 23 ±2 (M ±SE) footshocks of incrementing intensity to avoid drinking for 5 min. Groups SI and lSI required 38 ±2 and 35 ±3, and rSI, GP, and rGP required 24 ±2, 27 ±2, and 28 ±2 footshocks, respectively. Parallel results were found for sPA. In contrast to PA behavior, MM performance was poor in Groups rSI and GP, and markedly impaired in Group rGP. Particularly notable is that Groups SI and lSI, compared to Group rGP, were significantly worse in PA and better in MM performance: a double dissociation.

653.7

AMYGDALA CENTRAL NUCLEUS LESIONS ATTENUATE THE BRADYCARDIA, TACHYCARDIA AND BEHAVIORAL FREEZING ELICITED BY ACOUSTIC STIMULI IN RATS. B.J. Young* and R.N. Leaton. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

In a preliminary experiment phasic heart-rate (HR) responses of rats to a 120-dB startle stimulus were characterized by decelerations which habituated across trials, and accelerations which developed across trials in a manner that paralleled the development of freezing behavior. A 92-dB stimulus evoked little freezing or tachycardia yet evoked decelerations of similar magnitude to the 120-dB stimulus. Since lesions of the amygdala central nucleus (ACE) disrupt both conditioned freezing and HR responses, we studied the effects of ACE lesions in this startle-HR paradigm. Bilateral electrolytic lesions were made in one group of rats and another group served as sham-operated controls. Subgroups received 10 presentations of either an 87- or 120-dB white noise stimulus for 10 trials (60-s interstimulus interval) on four consecutive days. As predicted, ACE lesions impaired the development of both HR accelerations and freezing to the 120-dB stimulus. Surprisingly, the lesions also impaired HR decelerations to both the 87- and 120-dB stimuli. This latter finding conflicts with previous data which suggest no involvement of ACE in the unconditioned HR orienting response. In continued testing in a new context five presentations of a 1000-Hz, 85-dB tone were given to more directly contrast the present results with previous data. The HR orienting response remained impaired in the ACE animals. Thus, the ACE appears to play a role in mediating HR orienting responses as well as the development of fear-related tachycardia and conditioned freezing.

653.8

ACOUSTIC STARTLE STIMULATION SUPPRESSES IMMUNOLOGICAL FUNCTIONING AS INDEXED BY A CONTACT SENSITIVITY RESPONSE. R. Brown and J. Cranney* Univ. of NSW Australia, 2033.

The present studies investigated the immunological effects of novelty, startle stimulation and context conditioning in adult male Wistar rats. Behavioural indices of fear responding (freezing, grooming, defecation and exploratory behaviours) were investigated alongside immunological measures. Experiment 1 demonstrated that startle stimulation and exposure to a novel environment induced suppression of cell-mediated immune functioning, as indexed by the contact (skin) sensitivity response to a chemical allergen, specifically: diminished response magnitude, deceleration of the recruitment of that response and alteration in the nature of peak responding. Startle stimulation induced greater immunosuppression than just placing animals into a novel (startle chamber) environment alone. Experiment 2 demonstrated that the immunosuppressive effects of startle stimulation could become conditioned behaviourally in the rat. This suppression was more transient and of a smaller magnitude than that observed in rats exposed to unconditioned aversive stimulation, and manifested as the diminution of contact sensitivity response amplitude; freezing behavior correlated with immunosuppression.

653.9

EXCITOTOXIC LESIONS OF THE CENTRAL NUCLEUS OF THE AMYGDALA BUT NOT OF THE PERIAQUEDUCTAL GRAY BLOCK INTEGRATED FEAR RESPONDING AS INDEXED BY BOTH FREEZING RESPONSES AND AUGMENTATION OF STARTLE. M. Kiernan* and J. Cranney. UNIV. OF NSW, Australia, 2033.

Two experiments examined the effects of ibotenic acid lesions of the central nucleus of the amygdala (CeA) and the dorsal (dPAG) and ventral (vPAG) periaqueductal gray on the relationship between freezing responses and the sensitization of the acoustic startle response in adult male Wistar rats. CeA lesions attenuated both the non shock related sensitization of the startle and the sensitization of startle by shock, and attenuated post shock freezing and freezing elicited by shock associated cues. vPAG lesions attenuated freezing but failed to attenuate sensitization of startle, eliciting a tonic augmentation instead. dPAG lesions had no significant effect on either startle or freezing responses. These results support the hypothesis that the CeA constitutes part of the final common pathway of an integrated defensive response.

653.10

ABOLITION OF LATENT INHIBITION BY SYSTEMIC AMPHETAMINE TREATMENT. M. B. Noel*, A. Gratton & J. Rochford. Douglas Hospital Research Center, Dept. Psychiatry, McGill University, Verdun, Quebec, H4H 1R3, CANADA.

Preexposure to a to-be-conditioned stimulus (CS) retards conditioning when the CS is subsequently paired with an unconditioned stimulus (US). This phenomenon, known as latent inhibition (LI), can be abolished by systemic pretreatment with low doses of amphetamine. The majority of studies demonstrating dopaminergic involvement in LI have used relatively simple behavioral measures (e.g., conditioned licking) and have employed but a single test trial to assess LI. The present study was conducted to extend the generality of these results by using a more complex behavioral measure (lever pressing) and by employing multiple test trials. Male, Long Evans rats (300-325g) were deprived to 85% of their free feeding weights and trained (VI 30) to press a lever for sweetened milk reinforcement. Following acquisition, rats were preexposed to either 40 or 0 presentations of a tone CS. On the next day, all animals were administered 2 tone-shock (0.6 mA, 0.5 sec) pairings. Half of the animals were administered 2.0 mg/kg amphetamine (i.p.) 15 min prior to both the exposure and the conditioning day, the other half received vehicle. On the test day all animals were exposed (drug free) to three tone alone presentations, and the suppression of ongoing lever press responding was measured. LI was demonstrated by the finding that rats given 40 CS preexposures without drug were less suppressed on all three test trials than those not preexposed to the CS. Amphetamine treatment abolished LI; there were no significant differences in the level of suppression between amphetamine-treated rats preexposed to the tone and those not preexposed. These results confirm and extend the generality of previous evidence demonstrating that amphetamine-induced enhancement of dopaminergic transmission inhibits the ability to ignore irrelevant stimuli.

DIFFERENTIAL DISTRIBUTION OF PROTEIN KINASE C (PKCα,β and -γ) ISOENZYME IMMUNOREACTIVITY IN THE BRAIN OF THE DOMESTIC CHICK. J. J. Bolhuis[1], E.A. van der Zee[2], G. Horn[1] and P.G.M. Luiten[2]. [1]Univ. of Cambridge, Dept. Zoology, Cambridge CB2 3EJ, England and [2]Univ. of Groningen, Dept. Animal Physiology, Haren, The Netherlands (SPON: European Neuroscience Association).

PKC is involved in neural plasticity, and phosphorylation of a PKC substrate (MARCKS) in part of the chick hyperstriatum (IMHV) has been shown to correlate significantly with the strength of learning in filial imprinting (McCabe *et al*, Soc. Neurosci. Abs. 17, 140). The distribution of PKCγ and PKCα,βI,βII in the brain of day-old dark-reared chicks was determined immunocytochemically. Frozen coronal sections (20 µm) were incubated with MC5, or with 36G9, monoclonal mouse anti-PKCα,β or anti-PKCγ, respectively. PKCγ-stained cells were distributed widely in the telencephalon, incl. all hyperstriatal structures (incl. IMHV), the Hippocampus (H), Neostriatum (N), Ectostriatum (E) and Archistriatum (A). There was less dense staining in the Septum (S), and the least cellular staining was in the Paleostriatal complex (P). The distribution of PKCα,β-stained cells was more limited, with staining in A, H and S but not in the hyperstriatum. However, there was PKCαβ staining of fibres in part of IMHV (but little elsewhere in hyperstriatum ventrale), in N, P and in Lobus parolfactorius. These results raise the possibility that in IMHV, some axonal inputs contain αβ-PKC, whereas some postsynaptic cells contain the γ-form of PKC. (supported by the AFRC (UK)).

PASSIVE SHOCK AVOIDANCE (PSA) INDUCES CHANGES IN PKC-, MAP2- AND MUSCARINIC ACETYLCHOLINE RECEPTOR-IMMUNOREACTIVITY IN SINGLE CORTICAL NEURONS. E.A. Van der Zee*, B.R.K Douma, A.D. Strosberg, B. Bohus and P.G.M. Luiten. Lab. Animal Phys., Univ. of Groningen, Haren, The Netherlands.

Cortical activity is enhanced during PSA. In experiment I, changes in immunoreactivity (ir) for mAChRs, PKCγ and MAP2 after PSA were examined. 18 Young adult male Wistar rats were divided into 3 groups: naive controls (n=6), nonshocked controls, introduced to the testapparatus (n=6), and shocked animals (n=6). 24 Hr after the last trial, the animals were perfused. Cryosections were labeled for mAChRs (M35), PKCγ (36G9),and MAP2. In addition,fluorescencedouble-labeling was performed for mAChRs/MAP2and mAChRs/PKCγ. Cholinoceptiveneurons often express PKCγ,and mAChRs appeared to be highly colocalized with MAP2. Notably in the shocked group, the ir for all 3 markers was increased in individual neurons. These neurons were found in radial cortical columns, often in a lateralized fashion (either in left or right hemisphere). In experiment II, we examined the contribution of ACh to the enhanced ir. Of 6 rats, the nucleus basalis magnocellularis was unilaterally lesioned. Cortical columns with enhanced ir were still observed, both on the lesioned and nonlesioned side. However, clear deficits in PSA was observed when the columns overlapped with ACh depletion. The results reveal that 1) enhanced ir for mAChRs, MAP2 and PKCγ is found in single cortical neurons, 2) neuronal activation induced by PSA caused the changes in ir, 3) ACh is not required for this induction, but 4) learning deficits arise when the behaviorally activated neurons lack cholinergic innervation.

653.13

ROLE OF NITRIC OXIDE IN THE INDUCTION AND MAINTENANCE OF LONG LASTING POTENTIATION IN THE CHICK BRAIN SLICE. P.M. Bradley, B.D. Burns and A.C.Webb. Spon: Brain Research Association. Division of Neurobiology, Medical School, Newcastle upon Tyne, England.

The intermediate medial hyperstriatum ventrale (IMHV) is an area of the chick forebrain known to be involved in learning. We have shown that in a slice preparation it is possible to induce long lasting potentiation of a locally evoked field response within the IMHV by administration of tetanising stimulation at 5Hz. The present study was designed to investigate whether the transneuronal messenger nitric oxide (NO) was involved in the induction and/or maintenance of this potentiation.

A stable field response was evoked in the IMHV in a 500µm thick coronal forebrain slice by electrical stimulation at 0.1Hz. A single burst of 300 stimuli at 5Hz was then administered in an attempt to induce potentiation. The extent and duration of potentiation achieved during superfusion of the slice with Krebs' solution was compared to that obtained during superfusion of 1µm of the NO scavenger bovine haemoglobin.

In both situations the potentiating stimuli were followed by a rapid rise in the amplitude of the response. Under Krebs' this potentiation was maintained for at least 60 min whereas in the presence of haemoglobin no long term effects were seen and response amplitude returned to baseline values in a period with a mean duration of 20.2 ± 7.5 min (n=10).

The results presented here would suggest that nitric oxide has a role in the maintenance (but not the induction) of potentiation in the IMHV of the chick brain. Since our previous work has shown a predominantly postsynaptic locus for the changes associated with potentiation it may be that in the chick brain NO is acting as an intracellular rather than a transneuronal second messenger.

MIDAZOLAM IMPAIRS RETENTION OF BEHAVIORAL CONTRAST. J.A. Salinas*, H. Dickinson-Anson, & J.L. McGaugh. Center for the Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717.

Crespi (1942) showed that rats trained to run an alley for a large food reward display sharply increased latencies when shifted to a small reward. This effect is referred to as behavioral contrast and is usually interpreted as an aversive emotional reaction to a reduction in reward magnitude. Benzodiazepines have been shown to attenuate the behavioral effects of reward reduction, but the emphasis has been on their anxiolytic, not memory-impairing effects. To examine benzodiazepine effects on memory of a reward decrease we trained male Sprague-Dawley rats (175-200g) that were food deprived and maintained at 80% of body weight to run a straight alley (six trials per day) for either ten 45 mg food pellets or one 45 mg food pellet until asymptote was reached. Twenty minutes prior to the next training session, half the animals were injected (i.p.) with 1 mg/kg midazolam (MDZ) or saline. During the training session one half of the high reward group in each injection condition was shifted to one pellet. The reward conditions were maintained for two additional days of training. No further injections were given. Shifted animals receiving saline displayed a characteristic sharp increase in latency on the second day of shift training. This increase was not visible in the shift/MDZ animals on that day but it did appear on the third day. This study suggests that MDZ injected immediately prior to a reduction in reward magnitude impairs the retention of the aversive consequences of such a decrease.

INTRA-AMYGDALA INJECTIONS OF FLUMAZENIL DO NOT BLOCK THE AMNESTIC EFFECTS OF SYSTEMIC DIAZEPAM H. Dickinson-Anson*, C. Tomaz & J.L. McGaugh. Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717

It is well known that benzodiazepines (BZD) induce anterograde amnesia in humans and laboratory animals. Recent findings suggest that the memory impairing effects of BZD's involve the amygdaloid complex (AC). Bilateral intra-AC injections of the BZD antagonist flumazenil (FZ) and agonist midazolam enhance and impair, respectively, retention performance of rats trained in aversively motivated tasks. We recently reported that excitotoxic lesions of the AC block diazepam (DZP)-induced retention impairment. Furthermore, bilateral lesions of the basolateral nucleus (BL) attenuated systemic DZP-induced retention deficits. Lesions of the central (CE) or lateral (LAT) nuclei of the AC had no effect. These data indicate the BL nucleus is necessary for systemic DZP to influence memory processes. To investigate this implication male rats (250-300g) were implanted with bilateral cannula in either the CE or BL nuclei of the AC. One week later, they were trained on a one-trial inhibitory avoidance (IA) task and tested 48-h later (step-through latency). Twenty min prior to training the rats received either FZ (1.5 or 2.5 μg) or vehicle (VEH) in the CE or BL nuclei followed by either DZP (2.5 mg/kg) or VEH ip. Pre-training administration of VEH ip plus FZ in either amygdaloid nuclei produced enhanced retention performance. In contrast, a robust retention impairment was observed in animals that received DZP ip and intra-AC injections of VEH. The DZP-induced retention deficits were not attenuated by administration of FZ in the AC. These results suggest that although endogenous BZD activity within the AC can influence memory processes, systemic DZP may influence memory by acting on other brain systems. The present results are consistent with our previous findings suggesting that the BL nucleus must be intact in order for DZP to initiate its memory modulating effects in other brain systems. 654.3

THE ACQUISITION AND RETENTION DEFICITS OF DIAZEPAM IN A MODIFIED STEP-DOWN PASSIVE AVOIDANCE PARADIGM DO NOT TOLERATE FOLLOWING CHRONIC DRUG ADMINISTRATION IN RATS. A.D. Kastello and J.V. Cassella*. Behavioral Biology, Neurogen Corporation, Branford, CT 06405.

Avoidance paradigms are useful in studying learning and/or memory processes following various physiological or pharmacological manipulations. The present procedure used a modified step-down passive avoidance task allowing for assessment of acquisition and retention processes.In normal animals the shock-response retention function was non-monotonic. Pharmacological studies were conducted (drugs given IV prior to acquisition trials). Scopolamine (0.2-0.8mg/kg) impaired acquisition only while MK-801(0.025-0.5mg/kg) produced both acquisition and retention deficits. Acute dosing with the BZ agonists diazepam(0.12-0.5mg/kg) or triazolam (0.015-0.125mg/kg) impaired both acquisition and retention. Both the BZ partial agonist, RO 16-6028 (0.125-2.0 mg/kg), and the Type-I selective BZ agonist, alpidem (1.0-4.0 mg/kg) produced retention deficits only. A 0.5mg/kg(IV) dose of DZ produced marked sedation and significant acquisition and retention deficits. However, following chronic treatment with DZ (5 mg/kg,IP; b.i.d.; 7 days), a 0.5mg/kg(IV) dose of DZ produced the same avoidance deficits without sedation. Thus, this paradigm demonstrates that the learning and memory impairments of diazepam do not tolerate and suggests that the drug's sedative and amnestic effects are mediated by different mechanisms.

INTRASEPTAL INFUSIONS OF CHLORDIAZEPOXIDE IMPAIR PLACE LEARNING IN THE MORRIS WATER MAZE: REVERSAL BY FLUMAZENIL BUT NOT TETRAHYDROAMINOACRIDINE (THA). R. K. McNamara* & R. W. Skelton. Dept. Psychology, Univ. Victoria, P.O. Box 3050, Victoria, British Columbia, Canada, V8W 3P5.

Peripherally administered chlordiazepoxide (CDP) impairs place learning in the Morris water maze (MWM; McNaughton & Morris, 1987, Behav. Brain. Res., 24: 39). The present study sought to determine if this impairment is mediated by the septohippocampal cholinergic system.

Rats were implanted with a cannula aimed at the medial septum. CDP (10, 30 or 60 nmol) was dissolved in a 1 μl volume of aCSF and infused over a three minute period; controls were infused with aCSF. Rats were trained in the MWM (1 d, 20 trials followed by probe; 1 min ITI: 15 s on platform, 45 s in warming cage). Intraseptal infusions of CDP at concentrations of either 30 or 60 nmol, but not 10 nmol, impaired place learning; rats took longer swim paths to locate the submerged platform and did not show a bias for the correct quadrant during the probe trial. None of the CDP concentrations impaired performance on a visible platform task. On the following day, all rats were able to acquire a new platform position in the absence if intraseptal infusions, suggesting that the impairment found during initial acquisition was not due to septal damage. In a new group rats, systemic flumazenil (10 mg/kg) or THA (1 or 3 mg/kg) was coadministered with intraseptal CDP (60 nmol). Flumazenil, but neither dose of THA, reversed the place learning deficit produced by CDP. Together, these results suggest that the amnesic effects of CDP in the MWM are mediated by septal benzodiazepine/GABA-A receptors, independent of the septohippocampal cholinergic system.

INTRASEPTAL DIAZEPAM-BINDING INHIBITOR (DBI) AND FLUMAZENIL ENHANCE RETENTION OF A SINGLE SESSION SPATIAL WATER MAZE TASK. R.W. Stackman* and T.J. Walsh. Department of Psychology, Rutgers University, New Brunswick, NJ 08903.

Cholinergic cells in the medial septum (MS) innervate the hippocampus (HPC) and modulate spatial memory processes. GABA/BDZ receptors located on these cells are capable of functionally regulating the cholinergic activity in the HPC. Intraseptal injection of BDZ agonists decrease the activity of these neurons; while BDZ antagonists and inverse agonists increase their activity (Walsh et al., submitted). Systemic and intraseptal, but not intraamygdala, injection of the BDZ chlordiazepoxide impairs working memory in rats (Stackman & Walsh, 1992). The MS contains a high density of endogenous BDZ agonist-like molecules that are released during stressful events (Wolfman et al. 1991). DBI, an endogenous neuropeptide, induces a negative modulatory action at BDZ receptors, and behavioral effects characteristic of an inverse agonist. The involvement of DBI and BDZ receptors in spatial memory formation was evaluated in this experiment. Adult male Sprague-Dawley rats were implanted with single guide cannulae in the MS. The rats were trained in the Morris water maze for a single session of 16 trials, during which the platform's position remained constant. Immediately after the 16th training trial, rats were injected into the MS with either DBI (4 nmoles), flumazenil (10 nmoles), or artificial CSF. Retention of memory for platform location was assessed 24 hr. after training, by a 60 sec probe trial. During the first 15, and 30 sec of the probe trial, DBI- and flumazenil-treated rats spent a significantly greater amount of time in the training quadrant than the CSF-treated controls. These data indicate that intraseptal infusion of DBI and flumazenil enhanced retention, possibly via an antagonism of endogenous BDZ-like molecules released during the training event. These data support an endogenous BDZ mechanism in the MS that is capable of modulating the processing and retention of spatial information. Supported by NSF grant BNS 9109163 to TJW.

INTERACTIONS BETWEEN THE EFFECTS OF BASAL FOREBRAIN LESIONS AND CHRONIC TREATMENT WITH MDL 26,479 ON LEARNING AND MARKERS OF CHOLINERGIC TRANSMISSION. L.A. Holley[1], J.A. Miller[2], P. Chmielewski[2] and M. Sarter[1]*. [1]Dept. Psychology, Ohio State Univ., Columbus, OH 43210, and [2]Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

Behavioral and biochemical data have suggested that the triazole MDL 26,479 acts as a benzodiazepine receptor selective inverse agonist. It has been assumed that the beneficial behavioral effects of such compounds are likely to depend on the activation of cortical cholinergic afferents. The interactions between the effects of MDL 26,479 and basal forebrain lesions were tested. Lesioned animals were impaired in learning a conditional visual discrimination task and showed a marked decrease in cortical hemicholinium binding. Chronic treatment with MDL 26,479 (5 mg/kg; i.p.) produced a modest facilitation of learning in lesioned animals but did not significantly affect hemicholinium binding. Performance of all animals significantly correlated with frontal cortex hemicholinium binding. It is assumed that the relatively limited potency of MDL 26,479 to facilitate learning was based on the fact that the lesion destroyed about 95% of all basal forebrain cholinergic cell bodies and therefore significantly confined the drug's potential to activate cortical cholinergic transmission via the basal forebrain GABA-cholinergic link.

DISSOCIATION BETWEEN THE EFFECTS OF BENZODIAZEPINE RECEPTOR AGONISTS ON BEHAVIORAL VIGILANCE AND RESPONSIVITY. P. Dudchenko*, B. Paul and M. Sarter. Dept. Psychology and Neurosci. Program, Ohio State Univ., Columbus, OH 43210.

The effects of the benzodiazepine receptor (BZR) full agonists chlordiazepoxide (CDP) and midazolam, and the partial agonist ß-carboline ZK 91 296 on the performance of rats in a simple reaction time paradigm were examined. This task required the animals to respond to rarely and unpredictably occurring brief (50 msec) visual stimulus. The dose-dependent effects of midazolam on signal sensitivity and general responsivity occurred in parallel. In contrast, the effects of CDP on signal sensitivity were largely independent from effects on response bias. The partial agonist ZK 91 296 in general had little effect on performance. Extension of the stimulus presentation time attenuated the effect of CDP on signal sensitivity. These results support the hypothesis that BZR agonist-induced disruption of attentional abilities is not necessarily confounded by effects on general responsivity or sedation, and thus may represent a discrete pharmacological property of these compounds. We are currently examining the hypothesis that the CDP-induced impairment in behavioral vigilance depends on the integrity of the basal forebrain GABA-cholinergic link.

654.8

NEUROANATOMICAL DISSOCIATION OF THE ANXIOLYTIC AND AMNESIC ACTIONS OF CHLORDIAZEPOXIDE. W. B. Gallagher*, R. K. McNamara & R. W. Skelton. Dept. Psychology, Univ. Victoria, P.O. BOX 3050, Victoria, British Columbia, Canada, V8W 3P5.

Both clinical and experimental evidence have found systemic chlordiazepoxide (CDP) to reduce anxiety and impair new learning. Whether these two actions are causally related is unknown. The present study sought to determine if different neuroanatomical regions mediate the anxiolytic effects of CDP on exploration (thigmotaxis) in an open field and the amnesic effects of CDP on place learning in the Morris water maze.

Firstly, rats received systemic (i.p.) injections of either CDP (5 mg/kg) or saline and tested for anxiety in the open field and amnesia in the water maze (1 d, 20 trials followed by probe; 1 min ITI, 15 s on platform, 45 s in warming cage). Systemic CDP suppressed thigmotaxia (reduced anxiety) and impaired place learning (produced amnesia). New rats were implanted with a cannula aimed at either the medial septum, or bilateral cannulae aimed at amygdalea or frontal cortex. CDP (60 nmol) was dissolved in a 1 µl volume of aCSF and infused over a three minute period. Controls were infused with aCSF. Intra-amygdala infusions of CDP suppressed thigmotaxia but had little effect on place learning and intra-septal infusions of CDP had little effect on thigmotaxia but impaired place learning. Infusions of CDP into the frontal cortex had little effect on either thigmotaxia or place learning. These results suggest that the anxiolytic and amnesic actions of systemic CDP are mediated by the amygdala and medial septum, respectively. (Research Supported by B.C. Health Care Research Foundation and NSERC, Canada)

REVERSAL OF CHLORDIAZEPOXIDE-INDUCED IMPAIRMENT IN DISCRIMINATION PERFORMANCE BY PICROTOXIN. S. O. Cole* and J. V. Martin. Departments of Psychology and Biology, Rutgers University, Camden, NJ 08102.

The effects of chlordiazepoxide (CDP) alone and in combination with picrotoxin (PTX) on the performance of a previously-learned go-no go successive discrimination were studied in male Sprague-Dawley rats. CDP 10 mg/kg impaired discrimination in five successive drug sessions, with animals demonstrating recovery in a single post-drug session. The impairment in discrimination performance was due to an increase in responding during the no go periods of the task (errors of commission). The γ-aminobutyric acid (GABA) antagonist PTX (0.5, 1.0 mg/kg) reversed the impairment in discrimination performance and reduced the number of incorrect responses in a generally dose-dependent manner when co-administered with CDP.

Although the co-administration of CDP and PTX also produced a significant reduction in responding during go periods of the task (which further reduced the overall response rate), this effect worked against an improvement in discrimination performance rather than contributing to it. When administered alone, PTX produced no significant change in discrimination performance.

These findings suggest that the impairment in discrimination performance by CDP is mediated by actions on the central $GABA_A$ receptor-benzodiazepine receptor-chloride channel complex.

MEMORY DEFICITS RESULTING FROM DIENCEPHALIC DAMAGE IN MICE ARE REVERSED BY AN I.P. ADMINISTRATION OF METHYL β-CARBOLINE-3-CARBOXYLATE. D.J. Beracochea (*1), A. Krazem (2) and R. Jaffard (1). (1)Lab. Neurosciences Cognitives et Comportementales, CNRS URA 339, Univ. Bordeaux 1, Av. des Facultés,33405 Talence, France and (2) Université de Tizi-Ouzou, Algeria.

Diencephalic damage was induced either by a chronic (12-months) alcohol consumption (AC)(see **Bontempi et al** poster) or by experimental ibotenic acid lesions of the mamillary bodies (MB). Previous studies showed that both AC and MB lesions decreased anxiety in the open-field and in the elevated-plus maze, and induced memory impairments in spatial alternation tasks. We hypothetized that hypoanxiety might be in part responsible for these deficits. Accordingly, increasing anxiety in experimental subjects should attenuate the memory impairments. Three doses of β-CCM (0.25, 0.5, and 1.0 $mg.Kg^{-1}$) were used, according to their previously determined anxiogenic properties. Results showed that the administration of β-CCM improved alternation rates in all groups, as compared to saline-treated subjects.However, the alternation deficits were reversed by a lower dose in the AC group ($0.5mg.Kg^{-1}$) than in the MB group ($1.0 mg.Kg^{-1}$). Since AC induced weaker lesions of the MB than a direct administration of ibotenic acid, one can conclude that part of the facilitative effect of β-CCM might be a function of the severity of damage to the mamillary system.

STATE-DEPENDENT EFFECTS IN TASTE AVERSION LEARNING. Bernard M. Rabin* and Walter A. Hunt. Behavioral Sciences Dept., AFRRI, Bethesda, MD 20889 and Dept. of Psychology, Univ. of MD, Baltimore, MD 21228.

State-dependent learning can occur when the experimental conditions under which a response is acquired differ from those under which its recall is tested. As a result, the learned response may not be performed. Attempts to prevent conditioned taste aversion (CTA) learning may be confounded by the failure to maintain identical conditions on both acquisition and test days. Studies were run using histamine to block a radiation-induced CTA; AMPT to block an amphetamine-induced CTA; and diazepam to block a lithium chloride-induced CTA. In each experiment, the greatest disruption of CTA learning occurred when the drug was administered prior to the conditioned stimulus on the conditioning day, but not on the test day. Pretreating the animals with the drug on both conditioning and test days significantly reduced the effectiveness of the drugs in preventing the acquisition of a CTA.

655.2

COMPARISON OF AVERSIVELY MOTIVATED TASK (PASSIVE AVOIDANCE TASK) AND APPETITIVE WATER-FINDING TASK ON ACQUISITION OF LEARNING IN MICE. M. Hiramatsu[1]*, K. Maezawa[1], K. Ichihara[1], T. Nabeshima[2] and T. Kameyama[1]. [1]Dept. of Chem. Pharmacol., Meijo Univ., Nagoya 468, Japan and [2]Dept. of Neuropsychopharmacol. & Hospital Pharmacy, Nagoya Univ. Sch. of Med., Nagoya 466, Japan.

We examined the development of a latent learning behavior using 'water-finding task' in mice. If animals without deprivation have had previous experience of exploring an open field containing a water-tube, they find the water source more quickly than non-experienced mice when they are deprived water. In this method, mice are not required to perform a special behavior in the pre-exposure stage. We compared this learning behavior with that in one-trial passive avoidance task in mice. The mice were deprived of water for about 24 hr before the test trial. The latencies to entering the alcove (entering latency), drinking water (drinking latency) and starting to drink water after first entering the alcove (finding latency) were measured for each mouse. In water-finding task, finding and drinking latencies were time dependently prolonged: these latencies 5 and 6 days after training were significantly longer compared with those of 1-day group. Up to, at least, 14 days after training, step-down latency in the passive avoidance task did not alter. Cycloheximide treatment immediately after training significantly prolonged finding and drinking latencies but shorten step-down latency. These results indicate that the finding and drinking latencies seem to be indices of learning and memory. Extinction rate of memory from non-reinforced learning is faster than that from negatively reinforced learning. This result also indicates that the process of memory (motivation, acquisition and/or retention) may be different in these two types of behavioral tasks using appetitive and aversive stimuli.

655.3

BEHAVIOURAL, BIOCHEMICAL AND HISTOLOGICAL EFFECTS OF TRIMETHYLTIN-INDUCED BRAIN DAMAGE IN THE RAT.

B. Earley*[1], B.E. Leonard[1], J. Wettstein[2] and J-L Junien [2], Pharmacology Department[1], University College, Galway, Ireland and Institut de recherche Jouveinal[2], 94265, Fresnes, France.

The nature and extent of the behavioural, biochemical and histological changes induced by the organotin compound trimethyltin (TMT) were assessed. Male Sprague-Dawley rats were treated with a single injection of TMT (6.0, 7.0 or 8.0 mg/kg i.p.) and behavioural experiments were conducted 21 - 28 days afterwards. The behavioural consequences of TMT administration were dose-dependent and included (a) hyperactivity in the open-field test, (b) increased locomotor activity and (c) deficits in passive avoidance behaviour, T-maze alternation and Morris water maze performance. Post-mortem histological analysis revealed damage to hippocampal pyramidal cells, an effect which was particularly apparent at 8.0 mg/kg. After a single injection of TMT, HPLC and fluorimetric assays showed that 5-HT and GABA levels in the hippocampus and amygdala were decreased. Furthermore, using quantitative autoradiography, M_1 and M_2 receptor binding sites were found to be markedly diminished in the hippocampus. These results suggest that the toxic interaction of TMT with the hippocampus and other limbic brain regions may be responsible for its detrimental effect on learning and memory.

655.4

NEUROCHEMICAL CHANGES IN BRAIN OF RATS WITH TRIMETHYLTIN-INDUCED HIPPOCAMPAL LESION AND EFFECT OF NEURAL GRAFTS.

A.Masui,* M.Akaike , S.Tsutsumi , N.Ishida , H.Kanai , M.Sadamatsu and N.Kato. Dept. of Psychiatry, Shiga Univ. Med. Science, Otsu 520-21, Japan.

Trimethyltin(TMT) is reported to produce learning impairment, hyperactivity and tail mutilation and to induce a specific loss of pyramidal cells in hippocampal CA3 and CA4 subfields. We found fetal septal grafts, rich in cholinergic neurons, ameliorated learning deficits in TMT-treated rats.

We here examined whether TMT and neural grafting can affect brain levels of somatostatin and neuropeptide Y and the activity of choline acetyltransferase (ChAT). Both peptides are known to exist abundantly in hippocampus and limbic structures including entorhinal cortex, afferent pathway into hippocampus. Male Sprague-Dawley rats were gavaged with TMT-hydroxide (9mg/kg) at 6 wks of age and were grafted with fetal septal cells (ED 15) or CA3 cells (Day 1) a week later. Morris water maze task was performed 6 wks after transplants, and then the rats were subjected to neurochemical evaluation. Both peptides were found to markedly increase after TMT treatment in entorhinal cortex, but not in hippocampus. Transplants successfully ameliorated place-navigation deficits in TMT-treated rats, nevertheless failed to alter hippocampal levels of both peptides. In TMT rats a significant elvation of ChAT activities was noted in CA3 but not in CA1.

MEMORY EFFECTS OF NEUROSTEROIDS INJECTED INTO THE NUCLEUS BASALIS MAGNOCELLULARIS OF THE RAT.

W.MAYO, P. ROBEL, F. DELLU , M. LE MOAL and H. SIMON*. Laboratoire de Psychobiologie des Comportements Adaptatifs INSERM U259-Univ. Bordeaux II. Domaine de Carreire 33077 Bordeaux cedex FRANCE

Since the discovery of marked cell loss and various pathological alterations in the nucleus basalis magnocellularis (NBM) in patients suffering from senile dementia of the Alzheimer type, this structure has been the subject of much attention. The NBM has been reported to be the main source of cortical cholinergic innervation. Various afferents of the NBM have been identified, and particularly a GABAergic afferent originating in the nucleus accumbens, that forms contacts with NBM cholinergic cells. GABA-A and Benzodiazepines (BZD) binding sites have been detected in the NBM. Functionally, local injections of GABAergic agonists into the NBM have been shown to block or reduce the activity of NBM cholinergic neurons. Behavioral studies using local injections of GABAergic agonists or antagonists into the NBM have been shown that this structure was involved in memory processes.

Recently it has been demonstrated an interaction between endogenous steroids and the central GABA receptors. Steroids-GABA receptor interactions may have a role in the regulation of the NBM cortical projections. In order to test this hypothesis, we investigated the effects of local injection of Pregnenolone sulfate (a GABA-like antagonist) and Tetra-Hydro-Progesterone (a GABA-like agonist) into the NBM on performance in a new two-trial memory task.

Our results show that local injection of Pregnenolone sulfate into the NBM improves memory performances in the Y maze recognition task. Conversely the injection of Tetra-Hydro-Progesterone decreases memory performance in this task.

In conclusion, endogenous steroids can modulate memory processes and NBM-related dysfunctions. However, it remains to be elucidated if this effect results from an interaction at the GABA receptor level.

SELECTIVE DECREASE IN DECLARATIVE MEMORY PERFORMANCE IN NORMAL HUMAN SUBJECTS TREATED WITH DEXAMETHASONE

J.W. Newcomer*, S. Craft, T. Hershey, K. Askins. Depts. of Psychiatry and Psychology, Washington Univ., St. Louis, MO 63110.

A range of evidence supports the role of hippocampus in declarative memory performance. Hippocampal glucocorticoid (GC) receptors are an important neural target for GCs and brief physiologic GC exposure produces site-selective hippocampal GC receptor down-regulation. Four days of double-blind, placebo-controlled treatment with physiologic doses of dexamethasone (DEX) was given to normal subjects, hypothesizing an effect on declarative memory performance, but not performance on other cognitive measures. Subjects received either oral placebo (N = 9) or DEX (N = 10) on study days 1-4, in doses of 0.5, 1, 1, and 1 mg. Cognitive testing, using paragraph recall (immediate and 30 min. delay), serial addition, auditory trails/vigilance, and the Benton line orientation task, was performed on days 1 (baseline), 2, 5, and 12 (7 day recovery condition).

DEX, and not placebo, treatment resulted in a selective decrease in declarative memory performance, followed by post-treatment recovery. In DEX-treated subjects, repeated measures ANOVA found an overall effect of study day on delayed recall ($F[3,27] = 6.06$, $p < 0.01$), with a trend toward an effect on immediate recall ($F[3,27] = 2.37$, $p < 0.09$). The greatest decrease from baseline delayed recall performance was observed at day 5 ($F[1,9] = 7.80$, $p < 0.05$). No other cognitive measure showed a significant effect of study day. These results demonstrate a selective effect of DEX on declarative memory performance.

655.7

ACUTE ETHANOL DISRUPTS PATTERN CONDITIONING BUT NOT CONTEXT CONDITIONING IN ADOLESCENT AND ADULT ANIMALS.

L. Rajachandran*, N.E. Spear & L.P. Spear. Dept. of Psychology and the Center for Developmental Psychobiology SUNY, Binghamton, N.Y. 13902.

Effects of alcohol administration on conditioning to a visual stimulus and an olfactory context was examined in both adult (60-70 day old) and periadolescent (35-38 day old) rats. Conditioning occurred in a patterned chamber divided into two compartments , one with vertical black and white alternating stripes (CS-) and one with horizontal stripes (CS+); both contained an orange contextual odor. Paired animals were given 6 training trials consisting of a 20 sec placement in the CS- chamber followed by a 20 sec exposure to the CS+ chamber, during which two 3 sec 1 mA footshocks were given. Unpaired animals received the same regimen of footshock exposure in a black chamber 10 min prior to exposure to the patterned chamber and the orange odor. Ethanol (2.0 g/kg) or saline was intragastrically administered 10 min prior to conditioning. Animals were given one of two 5 min preference tests after conditioning: either between the CS+ and CS- or between a novel lemon odor and the orange odor. Ethanol did not disrupt conditioning to the odor context; at both ages paired animals pretreated with saline or alcohol exhibited an equivalent aversion to the orange odor. However, conditioning to the CS+ was significantly impaired by alcohol. While paired animals at both ages given alcohol did not acquire an aversion to the CS+, paired saline animals did learn the CS-US association. Thus it appears that a modest dose of alcohol impairs conditioning to a visual CS+ but not to the more general olfactory context in which the CS+ occurred.

PHARMACOLOGICAL MODULATION OF ACUTE-ETHANOL-INDUCED MEMORY BLACKOUTS IN RATS.

D.H. Epstein and L.A. Pohorecky*. Center of Alcohol Studies, Rutgers University, Piscataway, NJ 08855.

This study explored the neurochemical mechanisms of ethanol-induced amnesia. Behavioral interactions of ethanol (ET) with drugs whose actions are neurotransmitter-specific were evaluated in a paradigm that assessed the clinically relevant type of memory (episodic) under clinically relevant conditions (intoxication during acquisition). Male Long-Evans rats were trained in a Y-maze active-avoidance task whose episodic-memory component took the form of repeated reversals, each of which had to be remembered over a delay of up to 180 minutes. ET (20% w/v in saline, 2 g/kg IP) was shown to produce delay-dependent deficits in memory consolidation, which were not dependent on deficits in acquisition or procedural memory. This ET-induced amnesia was partly prevented by coadministration of the antiGABAergic drug Ro 5-3663 (5 mg/kg IP), mimicked and enhanced by $GABA_A$-receptor activation with chlordiazepoxide (1, 3, or 10 mg/kg IP), and also mimicked and enhanced (but to a lesser degree) by general GABAergic augmentation with aminooxyacetic acid (15 mg/kg IP). This finding suggests that $GABA_A$ receptors have a greater role than $GABA_B$ receptors in ET-induced amnesia. Activation of $5\text{-}HT_{1A}$ receptors with 8-OH-DPAT (.16, .32, or .64 mg/kg IP) unexpectedly produced the most severe and behaviorally specific amnesia of any of the treatments, but the interaction of 8-OH-DPAT with ET, and the two drugs' differing interactions with a $5\text{-}HT_{1A}$ antagonist ([-]propranolol, 8 g/kg IP), ruled out $5\text{-}HT_{1A}$ activation as the mechanism of ET-induced amnesia. The significant but not complete prevention of blackouts by GABAergic antagonism suggests the involvement of other transmitter systems.

STAGES OF MEMORY FORMATION IN 2 AREAS OF CHICK BRAIN. M.R. Rosenzweig*, D.W. Lee, S.S. Shrawder, & E.L. Bennett. Dept. of Psychology, Univ. of California, Berkeley, CA. 94720, USA.

Two-day-old chicks were given bilateral i.c. injections into the intermediate medial hyperstriatum ventrale (IMHV), trained on a 1-trial peck avoidance task using a target bead dipped in methyl anthranilate (MeA) then tested from 10 s to 24 h posttraining. After strong training (100% MeA), memory formation is impaired by 5 min posttraining by glutamate (GLUT, a short-term memory inhibitor), by 20 min by ouabain or scopolamine (OUAB or SCOP, intermediate-term memory inhibitors), and by 90 min by anisomycin (ANI, a long-term memory inhibitor). Memory for weak training (10% MeA) is also impaired by GLUT and ANI at the same doses and times as for strong training. Neither ITM inhibitor performed as predicted: OUAB impaired weak memory only at a dose that resulted in severe side effects, and SCOP inhibited weak memory at 24 h only. In contrast, injections of OUAB into lobus parolfactorius (LPO) resulted in significant memory impairment at the same doses and times as for strong training. Supported by NSF grant BNS-88-10528 & NIDA grants DA04795 and DA05396.

655.10

SEASONAL MODULATION OF LEARNING AND MEMORY IN CHICKS. D.W.Lee*, G.G. Murphy, E.L. Bennett, & M.R. Rosenzweig. Dept. of Psychology, Univ. of California, Berkeley, CA. 94720, USA.

Two-day-old chicks were trained on a 1-trial peck avoidance task using a target bead dipped in either 5, 10, or 100% methyl anthranilate (MeA). Groups were tested at times from 10 s to 24 h posttraining. Runs were conducted during 2 summers (Jun-Aug) and winters (Nov-Jan). At every test time, groups of chicks trained with 100% MeA showed the highest avoidance, followed by 10%, then 5% MeA; retention is dependent upon strength of training.

Winter chicks did not differ from summer chicks during training but showed less retention at test. They were also heavier and more active, but neither measure correlated with test performance. Performance for each strength of training was positively correlated to daylength.

In summer, test performance averaged over all 3 training strengths showed retention deficits ("dips") at 1', 15', and 60' test times. In winter, dips were present at 1-5', 30', and 90' test times - thus winter not only impairs but also slows down memory formation on this task.

655.11

MOLECULAR MECHANISMS FOR MEMORY FORMATION IN THE 2-DAY OLD CHICK: THE ROLE OF PKC AND OTHER KINASES. P.A. Serrano*, M.L. Leissring, E.L. Bennett, and M.R. Rosenzweig. Department of Psychology, University of California, Berkeley, CA. 94720.

The three stage model of memory formation proposed by Gibbs and Ng (1977) and extended by results from our laboratory was used to determine the role of protein kinase (PK) activity during memory formation. Groups of chicks were trained on a 1-trial peck-avoidance task 5 min after amnestic agents were injected bilaterally into the intermediate medial hyperstriatum ventrale (IMHV). The time of appearance of amnesia induced by these PK inhibitors indicates the stage of memory formation disrupted by each agent. Our results show that intermediate-term memory (ITM) formation can be disrupted by agents affecting calcium or CAM kinase activity (e.g., W-9, W-13, HA-1004, TFP, A-3). Long-term memory formation can be disrupted by inhibiting PKC, PKA or PKG by agents such as H-7, H-8, H-9, ML-9 and HA-156; these agents had no effect on ITM. W-9, TFP, H-7 and HA-156 produce amnesia when injected into the left IMHV but not when injected into the right IMHV.
Supported by NSF grant BNS-88-10528

655.12

IMPAIRMENT AND ENHANCEMENT OF SPATIAL DISCRIMINATION LEARNING INDUCED BY THE INTRA-HIPPOCAMPAL INJECTION OF POLYMYXINE B : A PROTEIN KINASE C INHIBITOR. X. Nogues, J. Micheau* and R. Jaffard. Lab. Neurosciences comportementales et cognitives, URA CNRS 339, Univ. Bordeaux I, Avenues des Facultés 33405 Talence Cedex France.

Electrophysiological and morphological data suggest that protein kinase C (PKC) is implicated in several forms of neuronal plasticity. Thus it has been proposed that activation of PKC and phosphorylation of particular substrates are critical events in the neuronal plasticity leading to an organic support of memory traces. In accordance with this statement, we have previously shown that spatial learning induced a decrease in cytosolic PKC activity in the hippocampus (NOGUES et al., 1990, Soc. Neurosci. Abst., Vol. 16, 316-14). In order to investigate the functional aspects of these modifications, we have compared the mnemonic effects of intrahippocampal injections of either polymyxine B (PMB, 10 mM) or 2% lidocaïne (0.2 µl bilaterally) on a mixed reference working memory task in a radial maze. When injected 15 minutes before each daily session, PMB was shown to slow down acquisition rate of reference memory. However in contrast with all other groups PMB-treated animals exhibited no forgetting on a retention test performed 16 days following acquisition. The beneficial influence of PMB treatment on forgetting might be explained by a post-acquisition rebound effect on PKC produced by the cessation of the PMB treatment. An alternative hypothesis (i.e. the induction of a direct extrahippocampal long-term storage) is currently under investigation.

IN VIVO AND IN VITRO EFFECT OF COGNITION ENHANCING DRUGS ON RAT BRAIN PROTEIN KINASE C ACTIVITY. L. Lucchi, S. Govoni, F. Battaini^, M. Trabucchi*^ Inst. Pharmacol. Sci, Univ. Milano, ^Dept.Exptl. Med. and Biochem. Sci., II[nd] Univ. of Roma, Italy.

Associative behaviour produces brain Protein Kinase C (PKC) translocation suggesting a role for this enzyme in learning and memory. The present data demonstrate that some cognition enhancing drugs promote PKC activation in rat brain following "in vivo" administration. In particular, the acute treatment with oxiracetam (OXI), a nootropic drug that stimulates cholinergic transmission and glutamate release, produced in rat cortex an increase of PKC activity in particulate fraction (+40%) paralleled by a decrease of enzymatic activity in the soluble fraction (-28%). The time course curve showed that the peak effect was reached 1 h after treatment, whereas at 5 hrs PKC activity was down-regulated. In order to understand the mechanisms of interaction between OXI and PKC "in vitro" studies were carried out. OXI was able to induce PKC translocation in cortical slices after 15 minutes of incubation at 200 nM concentration (+30% in particulate and -25% in soluble PKC activity). A bell shaped dose-curve was observed in this condition as well as in "in vivo" experiments: the peak effect was reached at 15' (OXI 200 nM). The results obtained may be related to a direct cortical effect of oxiracetam in stimulating PKC translocation. Another cognition enhancing drug was tested in a similar experimental protocol: 2 α-Glycerylphosphorylcholine (GPC), which stimulates acetylcholine synthesis and release. PKC activity was measured in soluble and particulate fractions from rat cortices after acute GPC treatment. The drug elicited an increase of particulate PKC (+50%) and a decrease of soluble fraction activity (-30%). The peak effect was reached 1 h after drug administration and at 5 hs enzyme down-regulation occurred. OXI and GPC did not produce significant effects on hippocampal PKC activity after acute treatment in "in vivo" as well as "in vitro" conditions. Experiments from literature indicate that specific cognition trainings preferentially increased selected PKC isoforms in rat cortex but not in hippocampus. These results are in line with the hypothesis that PKC translocation in brain areas important for cognition may contribute to learning and memory processes.

THE EFFECTS OF COCAINE ALONE AND IN COMBINATION WITH SEROTONERGIC ANTAGONISTS ON SCHEDULE-CONTROLLED BEHAVIOR OF SQUIRREL MONKEYS. S.L. Serdikoff *, C.A. Sannerud, C.W. Schindler & S.R. Goldberg. NIDA-Addiction Research Center, Baltimore, MD 21224.

Recent findings have established that there is a serotonergic (5HT) component involved in the behavioral effects of psychomotor stimulants. Additionally, it has been shown that cocaine (COC) potently inhibits 5HT reuptake as well as depresses the spontaneous activity of the dorsal raphe. In the present study, the effects of acute pretreatments of cocaine alone, cocaine together with the $5HT_2$ antagonist ketanserin (KET), and cocaine together with the $5HT_3$ antagonist MDL 72222 (MDL) were evaluated in 4 squirrel monkeys responding under a multiple FI 5 min - FR 30 schedule of food reinforcement. Control responding was characterized by lower overall response rates during the FI component as compared to the FR component (0.32 & 1.3 r/sec, respectively). During both components, COC (0.032 - 3.2 mg/kg, i.m.) produced an inverted U-shaped dose-response function for response rate with the higher doses also resulting in an increase in latency to respond. KET (0.1-10 mg/kg, i.m.) produced differential antagonism of COC's (.032-3.2 mg/kg, i.m.) effects on response rates during the two components; KET appears to have antagonized the rate-decreasing effects of high cocaine doses during the FI component and antagonized the rate-increasing effects of low cocaine doses during the FR component. During both components, however, response latencies following 1.0 mg/kg COC were shortened by concomitant KET administration. To date, MDL (5.6-20 mg/kg, i.m.) in combination with COC produces equivocal effects on responding under this multiple FI-FR schedule.

TOLERANCE TO THE REINFORCING PROPERTIES OF COCAINE: DOSE-EFFECT DETERMINATION USING A MULTI-DOSE SINGLE-SESSION METHOD. M. W. Emmett-Oglesby, R. Depoortere, C. Pickering, M. Hooper and J. D. Lane*. Dept. of Pharmacology, TCOM, 3500 Camp Bowie Blvd, Fort Worth, TX 76107

We tested the hypothesis that a chronic regimen of cocaine infusion would produce tolerance to the reinforcing properties of cocaine. We also assessed if a multi-dose single-session method, in which different doses of cocaine are tested in a single session, could be applied to demonstrate this tolerance phenomenom. The multi-dose method consists of switching among infusion pumps that drive syringes containing different concentrations of cocaine. Rats were first trained daily to self-administer 15 injections of cocaine (0.25 mg/0.1 ml for each injection) under a FR 2 schedule. They were then subjected to a regimen of chronic cocaine infusion (10 days) for induction of tolerance (5 mg in 20 infusions every 8 hours). At the end of the 10th day, a dose-effect relationship was assessed for self-administration of cocaine (0.125, 0.25 and 0.5 mg/0.1ml) using the muti-dose method. The chronic cocaine regimen produced tolerance, as indicated by a significantly faster intake of cocaine across the three doses tested. This study provides further evidence that tolerance occurs to the reinforcing properties of cocaine. It also demonstrates that a multi-dose method can be used to generate dose-effect data for self-administration of cocaine. Supported by grants DA RO1-4137 (M. E-O) and TX-ATP 3711 & 9768031 (J. L.).

656.3

DIFFERENT BEHAVIORAL EFFECTS OF COCAINE IN WINNERS AND LOSERS OF COMPETITION TESTING. M.C. Wilson, S.M. Chowdhury and J.C. Matthews* Dept Phcol. Sch. of Pharmacy, Univ. of Mississippi, University, MS 38677.

The objective of the study was to identify winners(W) and losers(L) in a fixed pair food competition(COMP) paradigm and to determine differential sensitivity to the effects of cocaine (C) in these pair housed rats. No significant differences were observed in cocaine induced locomotor activity(A) or in stereotypy(S) between W and L. A and S were significantly increased by 10 and 20 mg/kg of C in both W and L. In C based conditioned place preference, W and L did not demonstrate a significant change in time spent in the initially preferred chamber paired with saline. W spent significantly more time in the initially nonpreferred chamber after being paired with C(10 mg/kg). A similar but nonsignificant effect was seen in L. There were no significant differences in D_1 and D_2 receptor density(N. accumbens, caudate-putamen, and hypothalamus) or in plasma testosterone and cortisol levels between W and L. These data suggest that long term COMP testing and/or paired housing does not result in differential sensitivity to C.(Supported in part by the Res. Inst. Phar. Sci.)

THE AVERSIVENESS OF COCAINE WITHDRAWAL IS REVEALED IN A PLACE CONDITIONING PARADIGM. J.L.Parker* and D. van der Kooy. Dept. Anatomy, University of Toronto, M5S 1A8 Toronto, CANADA.

Opiate abstinence after prolonged opiate exposure results in an withdrawal syndrome consisting of somatic withdrawal symptoms and aversive motivational effects. Abstinence from stimulants, such as cocaine, produces somatic withdrawal symptoms that are much less dramatic. We now report that place conditioning paradigms can reveal the aversiveness of cocaine withdrawal following chronic exposure. Rats received 35mg/kg i.p. injections once daily for 10 days. Following this pre-exposure, 5 different groups of animals were injected with cocaine (35mg/kg) and placed in a visually and textually distinct environment 6, 11, 16, 20, and 24 hours later. Each animal was conditioned for one hour, and each animal received a total of four pairings. Place preferences were tested in a drug free state 10 days after the last injection and conditioning trial. The group trained at 20 hours after cocaine injection showed a significant aversion for the paired environment. No other group showed significant aversions. In a separate experiment, we asked if the 10 day pre-exposure phase was necessary for producing aversions for an environment paired with withdrawal from cocaine. Two groups of previously naive rats received four place conditioning trials at 11 or 20 hours following a 35mg/kg cocaine injection. No conditioned place aversions were seen in these two groups without cocaine pre-exposure. We conclude that in cocaine pre-exposed rats, the aversive motivational effects of withdrawal peak at 20 hours after injection and are of short duration.

656.5

EFFECT OF INTERSTIMULUS INTERVAL (ISI) ON COCAINE PLACE PREFERENCE CONDITIONING. W.H. Bridger* and E. Yadin. Department of Psychiatry, The Medical College of Pennsylvania/EPPI, Philadelphia, PA 19129.

The behavioral paradigm of place preference was used to examine the effect of the interstimulus interval (ISI) on conditioning, with the chamber cues acting as the conditioned stimulus (CS) and intravenous cocaine as the unconditioned stimulus (US). Rats fitted with jugular catheters were first allowed to spend 5 min in an apparatus consisting of two distinctly different chambers and a neutral middle section. Three free choice sessions were run and a side preference was determined. During the next eight 5 min conditioning sessions, a connector was attached to the catheter and animals were placed in one of the chambers, a guillotine door blocking its exit to the rest of the apparatus. Upon being placed in the chamber, animals received a 1 mg/kg dose of cocaine hydrochloride intravenously with a short ISI (1 sec) against their original preference. During alternating sessions they received the cocaine with a long ISI (60 sec in one group, 120 sec in another) in their originally preferred chamber. They were then given a 5 min free choice session. The percent of time spent in each chamber was recorded.

After conditioning with cocaine as the US with a 120 sec ISI (but not with a 60 sec ISI), rats showed preference to the chamber associated with the short ISI, a preference that was against their original choice. These results may have implications for the degree of addiction seen with various routes of cocaine administration in humans.

UNCONTROLLABLE STRESS INCREASES VULNERABILITY TO SELF-ADMINISTER COCAINE IN RATS. N.E. Goeders* and G.F. Guerin. Dept. of Pharmacology and Psychiatry, LSU Med. Center, Shreveport, LA 71130-3932.

Adult male Wistar rats were screened and assigned to groups of three based on similar responses to a novel environment and the locomotor stimulating effects of cocaine. Each group of rats was trained to respond on a discrete-trial 30 sec (100 trials/session), fixed-ratio 10 schedule of food reinforcement (45 mg). A 20 sec limited hold was in effect during each trial. When stable baselines of responding were established for all three rats in each group, a random-ratio schedule of shock presentation (0.6 mA) was added to the food schedule for the first rat in each group. This rat therefore had some degree of control over footshock delivery. Footshock for the second rat in each group was yoked to the first rat so that each time the first rat received response-contingent electric shock, the second rat would receive a simultaneous but non-contingent footshock. Approximately 50 shocks were delivered each session. The third rat was never shocked. When stable baselines of responding were obtained, the second component of the multiple schedule was initiated. During the second hour of the session, intravenous cocaine was available (0.2 ml delivered over 5.6 sec) when the rats pressed a second lever in the experimental chamber. The animals were initially tested with 0.031 mg/kg/infusion cocaine, and the cocaine dose was gradually increased (0.0625, 0.125, 0.25 mg/kg/infusion) every three to five days until self-administration was observed. In every case, the second rat (with no control over footshock presentation) self-administered cocaine sooner, at a lower dose and at a higher rate than either the rat with control over footshock delivery or the rat that was never shocked in each group. These data demonstrate that lack of control over environmental stress increases vulnerability to cocaine self-administration. This research was supported by USPHS grant DA06013.

PAVLOVIAN CONDITIONING OF HYPERTHERMIA BY COCAINE.

J. Broadbent*, J. F. Bachtold and C. L. Cunningham. Medical Psychology, Oregon Health Sciences University, Portland , OR 97201

The present study examined unconditioned and conditioned thermal responses to repeated infusions of cocaine. Rats implanted with an i.v. catheter and a biotelemetry device which measured core body temperature, were housed in cages enclosed in sound-attenuating chambers, and subjected to 16-hr sessions. Each session consisted of two 30-min trials. Subjects were presented with a light/noise cue (CS) for 30 min during the first trial: 15 min after the start of the CS, an i.v. infusion of 2 mg/kg of cocaine was administered to 'Paired' subjects. 'Unpaired' subjects received an identical cocaine infusion in the absence of the CS, 3.5 hrs later. 'Paired' animals did not receive any programmed events during this second trial. Initial infusions of cocaine produced little change in body temperature. However, with repeated exposure, cocaine was found to produce a mild hyperthermia in both groups. An anticipatory hyperthermia also became evident in the 'Paired' group following 20 conditioning sessions. This conditioned hyperthermia did not appear to summate with the thermal response to cocaine. Thus, in contrast to Pavlovian conditioning of thermal responses by ethanol and morphine, the cocaine-induced thermal conditioned response did not appear to mediate either tolerance or sensitization. Since previous data suggest that conditioned thermal responses alter drug self-administration, the present findings raise the possibility that conditioned responses may also play a role in cocaine self-administration. (Supported by NIDA grant DA03608.)

TASTE REACTIVITY RESPONSES ELICITED BY COCAINE, PHENCYCLIDINE AND METHAMPHETAMINE PAIRED SUCROSE SOLUTION.

L.A. Parker*. Department of Psychology, Wilfrid Laurier Univ., Waterloo, ON, N2L 3C5, CANADA.

The nature of flavor-drug associations produced by a range of doses of the reinforcing agents cocaine (5 - 40 mg/kg, sc), phencyclidine (.5 - 20 mg/kg, sc) and methamphetamine (2 - 10 mg/kg, ip) were assessed by the taste reactivity (TR) test and the conditioned taste avoidance (CTA) test. Even at the highest doses tested, none of the agents produced aversive TR responses. At doses that produced equivalent strength CTA, lithium did establish aversive TR responses. These results provide evidence that aversive TR responses are only produced by non-reinforcing drugs.

656.9

ELECTROPHYSIOLOGICAL RECORDINGS OF NUCLEUS ACCUMBENS NEURONAL ACTIVITY DURING A MODIFIED FR-3 SCHEDULE FOR COCAINE SELF-ADMINISTRATION.

D.J. Woodward*, J.Y. Chang and S.F. Sawyer. Department of Physiology & Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

We have previously demonstrated that neurons within the core region of the nucleus accumbens (NAc) exhibit anticipatory responses during cocaine self-administration bar pressing behavior. The purpose of the current study was to examine further correlations between neuronal activity in NAc and goal-directed behavior by using a modified fixed ratio 3 (FR-3) schedule to determine if the sequential bar pressing associated with different cues and consequences would evoke different neuronal responses in NAc. A bundle of eight 62μm diameter teflon coated stainless steel microwires were chronically implanted in the NAc for extracellular single unit recording. After recovery from surgery, rats were trained to self-administer cocaine with the modified FR-3 schedule. A retractable bar was mounted on one side of the conditioning chamber. The first bar press resulted in bar retraction; the second bar press turned on the light and retracted the bar; the third bar press turned off the light and delivered cocaine (1 mg/kg in 0.1 ml Ringer's solution, i.v.). A two second delay was imposed between each bar press during which the bar was kept in a retracted position. The anticipatory unit responses, observed as an increase in a firing rate before bar pressing, were not significantly different between each bar pressing, whether it led to cocaine delivery or not. In another experiment, in which a FR-1 schedule was associated with or without cocaine injection, the anticipatory response also remained essentially the same during extinction. These initial results suggest that the anticipatory neuronal responses expressed in the NAc are likely related more to a general goal-directed motoric behavior towards an object with significance rather than a reward-specific phase of the behavior. *Supported by DA02338, and MH44339.*

COCAINE-INDUCED CONDITIONED PLACE PREFERENCE IN RHESUS MONKEYS.

S.M. Pomerantz*, J. Wertz, B. Hepner, L. Waslo, J. Piazza. Depts. of Physiology and Psychology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Although numerous studies in rats have used a conditioned place preference (CPP) paradigm to assess the reinforcing actions of drugs, no studies have yet to demonstrate whether such a procedure can be employed in primate species. The aim of the present study was to develop a CPP paradigm in rhesus monkeys and evaluate the ability of cocaine to produce a CPP. A U-shaped test apparatus was designed comprising of a central compartment and two end compartments with colored side and floor panels. The experiment was run in three phases (Pretest, Drug Conditioning, and Posttest). In Pre- and Posttests, monkeys were able to explore the entire test apparatus for 30 min, whereas during conditioning, monkeys were restricted to one or the other end compartments for 30 min. Conditioning lasted 8 days. On odd-numbered training days monkeys were injected with cocaine (IM) and placed in the originally less-preferred compartment and on even-numbered days they were injected with saline and placed in the opposite, initially more-preferred compartment. The effect of 0, 50, and 100 μg/kg cocaine (N=8) and 400 and 800 μg/kg cocaine (N=4) on the acquisition of a CPP has been studied. Compared to their pretest, after being conditioned in one of the compartments with 0, 50, 100, 400 and 800 μg/kg cocaine, monkeys spent on average 5±24, 45±20, 91±25, 113±40, and 80±40 more 5-sec blocks in the cocaine-paired compartment, respectively. Moreover, since the increased time in the cocaine-paired compartment was also associated with decreased time in the saline-paired compartment a reversal in place preference was observed. These data demonstrate that a CPP procedure can be used in rhesus monkeys to investigate the reinforcing properties of drugs.

656.11

THE RUNWAY BEHAVIOR OF COCAINE-REINFORCED RATS RESEMBLES THAT OF SUBJECTS RUNNING FOR FOOD+SHOCK.

T.D.Geist* and A. Ettenberg. Dept of Psychology, Univ. California, Santa Barbara, CA 93106.

Rats traversing as straight-alley for positive reinforcement typically exhibit faster running times, or *goal latencies* (GL), as training proceeds. However, when reinforced with i.v. cocaine, we observed that subjects took progressively longer to enter the goal box over trials. Closer observation of the data revealed that the increasing GLs were the result of a unique "retreat behavior" (i.e., stopping and returning to the start box). We hypothesized that such behavior reflected an inherent "conflict" that stemmed from the drug's well documented reinforcing and anxiogenic properties. To test this idea, the runway behavior of animals experiencing other concurrent positive and negative stimuli (i.e., food and mild footshock) was examined. Hungry animals were trained to traverse a runway for food reinforcement coupled with footshock. These subjects showed higher GLs and *retreat frequencies* than a control group which received only food in the goal box. The nature and pattern of the retreat behavior in the food+shock group strongly resembled that of cocaine-reinforced rats.

656.12

EVIDENCE FOR CONDITIONAL NEURONAL ACTIVATION FOLLOWING EXPOSURE TO A COCAINE-PAIRED ENVIRONMENT: ROLE OF FOREBRAIN LIMBIC STRUCTURES

ERIN BROWN*, GEORGE ROBERTSON AND H. C. FIBIGER. Division of Neurological Sciences, Univ. of British Columbia, Vancouver, B.C. V6T 1Z3.

The classical conditioning of cocaine's behavioral effects with specific environmental stimuli is an important aspect of its actions. This property of cocaine is of major significance with respect to this drug's abuse potential, as intense craving can be evoked by stimuli previously associated with drug taking. To better understand the neurobiology of this phenomenon the expression of the putative metabolic marker *c*-Fos and locomotor behaviour were examined in rats that were exposed to an environment in which they had previously received cocaine.

Compared to saline treated controls, acute administration of cocaine produced an increase in locomotor behaviour that was accompanied by an increase in *c*-Fos expression within specific limbic regions (cingulate cortex, claustrum, lateral septum, paraventricular nucleus of the thalamus, lateral habenula and amygdala) as well as the basal ganglia (dorsomedial striatum and nucleus accumbens). Exposure of rats to the cocaine-paired environment also produced an increase in locomotion, as compared to pseudoconditioned and control subjects. In addition to this behavioural effect, conditioned subjects exhibited a significant increase in *c*-Fos expression within the cingulate cortex, claustrum, lateral septum, paraventricular nucleus of the thalamus, lateral habenula and the amygdala, suggesting an increased neuronal activation within these regions. In contrast to the dramatic effects observed within these limbic structures, no conditional activation was observed within the nucleus accumbens or dorsal striatum. The present findings suggest that specific limbic regions exhibit increased neuronal activation during the presentation of cocaine-paired cues and may be involved in the formation of associations between cocaine's stimulant actions and the environment in which the drug administration occurred.

THE 5HT1A RECEPTOR: RELATIONSHIP TO IMPULSIVE AND AGGRESSIVE BEHAVIOR IN COCAINE ABUSE.

Frederick G. Moeller*, Joel L. Steinberg, Donald Cherek, Frederick Petty, Gerald Kramer, Lenore Phillips, David Garver. University of Texas Southwestern Medical School, 4500 S. Lancaster, Dallas, TX 75216.

The neurotransmitter serotonin is linked to aggressive behavior in animals and humans. In order to examine the role of 5HT in aggressive and impulsive behavior in cocaine abuse, the 5HT1a agonist buspirone (0.4mg/Kg orally) was administered as a neuroendocrine challenge agent to 7 cocaine dependent male human subjects, and 9 healthy male controls. The ACTH, growth hormone and prolactin levels after buspirone administration were then compared between the healthy controls and the cocaine dependent patients. Hormone levels were also correlated with measures of aggression including the Buss-Durkee Hostility Inventory. Buspirone levels were obtained on all subjects to control for differences in metabolism between groups. Results of this analysis will be presented, and the implications for treatment of aggressive behavior in cocaine dependent patients will be discussed.

EFFECTS OF INTRA-ACCUMBENS AND INTRA-PREFRONTAL CORTEX COCAINE INFUSIONS ON SCHEDULE-INDUCED POLYDIPSIA.

G.H. Jones*, M.S. Hooks and J.B. Justice, Jr. Dept. Chemistry, Emory University, Atlanta, GA 30322.

Schedule-induced polydipsia (SIP), the excessive drinking induced by exposure to intermittent schedules of food-delivery, has been functionally linked to forebrain dopamine projections and in particular the mesolimbic dopamine system. This study compared the effects of cocaine microinfusions into the nucleus accumbens (NACC), the medial prefrontal cortex (MPFC), and IP cocaine injections on schedule-induced drinking, locomotor activity and panel presses to gain access to the food.

SIP was induced in male Wistar rats reduced to 85% of their free-feeding weight and exposed to a fixed-time 60 second schedule of food-presentation. When performance reached stable levels subjects were bilaterally infused with either vehicle, 12.5, 25, 50, or 100 ug cocaine HCl via chronically implanted guide cannula aimed to give access to either the NACC (n=12) or MPFC (n=12). The sequence of infusions was according to a Latin square design and infusions were administered immediately before the daily 30 min sessions. Following the series of intra-cranial infusions all subjects received IP injections of either saline, 2.5, 5, 10, or 20 mg/kg cocaine HCl.

The 3 routes of drug administration produced different profiles of behavioural effects. For example, both IP and NACC cocaine dose-dependently decreased SIP and increased locomotor activity suggesting a reduction in SIP through response competition. However, MPFC cocaine also dose-dependently decreased SIP but did not significantly affect locomotor activity. In addition, IP cocaine increased low rates of panel pressing without affecting high rates whereas NACC and MPFC cocaine had no effect on low rates but decreased high rates of responding.

A PHARMACOLOGICAL INVESTIGATION OF GBR 12909-INDUCED BEHAVIORAL SENSITIZATION.

B. A. Baldo*, S. C. Hinton, and A. E. Kelley. Department of Psychology, Northeastern University, Boston, MA 02155

The present study was designed to investigate the mechanisms underlying GBR 12909-induced behavioral sensitization. GBR 12909, a psychomotor stimulant which selectively inhibits dopamine reuptake, was repeatedly administered to male Sprague-Dawley rats. Specifically, chronic treatment consisted of intraperitoneal injections of 20 mg/kg GBR 12909 or vehicle, administered every other day over a 12-day interval. Following cessation of chronic treatment, the animals were challenged with vehicle, GBR 12909 (6 mg/kg), and the following drugs, which were tested in separate experiments: apomorphine (0.1 mg/kg), nomifensine (0.75 mg/kg, 1.5 mg/kg), d-amphetamine (0.25 mg/kg, 0.75 mg/kg), bupropion (20 mg/kg), and scopolamine (0.1 mg/kg, 0.5 mg/kg). The dependent variable was locomotor activity, measured in photocell testing cages.

Results show that animals chronically treated with GBR 12909 display a potentiated locomotor response to the 6 mg/kg GBR 12909 challenge, compared with their vehicle-pretreated counterparts. In addition, GBR 12909-sensitized rats display a hypersensitivity to other drugs which act at the dopamine uptake site: nomifensine, d-amphetamine, and bupropion. However, cross-sensitization to apomorphine, a direct dopamine receptor agonist, or to scopolamine, a cholinergic muscarinic antagonist, was not observed. These results are discussed with regard to possible presynaptic changes on dopamine neurons whch may underlie behavioral sensitization to cocaine-like drugs.

COMPARISONS BETWEEN DOPAMINE UPTAKE BLOCKERS IN RATS TRAINED TO DISCRIMINATE COCAINE OR BUPROPION.

P.Terry* and J.L. Katz. Psychobiology Laboratory, NIDA Addiction Research Center, P.O. Box 5180, Baltimore MD 21224.

Bupropion (Wellbutrin) is a novel, non-tricyclic antidepressant; it is a weak inhibitor of dopamine uptake, and of several ligands to the dopamine transporter. Although its neurochemical and behavioral profile *in vivo* resembles that of a psychomotor stimulant, bupropion does not reliably produce stimulant effects in humans. This experiment examines and compares the discriminative stimulus effects of bupropion and cocaine in rats. One group of rats was trained to press one lever when injected IP with cocaine (10.0 mg/kg), and another lever when injected with saline; a second group of rats was trained similarly, but with bupropion (17.0 mg/kg) instead of cocaine. In substitution tests, full dose-response curves were obtained for several monoamine uptake inhibitors. In both cocaine- and bupropion-trained rats all nine dopamine uptake blockers tested to date fully substituted for the training compound. Across a 20-fold range, ED_{50} values in both conditions were highly correlated ($r=0.81$; $p<0.05$). Serotonin and norepinephrine uptake blockers failed to substitute even partially for either training compound. The results demonstrate a surprising similarity between cocaine and bupropion in terms of discriminative stimulus effects, and given the limited abuse of bupropion, suggest that this compound deserves further study as a potential therapeutic agent in cocaine addiction.

656.17

INJECTIONS OF COCAINE PRIOR TO MEMORY REACTIVATION FACILITATE LATER LEARNING OF AN AVOIDANCE RESPONSE IN RATS.

W.A. Rodriguez*, M.Y. Phillips, S.B. Rodriguez, and J.L. Martinez, Jr. Dept. of Psychology, Univ. of Calif., Berkeley, CA 94720.

Two noncontingent footshocks (700 μA, 1 sec) were administered to rats in a dark compartment of a two-compartment, one-way avoidance, chamber. Twenty-four hr later, cocaine or saline was administered 5 min prior to a 30 sec re-exposure to selected stimuli present during the initial conditioning trials. On Day 3 the rats were trained to move from the chamber's dark compartment to the light compartment in order to avoid a footshock. Intermediate (5.0 or 7.5 mg/kg IP), but not low (3.3 mg/kg IP) or high (11.25 or 16.88 mg/kg IP), doses of cocaine given on Day 2 enhanced acquisition on Day 3 of the avoidance response. These results suggest that cocaine administered prior to the reintroduction of cues associated with a conditioning episode can modulate memory processes, and that the dose-response function for this effect is U-shaped.

COCAINE POTENTIATION OF LATERAL HYPOTHALAMIC BRAIN STIMULATION REWARD: A DOSE RESPONSE AND REPEATED TREATMENT ANALYSIS.

P. Bauco*, Y. Wang and R.A. Wise. Center for Studies in Behavioral Neurobiology, Dept. of Psychology, Concordia Univ., Montréal, Canada, H3G 1M8.

The curve-shift rate-frequency paradigm was used to assess the ability of cocaine to potentiate the rewarding impact of lateral hypothalamic brain stimulation. In Experiment 1 animals (n=7) received daily saline or cocaine (0.5, 1, 2, 4, 8, 16, and 32 mg/kg i.p.) in ascending dose order. Cocaine produced dose orderly parallel leftward shifts of the rate-frequency functions; cocaine lowered the "dose" of brain stimulation required to produce normal responding. The highest dose shifted the rate-frequency curve by 0.4 log units thereby reducing self-stimulation thresholds by approximately 60%. The aim of Experiment 2 was to determine whether repeated testing (as in Experiment 1) might progressively alter the effectiveness of cocaine. A new group of animals (n=6) was treated 5 times with cocaine (16 mg/kg i.p.) at 48-h intervals. The magnitude of the reward-potentiating effect of cocaine did not change from treatment to treatment; there was neither tolerance nor sensitization to cocaine's reward-potentiating action.

657.1

DIFFERENT GENOTYPE-DEPENDENT FACTORS MODULATE SENSITIVITY TO THE BEHAVIORAL EFFECTS OF AMPHETAMINE. S. Cabib*, A. Badiani, S. Puglisi-Allegra, Inst Psicobiologia e Psicofarmacologia (CNR), via Reno 1,Roma I-00198, Italy

The existence of robust strain differences in the effects of chronic amphetamine treatment suggests that genetic factors influence behavioral sensitization processes. However, this phenomenon is produced by different experimental paradigms either involving or not involving classical conditioning and also by chronic or repeated exposure to environmental stress. Thus the question arises as to wether similar strain differences are revealed by the different situations. DBA/2 are less sensible to the stimulatory effects of amphetamine on locomotion than C57BL/6, although they are more susceptible to behavioral sensitization induced by repeated amphetamine 7 days after the end of the treatment. On the other hand, no sensitization was observed in either strains of mice tested 24 hrs after the end of the treatment and C57BL/6 showed a rapid and robust sensitization when repeated psychostimulant injections were paired with the test environment. Following ten days of daily restraint sensitization developed to the behavioral effects of amphetamine in DBA/2 but not in C57BL/6 mice tested 24 hrs after the last stressful experience. Results obtained in B6D2F1 hybrids suggested that the response to repeated stress of the C57BL/6 strain is inherited through a dominant mode of inheritance. Finally, 7 days after the last stressful experience no sign of behavioral sensitization could be detected in this strain of mice.

These results indicate that behavioral sensitivity to amphetamine depends on interaction between genotype-dependent factors and organism's experience. Moreover, sensitivity to the behavioral effects of amphetamine does not predicts susceptibility to either stress- or amphetamine-induced sensitization. Finally, each treatment capable of inducing sensitization produces different strain-dependent responses to amphetamine.

657.2

DISCRIMINATIVE STIMULUS EFFECTS OF N- AND RING-SUBSTITUTED AMPHETAMINE ANALOGS IN METHAMPHETAMINE-TRAINED RATS. T.D. Steele*, G.A. Ricaurte, J.M. Witkin, and J.L. Katz, Department of Neurology, Johns Hopkins School of Medicine, and NIDA Addiction Research Center, Baltimore, MD, 21224.

Aromatic- and side-chain N-substitution is known to alter the behavioral and neurotoxic effects of substituted amphetamine analogs. The present studies evaluated the effects of ring-substituted and N-methylated amphetamine analogs in rats trained to discriminate the dopaminergic/serotonergic neurotoxin methamphetamine (MA) from saline. Of the compounds tested, only N,N-dimethylamphetamine (N,N-DMA) completely substituted for 1 mg/kg MA. Consistent with the reported potency difference for producing dopamine depletion (Ricaurte *et al.*, 1989), N,N-DMA was approximately seven-fold less potent than the parent compound in evoking MA-appropriate responding. The ring-substituted analogs *p*-methoxyamphetamine, *p*-methoxymethamphetamine, and 3,4-methylenedioxymethamphetamine (MDMA), which are selective serotonergic neurotoxins, only partially substituted for MA. The maximum degree of MA-appropriate-responding for the three compounds ranged from 35-50%. All test compounds produced a dose-related decrease in response rate. Thus, N-methylation appears to cause parallel decreases in behavioral potency as well as dopaminergic neurotoxic activity of MA. In contrast, aromatic substitution can alter or attenuate MA-like discriminative cues, in addition to conferring selective serotonergic neurotoxic activity. Further evaluation of structural analogs may aid in dissociating the behavioral and neurotoxic effects of compounds in this series. (Supported by USPHS DA 06275)

INDIVIDUAL DIFFERENCES IN FEEDING CAN PREDICT INDIVIDUAL DIFFERENCES IN THE LOCOMOTOR RESPONSE TO AMPHETAMINE. [1]T. L. Sills* & F. J. Vaccarino[1,2]. Departments of [1]Psychology and [2]Psychiatry , University of Toronto, Toronto, Ont., M5S 1A1.

Previously we demonstrated individual differences in the feeding response to a low dose of amphetamine (AMP); AMP stimulated intake in low baseline feeders and inhibited intake in high baseline feeders. Individual differences in the locomotor response to AMP, as a function of baseline activity, have also been reported. Intrinsic variation in nucleus accumbens dopamine activity has been suggested to underlie individual differences in both feeding and locomotion. In light of the feeding/locomotor parallels, the present experiment examined whether individual differences in baseline feeding would be predictive of individual differences in the locomotor response to AMP.

Thirty-four male Wistar rats (Charles River, Quebec) were divided into low and high feeders based on a median split of their sugar intake in response to 0.9% saline administration (ip). The locomotor response of each group to both a novel environment and a 1.75 mg/kg dose of AMP (ip) was subsequently determined.

Results indicate that low feeders were significantly less active in response to a novel environment than high feeders. Similarly, low feeders exhibited significantly less locomotion in response to AMP than high feeders. These results are consistent with previous observations of individual differences in the locomotor response to AMP. Further, these results are consistent with the notion that individual differences in both the feeding and the locomotor response to AMP reflect intrinsic variation in a common substrate.

THE EFFECTS OF CROWDING ON LOCOMOTOR ACTIVITY FOLLOWING CHRONIC METHAMPHETAMINE ADMINISTRATION. M. A. Blackshear* and B. Peoples, Department Of Biological Sciences, Tennessee State University, Nashville, TN 37209-1561

This study compares the effects of chronic methamphetamine administration on locomotor activity in isolated and crowded mice, and examines the effects of crowding on methamphetamine-induced "reverse tolerance". Swiss ICR male mice (26-30g) were used as experimental animals. The animals were either singly housed with 562cm^2 floor space/mouse or crowded with only 56cm^2 floor space/mouse throughout the duration of the study. Methamphetamine was administered at a dose of 4 mg/kg. For the acute studies, the mice received a single injection of methamphetamine, while in the chronic studies, methamphetamine was administered daily for 7 days. Locomotor activity was monitored immediately after drug administration on day 1 (acute studies) and again (on day 9) at 48 hours after the last dose following a challenge dose of 1 mg/kg of methamphetamine. Control animals were housed in a similar manner and received physiological saline. Predictably, methamphetamine induced locomotor activity was higher on day 9 than on day 1 in mice that were singly housed (5,883 ± 778 vs 7,744 ± 525, respectively for days 1 and 9. In both instances, locomotor activity was higher in the drug treated animals than in the controls. In contrast, methamphetamine-induced changes in locomotor activity in crowded mice were essentially the same on day 1 and day 9 (5998 ± 974 vs 5532 ± 821 for day 1 and day 9, respectively) and suggests the development of tolerance, rather than reverse tolerance. Considering that reverse tolerance is thought to be a form of receptor sensitivity that is mediated by dopamine release, these findings suggest that the effects of crowding may precipitate changes in dopamine receptor sensitivity.

INVOLVEMENT OF SITUATIONAL VARIABLES ON THE EXPRESSION OF BEHAVIORAL SENSITIZATION TO AMPHETAMINE. S.H. Ahmed, L. Stinus, M. Le Moal and M. Cador*, Unité INSERM 259, rue Camille Saint Saëns 33077 Bordeaux Cedex, France.

Behavioral sensitization is a progressive and long lasting enhancement to the psychostimulant effects of amphetamine (AMPH). In a conditioning paradigm, it has been shown that the expression of this phenomenon is under situational control. However, the two sets of contextual stimuli used in this paradigm for an association with the presence or absence of the unconditioned effects of AMPH usually do not possess equivalent predictability value. In the present study, this possible bias has been circumvented by using the following protocol: two very distinct situational contexts both different from the home cage have been used. One was paired with AMPH injection (1 mg/kg, s.c., for 6 days, 2 days apart), the other with vehicle injection. Tests for sensitization were conducted by injecting AMPH (0.5 mg/kg, s.c.) in one of these two situational contexts and the locomotor activity was recorded. The main results are: 1) the paired group (rats tested in the situational context paired with AMPH) showed behavioral sensitization compared to the control group (rats that have received vehicle in the two contexts). The unpaired group (rats tested in the situational context paired with vehicle) failed to exhibit behavioral sensitization 2) when comparing the unpaired group with the control group, a great variability between rats appeared, some rats showed a response similar to the control group whereas other animals showed a response *below* the control group. In this latter subgroup, the influence of the situation appears to be more than an inhibition of the conditioned component of the behavioral response to AMPH but a reduction of its unconditioned effects. This variability can be explained either by a difference in the sensitization process or a difference in the capacity to index context. Our preliminary results indicate that this variability could reflect a difference in the capacity of contextual indexation between animals.

DIFFERENTIAL EFFECTS OF NUCLEUS ACCUMBENS LESIONS ON THE CONDITIONED PLACE PREFERENCE INDUCED BY MORPHINE OR AMPHETAMINE. M.C. Olmstead* and K.B.J. Franklin, Dept. Psychology, McGill University, Montreal, Canada, H3A 1B1

It has been suggested that the mesolimbic dopamine system, originating in the ventral tegmental area and projecting to the nucleus accumbens (NAS) is involved in the reinforcing effects of both psychomotor stimulants and opiates. The post synaptic elements of this system have also been implicated in drug reinforcement. The present study further examined the role of the NAS cell bodies on morphine and amphetamine reinforcement.

Excitotoxin lesions were produced by bilateral microinjections of kainic acid (0.5 ug in 1 ul) into the NAS. Following recovery, different groups or rats were tested for the development of a CPP to morphine (2 mg/kg X 3 pairings) or amphetamine (1.5 mg/kg X 3 pairings). In both experiments, sham lesioned animals developed a CPP for the drug paired environment. Lesioned animals also developed a CPP for the morphine paired environment. Lesioned animals conditioned with amphetamine, however, did not show a significant preference for the drug paired versus the saline paired environment. These results support the suggestion that the reinforcing effects of psychomotor stimulants and opioids do not involve identical neural substrates.

3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA) INHIBITS GLUTAMATE-EVOKED FIRING OF NUCLEUS ACCUMBENS CELLS. S.R. White* and K.C. Paros. Dept. of VCAPP, Washington State Univ., Pullman, WA 99164.

MDMA is a recreationally used amphetamine derivative that has been reported to release serotonin (5HT) and, less potently, dopamine (DA) from nerve terminals in the forebrain (Schmidt et al., Biochem. Pharmacol. 36, 1987, 747). The nucleus accumbens (NAc), a major component of the brain reward pathway, is innervated by both 5HT- and DA-containing nerve terminals. This study examined the effects of local application of MDMA on excitability of NAc neurons *in situ*. Extracellular single unit recording was combined with microiontophoretic drug application in urethane-anesthetized male rats. NAc cells were driven at a slow, stable firing rate by cycled pulses of glutamate. Microiontophoretic application of MDMA (10-40 nA, 60 sec) produced a slowly developing, dose-dependent inhibition of glutamate-evoked firing that was not mimicked by application of equivalent currents applied to a pH control solution. Application of 5HT and of DA produced a dose-dependent inhibition of glutamate-evoked firing that was similar to the effect of MDMA. The nonselective DA antagonist haloperidol partially attenuated but did not block the MDMA effect. These results suggest that MDMA-induced inhibition of NAc neuronal excitability may be mediated by both DA and 5HT receptors. (Support by Washington State Alcohol and Drug Abuse Program.)

DIZOCILPINE (MK-801) POTENTIATES LOW-DOSE FACILITATION OF BRAIN STIMULATION REWARD BY BOTH AMPHETAMINE AND MORPHINE.

W. A. Carlezon, Jr.* and R. A. Wise Center For Studies in Behavioral Neurobiology, Concordia Univ., Montreal, QC, CANADA H3G 1M8

It has been reported that the non-competitive NMDA antagonist dizocilpine (MK-801) can block both the behavioral sensitization observed after repeated amphetamine, and the tolerance and dependence observed after repeated morphine. The purpose of the present study was to evaluate the effects of blockade of the NMDA receptor on the reward-facilitating effects of amphetamine and morphine using brain stimulation reward (BSR). In rats (n=8) with stimulating electrodes aimed at the medial forebrain bundle (MFB), acute administration of a low dose of amphetamine (0.25 mg/kg, ip) caused a leftward shift in the function that relates stimulation frequency to response rate, causing a 14% decrease in BSR threshold. Dizocilpine, at a dose (0.05 mg/kg, ip) that elicited a minimal (9%) decrease in threshold, potentiated the threshold-lowering effects of amphetamine: the combination produced a 29% decrease in threshold. Furthermore, after tolerance had developed to its sedative side effects, a small (12%) decrease in threshold could be observed after administration of morphine (2.5 mg/kg, ip); this threshold-lowering effect was also potentiated (to 23%) by dizocilpine. These effects do not appear to be due to sensitization to amphetamine, morphine, or dizocilpine. Thus, the stimulant effects of the NMDA antagonist dizocilpine summate with those of the indirect dopamine agonists amphetamine and morphine, implying that disruption of normal glutamatergic tone can have significant effects on the rewarding impact of habit-forming drugs.

657.9

THE NONCOMPETITIVE NMDA ANTAGONIST MK-801 FAILS TO BLOCK THE REWARDING OR LOCOMOTOR-ACTIVATING EFFECTS OF AMPHETAMINE IN RATS. D.C. Hoffman* and H. Donovan. Behavioral Biology, Neurogen Corp., Branford CT 06405.

The noncompetitive NMDA receptor antagonist MK-801 prevents the development of sensitization to the locomotor-activating effects of amphetamine (Karler et al., 1989; Wolf and Khansa, 1991). In the present study, the possibility that the NMDA receptor might also play a role in the rewarding effects of amphetamine (as measured in the conditioned place preference paradigm) was investigated. Male Sprague-Dawley rats received amphetamine (2.0 mg/kg IP) paired with one side of a two-compartment box and saline paired with the other side. During these pairings, locomotor activity was measured. On the test day, the amount of time drug-free rats spent in each compartment was determined. Rats trained with amphetamine alone showed a significant increase in time spent on the drug-paired side from pre- to post-conditioning, indicating a place preference. When rats were injected with MK-801 (0.03, 0.1, 0.3 mg/kg SC) prior to amphetamine, no significant effects on amphetamine place conditioning were observed. Rats treated with MK-801 alone showed no consistent place conditioning effects, although a place preference was observed at the intermediate dose. On conditioning days, MK-801 produced a dose-dependent enhancement of amphetamine-induced locomotor activity, however, MK-801 alone caused a similar increase in activity. These data suggest that the NMDA receptor is probably not involved in either the rewarding or locomotor-activating effects of amphetamine.

657.10

THE NON-COMPETITIVE NMDA ANTAGONIST, MK801, BLOCKS THE DEVELOPMENT OF SENSITIZATION TO THE LOCOMOTOR ACTIVITY EFFECTS OF APOMORPHINE.

J. Stewart*, A. Jakob and J.P. Druhan. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montréal, Québec, Canada, H3G1M8.

Several studies have shown that the NMDA antagonist, MK801, blocks the development of sensitization to amphetamine-induced activity. Here we show that this effect cannot be explained by interference by MK801 with the release of dopamine (DA) by amphetamine in that MK801 also blocks the development of sensitization to the direct mixed DA receptor agonist apomorphine (APO). During preexposure, rats were pretreated with either 0.25 mg/kg MK801, i.p., or saline prior to injections of 2.0 mg/kg APO HCl, i.p. or saline, on five occasions every three days. Group PAIRED received APO in the activity boxes and saline in the home-cage, group UNPAIRED, saline in the activity boxes and APO in the the home-cage, and group CONTROL, saline in both places. All animals were tested for conditioned activity following injections of saline and for sensitization following 0.5 mg/kg APO.

MK801 blocked the development of sensitization to APO seen over the five preexposure days and conditioning when animals were tested in the activity boxes with saline only. On the test for sensitization, the saline-pretreated PAIRED group that had received repeated injections of APO in the activity boxes showed marked sensitization compared to the UNPAIRED and CONTROL groups which did not differ from each other. There was no evidence for sensitization in the MK801 pretreated groups.

657.11

AMPHETAMINE SENSITIZATION AND NMDA RECEPTORS: NEUROCHEMICAL AND ELECTROPHYSIOLOGICAL CORRELATES IN THE MESOACCUMBENS DOPAMINE SYSTEM. R.J. Brooderson*, F.J. White and M.E. Wolf. Departments of Psychiatry and Pharmacology, Wayne State University School of Medicine, Detroit, MI 48207.

The repeated intermittent administration of d-amphetamine (AMPH) results in a progressive augmentation of its locomotor stimulant effects, a phenomenon known as behavioral sensitization. We have shown previously that the development of AMPH sensitization requires stimulation of N-methyl-D-aspartate (NMDA) receptors since sensitization does not occur when AMPH is coadministered with the noncompetitive NMDA antagonist MK-801. The purpose of the present experiments was to further characterize the roles of dopamine (DA) and NMDA receptors in AMPH sensitization. Rats were treated for 5 days with either saline, AMPH (5 mg/kg, i.p.), or MK-801 (0.25 mg/kg, i.p.) followed 30 min later by AMPH. The following were performed after either 3 or 10 days off: 1) electrophysiological studies of postsynaptic D1 and D2 receptor sensitivity in the nucleus accumbens (NAc), 2) electrophysiological studies of DA autoreceptor sensitivity in the ventral tegmental area (VTA), and 3) microdialysis studies of AMPH-stimulated DA levels in the NAc. AMPH-treated rats were behaviorally sensitized at both 3 and 10 days off. At 3 days off, autoreceptor sensitivity in the VTA and AMPH-stimulated DA release in the NAc were similar in the saline and AMPH groups. However, supersensitivity of both D1 and D2 receptors in the NAc was observed in the AMPH group. MK-801 coadministration prevented the development of D1 receptor supersensitivity. Studies at 10 days off are in progress. Supported by DA-07735 (MEW), DA-04093 (FJW), MH-40832 (FJW), NARSAD (MEW), the PMA Foundation (MEW) and Institutional NRSA GM-08164 (RJB).

657.12

BEHAVIORAL SENSITIZATION TO MK-801: NEUROCHEMICAL AND ELECTROPHYSIOLOGICAL CORRELATES IN THE MESOACCUMBENS DOPAMINE SYSTEM. M.E. Wolf*, F.J. White, R.J. Brooderson and M.R. Khansa. Departments of Psychiatry and Pharmacology, Wayne State University School of Medicine, Detroit, MI 48207.

We have shown previously that repeated administration of MK-801, a noncompetitive N-methyl-D-aspartate (NMDA) antagonist, results in sensitization to its locomotor stimulant effects (Brain Res. 562: 164, 1991). The present study sought to further characterize this phenomenon. Rats were treated with either saline or MK-801 (0.25 mg/kg, i.p.) for 5 days and challenged with MK-801 after 3 days off. Studies in which the D1 antagonist SCH 23390 (50 μg/kg, i.p., 15 min before MK-801) was coadministered on either the treatment days or the test day indicated that neither the development nor expression of sensitization to MK-801 required dopamine (DA) receptor stimulation. Microdialysis studies demonstrated that MK-801 challenge was associated with only a modest (10-15%) increase in DA levels in the nucleus accumbens and that this effect was not augmented in MK-801 sensitized rats. Electrophysiological studies showed that repeated administration of MK-801 resulted in supersensitivity of both D1 and D2 receptors in the nucleus accumbens. These results suggest that MK-801 sensitization does not require DA receptor stimulation for its induction but may share other features with sensitization to amphetamine and cocaine. Supported by DA-07735 (MEW), DA-04093 (FJW), MH-40832 (FJW), NARSAD (MEW), the PMA Foundation (MEW) and Institutional NRSA GM-08164 (RJB).

657.13

AMPA/KAINATE RECEPTORS IN THE NUCLEUS ACCUMBENS ARE INVOLVED IN MEDIATING CONDITIONED PLACE PREFERENCE ELICITED BY AMPHETAMINE, COCAINE, AND MORPHINE. F.G. Kaddis, R.T. Layer, N.J. Uretsky*, and L.J. Wallace. College of Pharmacy, Ohio State University, Columbus, OH 43210.

Activation of AMPA/kainate glutamatergic receptors in the nucleus accumbens (NACC) may be a component of the mechanism of drug induced reward. To test this, the antagonist DNQX was injected into the NACC just prior to administration of amphetamine, cocaine, or morphine during the training phase (acquisition) of a conditioned place preference (CPP) paradigm. Rats were then tested for CPP in the absence of drugs. In other experiments, DNQX was given just prior to testing for place preference (expression) but not during training. Bilateral intra-NACC administration of DNQX (1 µg/0.5 µl/side) inhibited acquistion of CPP induced by amphetamine (1 mg/kg) and cocaine (20 mg/kg) but not morphine (10 mg/kg). During acquisition, DNQX attenuated the locomotor stimulation elicited by amphetamine during the first but not subsequent sessions and that by cocaine during all training sessions. However, DNQX made morphine treated rats akinetic. When given prior to testing, DNQX inhibited the expression of CPP induced by amphetamine and morphine (experiments with cocaine are in progress) but did not affect locomotor activity. Our results suggest that activation of AMPA/kainate receptors is involved in the primary reward stimulation (acquisition of CPP) of psychostimulants but not opiates and in behaviors related to memory of primary reward stimulation (expression of CPP) for both classes of drugs. Furthermore, locomotor activity during conditioning is not necessary for acquisition of CPP.

ALTERED STRIATAL MAO-B KINETICS FOLLOWING RECOVERY FROM CHRONIC DEPRENYL TREATMENT IN RATS. I.A. Terleckyj* and W.J. Nicklas, Dept. of Neurology, UMDNJ-RWJ Med. Sch., Piscataway, NJ 08854, U.S.A.

Monoamine oxidase (MAO) is the enzyme responsible for the neuronal metabolism of aminergic transmitters and exists in two isoforms, MAO-A and B. We have previously shown that daily administration of deprenyl (DEP), an irreversible MAO-B inhibitor, to rats and mice at doses acutely selective for inhibiting MAO-B results in cross-inhibition of MAO-A in the CNS (Heikkila,1990). This effect is both time and dose-dependent and has also been observed in Parkinsonian patients who received DEP for 1 week (Riederer,1986). To further examine the effects of chronic DEP administration, male Sprague-Dawley rats were given either 0.2mg/kg or 0.02mg/kg DEP s.c. for 10 consecutive days. Another group of animals received a single injection of 0.7mg/kg DEP. Animals were sacrificed 4 days following final inhibitor administration to allow for 20-30% recovery in enzyme activity. [C^{14}]benzylamine was used as substrate for MAO-B in a radioenzymatic assay to measure K_m and V_{max} in neostriatum (STR) and remaining cerebral hemispheres (CER). In both regions, V_{max} was similar between the 0.2 and 0.7mg/kg groups (STR = 1.72nmol/mg tissue/hr, CER = 2.11) which differed from the 0.02mg/kg group (STR = 2.12, CER = 2.83). In STR, MAO-A inhibition occurred only in the 0.2 mg/kg group (13%) when serotonin was used at V_{max} conditions. A significant decrease in K_m occurred in STR of animals receiving 0.02mg/kg (65μM ± 10.8) compared to naives (97 ± 22), whereas the 0.2mg/kg and 0.7mg/kg groups displayed insignificant changes. However, no alteration in K_m was observed in CER. Whether the difference in K_m reflects an allosteric modification of MAO-B or expression of a different isoform remains to be elucidated.

658.2

CYCLIC AMP, BUT NOT BASIC FGF, INCREASES THE IN VITRO SURVIVAL OF MESENCEPHALIC DOPAMINERGIC NEURONS AND PROTECTS THEM FROM MPP$^+$ -INDUCED DEGENERATION. **J. Hartikka* and H. Lübbert. Preclinical Research, Sandoz Pharma Ltd, CH - 4002 Basel, Switzerland.**

We have tried to identify substances which affect the survival of dopaminergic neurons using primary cell cultures prepared from fetal (E14) rat substantia nigra. Exposure of mesencephalic cultures to forskolin or cAMP analogues during the first three days after plating increased the dopamine uptake activity by 100 - 200%. The response of dopaminergic neurons to forskolin could be greatly enhanced by exposing the cultures simultaneously to phosphodiesterase inhibitors IBMX or Ro 20-1724. In 3-day old cultures treated with forskolin or cAMP analogues, the number of dopaminergic neurons was increased by 58%.

Exposure of cultures to 1 µM of MPP$^+$ for 24 hours at the end of a 6 - day long culture period reduced the number of TH$^+$ neurons by 50%. Cyclic AMP, but not basic FGF, was able to prevent the degeneration of dopaminergic neurons induced by MPP$^+$.

The results suggest that increased intracellular levels of cAMP protect dopaminergic neurons in situations of stress like the process of dissociation, or the exposure to neurotoxic compounds. Our results reveal novel possibilities for the treatment of Parkinson's disease.

658.3

L-DOPA TOXICITY IN CULTURES OF RAT MESENCEPHALIC DOPAMINE NEURONS. P.J. Kontur*, K.L. Marek, D.E. Redmond, Jr. and R.H. Roth. Neural Transplant Program, Depts. of Pharmacology, Psychiatry and Neurology, Yale U Sch of Med, New Haven, CT 06510.

Treatment of Parkinson's disease by transplantation of fetal brain tissue may be compromised by the effects of the continued administration of L-DOPA on the developing dopamine (DA) neurons in the graft. Cell cultures obtained from mesencephalic brain tissue of rat embyos 13 to 13.5 days of gestation were used to study the potential toxicity of L-DOPA on the development, survival and function of DA neurons. DA neurons were identified and characterized using neurochemical (HPLC analysis of monoamines, uptake of exogenous tritiated dopamine and activity of tyrosine hydroxylase) and immunohistochemical techniques. DA neurons show extensive fiber formation after visualization using an antibody to tyrosine hydroxylase. DA and 3,4-dihydroxyphenylacetic acid levels in the cultures reach a plateau after 10 days *in vitro*. Cocaine-sensitive tritiated DA uptake increased to a plateau between 3 and 7 days *in vitro* where it remained for up to 17 days. Addition of 5x10-5 or 10-4M L-DOPA to the culture media for 4 days resulted in cellular degeneration, a 50-55% decrease in DA levels and a total loss of cocaine-sensitive tritiated DA uptake. Concentrations of 10-6 and 10-5M L-DOPA caused 20-30% decreases in DA levels and 10-30% decreases in cocaine-sensitive tritiated DA uptake. The demonstration of morphological and biochemical changes in cultured DA neurons after short-term administration of L-DOPA suggests that L-DOPA may affect the development of transplanted fetal DA neurons. DIHYDREXIDINE DISPLAYS HIGH POTENCY AND FULL EFFICACY AT D_1 DOPAMINE RECEPTORS IN PRIMATE STRIATUM. C.P. Lawler[1,#], V.J. Watts[1], J.H. Gilmore[1], S.B. Southerland[1], J.R. Atashi[1], H.P. Smith[1], C.A. Mathis[2], D.E. Nichols[3], and R.B. Mailman[1]. University of North Carolina[1], Chapel Hill, NC, 27514-7250, University of Pittsburgh[2], Pittsburgh PA, 15213, and Purdue University[3], West Lafayette, IN, 47907.

Dihydrexidine (DHX; trans-10,11-dihydroxy-5,6,6a,7,8,12b-hexahydro benzo[a]phenanthridine) has been reported to be a high potency, full efficacy D_1 dopamine receptor agonist in rat striatum (*Mottola et al., in press; JPET*). We have suggested previously that such an agent may have clinical utility for the treatment of idiopathic Parkinson's disease; this hypothesis has been supported by recent *in vivo* studies demonstrating dramatic anti-Parkinsonian effects of DHX in MPTP-treated monkeys (*Taylor et al. Eur. J. Pharmacol. 199:389, 1991).* In view of these encouraging results, the present studies examined further the pharmacological properties of DHX in primate brain. *In vitro* binding studies in postmortem human brain demonstrated that DHX competed for D_1 receptor sites (labeled with ^{3}H-SCH23390) with low nanomolar potency. Affinity of DHX for D_2 receptors in human brain was assessed using competition with [^{125}I]-epidepride; DHX was significantly less potent at competing for D_2 sites than for D_1 sites. These data from antagonist binding studies suggest that, in primate brain, as in rat brain, DHX has at least ten-fold selectivity for D_1 over D_2 receptors. Functional activity of DHX in primate brain was assessed by the ability of DHX to stimulate adenylate cyclase in adult rhesus monkey putamen. DHX had both high potency and full efficacy (relative to dopamine) in stimulating cAMP synthesis; conversely, SKF38393 was only a partial agonist in monkey putamen, similar to its effects in rat brain and various cell lines expressing D_1 receptors. The potency and efficacy of these two agonists did not show large inter-species differences; this aspect of our studies fails to confirm a previous report of significantly lower efficacy of SKF38393 in primate vs. rat striatum (*Pifl et al. Eur. J. Pharmacol. 202:273, 1991*). (Supported, in part, by PHS Grants MH40537 and MH42705).

POSTSYNAPTIC SUPERSENSITIVITY IN STRIATAL D_1 DOPAMINE RECEPTORS IN MPTP-TREATED MICE. L.L. Cook[1]*, D.B. Miller[2], J.P. O'Callaghan[2], J.M. Petitto[1], D.E. Nichols[3], M.H. Lewis[1] and R.B. Mailman[1]. Brain and Development Research Center, Univ. of North Carolina[1], Chapel Hill, NC; Neurotoxicol. Div., EPA[2], RTP, NC; and Purdue Univ.[3], West Lafayette, IN.

Although much is known about the postsynaptic compensation after denervation with 6-hydroxydopamine, few studies have evaluated such effects after MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) treatment. C57BL/6 mice were used to evaluate possible functional supersensitivity of striatal D_1 receptors, since MPTP produces selective degeneration of substantia nigra-caudate neurons in this strain. Dihydrexidine (DHX) was used as a probe because it is a potent full efficacy D_1 agonist with some D_2 agonist properties (Brewster et al., J. Med. Chem., 33:1756, 1990). Female C57BL/6 mice (7-8 months of age) were administered a single SC injection of 15 mg/kg MPTP. Three weeks after dosing, mice were tested for behavioral supersensitivity, and striatal tissue was collected to measure dopamine concentrations, density of D_1 and D_2 receptors, and D_1/D_2 effects on regulation of adenylate cyclase. MPTP caused a 78.5% depletion of dopamine, but did not cause behavioral supersensitivity to apomorphine (0.45-3.0 mg/kg). Using ^{3}H-SCH23390 and ^{3}H-spiperone as ligands, the densities of striatal D_1 and D_2 receptors were found to be unchanged in MPTP-treated mice. The efflux of cAMP from superfused striatal slices was measured following stimulation by 1.0 μM DHX, both in the absence and presence of the D_2 antagonist sulpiride (30 μM). Unlike what is found in rat striatal minces, DHX alone did not increase cAMP efflux. Sulpiride significantly potentiated the DHX-induced cAMP efflux, indicating a pronounced D_1/D_2 interaction in the mouse striatum. In the presence of sulpiride, the efflux of cAMP from striatal slices of MPTP-treated mice was 56% greater than in controls, demonstrating a lesion-induced change in D_1/D_2 functional interactions. Thus, in this model, there may be both D_1 and D_1 functional supersensitivity concomitant with an absence of behavioral supersensitivity. (Supported by ES01104, MH40537, and MH42705 and the Foundation of Hope).

CHRONIC SINEMET (L-DOPA) ALTERS DOPAMINE RECEPTORS IN MPTP-TREATED MONEKYS. L. Rioux*, P.A. Frohna, J. S. Schneider and J.N. Joyce. Dept. Psychiatry, Univ. Penn. Sch. Med, and Dept Neurology, Hahneman Univ. Sch. Med., Philadelphia , PA , U.S.A..

Administration of MPTP to monkeys results in a parkinsonian syndrome that can be corrected by administration of L-DOPA (Sinemet). Chronic treatment with L-DOPA also can lead to dyskinesias in parkinsonian animals. In order to understand the involvement of the DA system in this syndrome, the present study examined the regional integrity of the DA system using quantitative autoradiography for the pre-synaptic DA system ([^{3}H]mazindol binding to DA uptake sites), D1 receptors ([^{3}H]SCH 23390), and D2 ([^{125}I] epidepride) in the basal ganglia (caudate-putamen (CPu), nucleus accumbens (Nas), globus pallidus internal (GPi) and external (GPe)) of symptomatic monkeys. The monkeys were divided into three groups: control, MPTP monkeys and MPTP monkeys receiving L-DOPA. The MPTP-treated monkeys were sacrificed 6-11 weeks after the last injection of MPTP and the L-DOPA treated monkeys 30-48 hrs after the last dose of L-DOPA. One hemisphere was used for measurement of DA and metabolites, and the other for autoradiographic studies. MPTP induced losses of [^{3}H]mazindol binding in the striatum (> 90%), slightly more in dorsal areas (98%) than ventral ones (91%), while relatively sparing the NAS (64% loss). D2-receptor density and distribution was largely unchanged by MPTP and L-DOPA treatment. In MPTP monkeys, a substantial increase of D1 receptor density was observed in CPu and GPi. In MPTP-treated monkeys receiving L-DOPA, a further increase of D1 receptor density was observed in most regions of striatum, but not GPi. Interestingly, L-DOPA induced an increase in D1 receptors in the GPe. Contrary to previous reports, D1 but not D2 receptor density is increased following MPTP. L-DOPA-induced D1 increases may be related to the development of dyskinesias. **Funded by R29 MH 4385, FRSQ fellowship, and the Benign Essential Blepharospasm Research foundation**

SYSTEMIC CHLOROQUINE PROTECTS AGAINST STRIATAL DOPAMINE DEPLETION INDUCED BY UNILATERAL INTRA-NIGRAL MPP+ INJECTION IN RATS. G.T. Golden*, G.M. Alexander, R.J. Schwartzman, G.G. Smith, D.S. Martin. Thomas Jefferson Medical College, Philadelphia, PA 19107 and VAMC, Coatesville, PA 19320.

Intracellular iron may induce Parkinson-like conditions due to enhanced formation of toxic O2 species and/or autoxidation products. Chloroquine is a lysosomotropic amine shown to reduce the sensitivity of cells to oxidative stress by preventing the mobilization of ferric iron from ferritin. Adult, male LEH rats (n=12) were tested for 'dominant' rotational behavior with amphetamine and apomorphine. Rats received chloroquine (30mg/kg) or DH20 ip for 21 days. On day 22 four rats from each group had the SN in either the dominant or the non-dominant hemisphere injected with MPP+ (15 nM in 2 ul) and two rats from each group had the SN injected with normal saline. Rotation was tested in a computerized activity monitor where CW turns, CCW turns and incomplete turns were monitored before and after SN injection of MPP+ or control vehicle. The injected and non-injected striati were analyzed for DA, 7-8 weeks post SN injection. Striatal DA levels were Chlor TX + MPP+ (Inj-70.2 ±13.2, Non-inj-75.5±4.7); Control Tx + MPP+ (Inj-57.1 ±12.2, Non-inj-75.1±9.8). The Chlor Tx + Control Vehicle and the Control Tx + Control Vehicle showed no striatal DA differences between injected and non-injected sides. We conclude that pretreatment with chloroquine protects against DA depletion produced by intra-nigral injection of MPP+. Supported in part by NIH Grant #NS27101 and the VA.

STRIATAL DOPAMINE RECEPTORS AND GABAA RECEPTORS IN DYSKINETIC AND NON-DYSKINETIC MPTP-MONKEYS TREATED CHRONICALLY WITH CY 208-243, C. Gagnon[1]*, B. Gomez-Mancilla[2], P.J. Bédard[2] and T. Di Paolo[1], [1]Sch. of Pharmacy, Laval Univ. and Dept of Mol. Endo., CHUL, Quebec, G1V 4G2; [2]Dept of Pharmacol., Fac. Med., Laval Univ., Quebec, G1K 7P4, Canada.

Two out of four MPTP-monkeys developed dyskinesias following chronic treatment with the D-1 agonist CY 208-243 (CY). ^{3}H-SCH 23390 (SCH) (D-1 antagonist), ^{3}H-spiperone (D-2 antagonist), ^{3}H-SKF 38393 (SKF) (D-1 agonist), ^{3}H-N-propylnorapomorphine (NPA) (D-2 agonist) and ^{3}H-muscimol (GABAA agonist) specific binding were compared in the striatum of these monkeys. Non-dyskinetic MPTP-monkeys were less denervated than dyskinetic animals, as shown by the higher striatal dopamine (DA) levels in non-dyskinetic monkeys. ^{3}H-SCH and ^{3}H-SKF binding were similar in the striatum of both groups of MPTP-monkeys, whereas ^{3}H-spiperone, ^{3}H-NPA and ^{3}H-muscimol binding were higher in the posterior striatum of dyskinetic monkeys compared to non-dyskinetic animals. ^{3}H-SCH/^{3}H-spiperone and ^{3}H-SKF/^{3}H-NPA ratios were lower in the posterior striatum of dyskinetic compared to non-dyskinetic MPTP-monkeys. ^{3}H-SKF/^{3}H-SCH, ^{3}H-NPA/^{3}H-spiperone, ^{3}H-muscimol/^{3}H-SCH and ^{3}H-muscimol/^{3}H-spiperone ratios were similar in the striatum of both groups of MPTP-monkeys. ^{3}H-muscimol/^{3}H-SKF ratio was increased in the posterior striatum, whereas the ^{3}H-muscimol/^{3}H-NPA ratio was decreased in the anterior striatum of non-dyskinetic compared to dyskinetic MPTP-monkeys. The degree of MPTP-induced denervation as well as the relative changes of D-1 and D-2 DA receptors as well as GABAA receptors in the striatum may explain appearance of dyskinesias in MPTP-monkeys treated chronically with CY. Supported by the Parkinson Foundation of Canada and the MRC.

EFFECT OF PARTIAL 6-OHDA LESIONS ON THE EXPRESSION OF TYROSINE HYDROXYLASE IN DOPAMINERGIC NEURONS OF THE SUBSTANTIA NIGRA AND THEIR PROJECTIONS. R.Raisman-Vozari*(1), V. Blanchard(1), M. Chritin(2), S.Vyas(1), M. Savasta(2), C. Feuerstein(2), F. Javoy-Agid(1) and Y. Agid(1). (1) INSERM U 289, 75013 Paris; (2) U 318, 38043 Grenoble, France.

In a preclinical phase of Parkinson's disease (PD) few neurological symptoms are observed despite an extensive damage of the dopaminergic system. The compensatory mechanisms involving either the activity or the amount of tyrosine hydroxylase (TH), the rate-limiting enzyme in catecholamine biosynthesis, has been proposed. The present study was designed to characterize the effects of partial lesions of nigro-striatal system on the expression of TH. Unilateral lesions were produced by the injection of 1 μl 6-OHDA (8 μg/4 μl) in the substantia nigra pars compacta (SNC). Animals were sacrificed either one or 7 months after lesions. TH was quantified by immunoautoradiography in the striatum along the dorso-rostral axis of the structure. TH protein amount and TH mRNA were quantified respectively in the SNC by immunoautoradiography and in-situ hybridization using computer assisted image analysis. 50 % loss of TH positive cells was observed one month after partial lesions by cell counting. Loss in the amount of striatal TH followed the neuronal loss but with a characteristic pattern of TH distribution. The decrease of the enzyme was more pronounced in the caudal striatum compared to more rostral planes. In addition a preferential loss was observed in the lateral region compared to the medial area. Parallel quantification of TH protein and TH mRNA on surviving dopaminergic cells indicated absence of TH compensatory mechanism one month after partial denervation of the dopaminergic system. Results obtained 7 months later will be presented. Results suggest that one month post-lesion period may represents either an early phase for compensatory mechanisms or that other compensatory events underlie the observed preclinical phase of PD.

NEUROMELANIN AND MPTP-INDUCED PARKINSONISM IN MONKEYS. M.T. Herrero[1,2*], E.C. Hirsch[1], M.R. Luquin[2], J. Laguna[2], F. Javoy-Agid[1], J.A. Obeso[2], Y. Agid[1]. (1) INSERM U289, 75013-Paris, France and (2) Neurologia Experimental, Univ. Navarra, 31080-Pamplona, Espana.

Neuromelanin (NM), a by-product of catecholamine metabolism, accumulates during aging in the primate brainstem. By analogy to Parkinson's disease in which a preferential vulnerability of melanized neurons is observed, it has been hypothetized that NM may contribute to dopaminergic cell death characteristic of both MPTP toxicity and Parkinson's disease.

In order to analyse the time-dependency of NM accumulation in primates and the influence to MPTP vulnerability of the NM presence in dopaminergic neurons, we have analyzed the number of melanized and non-melanized catecholaminergic neurons in the mesencephalon of cynomolgus monkeys. 5 control animals of different ascending age (from 0 to 13 years) have been used to study the effect of age on NM-accumulation. Age matched controls were compared with 7 MPTP-treated monkeys (2 severely disabled, 2 moderately affected, and 3 treated by L-dopa) in order to study the effect of MPTP on melanized neurons. Catecholaminergic neurons from the brainstem were identified by immunohistochemistry of tyrosine hydroxylase (TH), and NM was detected by Masson staining. Each neuron was plotted and total number of neurons in each catecholaminergic region was estimated using image analysis.

A time-dependent increase both of the number of NM-containing cells and the NM content per neuron was observed. However, since some melanized cells were also preserved, these results suggest that NM may participate in MPTP toxicity, but that other factors are also needed to explain the loss of dopaminergic neurons. In MPTP-treated monkeys the loss of catecholaminergic neurons was the most severe in regions containing the high proportion of melanized neurons, SNα+β and SN pars lateralis.

ENKEPHALIN, DYNORPHIN AND TYROSINE HYDROXYLASE mRNA IN THE WEAVER MUTANT MOUSE BRAIN S. Reid*, J. Lipkin, F.M. Leslie and S.E. Loughlin, University of California Irvine, CA 92717

In the weaver mutant mouse, a subpopulation of substantia nigra cells is lost during early postnatal development. As a result, caudate putamen dopamine levels are greatly decreased and a number of striatal neurochemical characteristics are affected. In other models, loss of striatal dopamine causes changes in endogenous opioid peptides and receptors. In rats, neurotoxic lesions of the nigrostriatal projection have been shown to decrease striatal opioid receptors, to decrease striatal dynorphin expression and to increase striatal enkephalin expression. In the weaver mouse, we have recently shown that striatal delta and kappa opioid receptors are decreased as compared to controls, while mu receptors are unchanged. In the present study, we compared tyrosine hydroxylase, proenkephalin and prodynorphin mRNAs in weaver and control littermate mice using in situ hybridization and quantitative autoradiography. Tyrosine hydroxylase mRNA decreased in the substantia nigra pars compacta of weaver mice, but appeared unchanged in the olfactory bulb. While striatal prodynorphin mRNA did not differ between control and weaver brains, proenkephalin mRNA significantly increased in the weaver striatum ($p < 0.025$). Thus, enkephalin is upregulated following genetically determined, early postnatal loss of striatal dopamine. The results suggest that upregulation of enkephalin is not necessarily associated with mu opioid receptor downregulation. Parallels between opioid system changes in weaver brains and Parkinson's disease suggest novel treatment strategies for symptoms not controlled by L-DOPA, such as dyskinesia or affective disorder. Supported by NS 26761 and the American Parkinson Disease Association SCC.

THE EFFECT OF ESTROGEN UPON L-DOPA EVOKED STRIATAL DOPAMINE RELEASE IN VITRO IN MPTP-TREATED FEMALE MICE. J.L.McDermott* and D.E.Dluzen, Department of Geriatric Medicine, University Hospitals, Cleveland, OH 44105, and Department of Anatomy, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Ovariectomized (OVX) retired breeder CD-1 and C57/Bl mice ± estrogen (EB) were treated with MPTP (10 mg/kg ip, q.i.d. x 1d). At 5-10 days post-MPTP, L-DOPA (5 μ M) evoked dopamine (DA) release from superfused corpus striatal tissue fragments was determined. Estrogen treatment of CD-1 mice treated with MPTP increased L-DOPA-evoked DA release ($\bar{x}$ ± SEM - areas under L-DOPA-evoked DA release curves in pg/70 minutes: OVX/MPTP = 316 ± 53, N=12 versus OVX + EB/MPTP = 494 ± 104, N=11). Moreover, MPTP failed to alter L-DOPA -evoked DA release from that obtained in estrogen-treated CD-1 mice (OVX + EB = 511 ± 48, N=12). In contrast, estrogen treatment of C57/Bl mice treated with MPTP did not significantly alter L-DOPA-evoked DA release (OVX/MPTP = 372 ± 89, N=12 versus OVX + EB/MPTP + 303 ± 37). However, MPTP did significantly reduce L-DOPA-evoked DA release in these C57/Bl mice (OVX + EB = 579 ± 69, N=11). In both strains estrogen treatment resulted in significant increases of L-DOPA-evoked DA release (CD-1: OVX = 335 ± 58, N=12 versus OVX + EB = 511 ± 48, N=12; C57/Bl: OVX = 219 ± 46, N=12 versus OVX + EB = 579 ± 69, N=11). These results demonstrate that OVX mice of both strains show enhanced striatal DA responsiveness to L-DOPA following estrogen treatment. Interestingly, while MPTP treatment did not reduce L-DOPA-evoked DA release from OVX females of either strain, the estrogen dependent augmented L-DOPA evoked response was completely abolished in C57/Bl, but not CD-1, mice treated with MPTP.

658.13

MPTP DOES NOT MIMIC THE EFFECTS OF PARKINSON'S DISEASE ON THE ADRENAL MEDULLA OF THE MOUSE. S.L. Stoddard*, G.J. Merkel, J.A. Cook, and S.W. Carmichael. Depts. of Anatomy and Microbiology, Indiana Univ. Sch. of Medicine, Fort Wayne, IN 46805 and Dept. of Anatomy, Mayo Clinic, Rochester, MN 55905

We have previously reported that the catecholamine content of the adrenal medulla is depressed in the parkinsonian patient [Stoddard et al. *Exp. Neurol. 104*, 218-222, 1989]. This condition may be a peripheral manifestation of Parkinson's disease. Since MPTP destroys dopaminergic cells in the substantia nigra and is used to produce a model of Parkinson's disease, we wished to determine whether this neurotoxin also affects peripheral targets. Mice (C57BL, ♂, 8-wk-old, N=30) were injected with *N*-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) (20 mg/kg; 3.0 mg/ml) at 0, 4, 8, and 24 hours, and sacrificed 4, 8, 12, or 16 weeks later. Catecholamines were extracted from both the adrenal glands and striatum by alumina adsorption, quantitated by high performance liquid chromatography with electrochemical detection, and expressed as ng/adrenal pair or ng/mg striatum. Catecholamine levels in MPTP-treated adrenals were compared to levels in age-matched control adrenals (N=21) using a simple randomized two-factor ANOVA. Although a slight decrease in catecholamine content was observed at 4 weeks in the MPTP-treated animals, the difference was not significant and catecholamine levels returned to control levels over time. These data suggest that, although MPTP mimics the central effects of Parkinson's disease by decreasing the dopamine content of the striatum, this neurotoxin does not produce the concomitant depletion of adrenal medullary catecholamines that is observed in human patients with idiopathic Parkinson's disease.

658.14

L-DOPA EFFECTS ON METHIONINE ADENOSYL TRANSFERASE (MAT) AND CATECHOL-O-METHYLTRANSFERASE: RELEVANCE TO PARKINSON'S DISEASE (PD) THERAPY. R. BENSON* AND C. CHARLTON, Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

It was observed that the injection of S-adenosyl methionine (SAM) into the lateral ventricles of rodents produced symptoms similar to those seen in PD patients, namely, tremors, hypokinesia, depletion of tyrosine hydroxylase and dopamine (DA), an increase in homovanillic to DA ratio and degenerative changes in the nigrostriatum; therefore, increased biological methylation may occur in PD. L-dopa, the major therapeutic agent for PD, is a potent methyl acceptor. It utilizes SAM when it is administered. Such a utilization, along with an increase in DA, may be related to the effect of L-dopa. It follows that the lack of efficacy from prolonged l-dopa therapy may be due to a rebound phenomenon, which tends to replenish the methylation system. To test this, mice were exposed to chronic l-dopa followed by analysis of brain and plasma MAT and COMT activities.

L-dopa (100mg/kg) treatments of 1, 2, and 3 times/day for 4 days increased brain MAT activity by 0.2%, 4.9% (not significant) and 21.3%, respectively. A treatment of 3 times/day for 8 days further increased (28.4%) brain MAT activity. MAT was not detected in the plasma. Preliminary data showed that L-dopa treatments of 1 and 3 times/day for 4 days increased brain COMT activity by 27.9% and 29.1%, respectively, above that of the controls. In contrast, the plasma COMT activity was decreased by over 80%. These results indicate that high frequency and chronic l-dopa treatments will induce increases in the activities of brain MAT and COMT, while decreasing plasma COMT. Increased MAT will increase SAM, which in combination with the increased COMT will lead to the increased metabolism of L-dopa and DA. (Supported by NIH GM08037 and NS 28432)

THE BIOCHEMICAL EFFECTS OF S-ADENOSYL-METHIONINE (SAM) IN RATS: RELATIONSHIP TO PARKINSON'S DISEASE. B. Crowell, Jr.*and C. Charlton, Dept. of Physiology, Meharry Medical College, Nashville, TN 37208

S-adenosyl-methionine (SAM) is a potent methyl donor that is involved in the metabolism of several biogenic amine neurotransmitters, including dopamine (DA), norepinephrine (NE) and serotonin (5-HT). When SAM is injected into the lateral ventricle of rats, tremors, hypokinesia, and abnormal posture are observed. These impairments along with the depletion of DA, NE and 5-HT have been observed in Parkinson's Disease (PD) patients. Therefore SAM may be involved in PD. The mechanism by which SAM induces motor impairments in rats is believed to be related to a depletion of DA.

We tested this hypothesis by injecting SAM into the lateral ventricle of rats and measuring changes in DA, NE and 5-HT. Measurements were made acutely (one injection and determination at 20 post-injection) and chronically (daily injection for 14 days and determination at 16 days post-injection). Both the acute and chronic administration of SAM depleted DA by 26.6 and 41.8% and increased HVA/DA ratio by 42.3 and 47.9% respectively. NE was depleted by 30.3% following the acute administration of SAM, whereas, 5-HT was depleted by 60.1% following only the chronic administration. These results showed that the biochemistry of DA, NE and 5-HT are affected following the administration of SAM.

NE and 5-HT are not known to play direct roles in PD, but DA depletion and an increase in the HVA/DA ratio do occur in PD and in animal models of the disease. Therefore, the administration of SAM into the lateral ventricle of animals may serve as a model of PD. This recently observed biochemical effect of SAM and the already established behavioral effects indicate that excessive SAM-dependent reactions may be involved in PD. EFFECT OF U-91356A, A NOVEL DOPAMINE AGONIST AND ANTIPARKINSON (AP) DRUGS ON STRIATAL ACETYLCHOLINE CONCENTRATION. V.H.Sethy*, N.F.Nichols and P.J.D. Schreur, CNS Diseases research, The Upjohn Company, Kalamazoo, MI 49001.

The potency and intrinsic activity of a dopamine agonist, U-91356A (U), has been compared with AP drugs apomorphine (A), bromocriptine (B), lisuride (L), quinpirole (Q) and pergolide (P) by measuring the striatal acetylcholine (ACh) concentration in non-reserpinized (NR) and reserpinized (R) rats. Some of the drugs have also been investigated in unilateral substantia nigra (SN) lesioned (6-hydroxydopamine) rats. In NR rats, the ED50s of Q, U, P, A and B, in descending order of potency, were 0.06, 0.21, 1.62, 1.72 and >10.0 mg/kg i.p. L failed to increase ACh levels by 50%. U was the most efficacious (100%) compound, and the relative intrinsic activities of Q, P, A and B were 80%, 63%, 45% and 30%, respectively. Reserpine (5 mg/kg i.p.) significantly ($p<0.01$) decreased ACh concentration. In R rats the, ED50s of AP drugs were several fold lower than in NR rats. In R rats, the slope of the dose-response curves for P and L were significantly different from those of U and Q. This may be due to the D2 selectivity of U and Q and non-selectivity of P and L for dopamine receptors. In addition, serotonergic and adrenergic effects of P and L may alter their dopaminergic response. The responses of Q and U for increasing ACh concentration were significantly higher on the lesioned side as compared to the intact side due to supersensitivity of D2 receptors following the degeneration of SN. The effects of AP drugs on striatal ACh concentrations indicate that U-91356A is a post-synaptic dopamine receptor agonist and may be useful for treatment of Parkinson's disease.

DECREASED EXTRACELLULAR BUFFERING CAPACITY DIMINISHES HIPPOCAMPAL SLICE SURVIVAL OF ANOXIA.
E.L. Roberts, Jr.* Department of Neurology and GRECC, VA Medical Center, University of Miami School of Medicine, Miami, FL 33136

The capacity of brain tissue to survive anoxia or ischemia may depend upon how well brain tissue buffers pH changes during and after such insults. This dependency was examined in hippocampal slices from male F-344 rats. Slices were placed into an interface chamber and bathed in an artificial cerebrospinal fluid (ACSF) of control (26 mM) or low (5 mM) bicarbonate buffering capacity. Slices were bubbled initially with gas mixtures containing 95% O_2, 5% CO_2 (control $NaHCO_3$) or 99% O_2, 1% CO_2 (low $NaHCO_3$). ACSF pH was 7.3-7.4. Slices were made anoxic (95% O_2, 5% CO_2 (control) or 99% N_2, 1% CO_2 (low $NaHCO_3$)) for approximately 9 min., then returned to the appropriate oxygen-containing gas mixture. During an experiment, extracellular K^+ activity (K^+_o) and the orthodromically-elicited CA1 pyramidal cell population spike were monitored. During anoxia, disappearance of the orthodromic population spike occurred sooner in low $NaHCO_3$ ACSF. After anoxia, slices exposed to low $NaHCO_3$ were less able to reestablish K^+_o homeostasis and did not recover population spike activity. These results support the view that sufficient HCO_3^- buffering capacity is required for recovery of ion homeostasis and synaptic transmission in brain tissue following anoxia. LACTATE ACCUMULATION DURING CEREBRAL ISCHEMIA: ATTENUATION BY INHIBITING EXCITATORY AMINO ACID-MEDIATED ION FLUXES AND ION PUMP ACTIVITY.
T. Kawamata*, Y. Katayama and T. Tsubokawa. Depart. Neurological Surgery, Nihon Univ. Sch. of Med., Tokyo 173, Japan.

Cerebral ischemia induces massive ionic shifts through the cell membrane resulting in cell swelling. This cell swelling has been though to be due to energy depletion. However, recently we have shown that excitatory amino acid (EAA) antagonists attenuate both ischemia-induced ionic shifts and cell swelling. Consequently we proposed that a major cause of the ionic shifts seen following ischemia is due to the stimulation of EAA-coupled ion channels resulting in an increase in energy demand in order to restore ionic balance. Therefore, inhibition of EAA-mediated ion fluxes could delay energy depletion during ischemia. To test this hypothesis, we measured cerebral lactate concentrations during the acute phase of cerebral ischemia as an indicator of energy metabolism and tested the effects of the Na+/K+ ATPase inhibitor ouabain and the EAA antagonists kynurenic acid (KYN) on the ischemia-induced lactate accumulation. Microdialysis probes were placed bilaterally in the hippocampal CA1-dentate area. One probe was perfused with Ringer's solution (control) and the other with ouabain or KYN. 30 min after the start of dialysis, ischemia was induced by decapitation and dialysate lactate concentrations were measured by HPLC. In the control probes, lactate concentration immediately increased and reaching maximum levels within 3-5 min after ischemia induction. This lactate accumulation was significantly delayed by ouabain and KYN. These results suggest that ion pumps are activated to restore ionic balance disrupted by EAA-mediated ion fluxes, resulting in increased energy demand which causes activation of glycolysis and lactate production. The attenuation of energy consumption and lactate accumulation may be one of the protective mechanisms of EAA antagonists against ischemic brain damage.

SNARF AND NEUTRAL RED INDICATE THE PRESENCE OF DISTINCT HYDROGEN ION COMPARTMENTS IN THE RAT HIPPOCAMPAL SLICE.
Tim S. Whittingham[1]*, Chii-Wann Lin[2], Alfred O. DiScenna[1] and Joseph C. LaManna[2,3]. Departments of Neurological Surgery[1], Biomedical Engineering[2] and Neurology[3], Case Western Reserve University, Cleveland, OH 44106.

We have previously reported the effects of amiloride analogs on intracellular pH estimated by the Neutral Red spectrophotometric method. We have extended these studies, comparing the pH estimates made from SNARF fluorescence to those of Neutral Red. The difference in control values and in response to anoxia or ammonium-induced acidification suggest that the two methods are monitoring separate pH compartments. Hippocampal slices were exposed to 50 μM Neutral Red or 10 μM SNARF-AM in HEPES-buffered artificial cerebrospinal fluid (ACSF) for 1 hr prior to a 30 min washout period to remove extracellular dye. The slices were transferred to an optical recording chamber and monitored for 30 min in control conditions. The ACSF was then switched to one of three experimental paradigms: 1) ACSF equilibrated with 100% nitrogen to produce anoxia; 2) ACSF containing 1 mM amiloride to block sodium-hydrogen antiport; or 3) ACSF containing 20 mM ammonium chloride. The control pH value for SNARF was 7.09 ± 0.02, compared to 7.59 ± 0.05 for Neutral Red. In response to anoxia, SNARF pH dropped 0.25 units in 10 minutes, and reached a value of 6.75 following 30 min of anoxia. In contrast, Neutral Red pH changed little in the first 10 minutes and was 7.08 after 30 min. Amiloride had no significant effect on SNARF pH during a 60 min exposure, but Neutral Red pH fell 0.8 units to 6.76. Finally, rebound acidification following exposure to 20 mM ammonium chloride caused SNARF pH to acidify by about 0.2 units with no subsequent recovery. Neutral Red pH also fell about 0.3 units, but recovered to control pH level in 10-15 minutes. Initial photographs indicate that SNARF appears to be more highly concentrated in the vicinity of the hippocampal somal layers, while Neutral Red exhibits a more uniform distribution in the slice.

METABOLIC FAILURE LEADS TO THE DETERIORATION OF THE BORDER ZONE IN REVERSIBLE FOCAL ISCHEMIA.
W.R. Selman, W. D. Lust, S. Pundik, C.M. Jenkins, S.U. Bhatti and R.A. Ratcheson*. Lab. of Exper. Neurol. Surgery, Case Western Reserve Univ., Cleveland, OH 44106

Experimental studies have shown that the benefits of reperfusion are limited to the first 2 hours following occlusion of the middle cerebral artery in spontaneously hypertensive rats (SHR). Even the border zone (BZ) surrounding the ischemic core deteriorates under these conditions. To determine what triggers the onset of irreversible damage, the metabolic status of the BZ was determined at one hour of reflow following increasing periods of focal ischemia. The MCA was occluded for 1, 2 or 4 h after which reperfusion was initiated and the brains were frozen in situ at 1 h of reflow. The brains were sectioned, lyophilized and ATP, P-creatine, glucose, lactate, GABA and glutamate were measured in the cerebral cortex adjacent to the ischemic core. While glucose recovered in the BZ of all groups, lactate levels were 2-, 4.5- and 11.8-fold over those of control and ATP levels were 61, 42 and 22 % of control at 1 h of reflow after 1, 2 and 4 h of occlusion, respectively. Accompanying these metabolic changes were significant increases in GABA and decreases in glutamate. GABA levels were 1.6-, 3.6- and 7.5-fold greater than those of control, while those for glutamate were 76, 64 and 36% of control at 1 h of reflow after 1, 2 and 4 h of ischemia, respectively. These metabolic derangements in the BZ during reflow following increasing periods of focal ischemia indicate that a persisting lesion in the metabolic machinery during reperfusion may be a factor in the evolution of border zone damage following focal ischemia.

WHOLE CELL PATCH CLAMP ANALYSIS OF MEMBRANE CHANGES DURING HYPOXIC AND NORMOXIC SPREADING DEPRESSION IN HIPPOCAMPAL CA1 PYRAMIDAL AND GLIAL CELLS.
G. Czéh, P.G. Aitken, G.G. Somjen*, Dept. Cell Biol., Duke Med. Ctr, Durham, NC 27710

Spreading depression (SD) can be provoked in normoxic hippocampal tissue by various events. A similar if not identical phenomenon can be provoked by hypoxia. The identity of normoxic and hypoxic SD is open to question. We used the whole cell patch technique in voltage- and current-clamp modes to study SD in pyramidal and glial cells in CA1 region of hippocampal slices. Population responses were recorded by extracellular electrode near the patched cell; this extracellular potential, rather than the bath ground, was used as the voltage clamp reference. Patch pipettes contained either cesium or potassium gluconate. Glial cells were identified by lack of active responses to depolarizing voltage steps and to orthodromic volleys. SD was provoked by local irrigation of high K^+ solution or by 3-5 minute periods of hypoxia. In some cells both types of SD were provoked sequentially. We found: (1) Neural responses did not differ observably during normoxic vs. hypoxic SD. In I-clamp cells depolarized at first slowly, then rapidly to V_m near 0 mV, accompanied by complicated changes in firing properties. In V-clamp neurons held at or near resting potential exhibited an increased inward current during SD, to levels as high as 2 nA. I/V plots of responses to ramp commands during SD revealed a 60-70% decrease of membrane input impedance and current reversal at or slightly positive to 0mV. (2) The input impedance of glial cells did not decrease during SD. (3) The inward current during SD reversed to outward at holding potentials near +30 mV (with cesium pipettes). These findings suggest that at the level of the cell soma membrane there is no important difference between normoxic and hypoxic SD, and that glial membrane changes during SD are a passive response to increased extracellular K^+. [Supported by NS-17771]

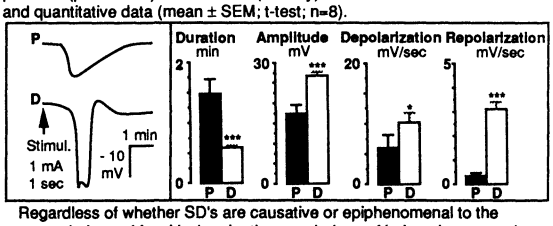
DISTINCT PROFILES OF PROPAGATING SPREADING DEPRESSIONS: A DIAGNOSTIC TOOL FOR THE PENUMBRA.
M. De Ryck*, R. Marrannes, E. De Prins and G. Clincke. Janssen Research Foundation, Department of Neuropsychopharmacology, B2340 Beerse, Belgium.

A photochemical thrombotic infarct (Stroke,1989,20,1383-1390) was induced in rat parietal cortex (n=31), where two glass micropipettes recorded DC activity and K^+_o or pH_o. A platinum stimulating electrode was placed frontally. In sites 100-500 µm proximal (P) to the infarct edge, infarct-related spreading depressions (SDs) progressively increased in duration, decreased in amplitude, and developed slower repolarization slopes: they became attenuated and shallow. By contrast, in sites 1-3 mm distal (D), SDs maintained a sharp profile, while somewhat increasing in duration. However, infarct-related SDs always ceased. When electrically induced SDs were then allowed to propagate towards the infarct, they were drastically deformed in the proximal (penumbral) but not distal (healthy) tissue. See illustrated individual and quantitative data (mean ± SEM; t-test; n=8).



Regardless of whether SD's are causative or epiphenomenal to the neuropathology of focal ischemia, the morphology of induced, propagating SD's can be used as a diagnostic tool for the penumbra.

660.3

RELATIONSHIP BETWEEN DEPOLARIZATION AND HISTOLOGICAL CHANGE AFTER FOCAL ISCHEMIA IN THE RAT. Y. Takeda, M. Jacewicz*, Y. Takeda, and W. A. Pulsinelli. Dept. of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021

We examined the temporal-spatial relationship between anoxic depolarization and focal injury in halothane-anesthetized Spontaneously Hypertensive Rats. The middle cerebral and common carotid arteries were occluded temporarily for 1 h or 3 h (n=5 per group). DC potential electrodes (DCPE) were inserted 800 μm below the cortical surface at 2 mm posterior and 1-6 mm lateral to bregma (1 mm intervals). At 24 h after occlusion the brains were perfusion-fixed, sectioned and stained with hematoxylin-eosin. The DCPE sites were identified by a needle track through each burr hole. The margin between depolarized and non-depolarized brain was found at 3.4±0.5, 3.4±0.5, 3.6±0.5, 3.8±0.8 mm lateral to bregma at 15 min, 1 h, 2 h and 3 h, respectively. The location of this margin was compared with histological markers of neuronal necrosis and infarction at 24 h for each animal (Table 1). These results indicate that, while the region of depolarized tissue does not change during 3 h ischemia, the margin of eventual tissue injury is established during the same interval, and includes territory not subjected to early depolarization.

Table 1. Margin of Tissue Injury vs. Depolarization
[mm medial (+) or lateral (-) relative to depolarization margin]

Ischemic Duration	Neuronal Necrosis	Infarction
1 h	+0.5 ± 0.4	-0.6 ± 0.9
3 h	+1.4 ± 0.5*	+0.7 ± 0.6*

(* $p<0.05$ vs. 1 h)

660.4

ROLE OF POST-SYNAPTIC MECHANISMS IN ANOXIC-INDUCED DEPRESSION OF NEOCORTICAL SYNAPTIC TRANSMISSION A. S. Rosen* and M. E. Morris. Dept. of Pharmacology, Univ. of Ottawa, Ottawa, Canada K1H 8M5.

Brief anoxia (5 min) differentially depresses EPSPs and IPSPs, recorded intracellularly in rat neocortical pyramidal neurons (*Rosen & Morris 1991, Soc. Neurosci. Abstr. 17:1079*). The depression is reversible and is not caused by occlusion due to the concurrent depolarization, nor by decreased Na^+ gradient due to Na-K-pump failure.

Anoxia may affect ATP-dependent processes related to postsynaptic receptors. Quisqualate (QUIS) (100 μM) and GABA (1 mM) were pressure-ejected in the slice close to the recording site (15-40 psi, 5-400 ms, 1 pulse/min). QUIS elicited strong depolarizing responses, which decreased in amplitude by ≈ 25% in the presence of N_2. GABA elicited at V_R depolarizing responses which became biphasic at more positive V_M (reversal of late phase at -70 mV). Anoxia depressed the responses to GABA by ≈ 26%. The limited effect of N_2 on the post-synaptic responses to locally applied transmitters cannot account for the entire synaptic depression observed (70% decrease in amplitude of the monosynaptic early EPSP) and suggests a dominant (though not exclusive) role of pre-synaptic factors in determining anoxic synaptic failure.

660.5

HYPOXIC SYNAPTIC DEPRESSION IS A RESULT OF ALTERATIONS AT A PRE-SYNAPTIC SITE AS REVEALED BY THE STUDY OF MINIATURE EXCITATORY POST SYNAPTIC CURRENTS. N. Hershkowitz* A. N. Katchman, S. Veregge. Department of Neurology, Georgetown Univ., Wash. D.C. 20007.

It is well established that hypoxia will result in suppression of neuronal activity by alterations at the synapse. It is less clear whether this represents a pre- or post-synaptic effect. We examined this by evaluating changes in miniature excitatory post synaptic currents (mEPSCs) as well as in the response to pressure-ejected glutamate following hypoxia in in vitro hippocampal slices using whole cell patch clamp. K-gluconate patch electrodes (V_H=-60mV) were used; hypoxia was induced by exposure to 95% N_2/ 5% O_2. We previously reported that after hypoxia there is an increase in the frequency of spontaneous transient inward currents. These currents are suppressed by kynurenic acid and occur in the presence of tetrodotoxin, identifying them as mEPSCs. The average amplitude of currents under normal conditions and in the presence of tetrodotoxin was 12.3 ± 0.7 pA (n = 17) and 13.2 ± 0.7 pA (n = 14), respectively. There was no change in average amplitude of these events after hypoxia even when amplitudes were evaluated at times during which there was nearly complete blockade of the orthodromically elicited responses. However there existed an increase in mean frequency of mEPSCs of 430%. Currents from pressure ejection of glutamate was inhibited by 10-15 % at a time when there was nearly 100% blockade of the orthodromically elicited synaptic response. These results indicate that hypoxic synaptic block occurs at a presynaptic locus and may be associated with an increase in presynaptic calcium concentration. (Supported by NINDS grant NSO1460-01).

660.6

ISCHEMIA-INDUCED CHANGES IN EXPRESSION OF HIPPOCAMPAL LTP AND PTP. N. Hori* and D.O.Carpenter, NYS Dept. of Health and School of Public Health, Albany, NY 12201

Pyramidal neurons in area CA1 of dorsal hippocampus are extremely vulnerable to ischemic episodes, and disappear 3 to 5 days after a non-lethal ischemic event. The reasons CA1 neurons are more vulnerable to ischemia than others are not certain. We have studied properties of injured but still viable CA1 neurons.

Male Wistar rats (200-250 gm) were used in all studies. Under pentobarbital anesthesia, the vertebral arteries were electrocauterized and the isolated carotid arteries were enclosed in a loop of thread. On the following day, the carotid arteries were ligated for 10 or 20 min. Animals that lost righting reflexes after ligature were used for acute brain slice experiments 24 hours later. At this time there are no morphologic indicators of neuronal death in hippocampus, although the neurons in CA1 degenerate after 3 to 5 days.

In slices of animals subjected to 10 or 20 min ischemia 24 hours earlier, field potential recordings made from area CA1 upon activation of the Shaffer collateral pathway from CA3 showed little change as compared to slices from control animals. The evoked response was not obviously reduced in amplitude, although there was a slight broadening of the population spike. Intracellular recordings from single pyramidal neurons in CA1 showed resting membrane potentials and input resistances which were similar to those in control slices.

There were, however, dramatic differences in indicators of synaptic plasticity. Post-tetanic potentiation was normal in slices of animals subjected to 10 min occlusions, but was considerably depressed in slices from animals with 20 min occlusions. Long term potentiation was diminished after a 10 min occlusion and was absent in slices from animals with 20 min occlusions. These results indicate that synaptic events, particularly those with a major presynaptic component, are the first to fail in the process of ischemic neuronal cell death. Supported by NS23807.

ANOXIA DECREASES HUMAN TEMPORAL NEURONAL EXCITABILITY BY SODIUM CHANNEL MODULATION. G.G.Haddad*, T.R.Cummins and C.Jiang. Dept. of Pediatrics, Sect. of Respir. Med. & Interdepart. Neurosci. Program, Yale University School of Medicine, New Haven, CT.

Although O_2 deprivation can be disastrous for central mammalian neurons, the underlying mechanisms are still unclear. For example, the basic mechanisms for the decrease in excitability that occurs in neocortical neurons during anoxia are not well understood. Using human brain slices and intracellular techniques, we have previously shown that excitability diminishes before any significant alteration in input resistance and membrane potential (Vm). In order to further understand mechanisms of excitability during anoxia, we asked whether O_2 deprivation alters voltage-dependent inward currents. We therefore studied freshly dissociated neurons from adult human cortex in order to effectively voltage clamp membrane currents. Using patch-clamp techniques, we isolated a TTX-inhibitable inward current (I_{Na}) by exposing cells to Cd^{++} and using Cs^+ in the pipette. I_{Na} was studied before, during and after brief exposure to anoxia (A) (PO_2 = 0 Torr) or Cyanide (CN). Neither CN nor A had an effect on the shape of the I-V curve but both reversibly decreased the magnitude of I_{Na} by 33 ± 8% and 48 ± 17% respectively (Vm = -70 mV). In addition, both CN and A had a major effect on the steady-state inactivation of I_{Na} in that the mid-point of the h_∞(V) curve was left-shifted by about 15-20 mV (n=18). ATP (2-10 mM) in the pipette eliminated the attenuation of I_{Na} to a large degree. We conclude that in human temporal neurons: a) the decrease in excitability with anoxia is related, at least in part, to I_{Na} inhibition and b) this I_{Na} inhibition depends on the decrease of intracellular ATP. We speculate that this decrease in I_{Na} during anoxia is a cellular adaptive measure to decrease excitability, minimizing the mismatch between O_2 supply and demand.

THROMBOTIC INFARCTION TRIGGERS SPREADING DEPRESSION-LIKE EVENTS IN DISTANT BRAIN REGIONS. H. Leistra, Z.C.-Feng, B.D. Watson*, M. Rosenthal and W.D. Dietrich, Dept Neurology, University of Miami School of Medicine, Miami, Fl. 33101.

In rats anesthetized with halothane/nitrous oxide, local cerebral thrombotic infarction can be induced by irradiating the intact skull with green light (560 nm) for 7 min following systemic injection of rose bengal. Initial goals were to define hemodynamic consequences of this insult by recording cerebral blood flow (CBF) with a laser doppler probe. 3 mm anterior to the infarct border, severe (approx 4X) transient hyperemic episodes (THEs) lasting 1-2 min were intermittently recorded. THE frequency declined over a 3-hr period. To define the mechanism of THEs, extracellular potassium ion activity (K^+o) and tissue oxygen tension (tPO_2) were recorded by microelectrodes implanted approx 0.5 mm below the cortical surface adjacent to the side of the doppler probe opposite to the infarct. Whenever THEs occurred, they were always preceded by a precipitous rise in K^+o (from approx 3 to over 50 mM. tPO_2 usually increased in association with these spreading depression-like events. Also characteristic of SD, K^+o clearance to baseline preceded baseline recovery of CBF. These data indicate that THEs are reactive to physiological events resembling spreading cortical depression which provoke increased demand for oxygen and blood flow. This conclusion is supported by findings that MK-801 (1 mg/kg; i.v.) inhibited subsequent SD-like episodes. These data suggest that the remote consequences of thrombotic infarction may be magnified by SD-like events or by the pathophysiological mechanisms underlying such events.

661.1

Acute Outcome Evaluation after Experimental Focal Cerebral Ischemia. Masaaki Uno, M. Christopher Wallace* Cerebrovascular Research Lab., Univ. of Toronto.

This study was designed to evaluate outcome methodology in 3 models of acute permanent focal cerebral ischemia. Fisher 344 rats were used in 3 different models: proximal middle cerebral artery occlusion (p-MCAO) via craniectomy, distal MCAO with ipsilateral common carotid occlusion (ipsi-CCO) and intravascular MCAO(I-MCAO) with a 4-0 suture. Sacrifice was performed at time intervals of 30 minutes to 4 hours after ischemia. Outcome methods included: tetrazolium Chloride perfusion fixation (TTCP) (n=45), Neutral Red (NR) injection (n=20) or 3H-forskolin binding (FK-b)autoradiography (n=25). There was well correlation between infarction volume demonstrated by TTCP (89.3±31.4), and histology (87.5±19.0) with p-MCAO at 4 hours. Similar results were obtained with cortical infarction (66.4±23.3, 69.9±19.3) with distal MCAO and ipsi-CCO. FK-b in caudate dropped (112±36 vs 187±22pmol/g) at 30 minutes post ischemia. Discrepancy between TTCP (87.3±34.8) and histology (42.2±63.4) was found after I-MCAO. NR demonstrated no changes in this model at 4 hours. Acute outcome evaluation affords continual monitoring of physiologic variables. Care must be exercised in choosing the appropriate model and acute outcome methodology.

661.2

GLOBAL ISCHEMIA IN RATS IMPAIRS SPATIAL WORKING MEMORY, BUT NOT SPATIAL MAPPING. J. E. Kelsey* and L. M. Genova. Dept. Psych., Bates College, Lewiston, ME 04240.

The intention of this study was to examine the nature of the memorial deficits produced by global ischemia and to examine the hypothesis that these deficits are produced by glutamate excitotoxicity. Global ischemia was produced in 10 male Wistar rats by bilateral cauterization of the vertebral arteries and occlusion of the carotid arteries for 30 min. Ten control rats did not have their vertebral arteries cauterized or their carotid arteries occluded. In Experiment 1, the ischemic rats were not impaired in their capacity to find a platform hidden below the surface of the water in a circular water tank. In contrast, in Experiment 2, the same ischemic rats were impaired in a spatial DNMTS task that required them to remember which arm of a Y-maze they had previously entered. Moreover, the choice accuracy of the ischemic rats decreased dramatically as the retention interval between forced and choice runs increased from 30 to 120 s, whereas the accuracy of the controls was unaffected. In Experiment 3, injections of the NMDA receptor antagonist, dextromethorphan (20 mg/kg i.p.), 1 hr before and 1 hr after the onset of ischemia did not affect the impairment produced by ischemia in the Y-maze. These results indicate that CA1 hippocampal damage produced by global ischemia produces a deficit in working memory, i.e., the capacity to remember where they have been (Experiment 2), but not in the capacity to form a spatial map, i.e., to localize where they are (Experiment 1). Moreover, Experiment 3 indicates that this deficit was not caused by glutamate excitotoxicity.

661.3

ASSESSMENT OF THE EFFECTS OF VARIOUS DURATIONS OF CEREBRAL ISCHEMIA FOLLOWED BY REPERFUSION ON THE PERFORMANCE OF GERBILS IN THE MORRIS WATER MAZE. R.P. Wiard, M.S. Carroll, O.G. Beek and B.R. Cooper*. Div. of Pharmacology, Burroughs Wellcome Co., RTP, NC 27709.

The effect of different durations of cerebral ischemia produced by bilateral carotid occlusion for 5, 10, or 15 minutes was determined on performance of a spatial memory test by male Mongolian gerbils. After recovering from the lesion for 21 days, the gerbils were trained in a Morris water maze to swim to a hidden platform which was located in a fixed location. Following 10 daily tests in the Morris water maze the animals were sacrificed and their brains were examined for hippocampal damage. The relationships between the duration of the ischemic insult, the extent of hippocampal damage, and the degree of impaired performance in the memory task was defined. In a second study, the ability of hypothermia (30°C) was studied using both histological and behavioral measures. Maintaining low body temperature during ischemia markedly decreased both indices of ischemic damage.

661.4

EFFECTS OF INCOMPLETE GLOBAL FOREBRAIN ISCHEMIA IN RATS ON SUBSEQUENT PERFORMANCE IN A NOVEL WATER MAZE. G.J. Kant* and F.C. Tortella. Dept. Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

The present studies were conducted to evaluate a novel water maze task for studying the behavioral effects of ischemia-induced neural injury. A four vessel occlusion procedure was used to produce temporary (15 min) forebrain ischemia in rats. The maze was a traditional type of maze (not an open Morris maze), set inside a small wading pool such that rats had to learn and remember to swim through a series of doors to reach an exit platform. Both swim time and incorrect door choices were recorded. In the first study, ischemic rats trained to swim a maze prior to surgery had poorer performance post-ischemia than non-operated controls or operated non-ischemic rats with respect to both the previously-learned maze and the learning of a new maze configuration. In a second study where rats were not trained prior to surgery, both ischemic and operated non-ischemic rats required more time to learn the water maze task than did non-operated controls. In a 3rd study that reduced ischemia to 5 min, no apparent differences between control and ischemic animals were seen.

661.5

EARLY NEURONAL DAMAGE IN THE NEWBORN PIGLET INDUCED BY HYPOXIA AND ELEVATED INTRACRANIAL PRESSURE. C.S. Easley, A.E. Kopelman, F.S. Wartman, and T.M. Louis*. Depts. of Pediatrics and Anatomy/Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858-4354.

Perinatal asphyxia occurs in 5% of all births and can result in permanent brain damage or death. Neurologic damage is caused by brain hypoxia and ischemia. Despite its clinical importance, few animal models of early hypoxic ischemic brain damage are available. To study this problem,we examined the effect of hypoxia and elevated intracranial pressure (ICP) on brain histopathology. We produced hypoxia in isoflurane- anesthetized piglets by administering a 1:1 mixture of air and nitrous oxide for 2 h. To produce brain ischemia, warm saline was injected through a burr hole into the epidural space under the right parietal bone. ICP was maintained at 20 mm Hg above the mean systemic blood pressure for 20 min. We reduced the elevated ICP and survived the piglets for 8 h. We studied the hippocampal histopathology using a silver impregnation method highly selective for degenerating neurons. Damaged neurons were found in the CA3/CA4 and hilar regions of the hippocampus. Only the piglets exposed to a combination of ICP and hypoxia showed silver impregnated neurons. The hypoxic ICP piglet should prove useful as a model for determining the mechanisms of hypoxic ischemic brain damage in the newborn. RECOVERY OF SENSORIMOTOR FUNCTION FOLLOWING PHOTOTHROMBOTIC OCCLUSION OF THE DISTAL MIDDLE CEREBRAL ARTERY IN RATS. C.G. Markgraf*, M. Castro, A.S. Wilkens, E.J. Green, P.M. McCabe, W. D. Dietrich, N. Schneiderman and M.D. Ginsberg. Cerebral Vascular Disease Research Center and Dept. of Psychology, University of Miami School of Medicine, Miami FL 33101

We have developed a photothrombotic model of distal middle cerebral artery occlusion (dMCAO) in rats, using the interaction of a laser light and rose bengal dye. This model is advantageous in that it produces more consistent infarcts and is more clinically relevant than the mechanical dMCAO model. The present study sought to determine the long-term behavioral consequences of the photothrombotic model. Sensorimotor and cognitive behaviors were examined following dMCAO in 10 Sprague-Dawley rats and 10 sham operated rats. Beginning on Day 2 post-ischemia (PI) and continuing to Day 30 PI, all rats were tested twice weekly using a battery of 5 tests that measure aspects of sensorimotor integration. Subsequently, from Day 35-43 PI, animals were trained in a water maze task. Histological analysis at 8 weeks revealed that the dMCAO group had a mean ±S.E.M. infarct volume of 98.36 ± 28.0 mm^3. Significant deficits were seen on the two most sensitive tests: elicited limb placing and posture reflex. The severity of the deficits were positively correlated with the extent of the ischemic damage for these two tests. Sensorimotor function recovered to control levels on the posture reflex test by PI Day 20, but limb placing performance did not show complete recovery by PI Day 30. There were no deficits in muscle strength or in learning the spatial mapping water maze task. Behavioral deficits are seen to be reflective of the various cortical areas damaged, and the different recovery patterns might be attributed to the different demands of the tasks. These results help establish the dMCAO model as a useful and relevant rodent model of focal cerebral ischemia. Supported by NS 05820.

EFFECTS OF FOCAL CEREBRAL INFARCTION OF THE FRONTAL CORTEX ON A VIBRISSAE - DEPENDENT BEHAVIORAL RESPONSE IN RATS. A.J.Pazos, E.J. Green*, W.D. Dietrich, P.M. McCabe, C.P. Earl, B.D. Watson, B.E. Hurwitz, M.D. Ginsberg and N. Schneiderman. Depts. of Psychology and Neurology, University of Miami, Coral Gables, FL 33124.

Previous metabolic studies in this laboratory have demonstrated a decrease in the uptake of 2-deoxyglucose in the cortical barrel field 5 days following thrombotic infarction of the frontal cortex. The present study sought to document the behavioral correlates of this "functional diaschisis" by assessing the effect of a photochemical infarction of the frontal cortex on an appetitively motivated response in a T-Maze using a vibrissal deflection cue.

Adult male Wistar rats were randomly assigned to one of two groups. Rats in the first group were trained to turn right in the T-Maze in response to a right vibrissal stimulation, and left in response to no vibrissal stimulation; rats in the second group were trained to perform the opposite response. Rats received 50 randomly alternating daily trials (25 right turn trials and 25 left turn trials) until the behavioral criterion was achieved (80% or better correct on both the left and right turn trials).

Following training, focal insults to the left frontal cortex were produced in half of the animals in each training group through the interaction of a photosensitive dye (rose bengal) injected into the rats' tail vein, and the direct irradiation of the cranium with a light beam (Watson et. al., 1985). The other half of the animals underwent the same procedure, except saline was injected in place of rose bengal (shams). Behavioral testing starting 24 hours after the insult revealed substantial deficits in the left and right turning of lesioned animals relative to pre-insult levels. These deficits recovered to pre-insult levels within 3-4 days following the insult. Shams exhibited no behavioral deficits. These results indicate that frontal cortex infarctions are associated with significant behavioral deficits in the performance of a task that requires cortical barrel field integrity. Supported by NS 05820.

EFFECT OF LIPOPOLYSACCHARIDE ON VON WILLEBRAND FACTOR AND FACTOR VIIIC PRODUCTION IN RATS WITH AND WITHOUT RISK FACTORS FOR STROKE. D.A. Doron*#, E. Heldman#, A.Siren^, Harvey B. Pollard# and John M.Hallenbeck&.#LCBG, NIDDK,&SB, NINDS, National Institutes of Health Bethesda, Maryland 20892 and ^Department of Neurology Uniformed Services University of the Health Sciences, Bethesda, Maryland 20814.

We have previously reported that following a provocative dose with Lipopolysaccharide (LPS), rats with the risk factor for stroke hypertension developed more stroke events than normal rats. We have also demonstrated that hypertensive rats (SHR) produce more TNF-α, in blood and cerebrospinal fluid than normotensive rats (WKY) when challenged with LPS injected iv or icv. It is therefore possible that monokines, may act by changing levels of intravascular mediators of thrombosis and coagulation such as von Willebrand factor (vWF) and factor VIIIc. To test this hypothesis we asked whether this factors were differentially affected by LPS in SHR and WKY. We report here that hypertensive rats have higher levels of vWF than control rats after a single injection of LPS. When SHR rats were injected with a single iv dose of 1.8 mg/kg of LPS, vWF concentration increased in a time and dose dependent manner, reaching a peak after 2 hr and with a maximum response at a dose of 1.8 mg/kg. When the response of the hypertensive rats to a challenge with LPS was compared with the normotensive rats, the SHR animals showed significantly higher levels of vWF compared to WKY rats, after a 1.8 mg/kg of LPS was injected either iv or icv. No significant differences were found at lower doses. LPS injected iv at a concentration of 1.8 mg/kg had an inhibitory effect on factor VIIIc activity which resulted in an increase in the vWF/VIIIc ratio. These and other data strongly suggest that the effect of LPS in vivo is not direct on the endothelial cells but most likely mediated through the release of monokines by activated macrophages and microglias.

BEHAVIORAL, PHYSIOLOGICAL AND PHARMACOLOGICAL ASPECTS OF STIMULUS-INDUCED POST-ANOXIC MYOCLONUS IN THE RAT. P.H. Schwartz*, R.R. Matsumoto, M.J. Hussong, C. Nguyen, P. Vo, and D.D. Truong. Dept. of Neurol., Col. of Med., Univ. of Calif., Irvine, CA 92717.

We investigated the nature of acoustic-induced myoclonus (AIM) in rats that had undergone cardiopulmonary arrest and resuscitation, an insult that gives rise to spontaneous myoclonus and AIM. After 3 days to four months AIM was measured using two methods: visual scoring and quantitative measurement of whole-body AIM force. AIM was non-habituating, regardless of the length of time after the insult, within sessions; the force of the response increased then decreased between sessions run on a single day and decreased slowly over sessions run on sequential days. In addition, AIM was supranormal, compared to normal controls, shortly after the insult but declined to subnormal several weeks later, regardless of prior testing. The waveform of the force of AIM was significantly different from control animals: there was a decreased latency to peak force and an increase in the initial response. In addition, a secondary longer-latency response was present that was not seen in controls. AIM was decreased by the anti-myoclonic drugs clonazepam (0.5 - 1.0 mg/kg), 5HTP (50 - 300 mg/kg), TFMPP (0.5 - 2.0 mg/kg), and valproate (100 - 300 mg/kg). These data indicate that cardiac arrest in the rat gives rise to a model of human post-hypoxic myoclonus (PHM) that can be further studied to understand the mechanisms of PHM and its therapeutic treatment.

MICE BRAIN REGIONAL METABOLITES AND BLOOD VOLUMES (BV) AFTER 30 SEC OF GLOBAL ISCHEMIA IN A SMALL ANIMAL CENTRIFUGE (SAC). A. R. Shahed*, S. Galindo, Jr., J. A. Barber and P.M. Werchan. Operational Tech. Corp. Krug Life Sci. and Armstrong Laboratory, Brooks AFB, TX 78235.

Recently we have used a SAC to study the effect of high +Gz (head-to-foot) exposure on cerebral metabolism and to understand the mechanism of gravity induced loss of consciousness (G-LOC). G-LOC has been proposed to result from a critical reduction in cerebral blood flow (CBF) during +Gz exposure. We have shown that a 30 sec +35 Gz exposure causes G-LOC and global ischemia in mice (Soc. Neurosci. Abstr., Vol. 17(2):1262, 1991). We proposed that G-LOC may occur to conserve energy and minimize acidosis during +Gz exposure. Measurement of CBF in the dynamic environment of SAC is difficult. The brain is heterogeneous in structure, function and CBF. Therefore the objective of the present study was to measure BV and regional energy metabolism during +Gz stress. **Methods:** Fully awake mice were exposed to +35 Gz for 30 sec in the SAC (to induce global ischemia) and brain sampled at various time points during and after deceleraration by microwave fixation. The brain was dissected in 5 regions and tissue extracts were analyzed for metabolites and total iron to determine the BV. Control mice were exposed to 0.5 Gz for 30 sec and the brain sampled. **Results:** Data show that the level of lactate increased and glucose, Cr-P and ATP decreased significantly in all regions after 30 sec except the cerebellum (CB). The level of metabolites did not return to control levels 60 sec after deceleration. BV decreased more than 50% in all regions except the mid brain (25 %) and CB (no change). There was a pronounced hyperemic response in the hippocampus, brain stem and mid brain 30 sec after deceleration. **Discussion:** It is concluded that high +Gz exposure effects regional metabolism uniformly. The presence of BV, although reduced, indicates trapped blood in the brain circulation. We propose that during +Gz exposure trapped blood may prolong the onset of G-LOC after CBF ceases.

661.11

COLLAGENASE-INDUCED INTRACEREBRAL HEMORRHAGE IN SPONTANEOUSLY HYPERTENSIVE RATS. D.R. Bramlett, T.L. Sailer, J.T. Simmonds, R.R. Notvest, J.T. Haskins*, J.A. Moyer. CNS Division, Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543-8000

Intracerebral hemorrhage is an important liability in the treatment of stroke. The collagenase-induced intracerebral hemorrhage model utilizing Sprague-Dawley rats was previously determined to be an effective and reproducible animal model for assessing damage as a function of brain edema (Rosenberg et al, Stroke 21:801,'90). In the present study, spontaneously hypertensive rats (SHR) were used because of the inherent hypertensive liabilities encountered in this species and their relevance to the clinical situation. To determine a time course, 2ul of 0.5 unit bacterial collagenase (Type VII) in saline was infused into the left caudate nucleus of adult male SHR rats. Groups were evaluated for water content at 6, 12, 24, 48, 72 and 168 hours post-infusion. Significant increases in water content occurred at 24 and 48 hours in the left hemisphere. The 48 hour timepoint was chosen for a dose response determination. Rats were infused with saline or bacterial collagenase (0.1, 0.5, or 1.0 unit) and brains were evaluated for water content. The edema values measured in the left hemisphere were 78.9, 79.2, 79.7, and 80.0 percent respectively. Groups treated with 0.5 and 1.0 unit collagenase had significantly more edema than the saline control group. The collagenase-induced intracerebral hemorrhage model provides significant and reproducible results in SHR rats and may be a useful model for the pharmacological assessment of therapeutic agents for the treatment of stroke.

"NEURONAL RESCUE" DURING CHRONIC BRAIN ISCHEMIA. G.A.S Park*, T. Fortin, B. Pappas, J. Saunders, J.C. de la Torre. University of Ottawa, Carleton University, National Research Council, Ottawa, Ontario Canada K1H 8M5.

Alzheimer-like deficits (ALD) can be induced in aged rats by provoking chronic brain ischemia (CBI) using a "reversible" 3-vessel occlusion (3-VO) technique developed by us.[1] CBI for 1 to 9 weeks results in selective CA1 hippocampal cell damage, spatial memory deficits, increased glial fibrillary acidic protein (GFAP) reactive astrocytosis and membrane phospholipid synthesis changes. To test whether interrupting CBI can prevent ALD by protecting CA1 neurons, 12 month moderately aged rats underwent 3-VO for 9 weeks.

After 3-VO, special plastic carotid artery occluders were removed to allow normal brain recirculation in Group DO rats at 1, 2 or 3 weeks and occluders were left in place in Group CO. A third group of rats (NO) had no vessels occluded. At 6 and 9 weeks, rats were tested on the Morris water maze to assess spatial memory acquisition. Following this, in vivo changes of phospholipid synthesis in the hippocampus using ^{31}P- NMR spectroscopy were measured. Prior to sacrifice at 9 weeks, CBF was measured in cortex and hippocampus using hydrogen clearance. After sacrifice, morphometry of CA1 neurons and hippocampal GFAP density was done.

Results indicate that a significant number of Group DO rats had no impairment of memory acquisition in the Morris water maze when deoccluded 1 and 2 weeks after 3-VO (as compared to normal Group NO). CA1 cell damage and reactive astrocytosis was also reduced in Group DO and this was associated with nearly pre-ischemic CBF levels in cortex and hippocampus. NMR spectroscopy indicated that phospholipid synthesis did not increase in the hippocampus of most DO rats. By contrast, non-deoccluded rats (Group CO) and 3 week DO rats showed memory impairment, increased CA1 cell damage and reactive astrocytosis while CBF remained depressed from pre-ischemic levels. CO rats also showed phospholipid synthesis increase in the hippocampal area.

We conclude that "neuronal rescue" is possible when CBF is normalized after 1 or 2 weeks CBI. These findings may be relevant in Alzheimer's disease and other dementias. (Supported by the Ontario Mental Health Foundation).

ANOXIA-INDUCED IMPAIRMENT OF GABAERGIC INHIBITION IN MATURE AND DEVELOPING RAT NEOCORTEX *IN VITRO*. Heiko J. Luhmann*. Inst. of Neurophysiology, Univ. of Cologne, D-5000 Cologne 41, FRG.

Hypoxia-induced functional deficits in excitatory and inhibitory synaptic transmission were analyzed in somatosensory cortical slices of young (P5-8), juvenile (P14-18) and adult (>P28) rats. Transient hypoxia was induced by switching the aerating gas in the interface-type recording chamber from 95% O_2 / 5% CO_2 to 95% N_2 / 5% CO_2. Extracellular field potential (FP) responses to orthodromic electrical stimulation and paired-pulse responses were recorded in supragranular layers to evaluate excitatory and inhibitory transmission, respectively. In adult cortex, hypoxia caused a reversible 45% reduction in the amplitude of FP responses and a complete loss of paired-pulse inhibition. The intracellularly recorded f- and l-IPSP was reduced in amplitude to 42 and 25%, respectively. The EPSP amplitude decreased to only 64%, suggesting a selective impact on inhibitory function. Spontaneous IPSPs, recorded in a bathing solution including APV and CNQX with electrodes containing 2 M K-nitrate, were suppressed by 20% in the early phase of hypoxia. The peak conductance of the f- and l-IPSP decreased from 140 to 92 nS and from 28 to 15 nS, respectively, and both IPSPs showed a significant shift in their reversal potentials towards more positive values. Prolongation of hypoxia induced a massive anoxic depolarization by 30-78 mV associated with complete loss of spontaneous and evoked synaptic activity. Upon reoxygenation spontaneous IPSPs were transiently increased by 118%, and the conductance of the f- and l-IPSP was markedly suppressed to 39 and 1.4 nS, respectively. All parameters recovered within the observation period and even repetitive hypoxic insults did not cause irreparable functional deficits when the interval between two subsequent anoxic periods was >60 min. In young and juvenile cortex, hypoxia-induced modifications in synaptic transmission were less clearly pronounced and post-anoxic hyperexcitability could not be observed. These data indicate a selective vulnerability of the inhibitory system to transient hypoxia in adult neocortex.

662.2

PHOTOCHEMICALLY-INDUCED LESION OF THE RAT RETINA: QUANTIFICATION OF CHOLINERGIC AND GABAERGIC NEURONAL DEGENERATION. G. Lombardi*, Fulvio Moroni[x], S. Faussone[xx] and F. Moroni. Department of Pharmacology, [x]Institute of Ophthalmology, [xx] Department of Anatomy and Histology, University of Florence, 50134 Florence, Italy.

Intravenous injections of the flourescein rose bengal dye and intense focal illumination have been used for the development of reproduceable models of cerebral and retinal ischemia (Mosinger J. L. and Olney J. W., Exp. Neurol., 105, 110-113, 1989). We quantified the photochemically-induced neuronal damage to obtain a reliable model to test drugs possibly active against ischemia. Rats were injected with 80 mg/Kg of rose bengal and one eye was exposed to cold light (peak absorption 560 nm) for different periods (5, 15, 30 min). The animals were then sacrificed at different times (1, 4 h and 2, 7 days) after the lesion. At light microscopy the retinae appeared edematous, the microvessels were enlarged and numerous neurons showed pyknotic nuclei; vacuoles were also present especially in the inner nuclear and in the ganglion cell layer. The extent of retinal damage was grossly related to the time of illumination. In other experiments the retinae were used for the determination of GAD (glutamic acid decarboxylase) and ChAT (choline acetyltransferase) activity, two enzymes whose decrease was considered directly related to the extent of retinal damage. The activity of the enzymes GAD and ChAT significantly decreased in a time dependent manner: no changes were present 1 h after the lesion, but 4 h later GAD and ChAT activity decreased by 50% and 40% respectively in retinae illuminated for 5 min and by 70% and 60% in those illuminated for 15 min, indicating a diffuse degeneration of the amacrine cells. This damage remained unchanged for at least 7 days.

DELAYED GABA NEURON LOSS IN THE SUBSTANTIA NIGRA FOLLOWING ISCHEMIA DEPENDS ON THE EXTENT OF STRIATAL INJURY. B.T. Volpe*, M. Cohen and M. Saji. Dept. of Neuro. and Neurosci., Cornell Univ. Med. School, at The Burke Inst. for Med. Res., White Plains, NY 10605.

Transient forebrain ischemia by the method of four vessel occlusion reproducibly damages the striatum and the hippocampus. However, it has been shown that the substantia nigra reticulata (SNr) is not damaged acutely. In order to test whether delayed injury occurred in the SNr of animals exposed to 20 minutes of ischemia, the survival period was prolonged, the extent of striatal injury was measured, and in situ hybridization for glutamic acid decarboxylase (GAD) identified GABAergic neurons in the SNr. Five of 13 animals sacrificed 1 week to 3 months after ischemia demonstrated focal GABA neuron loss in the medio-dorsal SNr accompanied by an increase in non-neuronal elements. Each of these 5 animals had ischemic damage in the caudate nucleus (CN) and lateral globus pallidus (LGP). The remaining 8 animals had no SNr damage, and the ischemic injury was confined to the CN alone. Seven animals were sacrificed 2-3 days after ischemia and none of these had SNr damage. Three of these 7 animals had ischemic damage in the CN and LGP, 4 of 7 animals had ischemic injury in the CN alone. All animals demonstrated severe CA1 hippocampal injury. These data suggest that ischemic injury to CN and LGP are necessary to induce GABA neuron loss in the SNr. Animals must survive longer than 3 days for the SNr injury to become evident. Disinhibition via transneuronal pathways may be one of several possible pathophysiologic mechanisms which would account for delayed injury distal from the site of immediate damage.

EFFECTS OF ANOXIA ON DENTATE GRANULE CELLS. M. Patil, A. DiScenna and D. Durand* Applied Neural Control Lab., Dept. of Biomedical Engineering, Case Western Reserve University, Cleveland, OH - 44106.

Dentate granule cells are considered more resistant to the effects of anoxia, and hence have not been as extensively studied as CA1 or CA3 cells (Aitken & Schiff, 1986). This work was aimed at investigating the response of granule cells to anoxia.

Intra- and extracellular recordings were obtained *in vitro*, from dentate granule cells of adult rat hippocampus, in control conditions and after exposure to 95% N_2. Anoxic response was observed within 2 min exposure to nitrogen. Extracellular recordings in anoxia showed hyperpolarization (about 10 mV) and a reduction in the amplitude of the population spike, which recovered to 40% of the initial value. Intracellular recordings showed an initial, transient hyperpolarization (3 - 4 mV in 4 of 7 cells examined) followed by a prominent depolarization (50 - 70 mV) in 21 of 23 cells. The onset of depolarization varied between 2-15 min after application of nitrogen, and rates of depolarization were also variable. Dendritic strength-duration data indicated an increase in the orthodromic firing threshold (in all 10 cells tested). This effect was reversible (wherever recovery was possible, n = 6). A simultaneous decrease in the EPSP amplitude was measured (in 10 cells: 100% in 4 cells, > 40% in 6 cells). Somatic excitability, as indicated by the response to 100 msec depolarizing current pulses, increased at the onset of depolarization in 6 of 8 cells, but was abolished during further depolarization (in all 4 cells tested). Somatic impedance decreased between 10 - 30% during anoxia. Post-anoxic hyperpolarization was also observed in 4 of 6 cells.

The roles of NMDA receptors and ATP metabolism are being investigated to understand the mechanisms underlying anoxic effects such as the large depolarization observed in the granule cells.

ALTERED DENDRITIC MORPHOLOGY IN DiI-LABELED CORTICAL NEURONS DEPRIVED OF OXYGEN AND GLUCOSE *IN VITRO*. M.C. Bateman*, M.P. Goldberg Dept. of Neurology, Washington Univ. School of Medicine, St. Louis MO 63110.

Postsynaptic dendritic swelling is a characteristic feature of acute excitotoxic injury, but such change is difficult to visualize by conventional microscopy in living tissue. Stewart et al. (Ann Neurol 1991; 30: 758) observed excitatory amino acid-induced dendritic varicosities in fixed chick spinal cord stained with the lipophilic carbocyanine tracer, dil. We used a similar method to examine acute morphologic changes in unfixed neurons exposed to hypoxic conditions.

Primary neocortical cultures at 13-15 days in vitro were labeled by incubation in buffered saline containing either crystalline dil or a dil suspension (.5-5 μg/ml in 0.2% EtOH) (Honig and Hume, J Cell Biol 1986; 103: 172). This procedure resulted in intense fluorescent label completely filling a small proportion of the cultured cells within minutes (suspension) or hours (crystals), allowing visualization of dendritic morphology with little staining in the background glial monolayer. Immediately following 45-60 min deprivation of oxygen and glucose, phase contrast microscopy showed swelling in neuronal somata. By dil fluorescence, neurites demonstrated a pattern of focal swelling, or beading, ranging from fine varicosities between dendritic spines to dilatations several times the diameter of the neurite. A similar pattern of neurite swelling was observed following 5 min exposure to 500 μM glutamate or NMDA. Some varicosities were seen following washing alone. Neurite swelling could be attenuated by inclusion of 10 μM MK-801 in the incubation medium. Although the relationship of acute dendrite swelling to long-term neuronal injury remains to be established, such rapid alterations in dendritic structure might contribute to early failure of synaptic transmission in cerebral hypoxia-ischemia.

SELECTIVE VULNERABILITY OF MOSSY FIBER TARGETS IN THE RAT HIPPOCAMPUS AFTER TRANSIENT FOREBRAIN ISCHEMIA. M. Hsu* and G. Buzsáki. Ctr. for Molec. & Behav. Neuroscience, Rutgers University, Newark, NJ 07102.

The vulnerability of different cell types in the rat hippocampus to forebrain ischemia induced by the 4-vessel occlusion method was assessed by immunocytochemistry using an antibody against the 72kDa heat shock protein (HSP72). Our results showed a robust induction of HSP72-like immunoreactivity (HSP72-LI) in the vulnerable CA1 pyramidal cells as well as hilar neurons; the ischemia-resistant cell populations--CA3 pyramids and dentate granule cells--remained unstained. Although the only hilar neurons implicated to be vulnerable to ischemia are the mossy cells and somatostatin neurons, many different hilar cell types were also stained in our preparation. The most striking finding, however, was the strong HSP72-LI in a subpopulation of interneurons in area CA3 and their counterparts in the hilus. In CA3, their cell bodies and long horizontal spiny dendrites, oriented parallel to the mossy fibers and perpendicular to the CA3 apical dendrites, were restricted to the stratum lucidum of CA3; in the hilus, the horizontal spiny cells were located in the subgranular zone. Both the horizontal spiny cells in CA3 and the hilus were present also at more posterior and ventral locations where no other cell types expressed HSP72-LI. We propose that a determining factor in the susceptibility of these neurons to ischemia is the density of mossy fiber innervation they receive. Furthermore, their early impairment after ischemia may be related to delayed neuronal death in the CA1 pyramidal cells.

662.7

QUANTITATIVE EM IMMUNOCYTOCHEMISTRY REVEALS POSTISCHEMIC CHANGES IN THE DISTRIBUTION OF NEUROACTIVE AMINO ACIDS IN THE RAT HIPPOCAMPUS. R. Torp[1], F.F. Johansen[2], N.H. Diemer[2], B. Arvin[3], B.S. Meldrum[3] and O.P. Ottersen*[1] 1;Dept. of Anatomy, University of Oslo, N-0317 Oslo, Norway. 2;Inst. of Neuropathology, University of Copenhagen, DK-2100 Denmark. 3;Inst. of Psychiatry, London, SE5 8AF,UK.

Forebrain ischemia (20min) was induced in rats by the 4VO method. Ultrathin sections through CA1 and CA3 were obtained after different survival times (0, 1, 40 and 150h of reflow) and subjected to quantitative immunogold cytochemistry using antisera raised against glutamate, glutamine, GABA and homocysteic acid. The main observations were: 1; The concentration of glutamate in pyramidal cell bodies and dendrites are substantially reduced during ischemia (probably reflecting a loss to the extracellular space) but in surviving cells it returns to normal after 40h of reflow. Excitatory-type terminals showed only a minor decrease in the level of glutamate. 2; The glutamate/glutamine ratio in astrocytes was strongly increased at 0h (reflecting a metabolic block) but returned to pre-ischemic values after 1h. 3; The level of GABA in interneurons was elevated at 0 and 1h. 4; A homocysteic acid-like substance appeared in astrocyte processes in CA3 at 40h and in CA1 at 150h. The possibility that the latter change is related to the development of delayed neuronal death is currently under investigation.

EFFECTS OF O_2 AND GLUCOSE DEPRIVATION ON HUMAN AND RAT NEOCORTICAL NEURONS IN-VITRO. C. Jiang* & G. G. Haddad, Section of Respiratory Medicine, Dept. Pediatrics, Yale University School of Medicine, New Haven, CT 06510

The neocortex is extemely sensitive to O_2 and glucose deprivation. Such stress causes rapid loss of cortico-encephalographic activity and unconsciousness. To study the underlying mechanisms for the loss of neuronal electrical activity during O_2 and glucose deprivation, intracellular recordings were performed on neocortical neurons in humans and rats using in-vitro brain slices. Intracellular labelling and electrophysiological characterization showed that most neurons (layers 4 and 5) were pyramidal cells with a regular-spiking or a burst firing pattern. Anoxia induced a depolarization that was apparent mostly after 7 min in rats and 10 min in humans following a transient hyperpolarization (2-5 mV, 1-3 min). Rheobase markedly increased and spontaneous EPSPs were suppressed during anoxia, while membrane resistance (Rm) was only modestly (22%) reduced. Total deprivation of glucose depolarized neocortical neurons by 28±14 mV after 1-2 hours, while combined deprivation of both glucose and O_2 resulted in a major depolarization (mean≈50 mV) within 5-10 min in both human and rat neurons. Extracellular K^+ activity (K^+_o) increased by 1-2 mM during anoxia (20 min) or glucose deprivation (30 min), but deprivation of both O_2 and glucose elevated K^+_o by about 25 mM. We conclude that 1) rat neocortical neurons seem to be inherently more resistant to anoxia than brainstem neurons; 2) membrane excitability of neocortical neurons is markedly reduced during anoxia and this is not due only to a decrease in Rm; and 3) anaerobic glucose metabolism in the human neocortex is important for neuronal survival during anoxia.

662.9

INVOLVEMENT OF THE NMDA RECEPTOR IN ANOXIA-AGLYCEMIA INDUCED DAMAGE IN THE HIPPOCAMPUS. S. Papas*, V. Crépel and Y. Ben-Ari, INSERM Unit 29, 123 Bd. de Port-Royal, Paris, 75014, France.

Although there is increasing evidence that the N-methyl-D-aspartate (NMDA) receptor is involved in the induction of anoxic/ischemic injury, its exact role is unclear. For example, protective effects of NMDA antagonists have been found to vary with the ischemic model used. We have used two protocols to examine the involvement of the NMDA receptor in the inhibition of synaptic transmission induced by anoxia and aglycemia (AA) in CA1 of the hippocampal slice.

In initial studies, the protective effects of a non-competitive NMDA antagonist, MK-801, against AA induced damage was examined. Inhibition and recupertion of synaptic transmission was determined by the disappearance and percent recovery of the CA1 field EPSP in the 30 min period after AA insult. Rat hippocampal slices incubated in MK-801 (0.1 μM, 1 μM, or 10 μM) for 15 min prior to various periods (3 min to 4 min 30 s) of AA (95%N_2/5%CO_2, glucose replaced with sucrose) showed greater percent recovery of EPSP amplitude than did control slices incubated in Krebs. Slices treated with 0.1 μM MK-801 had greater EPSP recuperation following 3 min 30 s AA (29 ± 13% vs 10 ± 10% in controls, $p<0.05$). Larger concentrations of MK-801 showed protective effects in more than one time period of AA. In a second investigation, NMDA currents were enhanced during AA by incubating slices in Mg^{++} free Krebs. Slices subjected to AA in the absence of Mg^{++} showed a smaller percent recovery of EPSP amplitude following 2 min (34 ± 15% vs 81 ± 11% in controls, $p<0.05$) and 2 min 30 s (25.5 ± 14% vs 77 ± 10% in controls, $p<0.005$) of AA. Thus, the NMDA receptor appears to play a role in the inhibition of synaptic transmission induced by anoxia and aglycemia in the hippocampal slice.

662.10

HYPOXIA OR GLUCOSE DEPRIVATION ACTIVATES TWO SEPARATE KAINATE RECEPTOR SUBTYPES IN HIPPOCAMPAL SLICES. B.M. Rigor*, C.A. West, and A. Schurr. Dept. of Anesthesiology, Univ. of Louisville Sch. of Med., Louisville KY, 40292.

The exposure of rat hippocampal slices to conditions that are known to reduce energy supplies (hypoxia or glucose deprivation, GD), make them hypersensitive to the excitotoxins glutamate and N-methyl-D-aspartate (NMDA). Thus, slices deprived of either oxygen or glucose show an increase in the degree of neuronal damage (as measured electrophysiologically) if they are concomitantly exposed to low concentrations of NMDA. This increased neuronal damage could be abolished by supplying slices either with antagonists such as 2-amino-5-phosphonovalerate (APV) or 7-chlorokynurenate, or by perfusion with high [Mg^{2+}] or low [Ca^{2+}].

Here we studied the effects of hypoxia or GD combined with exposure to kainate (KA) on the degree of hippocampal neuronal damage. KA was 3-5 times more potent than NMDA in enhancing either hypoxic- or GD-induced neuronal damage in hippocampal slices. The KA-enhanced hypoxic neuronal damage could be attenuated by APV, kynurenate, elevated [Mg^{2+}] or depletion of Ca^2. The KA-enhanced GD neuronal damage was unaffected by APV or high [Mg^{2+}] but completely abolished by Ca^{2+} depletion.

These results indicate that KA receptor channels gate Ca^{2+} in addition to Na^+. Moreover, the results strongly suggest the existence of two distinct KA-receptor subtypes which are differentially activated by hypoxia or GD.

662.11

QUINOLINATE: A MODULATOR OF GLUTAMATE RECEPTORS' AGONISTIC ACTIVATION IN HYPOXIC RAT HIPPOCAMPAL SLICES. A. Schurr*, C.A. West, and B.M. Rigor. Dept. of Anesthesiology, Univ. of Louisville School of Medicine, Louisville KY, 40292.

Excitatory amino acids (EAAs) in the central nervous system are involved both in neurotransmission and excitotoxicity. Quinolinic acid (QUIN) is an endogenous tryptophan metabolite and an excitotoxin, and has been shown to cause Huntington's disease-like striatal lesions. The hypoxic rat hippocampal slice preparation and its electrophysiology were employed to study QUIN's modulatory role in the activation of the N-methyl-D-aspartate (NMDA) and kainate (KA) subtypes of the glutamate (GLU)-receptor. The degree of neuronal damage in this preparation was used to measure the excitotoxic potency of several GLU ligands.

When given at sub-toxic doses, QUIN potentiated the excitotoxicity of GLU, NMDA, and KA in hypoxic hippocampal slices. While the NMDA competitive antagonist DL-2-amino-5-phosphonovalerate (APV) blocked the QUIN-potentiated NMDA toxicity, 7-chlorokynurenate (7-Cl-KYN), a competitive antagonist of the NMDA-receptor glycine modulatory site, did not. The non-toxic analogue of QUIN, 6-methyl-QUIN, potentiated NMDA toxicity as effectively as QUIN itself. We concluded that QUIN has a specific modulatory binding site on both the NMDA and the KA receptor complexes, different from the glycine modulatory site on the NMDA receptor. We postulate that QUIN can increase both the excitatory and the excitotoxic efficacy of EAAs by potentiating the agonistic activation of GLU receptors.

GLUTAMATE ANTAGONISTS REDUCE DELAYED NEURONAL DAMAGE AFTER TRANSIENT ISCHEMIA IN THE ORGANOTYPIC CULTURE OF RAT HIPPOCAMPUS. C. Shin*, J. Wilson and Y. Tamaki, Epilepsy Research Laboratory, Duke and VA Med. Ctrs., Durham, N.C. 27705.

Organotypic cultures of rat hippocampus could prove useful as an *in vitro* model of ischemia since the cytoarchitecture and intrinsic synaptic connectivity are preserved. We used hypoxia-hypoglycemia to simulate ischemia and tested the effectiveness of the glutamate antagonists in reducing the delayed ischemic damage in the pyramidal neurons of the organotypic culture.

Cultures were exposed to 2-deoxyglucose substituted HBSS equilibrated with 95% N_2-5% CO_2 atmosphere. D-APV and CNQX were applied, singly and combined, either during and after or only after the ischemic period. Neuronal injury was assessed 24 hours later by assigning a severity index (0=none, 4=severe) to propidium iodide fluorescence, which predicts later histology.

With 30 minutes of ischemia, CA1 selective neuronal injury was obtained (CA1, 2.2 v. CA3, 0.7; n=6, $p < 0.03$). Both D-APV (100 μM, n=8) and CNQX (100 μM, n=8), applied during and after the ischemic period reduced the neuronal injury index in CA1 to 0.1 ($p < 0.005$) and to 0.0 in CA3 ($p < 0.05$, Mann-Whitney U). With 45 minutes of ischemia, more extensive injury was produced, but again with more severe involvement of CA1. D-APV, but not CNQX, showed protective effect. Concomitant application of D-APV and CNQX produced an effect similar to D-APV alone. Drugs applied only after the 45 minute ischemia afforded no significant protection.

These results show that CA1 selective neuronal injury is seen after transient ischemia in the organotypic cultures and that both NMDA and AMPA receptor mediated mechanisms contribute to the process. The organotypic culture could provide a very useful model to dissect out the mechanisms underlying the delayed neuronal damage induced by transient ischemia.

662.13

ASSESSMENT OF ISCHEMIC DAMAGE TO ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS USING PROPIDIUM IODIDE FLOURESCENCE DW Newell, S Hsu, ATMalouf*, VM Papermaster, IE Franck Department of Neurological Surgery, University of Washington School of Medicine, Seattle, WA 98195

The objective of this study was to determine if the time course of selective damage to the hippocampus by ischemia could be assessed using propidium iodide staining as an index of membrane integrity. Organotypic cultures were prepared from rat pups (4-6 days old) and grown on glass cover slips in roller tubes for 2 weeks. Cultures were then placed in balanced salt solution with no glucose in an anerobic chamber for 30 minutes (artificial ischemia). Control cultures were placed in balanced salt solution containing glucose for an equivalent time period. Both groups were maintained in the presence of propidium iodide dye and periodically examined using an inverted flourescent microscope and images were digitized and analyzed using Optimus software. Immediately following artificial ischemia all exposed cultures showed marked swelling of the entire pyramid cell layer and dentate compared to controls. There was an increase in the delayed appearance of flourescence in the pyramidal cells in CA1, which was significantly different from controls at 18 hours following ischemia. Selective vulnerability to ischemia in the hippocampal subfields was also observed in the following order CA1>CA3>Dentate. In conclusion the organotypic cell culture model offers new insights into the time course and selectivity of ischemic cell damage in the hippocampus.

662.14

The development of agonist-specific regional vulnerability in organotypic hippocampal culture accounts for sensitivity to in vitro ischemia and hypoglycemia. R. C. Tasker* and J. J. Vornov, Dept Anesthesiology, and Neurology, The Johns Hopkins School of Medicine, Baltimore, MD 21205

We have described models of hypoglycemia and ischemia in organotypic hippocampal culture which preserve the characteristic regional vulnerability observed in animal models. Hypoglycemia is achieved by incubation with 2-deoxyglucose to block glycolysis. Potassium cyanide is added to also block oxidative phosphorylation to model ischemia. The distribution of injury is distinct in each case. NMDA receptor antagonists are protective in both, even if added 30 minutes after the end of the insult. We now report distinct patterns of agonist-specific injury during *in vitro* development of cultures.

Hippocampal slice cultures were prepared from 7 day-old rat pups and examined after 2, 5, or 12 days in vitro. Propidium iodide was used to directly observe membrane injury in the living cultures. At 24 hours, cultures were examined histologically. NMDA (3, 10, 100 μM, 30 min exposure) in 2 and 5-day-old cultures caused injury either localized to CA1 alone or to CA1 and CA3. Severity of histologic damage was greater with increasing age of the culture. Glutamate (1 mM, 30 min) caused injury in CA1 and CA3 in 2 day, but not 5 day-old cultures. Hypoglycemic injury had the same pattern of development as NMDA toxicity, while vulnerability to ischemia paralleled vulnerability to glutamate. These developmental patterns suggest enhanced postnatal sensitivity to glutamate neurotoxicity, distinct from direct NMDA receptor-mediated injury.

ISCHEMIA: GLIA

663.1

GLIAL AND NEURONAL CHANGES IN THE HIPPOCAMPUS FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA IN THE RAT. W.R.Woodward*, C.J.Pepin, D.D.Copeland, N.Lessov, C.K.Meshul, T.E.Williams, F.P.Eckenstein. Depts. of Neurology, Pharmacology, and Cell Biology and Anatomy, Oregon Health Sciences Univ. and VA Medical Ctr., Portland, OR 97201

The Siesjõ 2-vessel occlusion model of global forebrain ischemia in rat was used to investigate the time course of changes in specific populations of hippocampal glial cells and neurons following ischemic injury. Astrocytes and microglial cells were immunostained with an anti-basic fibroblast growth factor (bFGF) monoclonal antibody and the OX42 monoclonal antibody respectively, while two subpopulations of pyramidal neurons were stained with monoclonal antibodies to the calcium binding proteins, calbindin and parvalbumin. In the 7 days following ischemia, there is a significant increase in the number of bFGF-staining astrocytes in CA1 as well as in the intensity of bFGF-staining in astrocytic nuclei. Concurrently, there is a substantial rise in glial fibrillary acidic protein (GFAP)-immunoreactivity. Changes in bFGF following ischemia are consistent with a role in promoting astrocyte proliferation and in regulating gene control of astrocyte function. In addition the microglial marker, OX42, shows a large elevation that is restricted to CA1 and the hilus of the dentate, areas of hippocampus which are most vulnerable to ischemic injury. The increase in OX42 staining reveals the importance of microglia in resolving the damage to hippocampus following injury. In contrast to the glial proliferation, there is a greater than 90% loss of viable neurons in CA1. In the 7 days following ischemia, the subpopulation of CA1 neurons immunoreactive for calbindin were completely eliminated, whereas the parvalbumin-staining neurons were spared, consistent with a possible protective role for parvalbumin but not calbindin in these neurons. Supported by NIH Grant NS17493, the Oregon Heart Association and the Veterans Administration.

663.2

ASTROGLIAL AND MICROGLIAL REACTIONS IN EARLY STAGES OF ISCHEMIA. C.A. Pardo[1]*, L. Monsein[2], V. Mathews[2], P. Barker[2] and R.N Bryan[2]. Neuropathology Lab[1]. and Neuroradiology Div.[2] The Johns Hopkins University School of Medicine, Balto., MD 21205.

The development of astroglial and microglial reactions and macrophage migration were studied in models of regional ischemia in baboon models, including: complete ischemia (CI) by irreversible occlusion of the middle cerebral artery (MCA); and incomplete ischemia (IIR) by reversible occlusion of MCA followed by reperfusion. GFAP and vimentin as well as macrophage/microglial markers (e.g., HLA-DR, CD68, LN4, and ED2) were used to study cell response following ischemia. In both models, early astroglial and microglial activation and macrophage migration were observed in the perinecrotic region as early as six hours postischemia but were most prominent in IIR. Astrocytes showed hyperplastic reactions and extension of glial processes and, in cortical ischemic regions, astrocytes issued long processes resembling radial fibers. These findings suggest that glial cells have an important role during early stages of ischemia.

663.3

CLUSTERING OF LIVE AND DEAD ASTROCYTES IN CULTURE: MODULATORY ROLE OF GAP JUNCTIONS. Robert S. Goldman*. Department of Neurology, Medical College of Wisconsin, Milwaukee, WI 53226.

Iodoacetic acid (IAA), which interferes with anaerobic metabolism, killed rat hippocampal astrocytes in culture in a dose dependent manner. With intermediate doses of IAA cell death was consistantly observed to occur in a distinctly non random spatial distribution; the dead cells formed clusters. Using a two color fluorescence assay, and video microscopy, the spatial distribution of live and dead cells was studied over an area of 5x5 mm. Using a modification of nearest neighbor analysis the extent of clustering was quantified. The clustering effect was robust; the probability of cell death was higher than would be expected based on a random spatial distribution up to hundreds of cells away from a dead cell; and was higher than expected up to hundreds of microns from a dead cell. Although the live and dead cells could represent two subpopulations, the astrocytes stained uniformly GFAP positive and A2B5 negative, suggesting that they represent a single population. Exposure to IAA in the presence of the gap junction blocker octanol (500uM) significantly reduced, though did not entirely eliminate, the clustering. This evidence suggests that the non random spatial distribution of cell death is due, in part, to diffusion of a toxic molecule(s) through gap junctions. Previous studies have indicated that IAA-induced astrocyte death is related to elevation of intracellular calcium, raising the possibility that the toxic molecule may be either calcium itself or inositol trisphosphate.

663.4

APPEARANCES OF PHAGOCYTIC CELLS AND REACTIVE ASTROCYTES IN THE CA1 AREA OF GERBIL HIPPOCAMUS FOLLOWING ISCHEMIA. Y. Uchiyama1, T. Nitatori1, Y. Karasawa2, H. Araki2*, and E. Kominami3. Dept. of Anat.1, Sch. of Med., Iwate Med. Univ., Iwate, 020 Japan, Lab. of Pharmacol.2, Taisho Pharmaceutical Co., Saitama, Japan, and Dept. of Biochem.3, Juntendo Univ. Sch. of Med., Tokyo, Japan

We examined by immunohistochemistry behaviors of glial cells in the CA1 area of gerbil hippocampus after brief ischemia. Three days after the ischemic operation immunodeposits for cathepsin H (CH), a lysosomal cysteine proteinase and cystatin ß (Cß), its endogenous inhibitor appeared in small cells located in the CA1 molecular layer. At 7 days strongly immunopositive cells for CH and Cß occupied the CA1 pyramidal layer. By electron microscopy, numerous microglia-like cells having debris of pyramidal neurons were seen in the CA1 pyramidal layer at 7 days, suggesting that CH- and Cß-immunopositive cells are microglia-like cells. To determine the origin of the microglia-like cells in the pyramidal layer, fluorescent latex particles were injected from the femoral vein of gerbil 7 days after the ischemic operation. Two days after the injection, cells showing fluorescence of latex particles appeared in the CA1 pyramidal layer and the same cells were confirmed to demonstrate immunoreactivity for CH or Cß. The results suggests that CH and Cß are excellent markers for microglia-like cells in the central nervous tissue, which originate from peripheral blood monocytes. At 14 days both GFAP and vimentin immunopositive astrocytes and their processes occupied the CA1 pyramidal layer.

INVOLVEMENT OF SODIUM CHANNELS IN ANOXIC INJURY IN MAMMALIAN CENTRAL NERVOUS SYSTEM WHITE MATTER: ULTRASTRUCTURAL CORRELATES J.A. Black*, P.K. Stys, B.R. Ransom, and S.G. Waxman. Dept of Neurology, Yale Univ Sch of Med, New Haven, CT and Neuroscience Research Center, VA Med Ctr, West Haven, CT 06516

The *in vitro* rat optic nerve has provided a reliable, quantitative model of white matter anoxic injury. Previous studies have correlated optic nerve dysfunction following anoxia with ultrastructural changes in the nerves,which include mitochondrial swelling, cytoskeletal dissolution, and the appearance of empty spaces adjacent to axons within the myelin. Electrophysiological evidence suggests that anoxia results in a cascade of events leading to reverse operation of the Na^+-Ca^{2+} exchanger, and subsequent entry of calcium into the axons (Stys et al. 1992).

Optic nerves were maintained in Ringers containing 1 μM tetrodotoxin (TTX) during anoxia (60 min). At the end of the anoxic period, the nerves maintained in TTX-Ringers were ultrastructurally similar to control optic nerves maintained in oxygenated, normal Ringers for an equivalent length of time. These experimental nerves exhibited slight swelling of some mitochondria, but neurofilaments, microtubules, and paranodal loops maintained their integrity. Empty spaces between the myelin sheath and axon were not apparent in the nerves maintained during anoxia in TTX-Ringers. At rare nodes, accumulations of membranous profiles were observed in the nodal axoplasm. Reoxygenation in normal Ringers did not substantially change the ultrastructure of the experimental nerves. These observations provide morphological evidence for the involvement of sodium channels in anoxic injury in white matter and, together with our previous work, support the idea that anoxic injury involves sodium influx that leads to reverse operation of the Na^+/Ca^{2+} exchanger. [Supported in part by VA and NIH]

663.6

EFFECTS OF EXTRACELLULAR CALCIUM ON ULTRASTRUCTURE IN ANOXIC INJURY IN MAMMALIAN CENTRAL WHITE MATTER. S.G. Waxman*, J.A. Black, B.R. Ransom and P.K. Stys, Dept. of Neurology, Yale Univ. Sch. of Med., New Haven, CT 06510 and Neuroscience Research Center, VA Med. Ctr., West Haven, CT 06516

We have developed a reproducible, quantitative model of anoxic white matter injury using the rat optic nerve *in vitro*. Optic nerve function rapidly fails when the nerve is exposed to anoxia. Ultrastructural changes in anoxic optic nerves include large, distended myelin sheaths associated with vacuoles adjacent to the axon, mitochondrial swelling, loss of microtubules, and detachment of terminal paranodal oligodendroglial loops. Reoxygenation of the nerve is associated with partial recovery of function and restoration of nodal integrity and disappearance of internodal vacuoles.

Loss of optic nerve function, as measured by the area under the compound action potential (CAP), is dependent upon the molar concentration of extracellular calcium ($[Ca^{2+}]_o$). Optic nerves maintained in Ca^{2+}-free Ringers throughout the anoxia period (60 min) regain 100% of the compound action potential following 60 min in normal, oxygenated Ringers. Ultrastructurally, optic nerves in Ca^{2+}-free Ringers at the end of the anoxia period show few pathological changes. While mitochondria were generally swollen and disrupted, microtubules were intact and few internodal vacuoles were present. Paranodal loops generally maintained their integrity, though paranodal detachment was occasionally observed in some larger axons. Following 60 minutes of reoxygenation in normal Ringers, the nerves subjected to anoxia in Ca^{2+}-free Ringers exhibited similar ultrastructure to control nerves. These observations support the idea that, during anoxia, myelinated fibers are damaged by an influx of calcium. [Supported in part by the VA and NIH]

ISCHEMIA: TEMPERATURE EFFECT

664.1

BRAIN VERSUS BODY TEMPERATURES IN BLOODLESS PROFOUNDLY HYPOTHERMIC DOGS. M.L. Leavitt*, J. Bailes, E. Teeple, A. Elrifai, M. Taylor, T. Shih, J.C. Maroon, K. Ciongoli, C. Devenyi and B. Bazmi. Allegheny General Hospital, Pittsburgh, PA 15212 and Cryomedical Sciences, Inc., Rockville, MD 20850.

The purpose of this study was to compare temps. measured from the brain (B), esophagus (E) and subcutaneous tissues of the back (SQ) in profoundly hypothermic dogs (N=14) to better understand the appropriate level of hypothermia needed for cerebral protection. Flether-anesthetized dogs were cooled externally to E=24.3°C (B=18.1°, SQ=11.3°) at which time bleeding was started. Following total exsanguination, internal cooling was achieved by continuous circulation of a cold oxygenated solution (Cryomedical Sciences, Inc.) for 3 hr. at E<10°C. Rewarming and return of the blood were next performed. Prior to blood substitution, E=30°, B=22.8° and SQ=12.6°C. Temperatures recorded from the 3 sites were not significantly different from each other during asanguineous perfusion. Throughout the first 46 min. of rewarming, E was greater than B and SQ; B was consistently closer to SQ than to E. The maximal disparities between E to B and E to SQ were 9.8°C (p<.001) and 8.0°C (p<.001) respectively at 18 min. of rewarming at which time the SQ to B disparity was only 1.7°C. There were no significant differences between the 3 sites upon rewarming to 33.2°. Thus, significant differences were noted between E vs B and SQ during rewarming when there was similarity between B and SQ. These data suggest that SQ temp. may be a better index of B temp than core (E) temp. during rewarming and the risk caused by direct brain monitoring could be avoided by use of a SQ probe.

664.2

SERUM LEVELS OF CREATINE KINASE (CK) IN HYPOTHERMIA AND COMPLETE BLOOD SUBSTITUTION. A.Elrifai, J.Bailes, E.Teeple, M.Leavitt, S.Shih, M.Taylor and J.Maroon*. Allegheny-Singer Research Inst., Allegheny General Hospital & Cryomedical Sciences, Inc., Pittsburgh, PA 15212.

Recent studies have shown that creatine kinase (CK) & its brain fraction (CK-BB) activity in CSF is a good prognosticator of cerebral damage after an insult & also post profound hypothermia. To evaluate a less invasive course in a dog model to study the effect of profound hypothermia with blood substitution (J Neurosurg 74:781-788, 1991), serum CK & CK-BB were determined at 1, 2 & 3 days post-op. Neurologic Deficit Scores (NDS: 0= normal, 1= minimal abnormality, 2= weakness, 3= paralysis, 4= coma, 5= Death) were determined for 19 animals, of whom 13 survived long term & 6 died at 1-3 days post-op. Animals were grouped based on the NDS score. Maximum serum CK & CK-BB occurred at the first day post-op.

n= ( )	NDS	Day 1	Day 2	Day 3
CK-BB	=0	102± 41(6)	40± 14(5)	27± 5(6)
IU/L	≥1	136± 30(7)	121± 72(3)	57± 31(5)
P		N.S.	N.S.	N.S.
CK	=0	2.0± 1.8(6)	1.6± 1.5(5)	0.5± 0.5(6)
IU/L(10^4)	≥1	13.1± 7.1(13)	11.9± 6.4(8)	3.2± 1.2(7)
P		N.S.	0.03	0.01

Serum CK & CK-BB value may prove to provide a predictive scheme for neurological outcome however its reliability needs to be tested in a larger series.

664.3

HYPOTHERMIC PROTECTION AGAINST ISCHEMIC INSULT: ASSESSMENT USING HISTOLOGICAL, BEHAVIORAL AND ELECTROPHYSIOLOGICAL MEASURES. S.M. Nurse*, R.S. Neuman and D. Corbett. Division of Basic Medical Sciences, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, Canada, A1B 3V6.

A 5 min period of global ischemia produces extensive cell loss in certain brain regions, such as the CA1 subfield of the hippocampus. We investigated the ability of mild brain hypothermia [induced at the initiation of a 5 min carotid artery occlusion and terminated upon reperfusion] to prevent histological, behavioral and electrophysiological changes associated with ischemia.

This short interval of intraischemic hypothermia provided dramatic protection of CA1 neurons. Behavioral deficits, such as increased exploratory activity in an open field maze, were attenuated by the hypothermic treatment. Finally, periods of forebrain ischemia normally result in an extensive reduction of the extracellular field potential recorded in stratum radiatum. Hypothermic intervention prevented this decline in the fEPSP. Preservation of hippocampal function, as assessed by field potentials recorded in CA1, directly parallels the degree of behavioral and histological protection.

664.4

TEMPERATURE CHANGES ASSOCIATED WITH FOREBRAIN ISCHEMIA IN THE GERBIL. F. Colbourne *, S. M. Nurse and D. Corbett, Fac. Med., Memorial University of Newfoundland, St. John's, NF, Canada A1B 3V6.

Mild hypo- or hyperthermia, especially during occlusion, can markedly affect ischemic outcome. We have systematically examined brain, skull and rectal temperatures in gerbils (n=10) subjected to 5 min of bilateral carotid artery occlusion. During surgery skull and body temperatures were maintained with heating blankets. Brain, skull and rectal temperatures were monitored during ischemia and brain temperature was recorded for 3 h into the postischemic period. Intraischemic brain temperature fell by ~ 1.5°C even though skull and rectal temperatures remained at 37°C. Since skull and brain temperature can become dissociated after brief periods of anesthesia, we examined the relationship between skull and brain temperature during extended anesthesia. An 85 min period of postischemic halothane anesthesia did not reduce CA1 cell loss (Kuroiwa et al. 1990) if brain and skull temperatures were maintained at 37°C. In cases when brain temperature fell below skull temperature CA1 cell loss was attenuated. Skull temperature does not reliably reflect brain temperature during periods of prolonged anesthesia.

664.5

THERMAL SENSITIVITY OF HYPOXIC RESPONSES IN NEOCORTICAL BRAIN SLICES. K. Hiramatsu, N.F. Kassell *, K.S. Lee. Dept. of Neurosurgery, University of Virginia, Charlottesville, VA22908.

Electrophysiological responses to transient hypoxia were studied in neocortical brain slices from adult gerbils. Evoked responses and DC potentials were recorded in layer III of the frontoparietal cortex under normoxic and hypoxic conditions. The excitatory synaptic component of the evoked wave form was identified by its sensitivity to calcium and DNQX (6,7-dichloroquinoxaline-2,3-dione). Under normoxic conditions, excitatory synaptic responses were reduced in a temperature-dependent manner. At lower temperatures, the delays to synaptic loss and hypoxic depolarization were prolonged significantly. Synaptic recovery from a fixed period of hypoxia was enhanced greatly when transient hypoxia was administered at reduced temperature. These findings demonstrate that glutamatergic synaptic transmission is reduced under hypothermic conditions, but that these responses are sustained for a longer period of time during hypoxia. The data also demonstrate directly that hypothermia protects against hypoxic damage to excitatory synaptic mechanisms in the cortex.

664.6

DELAYED HYPOTHERMIA DOES NOT CONTRIBUTE TO NEUROPROTECTION IN GERBILS. C.A. Hoffman and C.A. Boast* Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

It has repeatedly been shown that hypothermia following ischemia can provide neuroprotection; therefore, the interpretation of the neuroprotective effect of many drugs is confounded by drug-induced hypothermia. One technique to eliminate this problem has been to maintain animals at a normothermic temperature for 8 hours after the ischemic episode. The present experiments were conducted to determine whether a shorter duration of temperature maintenance was sufficient to eliminate this confound. Female gerbils were placed on a heating pad and subjected to a 5 minute bilateral carotid occlusion under halothane anesthesia. Immediately after surgery a rectal probe was inserted, the gerbil was restrained in a refrigerator and the probe was connected to a temperature maintenance system (YSI controlling indicator with attached heat lamp and fan). Temperature was either maintained at 32°C for the entire 6 hour period, or at 36.5°C for 2 hours, followed by reduction to 32°C for 4 hours. Brains were harvested four days later and hippocampal damage was rated on a 0-4 scale. Six hours of hypothermia (32°C) produced significant neuroprotection, reducing the median brain damage rating to 2, while delaying the onset of hypothermia for two hours produced no neuroprotection (a brain damage rating of 3). From these data we conclude that hypothermia beginning two hours post occlusion does not provide neuroprotection, allowing for: 1) a shorter period of temperature maintenance when drugs are administered within the first 2 hours after ischemia; and 2) no temperature maintenance requirement for compounds administered after this two hour period.

664.7

MILD HYPOTHERMIA : EFFECT ON INFARCT SIZE AND BRAIN NITRIC OXIDE PRODUCTION IN FOCAL ISCHEMIA. Abraham Kader,Rosario R. Trifiletti,Robert A. Solomon and Robert R.Goodman *. Departments of Neurology and Neurosurgery, The Neurological Institute of New York, Columbia University College of Physicians and Surgeons. New York, NY 10032.

The effect of mild hypothermia on cerebral injury was evaluated in a rat model of permanent (R) middle cerebral artery (MCA) occlusion. The MCA occlusion was performed in rats at temporalis muscle temperatures of 33°C or 36.5°C.Twenty-four hours after MCA occlusion, rats were sacrificed and the percent infarcted (R) hemisphere determined in brain sections with 2,3,5-triphenyltetrazolium chloride (TTC). We found a percent infarcted volume of 8.2 ± 2.2% (n=8) in the 33°C group as compared to 19.6 ± 1.6 % (n=13) in the 36.5°C group, indicating significant reduction in infarct size by mild hypothermia (P<0.01).

To begin to explore factors accounting for hypothermic neuroprotection, we determined markers of nitric oxide production (NO2- and cGMP) after 10 minutes of ischemia at 33°C or 36.5°C. We found an increase (ipsi- vs. contralateral MCA cortex) in brain nitrite of 136 ± 102% (n=7) in the 36.5°C group as compared to -8 ± 21% (n=5) in the 33°C group (P< 0.05). cGMP was increased (in ipsi- vs. contralateral MCA cortex) by 51 ± 21% (n=7) in the 36.5°C group as compared to 17 ± 18 % (n=6) in the 33°C group.(P<0.05). No significant differences in nitrite or cGMP were found in ipsi- or contralateral cerebellum, which is not rendered ischemic in this model. These data suggest that the mechanism of hypothermic neuroprotection may be due in part to decreased production of nitric oxide in ischemic brain.

664.8

INFLUENCE OF THERAPEUTIC HYPOTHERMIA ON THE RELEASE AND UPTAKE OF EXCITATORY AMINO ACIDS. A.M. Palmer*, P.J. Robichaud and L. Coppula. Departments of Psychiatry and Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15213.

Large increases in the extracellular concentrations of excitatory amino acids (EAAs) and a large depletion of the energy charge are considered to play a major role in mediating the secondary brain injury that occurs following cerebral ischemia. Modest decrements in brain temperature (to 30-36°C) during ischemia substantially attenuate neuronal damage in vulnerable brain regions and improve neurologic outcome (*J Cereb Blood Flow Metab* 7: 729-138; 10: 57-70). This study aims to elucidate the mechanism by which moderate hypothermia prevents the excitotoxic rise in extracellular EAA concentration that occurs during cerebral ischemia (*Stroke* 20: 904-910). The superfused efflux of preaccumulated D-[^{3}H]aspartate was determined in minislices of rat cerebral cortex (flow: 1.6 ml/min; collection time: 0.5 min) and uptake of D-[^{3}H]aspartate determined in cerebrocortical homogenates. The energy charge of these preparations was depleted by applying cyanide, an inhibitor of electron transport. The superfused efflux of preaccumulated D-[^{3}H]aspartate and the Na^+-dependent uptake of D-[^{3}H]aspartate was determined at both normothermic (37°C) and hypothermic (32°C) temperatures. Cyanide (10 μM - 10 mM) increased the efflux of D-[^{3}H]aspartate evoked by 50 mM K^+ and inhibited D-[^{3}H]aspartate uptake in a dose-dependent fashion. However, neither of these changes was influenced by hypothermia. In contrast, cyanide-induced increase in the basal efflux of D-[^{3}H]aspartate was attenuated (by 60-66%) by reducing the incubation temperature from 37° C to 32°C. Thus, therapeutic hypothermia does not influence the release and uptake of EAAs but rather attenuates cyanide-induced efflux of EAAs by another mechanism, probably by militating against cell lysis. (This work was supported by NINDS Grant 1P20NS30318-01).

664.9

TEMPERATURE - DEPENDENT CYCLOHEXIMIDE PROTECTION OF HIPPOCAMPAL ISCHEMIC DAMAGE. G.D. Miller* and J.N. Davis, VA Neurology Laboratory and Duke Univ., Durham, NC.

Neurons in the CA_1 region of the hippocampus undergo delayed neuronal death after brief periods of ischemia. Recent reports suggested that inhibition of protein synthesis with either cycloheximide (CHX) or anisomycin (ANISO) protected these neurons from ischemia. However many variables including temperature, serum glucose and plasma glucocorticoids can influence CA_1 neuronal damage and could be affected by CHX or ANISO administration. We studied 4 groups of gerbils all exposed to 5 minutes of bilateral carotid occlusion and then were sacrificed 5 days later. One group received ANISO (50 mg/kg starting 1 hr. before ischemia, n=8), another, CHX (2.5mg/kg, n=6), a third received sham injections (n=13) while the fourth received CHX (n=5) and was kept in a warm environment. Plasma glucose and cortisol levels did not differ amongst the groups. Similarly pre-ischemic and ischemic temperatures were the same. By contrast the post-ischemic temperatures were depressed in the animals treated with CHX and ANISO kept at room temperature. The animals receiving CHX and kept in a warm environment had post-ischemic temperatures comparable to sham injected animals. The ANISO and CHX treated animals with post-ischemic hypothermia had significant protection of CA_1 neurons compared to sham injected animals. However the CHX injected animals kept in a warm environment did not show protection. We conclude that the reported effect of CHX and ANISO administration on CA_1 neuronal damage may be mediated by post-ischemic hypothermia induced by the protein synthesis inhibitors. MILD HYPOTHERMIA HAS EFFECTS ON CORTICAL AMINO ACID EFFLUX BUT DOES NOT PROTECT AGAINST PERMANENT FOCAL ISCHEMIA. E.H.Lo*, R.Newcomb, N.Panahian, N.Maidment, G.K.Steinberg. Center for Imaging and Pharmaceutical Research, Harvard Medical School, Boston MA 02129; Neurex Coorporation, Palo Alto; and Department of Neurosurgery, Stanford University, Stanford, CA 94305.

The effect of hypothermia on relationships between the spatial distribution of damage and alterations in neurotransmitter levels may be dependent on the severity of the ischemic insult. In this study, we examined the effects of mild brain hypothermia (33C, n=7) versus normothermia (37.5C, n=7) in a rabbit model of permanent focal ischemia (4 hr occlusion of left anterior, middle cerebral, and internal carotid arteries). In vivo microdialysis was used to measure brain extracellular environments in anterior ventrolateral and dorsal cortex of the ischemic hemisphere. These locations were defined in previous studies to correspond with regions of dense and boundary zone ischemia respectively. Glutamate was significantly increased by about 1 hr after the onset of ischemia (p<0.05). Alanine, GABA and taurine levels were also changed. Phospho-ethanolamine was increased after about 1 hr. In general, absolute concentrations of amino acids were lower in the hypothermic animals. Lowered temperature appeared to eliminate glutamate efflux in the ventrolateral probes. However, there was significant variability in glutamate efflux between animals; some animals with little or no efflux still demonstrated significant histological damage. Hematoxylin eosin stains revealed no hypothermic neuroprotection in the cortex or striatum. The lack of protection may correspond with the sustained release of glutamate in the dorsal cortex . The reason for decreased efflux of glutamate in the dense ischemic region of the ventrolateral cortex is not clear. The variability in glutamate release suggests that other mechanisms of injury may also be involved in severe ischemia. It is concluded that permanent focal ischemia may result in too severe an insult for hypothermic neuroprotection.

665.1

SELECTIVE ALTERATION OF CYTOSOLIC FREE CALCIUM IN CELL BODIES AND GROWTH CONES OF DIFFERENTIATED PC12 CELLS. G. Gibson* and L. Toral-Barza. Cornell Univ. Med. Coll. at Burke Medical Research Inst., White Plains, NY 10605

Our previous studies indirectly demonstrated that the nerve cell body and terminal responded differently to hypoxia. To directly test that possibility, the responses of cytosolic free calcium ($[Ca^{2+}]_i$) to K^+ depolarization, hypoxia (KCN), nifedipine and ω-CgTX were compared by fura-2 imaging of the cell bodies and growth cones of NGF-differentiated PC12 cells. Under resting conditions $[Ca^{2+}]_i$ was lower in the growth cones than the cell bodies. The response to K^+-depolarization was more rapid in the growth cone than in the cell body. Although nifedipine did not alter resting $[Ca^{2+}]_i$, it partially impaired the K^+-induced increase of $[Ca^{2+}]_i$ in the growth cone and almost totally blocked the response in the cell body. ω-CgTX nearly abolished the response to K^+ in the growth cone, but did not affect the K^+-induced increase in $[Ca^{2+}]_i$ in the cell body. Hypoxia increased $[Ca^{2+}]_i$ less in the growth cone than in the cell body and neither calcium antagonist altered the hypoxia-induced change. The combination of hypoxia and K^+ depolarization increased $[Ca^{2+}]_i$ more than either alone and the elevation was greater in the cell body. ω-CgTX greatly reduced the exaggerated increase in $[Ca^{2+}]_i$ due to K^+ in hypoxic growth cones, but nifedipine had only minimal effects. ω-CgTX did not alter this response in hypoxic cell bodies, but nifedipine greatly attenuated the K^+ response. Thus, any hypothesis to explain altered neuronal function during hypoxia must include regional differences in cellular calcium regulation and a differential response to calcium antagonists.

DECREASE IN INS(1,4,5)P_3 3-KINASE mRNA EXPRESSION IN FOCAL CEREBRAL ISCHEMIA. G. Y. Sun*, P. Wixom, T. A. Lin, T. N. Lin, R. T. Zoeller and C. Y. Hsu. Depts of Biochem. and Anatomy & Neurobiology, Univ. Missouri, Columbia, MO and Div. of Restoratory Neurology, Baylor College of Medicine, Houston, TX.

Disturbance of intracellular calcium homeostasis is thought to be an important mechanism underlying the ischemia-induced neuronal cell death. Ins(1,4,5)P_3 3-kinase and 5-phosphatase are responsible for metabolism of Ins(1,4,5)P_3, the second messenger for mobililization of intracellular calcium stores. Our recent studies have indicated a specific decrease in the Ins(1,4,5)P_3 3-kinase activity due to focal ischemia in rats induced by ligation of the right middle cerebral artery. Enzyme activity was further decreased during reperfusion after prolonged ischemic insult. In this study, changes in mRNA expression of Ins(1,4,5)P_3 3-kinase was examined. In situ hybridization with frozen coronal sections using oligomer probes indicated high levels of expression in the hippocampal CA1 neurons, dentate gyrus and cerebral cortex. Ischemic insult resulted in a decrease in mRNA expression in the neocortical area similar to the area of infarct. Northern blot analysis revealed no change in mRNA level in the right cortex during the ischemic insult but a decrease was found at 14 hr after ligation. Results indicate that besides the decrease in enzyme activity, focal cerebral ischemia also induced a decrease in the mRNA expression of Ins(1,4,5)P_3 3-kinase which occurred some time during the reperfusion period.

665.3

ISCHEMIA-INDUCED REGIONAL ALTERATIONS IN PKC ACTIVITY ARE SENSITIVE TO MODERATE CHANGES IN INTRAISCHEMIC BRAIN TEMPERATURE. R. Busto,* M.Y.-T. Globus, E. Martinez , I. Valdés , and M.D. Ginsberg. CVD Research Center, Univ. of Miami, Sch. of Med., Miami, FL, 33101.

Extracellular glutamate release and histopathological outcome following ischemia are sensitive to intraischemic brain temperature. Since PKC is implicated in neurotransmitter release and glutamate receptor mediated events, the relationship between intraischemic brain temperature and PKC activity was evaluated. Twenty min of 2-vessel occlusion plus hypotension was induced in rats whose intraischemic brain temperature was maintained at 30°C, 37°C, or 39°C. Using a PKC enzyme assay kit, cytosol and membrane PKC activity were determined in hippocampal, striatal, cortical, and thalamic homogenates at the end of ischemia and at 15min, 30min, 1h and 24h of recirculation. A reduction in cytosol and membrane PKC activity (43-50% and 45-49%, respectively; $p < 0.05$) was observed in the hippocampus, striatum and cortex of normothermic rats as early as 30min of recirculation. PKC activity remained diminished at 24h in the hippocampus and striatum but normalized in the cortex. No changes were documented in the thalamus. Ischemia-induced reductions in PKC activity were abolished in hypothermic animals. Conversely, postischemic PKC activity was significantly lower in the hippocampus and cortex of hyperthermic animals compared to normothermic ($p < 0.01$). Results indicate the ischemia-induced changes in PKC activity is a temperature sensitive process, suggesting that it may be involved in the effects of temperature on ischemic outcome.

665.4

CORRELATION OF CALBINDIN AND NEURONAL ANOXIC RESPONSES. M.E. Morris*, K.G. Baimbridge, H. El-Beheiry, D.S.K. Magnuson, G.V. Obrocea and A.S. Rosen. Dept. of Pharmacology, Univ. of Ottawa, Ottawa, Canada K1H 8M5.

The Ca^{2+}-buffering capacity of neurons which contain calbindin-D28K (CaBP) has been proposed to play a protectant role against excitotoxicity. It is hypothesized that cells with different early responses to anoxia may show differences in CaBP distribution and vulnerability. Experiments were carried out to correlate CaBP presence and anoxic-evoked changes in membrane parameters of identified neurons in neocortex, hippocampus (CA1/2) and mesencephalon of rat brain. Slices, perfused and equilibrated with 95% O_2/5% CO_2 at 34°, were exposed to 3-10 min of N_2 during intracellular recording and injection of Lucifer Yellow, followed by fluorescent CaBP antibody labelling. In CA1 N_2 evoked sustained depolarizations (17 ± 3.4 mV for 7 trials from V_M -68 ± 5.4 mV) in 4/5 pyramidal cells, characterized as CaBP+; 3 neurons which responded with hyperpolarization (≤10 mV from V_M -68 ± 2.8 mV) and showed burst activity before and during anoxia, were CaBP-. Although the neurons of other brain regions were depolarized by N_2, they were mainly CaBP-. These preliminary data suggest that, at least in the highly vulnerable CA1 area, differential responses may reflect differences in the Ca^{2+} buffering capacity of individual neurons/groups and explain different susceptibilities within that region.

665.5

EXPRESSION OF PROTEIN KINASE C ISOZYMES AND THE EFFECT OF HYPOXIA ON PKC IN RAT GLIAL CELLS. K. Kumar*, B. Kim, H. Rupp, & B. V. Madhukar. Departments of Pathology, and Pediatrics and Human Development, Michigan State University, E. Lansing, MI 48824.

Hypoxia and ischemia produce a number of intracellular changes conducive to the activation of Protein Kinase C (PKC) that has a number of isozymes. To study the presence of various isozymes of PKC in glial cells, and the effect of hypoxia on PKC, immunofluorescence (IF) studies were performed on glial cell cultures of the rat cortex. The antibodies tested were against α, β, γ and ε isozymes, and the catalytic domain (cd), of PKC. The relative degree of IF for each group of cells was compared by using an automated laser cytometric device. The data indicate that rat glial cells express at least three isozymes of PKC, ε, β, and α (in descending order of intensity). The IF for PKC - cd was more intense than for any of the isozymes. The glial cells were subjected to hypoxia by exposure to 100% N_2 for varying periods of up to 72 h. IF studies were performed as above. Even though this was not a quantitaive study, a decrease in the PKC - cd IF was demonstrated following 72 h of hypoxia. Decrease in the activity of PKC may lead to altered protein phosphorylation reactions, thereby playing critical roles in neuronal death due to hypoxia.

665.6

DIFFERENCE IN ALTERATIONS BETWEEN Ca^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE AND CALCINEURIN IN THE HIPPOCAMPUS AFTER TRANSIENT FOREBRAIN ISCHEMIA.

M. Morioka*, K. Fukunaga, S. Nagahiro, Y. Ushio and E. Miyamoto. Dept. of Neurosurgery and Pharmacology, Kumamoto University School of Medicine, Kumamoto 860, Japan.

After transient ischemia of the brain, the increase of the intracellular Ca^{2+} level is observed, which may trigger the intracellular process of neuronal death. We have investigated the regional and temporal alterations of Ca^{2+}/calmodulin-dependent protein kinase II (CaM kinase II) and calcineurin (CaN) (Ca^{2+}/CaM-dependent protein phosphatase) after transient forebrain ischemia. The immunoreactivity and enzyme activity of CaM kinase II decreased in all regions of the hippocampus at the early stage (6-12 hrs) after ischemia, but gradually recovered during the course of the time except for the CA1 region. Furthermore, an increase in Ca^{2+}/CaM-dependent activity was detected until 3 days after ischemia in all regions tested, suggesting that the concentration of intracellular Ca^{2+} increases. In contrast to CaM kinase II, immunohistochemistry and regional immunoblot analyses revealed that CaN was preserved until morphological degeneration of CA1 neurons. These results suggest differences between CaM kinase II and CaN in regard to regional and temporal loss after ischemia and the occurrence of the imbalance of the Ca^{2+}/CaM-dependent protein phosphorylation-dephosphorylation.

665.7

REGIONAL DEPRESSION IN CALCIUM/CALMODULIN DEPENDENT PROTEIN KINASE II (CaM-KII) IN FOCAL ISCHEMIA. S.K. Hanson, J.C. Grotta, M.N. Waxham, R. Earls, R. Strong, N. Dafny*. Dept. of Neurology and Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77030

Change in CaM-KII activity was evaluated in a rat model of focal ischemia. Activity in homogenate preparation of cortex measured by phosphorylation of synthetic peptide substrate was decreased by 76% ($p<0.0001$) in histologically defined infarct core (n=12) when compared with similar cortical regions in sham operated controls (n=4). Decreases in histologically defined infarct borderzone (defined at one hour of ischemia) were less dramatic (34%, $p=0.0007$). These changes were immediate so that depression in activity after 5 minutes was comparable to that seen after one hour of ischemia with no reperfusion. Reperfusion is associated with incomplete return of activity at 24 hours even in regions with no apparent histologic damage. CaM-KII downregulation is extremely sensitive to a focal ischemic insult and changes in activity are proportional to the amount of histologic damage.

665.8

BLOCK OF Ca^{2+} INFLUX DURING ISCHEMIA INHIBITS DOWN REGULATION OF Ca^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II AND PROTEIN KINASE C. J. Aronowski, J. C. Grotta[1] and M. N. Waxham*. Depts. of Neurobiology & Anatomy and [1] Neurology, Univ. Texas Medical School, Houston, TX 77030.

Excitotoxicity is generally considered to be a major factor for ischemia induced cell damage in vulnerable regions of the brain. Ca^{2+} influx evoked by glutamate through N-methyl-D-aspatate-gated ion channel (NMDA) as well as voltage-gated Ca^{2+} channels (VDCC) during ischemia induces undefined sequences of Ca^{2+}-dependent biochemical events which may lead to impairment of neuronal homeostasis and subsequent cell death. Recently we reported that 20 min. of global ischemia in rats induced by bilateral carotid artery occlusion caused dramatic decreases of Ca^{2+}/calmodulin-dependent protein kinase II (CaM-KII) and protein kinase C (PKC) activities in both hippocampus and cerebral cortex. This inhibition was detected immediately after ischemia and was not reversible for at least 2 h and only partially 7 days after ischemia (J. Neurochem. 58, 1743).

Here we describe effects of Dextrorphan (DEX), the well defined noncompetitive NMDA channel antagonist which also express VGCC antagonistic properties, on changes in activity of both CaM-KII and PKC induced by reversible global ischemia in rats. 15 mg/kg of intravenous DEX, 5 min before induction of 20 min of ischemia, significantly inhibited down-regulation of both kinases. The observed protection was detected immediately after ischemia as well as after 24 h of reperfusion. There was no effect of DEX on kinase activity observed after 2 h of reperfusion. Pretreatment, but not postreatment of animals with DEX subjected to 20 min of ischemia also resulted in histological protection of hippocampal and cortical neuronal tissue.

ANOXIA LIMITS DEPOLARIZATION INDUCED CALCIUM UPTAKE IN THE RAT HIPPOCAMPAL SLICE. I.S. Kass*, A.E. Abramowicz, G. Chambers and J.E. Cottrell. Anesthesiology Dept., SUNY Health Science Center, Brooklyn, NY 11203.

High cytosolic calcium levels are thought to lead to neuronal damage after anoxia. We found that Ca-45 uptake during anoxia was far less than the uptake measured during depolarization. We therefore examined whether anoxia could inhibit depolarization induced Ca uptake.

Hippocampal slices were subjected to either anoxia ($95\%N_2$-$5\%CO_2$), depolarization (12.5 uM veratridine) or a combination of the two. Ca-45 uptake was measured in the CA 1 region.

Calcium uptake increased from 9.0 ± .2 to 10.7 ± .2 nM/mg dry wt. ($P < .001$) during 15 min of anoxia. Veratridine for 10 min caused a 3 fold increase in Ca uptake to 30.2 ± .7. If anoxia was started 5 min before the onset of veratridine depolarization and continued throughout the depolarization (total anoxia = 15 min, veratridine = 10 min) then there was only a 2 fold increase in calcium uptake to 18.4 nM/mg.

Thus anoxia reduced the depolarization induced calcium uptake indicating that there might be a mechanism by which anoxia can inhibit the voltage sensitive calcium channel.

ELECTRODES BASED ON ETH-129 SHOW ASTROCYTIC Ca^{2+} RISES DURING SPREADING DEPRESSION. R.P. Kraig* & C.D. Lascola. Dept. of Neurology, Univ. of Chicago, Chicago, Il 60637.

Spreading depression (SD), a benign yet massive perturbation of brain, transiently converts astrocytes into reactive species (**1**). A rise in pH_i, associated with SD (**2**), may allow this glial metamorphosis to occur but what might trigger it is unknown. A rise in $[Ca^{2+}]_i$ stimulates enhanced anabolism, including proliferation, in other cells and thus, might trigger reactive astrocytosis (RA).

Ca^{2+}-ISMs based on ETH-129 were used to determine astrocytic $[C_{a2+}]_i$ changes during SD in anesthetized rats. SD was induced by electrical stimulation and astrocytes were identified by electrophysiologic criteria (**2**). Ca^{2+}-ISMs had a linear response and sensitivity for changes in pCa^{2+} to almost 8 and at least 10, respectively, in 100 mM K^+. Membrane potentials fell from 80-110 mV while $[Ca^{2+}]_i$ rose from the 100 nM range by orders of magnitude during SD. Both parameters returned to baseline after SD.

Resting astrocytic $[Ca^{2+}]_i$ in the nM range and rise with SD is consistent with that seen *in vitro* (**3**) and supports the validity of this data compared to previous work (**4**) (based on ETH-1001) that may have been erroneous due to an excessive Ca^{2+}-leak into cells. Perhaps, a coupled rise in pH_i and $[Ca^{2+}]_i$ synergistically increase astrocytic anabolic activity in RA.

ISCHEMIA: CLINICAL STUDIES

666.1

BRAIN FUNCTIONAL ABNORMALITIES IN CHRONIC ESSENTIAL HYPERTENTION. MJ Mentis, JA Salerno, B Horwitz, Murphy DGM, SI Rapoport*, MB Schapiro. Lab. Neurosci., Natl Inst on Aging, NIH, Bethesda MD.

To determine if chronic essential hypertension is associated with abnormal brain functioning, we performed a correlational analysis on the results from 17 hypertensive men (mean age± s.d.= 68±8yr) and 25 age-and sex-matched normotensive control subjects, who were studied with high resolution positron emission tomography (PET) using 18-fluorodeoxyglucose when off medication for at least 2 weeks. Hypertensives had been medically-treated for at least 10 yrs, and had no apparent end-organ involvement. All subjects were free from other medical, and cognitive disorders. A correlational analysis was performed to count the number of significantly different correlation pairs (sdc) between the two groups in the vascular areas of the brain. Correlations were performed from each vascular area of interest to all brain areas. There were significantly more sdc's with a smaller hypertensive value in the carotid distribution compared to the basilar, and within the carotid area, in the middle-anterior watershed area compared to the middle and anterior cerebral artery areas. These results suggest that well controlled hypertensives without clinical cognitive or other deficits, have abnormal brain correlations in the carotid artery area, and within this territory mostly in the middle-anterior artery watershed area. This latter pattern of functional abnormality - mainly in the watershed area - suggests a low flow state (ie episodes of hypotension) rather than high pressure as the immediate cause.

666.2

ANXIETY DISORDERS FOLLOWING STROKE. CS Castillo, SE Starkstein*, JP Fedoroff, TR Price, RG Robinson, Univ. of Iowa Coll. Med., Iowa City, Ia 52242

A series of 309 admissions to a stroke unit were examined for anxiety symptoms. Patients were diagnosed with DSM-III-R generalized anxiety disorder (GAD) symptom criteria. They were divided into groups of no anxiety (59.2%), worried but not fulfilling GAD criteria (13.9%), and GAD (26.9%). Patients were then divided into depressed and non-depressed groups based on the existence of DSM-III major or minor (dysthymic) depression. These groups were not significantly different in their background characteristics or the severity of physical impairment. Anxiety plus depression (74% of all GAD patients and 19% of all patients) was associated with left cortical lesions while anxiety alone was associated with right hemisphere lesions ($X^2=4.9$, $df=1$, $p=.043$). Patients with GAD had a greater frequency of posterior right hemisphere lesion than patients with right hemisphere lesions without GAD ($F=3.5$, $df=2,46$, $p=.038$) Two year follow-up at 3,6,12 and 24 months revealed a stable prevalence of GAD at each of follow-up intervals of approximately 30%. Patients who were initially not worried had a mean prevalence of 18% during the 2-year follow-up. The initially GAD (IGAD) patients had a mean follow-up prevalence of 44% while those that were initially worried had a mean prevalence of 30%. Prevalence in the follow-up depressed patients was 36.5% while in the non-depressed it was 18%. Initially not depressed IGAD (11% prevalence) patients had no cases on follow-up. Initially depressed IGAD maintained the highest follow-up prevalence, 49%. New onset GAD at follow-up averaged 58% of all GAD cases seen over 2 years and 80% also had depression. Findings suggest that anxiety disorder (independent of depression) is not related to background characteristics or to severity of impairment but is influenced by brain structures injured. Post-stroke GAD has a high incidence.

666.3

Motor Control of the Hand in Humans with Upper Motor Neuron Dysfunction Due to Stroke

D.S. Stokic, M.M. Dimitrijevic, A.M. Sherwood*, S. Delapasse
Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, Tx 77030

Upper limb volitional motor control impairment, in particular, the loss of fine precise movement of the hand and fingers is common following stroke. The evolution of recovery from stroke has a well described pattern with the majority of functional improvement occurring in the first 3 months after onset. Functional outcome measures have demonstrated the variable nature of clinical assessments and the inherent variability of clinical signs in the hemiplegic population.

We studied the features of motor control of the upper limbs in 29 hemiplegic subjects by recording surface EMG from the pectoralis major, deltoids, biceps brachii, triceps brachii, wrist extensor and flexor muscles of both sides. This simultaneous recording of motor activity provides a picture of the pattern used to perform the series of voluntary and reflex maneuvers. The hemiplegic subjects were divided on the basis of clinical observed volitional wrist movement into four groups: (1) no movement; (2) trace movement; (3) movement with limited range; (4) full range movement. In all of these groups, characteristic features of motor control are described, including grousps 1 and 2.

666.4

QUANTITATED EEG (QEEG): A TOOL TO DIAGNOSE OR MONITOR PATIENTS WITH ANEURYSMAL SUBARACHNOID HEMORRHAGE. P. Newlon*, M. Sumas, F. Schinco, B. Limperis, & S. Gudeman. East. Va. Med. Sch., Norfolk, Va., 23507.

EEG was recorded from 16 normal subjects and serially from 16 patients with cerebral aneurysms (14 had subarachnoid hemorrhage (SAH); 15/16 aneurysms were surgically repaired). The EEG was quantified (Cadwell Spectrum 32) and analyzed with regard to absolute and relative power, symmetry, and coherence over 4 frequency bands and 21 sites. In general, patients showed increased slowing, frontal power asymmetry, and increased coherence over temporal sites. Focal abnormalities in delta power and coherence were characteristic of an aneurysmal source in 12 preoperative studies. Anterior communicating artery aneurysms were linked with fronto-temporal absolute power, while coherence abnormalities in anterior, central and posterior sites were seen with internal carotid, middle cerebral and posterior communicating artery aneurysms, respectively. In 3 patients, QEEG suggested aneurysmal sources at a time when angiographic data were either negative or inconclusive. Abnormalities were also seen in patients with incidental aneurysm findings, suggesting that the QEEG does not simply reflect the presence of SAH. Postoperatively, 9 of 15 patients developed vasospasm by clinical or radiographic criteria. In 3 of 5 patients who received pre- and post-spasm QEEG studies, novel focal abnormalities in QEEG could be seen prior to the onset of vasospasm, and the brain regions involved were appropriate to the type of functional deficit that ultimately emerged.

Although preliminary, these results suggest that quantifiable changes in EEG power distribution over the scalp may be useful both in diagnosis of aneurysms in patients with SAH, and in the detection or prediction of impending vasospasm. Further studies are aimed at determining the reliability and validity of this technique to detect subclinical cerebral vasospasm and allow early intervention.

BALB/c SUBSTRAIN DIFFERENCES IN SUSCEPTIBILITY TO TMEV-INDUCED DEMYELINATING DISEASE AND POSSIBLE MECHANISMS. S.M.Nicholson*, J.L.Hoeft, L.Dech, C.Waltenbaugh, and R.W.Melvold. Dept. of Microbiology-Immunology and Institute for Neuroscience, Northwestern University, Chicago, IL, 60611.

We report differences among four BALB/c substrains in susceptibility to Theiler's murine encephalomyelitis virus (TMEV)-induced demyelinating disease (TMEV-IDD), a model for human multiple sclerosis. TMEV-IDD is believed to result from bystander damage to myelin inflicted as part of a delayed type hypersensitivity response directed against chronic, low level infection of the CNS by TMEV. We have found BALB/cByJ and BALB/cCum mice to be resistant to the development of TMEV-IDD, while BALB/cAnNCr and BALB/cJ are intermediately susceptible. We are attempting to define the genetic and immunological mechanisms involved in this differential susceptibility. Studies in our laboratory have shown that some resistant strains can be converted to a susceptible phenotype by the application, prior to infection with TMEV, of immunopotentiating regimens such as low dose cyclophosphamide or γ irradiation or administration of anti-I-J antibodies. Low dose irradiation efficiently converted resistant BALB/cByJ mice to a susceptible phenotype, indicating that the resistance of BALB/cByJ to development of the immune responses associated with development of TMEV-IDD is due to an active regulatory mechanism rather than an intrinsic inability to develop the destructive responses. Low dose cyclophosphamide was far less effective in producing the susceptibility in BALB/cByJ. Experiments have been initiated to identify the cellular mechanisms involved in the protective regulation.

667.2

IL-1 AND TGF-B1 CONTROL ASTROCYTOSIS IN HUMAN BRAIN. A. da Cunha+, J.J. Jefferson#, W.R. Tyor$, J.D. Glass&, F.S. Jannotta@ and L. Vitkovic+* +NIAID, #NCI, NIH, Bethesda, MD 20892; Dept $Neurology and &Pathology, The Johns Hopkins Univ, Baltimore, MD 21205; @George Washington Univ Med Ctr, Washington DC.

Astrocytic hyperplasia, an increase in number, and hypertrophy, an increase in size are common neurocellular manifestations of brain pathology. Published data indicate that interleukin-1 (IL-1) is elevated in experimental models of brain pathology; IL-1 causes proliferation of astrocytes under experimental conditions in vitro and in vivo and transforming growth factor beta 1 (TGF-B1) causes hypertrophy of astrocytes in vitro. The precise causes of hyperplasia and hypertrophy of astrocytes in brain of individuals with a variety of diseases are unknown. These astrocytic changes and IL-1 and TGF-B1 immunoreactive products (IRPs) were morphometrically measured in frontal cortex and subcortical white matter of 22 individuals who died with various diseases. The data demonstrate that the number and the size of astrocytes were correlated with amounts of IL-1 and TGF-B1, respectively, but not vice versa. These correlations were statistically significant. Further, these cytokines and the cellular changes of astrocytes were co-localized in all examined tissues. Thus, these cytokines appear to control astrocytosis.

667.3

INCREASED 3-HYDROXYANTHRANILIC OXYGENASE IMMUNOREACTIVITY IN MEASLES VIRUS-INFECTED MICE. C.L. Eastman*, F. Du, [1]T. Andersson, [2]A. Löve and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD, [1]Karolinska Institute, Huddinge (Sweden) and [2]Univ. Iceland, Reykjavik (Iceland).

Intracerebral injection of BALB/c mice with the hamster neurotropic (HNT) strain of measles virus produces a bilateral hippocampal lesion remarkably similar to that observed following injection of quinolinic acid (QUIN). Neurodegeneration can be observed in Nissl-stained sections five days after injection, can be prevented by the NMDA receptor antagonist MK-801, and is preceded by marked hippocampal astrogliosis. Since the endogenous NMDA receptor agonist QUIN is produced by astrocytes in the CNS, it is likely that QUIN metabolism may be altered during HNT infection. In the present study, 3-hydroxyanthranilic acid oxygenase (3HAO), QUIN's biosynthetic enzyme, was assessed immunocytochemically in control and HNT-infected mouse brains. Three days after HNT injection, many 3HAO-immunoreactive hypertrophic astrocytes were evident in the CA1 region of the hippocampus. By 7 days post-injection, hypertrophied 3HAO-containing astrocytes were observed throughout the hippocampus. The increase in 3HAO immunoreactivity is consistent with the hypothesis that enhanced production of QUIN may contribute to the neurodegeneration associated with HNT infection.

Supported by USPHS grant NS 16102.

667.4

CNS QUINOLINIC ACID INCREASE IN MURINE RETROVIRAL ENCEPHALOPATHY. C. A. Wiley*, M. P. Heyes and R. M. Nagra. Univ. of California, San Diego, Department of Pathology. La Jolla, CA 92093-0612.

Quinolinic acid (QUIN) is an agonist of *N*-methyl D-aspartate receptors and is a known excitotoxin. Increased concentrations of QUIN in cerebrospinal fluid have been implicated in the spongiform encephalopathy associated with human and simian immunodeficiency virus infections, but tissue levels of this compound are not known. Infection with a molecularly cloned neurotropic Murine Leukemia virus ***pNE-8***, or a temperature sensitive mutant ***ts-1*** lead to extensive neuronal and oligodendroglial infection and spongiform degeneration. Microglial activation and infection was only observed in ts-1 infecetd mice. Serum QUIN levels in both infections were similar to those of non-infected mice, however, QUIN concentration in the brainstem, cerebellum and spinal cord were increased by 4 to 10 folds in ts-1 infected mice. Microglial infection by ts-1 may be the major source of elevated QUIN levels. These murine models are ideal for studies of the pathogenesis of CNS damage in retroviral infection.

NEUROTOXICITY OF LENTIVIRUS DERIVED TAT PEPTIDE FRAGMENTS IN RAT STRIATUM. M.Hayman, G.W. Arbuthnott*,G. Harkiss. Preclin. Vet. Sciences, & Vet. Pathology, Univ. of Edinburgh, Summerhall, Edinburgh EH9 1QH. U.K.

Lentiviruses including VISNA in sheep and HIV in humans cause neuronal damage in spite of their not having been seen to replicate in neurones. We have studied the time course and dose dependence of neurotoxicity following direct injection of amino-acid sequences from proteins derived from both viruses into the striatum of rats.

We estimated the neurotoxic effect by measuring the volume of reactive microglial immunostaining in the striatum one week after the toxin injections. The minimal dose resulting in a measurable lesion was between 1 & 5 ug (0.8 - 4nM) of the peptide from VISNA.

Preliminary results suggest that while the cysteine residues can be modified without change in the toxicity the arginine doublet in the centre region is necessary.

Since these peptides derive from the tat sequences in the viral peptides and are thus expected to be passed on to neighbouring cells, secretion of them by infected glia could both damage nearby neurones and recruit more microglia thus explaining the neuropathological pattern seen in infected animals.

GENETICALLY DETERMINED HERPES SIMPLEX VIRUS 1 (HSV 1) RESISTANCE IN OLIGODENDROCYTES (OL) MAY PLAY A ROLE IN LIMITING SPREAD OF HSV 1 IN THE CENTRAL NERVOUS SYSTEM (CNS): DELAY OF IMMEDIATE EARLY (ICP4) AND EARLY (ICP8) ANTIGEN SYNTHESIS IN HSV 1 RESISTANT OLs FROM C57BL/6J AND BALB/cByJ MICE. *E.E. Thomas[1],A.Lau[2], L.F. Kastrukoff[2]* [1]Division of Microbiology, Department of Pathology, British Columbia's Children's Hospital and [2] Division of Neurology, Department of Medicine, University of British Columbia, Vancouver, Canada.*

Primary murine OL cultures from 3 inbred strains show HSV 1 replication differences, which correlate with in vivo infection (A/J, susceptible; BALB/cByJ, moderately resistant; C57BL/6J, resistant). The nature of the in vitro resistance at the cellular level was investigated using an indirect immunofluorescense assay (IFA) with monoclonal antibodies to ICP4, ICP8 and gC HSV antigens. OLs from HSV C57BL/6J mice showed restricted expression of all antigens: only small amounts of ICP4 and ICP8 (10% of cells) and no gC was detected until 72 hrs postinfection (p.i.) in contrast to OLs from A/J mice in which 80-100 % of cells expressed all three proteins 72 hrs p.i. Balb/c showed an intermediate protein expression pattern: 50% of cells were ICP4 pos., 30-50% ICP8 pos. and 20% gC pos. 72 hrs p.i. HSV adsorption (using ^3H labelled HSV) to the 3 OL strains was also studied, and no difference in adsorption pattern was noted. These results suggest the existence of an early, postadsorption HSV replicative block in C57BL/6J OLs and a less restricted early replication block in Balb/cByJ OLs. Electronmicroscopy studies confirm this observation. The selective differences in HSV resistance mediated by OLs, reflect differences in virus host cell interactions, and likely contribute to differences in mortality, viral spread, and pathological differences in the CNS of the different mouse strains.

VIRUS DNA SEQUENCES AND CNS DISEASE IN NEONATAL HERPES SIMPLEX INFECTION. P. Gressens[1], C. Langston[2], W.J. Mitchell[1] and J.R. Martin[1]* [1]NIH, Bethesda, MD; [2]Texas Children's Hospital, Houston, TX

This study uses polymerase chain reaction (PCR) to detect herpes simplex virus (HSV) genomic sequences in formalin fixed paraffin sections from perinatal HSV-1 and -2 encephalitis autopsy tissues and correlates these results with immunohistochemistry (IHC) and histological lesions. Brain sections from 10 mice with acute HSV-2 infection and from 20 uninfected controls were used to establish PCR conditions of specific HSV DNA amplification and detection. Primers which bracketed a 110 BP fragment of the HSV-2 thymidine kinase gene , 30 cycles of amplification and Southern blot hybridization with an appropriate oligonucleotide probe were selected as they gave 100% sensitivity and specificity in repeated tests with control mouse tissues. 56 neural (NT) and non-neural tissue (N-NT) blocks from 10 neonates were tested; previous IHC studies showed that in N-NT of 6 neonates antigen was HSV-2 and in 3 it was HSV-1 in type; 1 case, dead 7 weeks after clinical encephalitis, was negative for HSV antigen. HSV antigen-positive N-NT contained HSV DNA sequences, confirming the sensitivity of this PCR protocol. In NT, 22 blocks displayed histological lesions of possible viral origin but the IHC detected HSV antigen in only 9 blocks; in contrast, we obtained a specific band of amplified HSV DNA in all these blocks, including 1 neonate dying 7 weeks after birth. 15 NT and N-NT blocks were histologically normal and HSV antigen-negative; all, except 2 blocks from the 7 week old neonate, contained HSV DNA sequences. All PCR results were reproducible. PCR detects HSV DNA in CNS areas that contain no detectable HSV antigen but are histologically abnormal; this suggests that these histological lesions are virus-induced.

NEURONAL DEATH IN MOUSE SPINAL GANGLIA FOLLOWING HERPES SIMPLEX VIRUS TYPE-2 (HSV-2) INFECTION D.B. Henken*[1], M.E. Goldstein[2] & J.R. Martin[1], NIH, NINDS, LENP[1], LNC[2], Bethesda, MD, USA, 20892.

In this study, we examine whether HSV-2 infection causes neuronal death in mouse dorsal root ganglia (DRG). The right hind footpads of anaesthetized female BALB/c mice were inoculated with 10 μl of MS strain HSV-2 ($9.3x10^6$ pfu/ml) or medium. One month later, infected (n=4) and sham-inoculated (n=3) mice were perfusion-fixed. Spinal columns, including paired spinal ganglia, were decalcified and serial paraffin sections (10 μm) were stained with cresyl violet. Neuron numbers, somal areas and ganglion volumes for both the infected and the contralateral uninfected lumbar 4^{th} and 5^{th} DRG were determined for each mouse. Following HSV-2 infection, between 50 and 70% of neurons disappeared 1 month following inoculation. Neuron numbers in sham-inoculated and contralateral control ganglia were equivalent. Neuronal death did not target a specific subpopulation of neurons, based on somal size. Ganglionic shrinkage did not occur as a result of HSV-2 infection; neurons were replaced by large numbers of inflammatory cells. These results show that, in addition to other previously described host alterations following viral infection, HSV-2 infection results in neuronal death in the affected host ganglia. This is the first in vivo quantitative documentation of HSV-2 induced neuronal death.

ANALYSIS OF MYELIN PROTEINS IN POST MORTEM AIDS BRAIN. J.R. Möller, P.G. Durr, R.H. Quarles, B.D. Trapp, C. Power and J.T. Prince* NINDS, NIH, Bethesda, MD 20892 and Dept. of Neurology, Johns Hopkins University, Baltimore, MD.

Subcortical white matter samples from five AIDS patients and four age matched controls were histochemically and biochemically studied for changes in myelin proteins. The pathology observed histologically in the AIDS patients included diffuse subcortical white-matter pallor, as visualized by Luxol Fast Blue staining.

Tissue sections were stained with antibodies to myelin basic protein (MBP), proteolipid protein (PLP), myelin-associated glycoprotein (MAG) and with HNK1. No alterations were found in the distribution of the myelin proteins, including regions of diffuse white-matter pallor. Gliosis identified by GFAP staining was increased in HIV-infected individuals as compared to controls. Electron microscopy of subcortical white matter from HIV-infected patients revealed no indication of demyelination.

Samples for biochemical analysis were adjacent to areas examined histologically and were homogenized in 1% SDS and boiled for 10 min. Coomassie blue stained gels and Western blots were utilized for quantification of MBP, PLP, MAG, 2', 3'-cyclic nucleotide 3'-phosphodiesterase (CNP) and GFAP. No major quantitative changes in the myelin proteins in the samples from AIDS patients were found. These results do not provide morphological or biochemical evidence for extensive myelin loss in subcortical white-matter of AIDS patients.

667.10

TWO PATTERNS OF BLOOD-BRAIN BARRIER ABNORMALITIES IN THE ACQUIRED IMMUNE DEFICIENCY SYNDROME. C.K. Petito* and K.S. Cash, Dept. of Pathology, Cornell University Medical College, New York, NY, 10021.

Histological changes suggesting abnormalities in the cerebral vasculature in AIDS brains include the paravascular location of HIV-related microglial nodules, calcific vasculopathy in children, and white matter endothelial changes. Accordingly, blood-brain barrier (BBB) abnormalities were studied in formalin-fixed paraffin-embedded brains of AIDS patients with HIV encephalitis (HIVE) (n=17) and without HIVE (n=16); non-immunosuppressed patients served as controls (n=22). Immunohistochemical detection of fibrinogen(FIB) and IgG was used as a marker of vascular permeability. The immunoreactivity in the centrum semi-ovale was blindly graded as 0 - 4+. The sex ratios and post-mortem intervals were similar in all groups ($p > 0.05$) but the age of the 2 AIDS groups were significantly younger than controls (43.2 and 40.9 versus 62.5 yrs; $p < 0.05$). The two AIDS groups had significantly higher immunostaining for FIB and for IgG than the control group ($p< 0.001$ and $p < 0.0001$ respectively), but did not differ from one another. In addition, when the results were expressed as "negative" (0 or 1+ staining) or "positive" (2+-4+0, the frequency of positive staining for both FIB and IgG was higher in the 2 AIDS groups whereas the the frequency of negative staining for both proteins was higher in the controls ($p < 0.002$). Although more than 95% of HIV-related microglial nodules were negative for serum proteins, all focal lesions with tissue necrosis, including lymphoma, opportunistic infections and rarely, HIV contained extravasated serum proteins. This study shows that a diffuse BBB breakdown is present in approximately 50% of all AIDS patients at the time of autopsy and may be seen in the absence of any other brain pathology, including HIVE. These BBB abnormalities may be important in mediating some of the tissue damage that accompanies HIV infection of the brain such as the diffuse myelin pallor and gliosis which is common in HIV-infected patients. In addition, the BBB breakdown may not only facilitate viral entry into brain, but also increase the entry of blood-borne cytotoxic cytokines. Supported by NIH Grant R01-NS27416.

HISTOLOGIC LESIONS IN THE CENTRAL NERVOUS SYSTEM OF HIV-1 INFECTED MACAQUES. D. M. Anderson, H. D. Liggitt, L. Frumkin, M. Agy, W. Morton, D. Bowden*. Regional Primate Research Center, SJ-50, Univ. of Washington, Seattle, WA 98195.

We describe the occurrence of histologic lesions within the central nervous system of monkeys following infection with HIV-1 virus, the etiologic agent of human AIDS. Eight infant pigtailed macaques (*Macaca nemestrina*) were inoculated intravenously with a mixture of infected autologous peripheral blood mononuclear cells (PBMC) and free virus of three HIV-1 strains: LAI, JR-CSF, and JR-FL. A comparison group was infected with SIV. At 2, 5, 14, and 24 weeks following infection, animals were killed and examined histologically for lesions in the central nervous system.

Initial examination of the brains of two animals sacrificed 5 weeks after infection with HIV-1 showed choroiditis in both animals and extensive perivascular infiltrates in the occipital cortex of one. Choroid infiltrates were composed predominantly of lymphocytes; perivascular infiltrates were composed primarily of cells of macrophage origin with occasional astrocytes present. HIV-1 was isolated from PBMCs taken at the necropsy of each animal.

Tests for virus in the tissues are being conducted by immunohistochemistry and in-situ hybridization. Comparison of lesions in animals infected with HIV-1 with those of animals with SIV are in progress. We describe the first documented histologic lesions within the central nervous system in a macaque species following infection with HIV-1.

ENHANCEMENT OF HIV TRANSCRIPTION BY SUBSTANCE P AND CYTOKINES IN HUMAN AND RAT GLIAL CELLS. Sundar, K.S., P. Sista, N. Quan, L. S. Kamaraju, P. Simson*, and J. M. Weiss. Department of Medicine and Psychiatry, Duke University Medical Center, Durham, NC 27710.

Asymptomatic HIV seropositive subjects often exhibit evidence of CNS infection with HIV. Progression of the infection with HIV in the brain is suggested by the clinical manifestations of neurological disorders of AIDS dementia complex. The factors that could modulate HIV replication in the brain have not been investigated. We investigated the effects of cytokines on HIV transcription in human glioblastoma cells (1321N1) and primary rat astrocyte cultures, as well as the effect of substance P (SP) on HIV transcription and IL-1 production in human macrophage cells. HIV-LTR was linked to the cDNA of chloramphenicol acetyl transferase enzyme (CAT) and increased synthesis of CAT enzyme transcription was considered indicative of HIV transcription. The results indicate that: 1) SP dose-dependently enhanced HIV transcription in the macrophage, with the minimal effective dose at 10^{-10} M and SP also induced the synthesis of IL-1; 2) IL-1 (10-100 pg/ml) and TNFa (100-1000 pg/ml) significantly enhanced HIV transcription; and 3) IL-1 and TNFa in concert with each other synergistically enhanced HIV transcription. These results suggest that neural and immune mediators may promote the progression of HIV infection in the brain and contribute to neuropathology of AIDS.

667.13

FRAGMENTS OF THE ENVELOPE PROTEIN (GP120) FROM THE HUMAN IMMUNODEFICIENCY VIRUS ARE NEUROTOXIC TO CNS CULTURES

D.E. Brenneman*, H. Jaffe, T. Moody and J.M. Hill.
Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD, 20892;
Lab. of Neurochem. NINDS, NIH; Dept. of Biochem., George Washington Univ. School of Med., Washington D.C. 20037.

Previous studies have shown that purified envelope protein (gp120) from the human immunodeficiency virus produces neuronal cell death in hippocampal cultures derived from fetal mice (Brenneman et al., *Nature* 280: 345, 1988). Subsequent studies have indicated that cortical neurodystrophy and delays in developmental milestones occur in developing rats administered gp120 (Hill et al., *Soc. Neurosci. Abstrs.* 16: 615, 1990). Purified gp120 was radiolabeled and injected subcutaneously into one day old rats. The pups were either frozen and sectioned for *in vivo* autoradiography, or the brains were homogenized and assayed by FPLC for the presence and distribution of labeled gp120 and its proteolytic fragments. *In vivo* autoradiography revealed that radioactive material reached the brain and diffused into adjacent brain tissue. FPLC analysis revealed four major peaks of radioactivity. The chromatographic fractions corresponding to these peaks were assayed for neurotoxicity on dissociated cerebral cortical cultures. All four peaks exhibited neurotoxic activity that could be prevented by co-treatment of the test cultures with 1 nM peptide T. These data suggest that low molecular weight (<800 Dalton), neurotoxic gp120 fragments may play a role in the etiology of "NeuroAIDS".

667.14

EARLY DETECTION OF PROGRESSIVE CNS INVOLVEMENT IN HIV INFECTION. K.L.Coburn*, N.C.Moore, H.P.Katner, K.A.Tucker, W.S.Pritchard[1], D.W.Duke[2]. Mercer Univ. School of Medicine, Macon, GA 31207; [1]R.J. Reynolds Tobacco Co.; [2]Florida State Univ.

AIDS often is accompanied by progressive encephalopathy resulting in 'subcortical' dementia, but it is uncertain how early in HIV infection the brain involvement may begin. This study recorded EEG and ERP (auditory oddball) data from healthy controls and from patients at worsening stages of HIV infection. Neither digital frequency analysis nor nonlinear dynamical (chaos) analysis of the EEG showed differences between healthy controls and any patient group. ERP sensory components also did not differ between groups, but cognitive components showed progressive delays and amplitude reductions corresponding to increasingly severe clinical stages of HIV infection. The earliest changes were among asymptomatic HIV+ patients, suggesting that this test is a sensitive indicator of early subclinical CNS damage and may be of value in decisions regarding early aggressive antiviral therapy and in monitoring its effectiveness.

667.15

ENHANCED CELL MEMBRANE TRANSPORT AND ANTI-HIV-1 ACTIVITY OF ANTI-rev ANTIBODIES FOLLOWING CATIONIZATION. **W.M. Pardridge, U. Bickel, J. Buciak, J. Yang, and C. Markham*. Departments of Medicine and Neurology and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA, 90024.**

The replication of the human immunodeficiency virus (HIV) in acquired immune deficiency syndrome (AIDS) is dependent on the function of the rev protein. In order to develop anti-rev antibodies capable of transport across the brain capillary barrier, i.e., the blood-brain barrier (BBB), and into lymphocyte intracellular spaces, a rabbit polyclonal antiserum directed against a 16-amino acid synthetic peptide encompassing the active site of the rev protein of HIV-1 was prepared. The antibody fraction was affinity purified, and cationized with hexamethylenediamine and carbodiimide. The isoelectric point (pI) of the native anti-rev antibodies was 5.2 and the pI of the cationized anti-rev antibodies averaged 8.5 based on isoelectric focusing studies. The cationization was performed with site protection using synthetic peptide, and radioimmunoassay experiments showed that the affinity of the anti-rev antibody for the synthetic peptide was virtually unchanged following site protected cationization. The cationized and native anti-rev antibodies were radiolabeled and the cationized antibodies were found to undergo enhanced uptake into either human lymphocytes or bovine brain capillaries as compared to the native anti-rev antibodies which showed minimal cellular uptake. Cationized anti-rev antibodies, but not native anti-rev antibodies or cationized nonspecific antibodies, resulted in a 36% decrease in ^{3}H-thymidine incorporation in the human lymphocytes, but a 90% decrease in HIV-1 replication in human peripheral blood lymphocytes grown in primary tissue culture.

667.16

INHIBITION OF GP120 BINDING TO GALACTOSYL CERAMIDE AND HIV INFECTION BY POTENTIAL ANTI-HIV COMPOUNDS. S. Bhat[@], T. Otsuka[#], A. Srinivasan[#] and D.H. Silberberg[@], [@]Dept. Neurol. Univ. Penn. Med. Ctr. and [#]The Wistar Institute, Philadelphia, PA 19104.

In an attempt to find compounds capable of inhibiting the binding and infection by HIV in neural cells, we studied the effect of benzopurpurin and related compounds on the binding of gp120 to GalCer and sulfatide. By using an HPTLC binding assay, we show that the binding of gp120 to GalCer and sulfatide is inhibited by benzopurpurin and related compounds. These compounds also inhibit the binding and entry of HIV into the neural cell line, SK-N-MC. We also show that this method can be used for screening of potential anti-HIV compounds.

668.1

METABOLIC CHANGES IN CARDIAC AND SKELETAL MUSCLE OF DYSTROPHIC HAMSTERS WITH HYPERTROPHIC CARDIOMYOPATHY. P.L. Johnson, R.K. Handa, M.P. Gupta, and S.K. Bhattacharya*, Surgical Research Lab, University of Tennessee, Memphis, TN 38163.

Membrane-mediated excessive intracellular Ca accumulation plays a fundamental pathogenetic role in hereditary muscular dystrophy. To study the dystrophic muscle metabolism, glycogen, glucose-6-phosphate (G6P), hexokinase (HK), G6PDH, pyruvate, lactate, and creatine phosphate (CrP) were quantitated in ventricular myocardium (VM) and rectus femoris (RF) muscle of CHF-148 normal albino hamsters (NH) and CHF-146 dystrophic hamsters (DH) with hypertrophic cardiomyopathy. We observed a marked decrease in glycogen, G6P and CrP, concomitant with a significant increase in HK and G6PDH in VM and RF of DH. The stimulation of HK and G6PDH, with reduced glycogen and G6P, highlighted the shift of muscle metabolism in DH towards the pentose shunt pathway (PSP). Unaltered pyruvate and lactate levels, together with lower G6P in dystrophic RF (79%) and VM (70%), strongly suggest that the metabolic path in DH is selectively favored towards PSP for the generation of NADPH, reentering the glycolytic pathway at the site of glyceraldehyde-3-phosphate, and thus conserving one ATP in the process. A 75% decrease of CrP in dystrophic VM, compared to a 22% decrease of ATP, suggests that CrP acts as a buffering system for the maintenance of ATP. These findings concur with our report of decreased cellular energy charge in DH (Soc. Neurosci. Abstr., 17:1609,1991). We conclude that muscle metabolism in DH is directed towards the conservation and generation of ATP through the CrP/Cr system, due to an increased energy demand to pump excessive intracellular Ca^{2+} from degenerating myofibers. **(Supported by NIH Grant R01-AR38540)**

668.2

ROLE OF ADP PHOSPHORYLATING, GLYCOLYTIC AND KEY MITOCHONDRIAL ENZYMES IN CELLULAR ENERGETICS OF CARDIAC AND SKELETAL MUSCLE OF DYSTROPHIC HAMSTERS WITH CARDIOMYOPATHY. S.K. Bhattacharya, P.L. Johnson*, M.P. Gupta, and R.K. Handa, Surgical Research Lab, University of Tennessee, Memphis, TN 38163.

Generation of energy rich biomolecules such as ATP and creatine phosphate (CrP) is crucial for physiologic functioning of heart and skeletal muscle. Because of our recent findings of diminished ATP and CrP levels in the cardiac and skeletal muscle of CHF-146 strain dystrophic hamsters (DH) with hypertrophic cardiomyopathy and hereditary muscular dystrophy, we investigated some of the key enzymes of ADP phosphorylation, glycolytic pathway, Krebs cycle, and mitochondrial respiratory chain. Biochemical assays were performed in post 10,000g supernatants of ventricular myocardium (VM) and rectus femoris (RF) muscle of CHF-148 normal albino hamsters (NH) and DH. In dystrophic VM, a significant decrease in the activity of glycolytic enzymes like pyruvate kinase (PK), aldolase (ALD) and lactate dehydrogenase (LDH) was observed by 29%, 39% and 37%, respectively. Activity of creatine phosphokinase (CPK) was reduced by 37% in dystrophic VM. Several mitochondrial key enzymes such as succinate dehydrogenase (SDH), citrate synthetase (CS), NADH-cytochrome-*c*-reductase (NCCR), succinate cytochrome-*c*-reductase (SCCR) and NADH ferricyanide reductase (NFR) were also reduced in dystrophic VM by 34%, 31%, 27%, 52% and 19%, respectively. Similarly, dystrophic RF revealed significantly lower PK (34%), LDH (29%), ALD (47%), CPK (33%), adenylate kinase (33%), SDH (37%), CS (29%), NCCR (48%), SCCR (21%) and NFR (23%), compared to NH. These data strongly suggest a severe impairment of glycolytic pathway, as well as mitochondrial energy metabolisms at the level of the Krebs cycle and electron transport chain system in dystrophic VM and RF, contributing to marked depletion of energy rich biomolecules and progressive muscle wasting in DH. **(Supported by NIH Grant R01-AR38540)**

VIMENTIN (VM) mRNA EXPRESSION IN NORMAL & DISEASED HUMAN SKELETAL MUSCLE. A.K.Misra, N.K.Menon*, S.S.Schreiber and W.K.Engel. Neurology Svc, VA Outpatient Clinic & Dept.of Neurology, USC Sch. of Med, Los Angeles, CA 90013.

Intramyofiber VM, a cytoskeletal intermediate filament protein, is expressed in fetal myotubes during myogenesis, presumably important in their early development. As maturation proceeds, desmin replaces VM in the myofibers. In normal mature muscle, VM reappears in myofibers regenerating following injury or disease. We studied VM mRNA expression in biopsied muscle samples of normal(1), Duchenne muscular dystrophy(DMD,1), scapulohumeral muscular dystrophy(SHD,1), myotonic muscular dystrophy(MyD,1), sporadic adult-onset myotubular myopathy(SAOMM,1) and polymyositis(PM,2). 10u cryosections were hybridized in situ with a 35-S labeled cRNA probe and analysed by emulsion autoradiography. Serial sections were stained with the modified trichrome. All samples showed VM mRNA in Schwann cells, fibroblasts and blood vessels. In normal and MyD, no intramyofiber VM mRNA was seen. In contrast, intramyofiber VM mRNA was seen in 1) regenerating-degenerating myofibers in PM, DMD and SHD., 2) a few myofibers with central nuclei in SAOMM. VM reexpression in diseased myofibers suggests a VM-associated regenerative phenomenon, which may be amenable to therapeutic manipulation.

SELECTIVE ACTION OF INTRATHECAL BACLOFEN IN SPASTIC PARESIS. G.L. Almeida, M.L. Latash, R.D. Penn*, D.M. Corcos, and G.L. Gottlieb. Universidade Estadual de Campinas/Conselho Nacional de Pesquisa, Campinas, SP 13100, Brazil, Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612, University of Illinois, Chicago, IL 60612.

Effects of intrathecal baclofen were studied in six patients with spasticity due to spinal cord injury and two subjects with hemi-syndromes and spasticity due to brain trauma. Kinematic and EMG patterns were recorded during attempts at single-joint elbow or ankle voluntary movements and isometric contractions. Reflex responses to passive ankle dorsiflexion and Babinski's reflex were also recorded. Intrathecal injection of baclofen effectively suppressed spastic signs in all the spinal cord injury patients. Suppression of muscle tone and exaggerated reflexes was accompanied by a general improvement of the patterns of muscle activation. This involved the elimination of clonus and a decrease in the co-contraction of antagonist and distant muscle groups. In one of the brain trauma patients, baclofen suppressed the spastic signs and H-reflexes bilaterally. Voluntary movements in his "bad side" improved, while movements in the "good side" remained unchanged. Baclofen was ineffective in another brain trauma subject. It did not induce any negative changes in the voluntary motor performance in both "good" and "bad" sides of this subject. The subject displayed similar peak speeds, torques, and EMG patterns before and after the drug. We hypothesize that adaptive changes in the spinal cord to a traumatic lesion include an increase in the number and/or affinity of the GABA-ergic receptors leading to the selective action of intrathecal baclofen.

668.5

THE PROGRESSION OF MOVEMENT DISORDERS IN PATIENTS WITH RSD. C.J. Hunker* and M. Backonja. Dept. of Neurology, U. of Wisconsin, Madison, WI 53792.

Neuropathic pain syndromes with sympathetic involvement traditionally known as reflex sympathic dystrophy (RSD) often present associated muscle weakness, tremor, dyskinesia, dystonia, and synkinesia as primary movement disorders in affected limbs (Schwartzman & Kerrigan, 1990; Hunker and Backonja, 1991). These data supported a CNS pathogenesis; a formerly contested issue. The progression of pain features to 'non-affected' body parts has been anecdotely reported in humans and demonstrated empirically in animal models. A similar course for movement control aberrations has not been investigated. Maximal and controlled voluntary contractions were examined in 25 RSD patients via isometric wrist and thumb/index finger tasks along with accelerometer recordings from pain-affected and non-affected limbs at six to twelve month intervals. In each case, non-affected limbs weakened over time even in the absence of pain and tended to follow the same muscle weakness distribution as the pain-affected extremity. Muscle force control abnormalities in the form of tremor, dyskinesia, and dystonia were also recorded from contralateral limbs in 60% of the patients. The progressive involvement of contralateral limbs with the RSD-associated movement disorders further support the putative CNS pathophysiological substrate.

MYASTHENIA GRAVIS PATIENT PLASMA REDUCES DEPOLARIZATION-DEPENDENT UPTAKE OF CALCIUM INTO ISOLATED NERVE TERMINALS OF THE RAT. S.J. Hewett*, A.M. McLane, and W.D. Atchison, Dept. Pharmacol./Toxicol. and Neuroscience Program. Michigan State Univ. E. Lansing, MI 48824.

Myasthenia gravis is an autoimmune, neuromuscular disease, in which the postjunctional nicotinic acetylcholine receptor is generally considered to be the pathogenic site. It has generally been assumed that disruption of presynaptic processes contributes little to the muscle weakness in these patients. Recent evidence indicates that some patients with myasthenia gravis also have anti-presynaptic membrane receptor antibodies for somatic motor nerves (*J. Neurol. Sci.* 102, 39-45, 1991). We discovered unexpectedly that plasma from a patient with myasthenia gravis reduced $^{45}Ca^{2+}$ uptake into isolated nerve terminals. The present study was thus undertaken to determine whether acute application of plasma from several patients with myasthenia gravis would reduce depolarization-dependent uptake of $^{45}Ca^{2+}$ into rat cortical synaptosomes. Net influx of ^{45}Ca during 10 sec of K^+-induced depolarization (42.5 mM KCl) was significantly reduced by plasma from three patients with myasthenia gravis as compared to their non-disease plasma-treated paired control. Conversely, uptake of $^{45}Ca^{2+}$ in the presence of non-depolarizing concentrations of KCl (5mM) was not reduced significantly by plasma from the myasthenic patients. Lactate dehydrogenase release from synaptosomes incubated with plasma from patients with myasthenia gravis was not increased over controls indicating the effect was not due to decreased synaptosomal viability. These studies, to our knowledge, are the first to demonstrate direct alterations in nerve terminal function following incubation with myasthenic plasma. Supported by the Muscular Dystrophy Association, the Myasthenia Gravis Association- Detroit Chapter and NIH grant NS20683. WDA is supported by RCDA K04-ES00178.

POSTURAL STABILITY AND VARIABILITY IN TARDIVE DYSKIENSIA.
K. M. Newell*, R. E. A. van Emmerik and R. L. Sprague.
Department of Kinesiology, University of Illinois at Urbana-Champaign, Urbana, IL 61801

Stereotypic motions are a characteristic feature of tardive dyskinesia (TD). These motions can arise in a variety of tasks including bi-pedal posture. This study examined the structure of the center of pressure profile in 3 groups (rhythmical TD, non rhythmical TD, normal control) of trials. Our findings suggest that: a) there is structure to the usually construed random pattern of the "normal" center of pressure; b) that some of the *developmentally disabled tardive dyskinetic subjects* exhibited a rhythmical center of pressure pattern that is consistent with a limit cycle attractor organization; c) normal center of presure has a higher dimensionality; and d) that variability of the center of pressure can only be interpreted as reflective of stability when the same attractor dynamics are evident in organizing the posture. These findings suggest: (1) that center of pressure variability needs to be interpreted in relation to dimensionality of the supporting dynamic; (2) significant limitations to traditional interpretations of the relation between center of pressure variability and posture stability; and (3) new ways to analyze human postural dynamics.

BROAD A BAND DISEASE: A NEW CONGENITAL MYOPATHY ASSOCIATED WITH LEBER'S CONGENITAL AMAUROSIS.
R. E. Mrak*, B. Lange, and M. C. Brodsky. Departments of Pathology, Pediatrics, Neurology and Ophthalmology; Univ. Arkansas Medical Sciences and VAMC, Little Rock, AR 72205.

A two year-old boy with Leber's congenital amaurosis displayed diffuse hypotonia with delayed motor milestones, depressed deep tendon reflexes and normal sensation. Histological and histochemical evaluation of biopsied thigh muscle showed no abnormality. One-μm plastic sections and electron microscopy showed numerous foci of broadening or smearing of the A band with loss of a distinct I band. Z-lines were normal except for a fine waviness in these areas. The inter-Z-line sarcomere had a staining density intermediate between normal A and I bands, and the thick filaments in these lesions appeared misaligned. The smaller lesions involved a single sarcomere of a single myofibril, while larger lesions extended laterally across 3-4 myofibrils and longitudinally along 3-4 sarcomeres. There were 24 such lesions in 10 random 3400 μm^2 fields, but none in 9 other hypotonic patients with "unstructured" myopathies. These findings suggest an abnormality of the M-line or of the structural protein connectin. These findings differ from those of previously-described congenital myopathies, and represent the first described morphological abnormality of muscle in a patient with Leber's congenital amaurosis.

ULTRASTRUCTURAL PATHOLOGY OF SKELETAL MUSCLE IN PROGRESSIVE SYSTEMIC SCLEROSIS.
A. Márquez, H. Rivera, H.J. Finol* I. Montes de Oca and B. Muller. Institute of Experimental Medicine, Venezuela Central University, Apartado 50587, Caracas 1050, Venezuela.

Upon careful examination the majority of patients with progressive systemic sclerosis (PSS) are found to have muscular proximal weakness and wasting, elevation of plasma level of muscle enzymes and alterations in EMG. Using light microscopy two different pathologic entities have been described, simple myopathy and myositis. Ultrastructural studies on the muscle lesions have emphazised the vascular changes. In this work we report the whole spectrum of changes observed by electron microscopy in the study of needle muscle biopsies from five patients with positive diagnoses of PSS and a muscle compromise.The changes observed were: a varied degree of fiber atrophy, fiber necrosis, mitochondrial alterations, vacuolation of sarcotubular system, lysosomal proliferation, presence of filamentous and concentric laminated bodies. Capillary alterations included hypertrophy of endothelium with lumen occlusion, autophagic vacuoles and widening and reduplication of basement membrane. Cell infiltration included lymphocytes , macrophages and mast cells. This work indicates a multifactorial pathogenesis, neural, vascular and autoimmune for the muscle damage in PSS.

This work was supported by CDCH of UCV (03-2709/92), Fundación Polar and The British Council Venezuela).

ELECTROMYOGRAPHIC CHANGES COMPARING MEDIAL AND LATERAL SURGICALLY TRANSFERRED RECTUS FEMORIS MUSCLE IN CHILDREN WITH CEREBRAL PALSY
B.R. Etnyre,* Rice University, Houston, TX 77035, C. Chambers, and N. Scarborough, Shriner's Hospital for Crippled Children, Houston, TX 77251

Children with cerebral palsy characteristically present with muscle contractures which result in gait abnormalities including excessive hip flexion, and internal hip rotation and adduction. Surgical procedures on rectus femoris muscles may be performed to correct these problems. The purpose of this procedure is usually to reduce the effect of the rectus femoris on hip flexion and reduce the internal rotation and adduction of the hip. The desired result is a reduction in the over activity of the spastic muscles for improved range of motion. Rectus femoris muscle transfer procedures include release and reattachment either medially to the sartorious or laterally to the iliotibial band. The purpose of this study was to examine the electromyographic (EMG) and dynamic knee flexion changes following surgical transfer of the rectus femoris medially or laterally. Rectus femoris EMG and percentage time to peak knee flexion were the critical variables observed. EMG was collected through a telemetry system. Dynamic range of motion was recorded using a VICON system with six cameras. Data were collected pre- and post-operatively and analyzed and plotted using a PDP 11/73 computer. Sixty-six spastic hemiplegic, diplegic or quadriplegic patients (4.1 to 18.1 years of age) were observed allowing analysis of 119 lower limbs. A 2 x 2 (type of surgical procedure by pre- and post-surgical gait measures) analysis of variance was performed for percentage of rectus femoris EMG and time (as percentage of gait cycle) to peak knee flexion. A .05 significance level was used for all comparisons. Significant interactions for type of procedure by pre-post rectus femoris EMG, $F(1,117) = 4.8$, $p > .05$, and time to peak flexion, $F(1,117) = 8.9$, $p = .004$, were revealed. Although neither average percentage of EMG nor time to peak flexion was reduced to normal values using either procedure the medial transfer procedure produced more favorable average outcome than the lateral transfer procedure.

SPONTANEOUS RIGIDITY RECORDED IN A MUTANT RAT (TAIEP) WITH IMMOBILITY EPISODES.
J. Valencia and J. Aceves*, Dept. de Fisiología, Biofísica y Neurociencias, CINVESTAV-IPN, México, D.F., and Centro de Invest. en Ciencias Fisiol., Inst. de Ciencias, Univ. Autónoma de Puebla, Puebla, Pue.

Here we tested whether the immobility episodes of TAIEP rats were associated with muscular rigidity in both flexor and extensor muscles, and whether the rigidity was related with a decrease in striatal dopamine (DA). To verify this, the spontaneous electromyographic activity of the Gastrocnemius-Soleus (GS) and Tibialis-Anterior (TA) muscles was recorded in the mutant rats (n=4), and also, during the immobility episodes. DA was assayed by HPLC. Both muscles showed spontaneous tonic activity periods lasting more than 8 min., in duration. The average firing frequency for GS was of 21.2±1.1 Hz and for TA, 38.6±3.5 Hz. This tonic activity was not detected in any animal of the control group (n=5). During the immobility the firing frequency of the muscular fibers increased to more than 100 Hz, returning to basal levels afterwards. The high firing frequency was observed only during the immobility episodes. DA content in the mutant rats (n=6) was 55% higher than the age-matched controls (n=6). In conclusion, the immobility episodes were associated with muscular rigidity in both flexor and extensor muscles, but the rigidity was not accompanied by a decrease in striatal DA.

AMPHETAMINE DISRUPTS PREPULSE INHIBITION OF THE ACOUSTIC STARTLE REFLEX: A REPLICATION D.A. Ott* A.J. Diehl, and R.J. Mandel. Dept. of Psychology, Univ. of Illinois, 603 E. Daniel St., Champaign, IL 61820

It has been reported that amphetamine inhibits the ability of rats to use a low amplitude warning stimulus (prepulse) to inhibit their acoustic startle response. It appears that the prepulse inhibition phenomenon can be modulated by dopamine agonism specificially in the nucleus accumbens and schizophrenic humans show a similar pattern of deficit in the same task (for review see Geyer et al., *Brain Res. Bull.* 25:485-498, 1990). Here, we report a replication of one of Geyer et al.'s findings; that amphetamine (AMPHET) disrupts prepulse inhibition. The figure below represents the data from 8 normal female Sprague-Dawley rats ± 2 mg/kg AMPHET sulfate i.p. These data are reported to demonstrate that the effect of systemic AMPHET can be obtained in a different laboratory using an entirely different appartus but similar experimental parameters. Dose-response experiments are underway to compare the AMPHET ED_{50}'s for prepulse inhibition versus locomotor activity.

A QUANTITATIVE TECHNIQUE FOR COMPARISON OF GYRAL AND SULCAL PATTERNS FROM MRI BRAIN SURFACE RENDERINGS. A. J. Bartley,* D. W. Jones, D. R. Weinberger. Clinical Brain Disorders Branch, IRP, NIMH, Washington, DC 20032.

High-fidelity surface rendering algorithms applied to finely spaced (1.5mm) GRASS MRI scans produce faithful representations of the gyral and sulcal patterning of the brain *in vivo*. Typically visual assessment and rating are used to compare these renderings. We have explored the possibility of employing 2-dimensional cross-correlation techniques to obtain quantitative measures of similarities between brain renderings. The cross-correlation method generates a 2-D map of a similarity measure at all possible relative offsets of two images. The peak of this map gives both the relative position of maximal similarity and an objective measure of the magnitude of this similarity on a scale of -1.0 to +1.0.

We have applied this procedure to surface renderings from brain MRI's of normal twins. Surface rendering and cross-correlation calculations were performed on a MacIIci with readily available software. The cross-correlation maps were computed by means of a fast Fourier transform (FFT) algorithm. Our results indicate that the cross-correlation technique is reliable and useful for comparing gyral and sulcal patterns between brain regions and across individuals. The cross-correlation results were found to discriminate twin pairs from unrelated individuals more accurately than visual assessment of the same rendered images by 8 raters experienced in MRI analysis. This method may also have broader application in comparing images derived from a variety of modalities, e.g., microscopy, autoradiography, PET, etc.

ERYTHROCYTE TRANSKETOLASE ACTIVITY IN DEPRESSION. B.I. Diamond, M.F. Casanova, R.L. Borison* and T.H. Nguyen. Med. Coll. of Georgia, Augusta, GA 30912-3800.

Although Beriberi and Wernicke's serve as primordial examples of thiamine deficiency, the symptoms observed in these conditions manifest themselves only after a severe and protracted vitamin B1 depletion. Fatigue is the most common symptom in those cases with mild thiamine deficiency. It is therefore noteworthy that both thiamine deficiency as well as fatigue are frequently seen in the psychiatric patient population. This study explores for the presence of thiamine deficiency in depression, a disease often characterized by loss of energy and chronic tiredness. Thirty-one patients with major depression (DSM IIIR criteria) and 13 age-matched controls participated in the study. Physical examination and laboratory screening tests were used to identify any concomitant medical conditions and confounding nutritional abnormalities. Erythrocyte hemolysates were analyzed spectrophotometrically for the activity of NADH-dependent transketolase both in the presence (TPP) and absence (TK) of thiamine pyrophosphate. Repeated blood withdrawals were performed for a total of 150 assays. No significance between group differences were found for either the TK activity or the TPP effect (t test, $p>0.05$). Our results suggest that fatigue in major depression may be related more to the dysphoric mood than to a nutritional deficiency.

MANIA: RESPONSE TO LITHIUM ACROSS THE AGE SPECTRUM R.C. Young*, B. Kalayam, G. Tsuboyama, P. Stokes, S. Mattis, and G.S. Alexopoulos. New York Hospital-Cornell Medical Center, Westchester Division, White Plains, NY 10605.

Manic states are relatively common among geriatric psychiatric inpatients as well as among younger adult patients. While lithium salts are the first line treatment across the age spectrum, the extent to which optimum treatment conditions change with age has not been adequately investigated. We have therefore begun to study geriatric and younger adult inpatients treated with lithium salts. Twenty-four (n=24) inpatients meeting Feighner criteria for mania were monitored prospectively. They ranged in age from 23 to 89 years and were predominantly female. Manic Rating Scale (MRS) scores declined over 3 weeks of lithium treatment. Greater decrements in MRS were associated with higher plasma lithium levels ($p<.02$). Patients with lower Dementia Rating Scale scores had higher MRS scores ($p<.02$). These preliminary findings suggest that concentration-effect relationships for lithium exist across the age spectrum. The implications of cognitive dysfunction for management of manic psychopathology require further study.

IPRINDOLE TREATMENT INCREASES EXTRACELLULAR CONCENTRATIONS OF NA AND DA BUT NOT 5-HT IN THE PREFRONTAL CORTEX : EVIDENCE THAT IPRINDOLE INCREASES AVAILABILITY OF SYNAPTIC CATECHOLAMINE IN VIVO. T. Koyama*, M. Abe, T. Ohmori, S. Matsubara and I. Yamashita. Dep. of Psychiatry and Neurology, Hokkaido Univ. Sch. of Med., Sapporo, 060 Japan.

The effects of systemic administration of iprindole, clinically effective antidepressant which dose not inhibit amine uptake or exhibit monoamine oxidase inhibitor activity in vitro, on the in vivo extracellular concentrations of NA, DA and 5-HT were examined by brain microdialysis in the medial prefrontal cortex of freely moving rats. Iprindole treatment induced substantial increases in NA and DA outputs in a dose-dependent manner within the range of iprindole tested (25-50 mg/kg). The 5-HT efflux did not change after iprindole administration. The results suggest that iprindole increases availability of synaptic NA and DA in vivo by the different mechanism from the inhibition by itself of amine transport or catabolism. Therefore the results are consistent with the possibility that iprindole enhances the release mechanism of NA and DA, or that there are unknown metabolities of iprindole with amine uptake-or catabolism-blocking potential. Although further study is needed to clarify these possibilities, this finding is consistent with the hypothesis that antidepressants that increase synaptic NA or DA levels cause

BLUNTED DESENSITIZATION OF EPINEPHRINE-INDUCED PLATELET AGGREGATION IN DEPRESSED PATIENTS. J.E. Piletz* and D. Chikkala. Dept. of Psychiatry, Case Western Reserve Univ. & MetroHealth Med Center, Cleveland, Ohio 44109.

Elevated radioligand binding to platelet *high affinity* α2-adrenoceptors ($\alpha 2AR_H$) has been reported in depression. Herein we determined if depressed patients also (1) exhibit hypersensitivity to epinephrine-induced platelet aggregation, and/or (2) differ from controls in their desensitization of epinephrine aggregation in vitro. Desensitization is an important cellular regulatory response, and dysregulation of receptor function has been proposed in depression. Incubating unstirred platelets with 20 uM epinephrine desensitizes subsequent aggregation when the platelets are stirred. *No changes* in undesensitized aggregation were observed in depressed patients (n=20) vs. healthy controls (n=18). Moreover, there were no significant correlations between undesensitized aggregation and pre-epinephrine $\alpha 2AR_H$ Bmax (p^{125}I-clonidine saturations). By contrast, the extent of epinephrine-induced desensitization was *blunted* in depressed patients ($p \leq .05$ at 4,20,30 and 60 min post-epinephrine) and the $extent_{max}$ of desensitization was negatively correlated with the pre-epinephrine $\alpha 2AR_H$ Bmax ($r=-.48$, $p=.02$). Blunted desensitization in depression was most apparent during the first 0.5-2 min. post-epinephrine before stirring was initiated; in patients the extent of aggregation actually increased slightly during this period. Thereafter, a normal time course of desensitization was observed in depressed patients; the mono-exponential decay in epi-aggregation was not different in depressed patients vs controls ($t_{½}$ avg = 10.6 min vs 7.8 min). The data suggest that blunted receptor desensitization might give rise to up-regulated platelet $\alpha 2AR_H$ binding sites in depression. If blunted desensitization also occurs in the brain, this could underlie certain aspects of depression.

669.7

AUDITORY BRAINSTEM RESPONSE IN GERIATRIC DEPRESSION. B. Kalayam MD, CA Shamoian MD*, RC Young MD. Cornell Univ Medical College, New York, NY.

Depressed geriatric patients with onset of major depression in late-life (LOD) have more auditory disturbances compared to those with onset of depression in early-life (EOD) and elderly controls (EC) [Int. J. Geriatr. Psychiat 6:131-136;1991]. It has been proposed that central auditory changes may account for increased auditory disturbances in LOD patients. The findings from an investigation using auditory evoked response to examine lesion-sites is reported.

Nineteen subjects consisting of LODs (n=7), EODs (n=7) and ECs (n=5)have been studied. Differences were found between groups on rate-dependent latency shifts during ABR testing when stimulus rate was increased from 11 to 80 clicks/sec. LODs had greater increase for interwave intervals I-V and III-V compared to EODs ($p < .005$; ANOVA) and ECs ($p < .035$; ANOVA).

In neurologic disorders, abnormalities in rate dependent latency shifts on ABRs are attributed to occult degenerative changes in brainstem auditory pathways. Our preliminary findings suggest that: 1) LODs can be distinguished from EODs and ECs on physiologic measures of auditory brainstem activity, and; 2) central auditory changes may correlate with depressive features reported in elderly patients with sensorineural hearing loss.

●PLASMA MHPG IN MAJOR DEPRESSIVE DISORDER:DIFFERENCES BETWEEN RESPONDERS AND NONRESPONDERS.
●K.MINE [a], M.OKADA [a], M.NIWA [b]* and M.FUJIWARA [a].
●Psychosom.Med.,Fac.of Med.,Kyushu Univ., Fukuoka, [a]Dep.of Physiol. and Pharmacol.,Fac.of Pharmac.Sci.,Fukuoka Univ., [b]Dep.of Pharmacol., Fac.of Med.,Nagasaki,JAPAN.

The plasma levels of free(f-) and sulfo-conjugated(s-) forms of both norepinephrine(NE) and 3-methoxy-4-hydroxyphenylglycol(MHPG), both before and after treatments, were examined in patients with major depressive disorders without melancholia. In 11 patients showing a good response to treatment(responders), the plasma s-MHPG levels were significantly reduced after treatment, while no significant changes were seen in 9 patients showing no response to treatment(nonresponders). On the contrary, the plasma s-MHPG levels in 6 patients who had been suffering from somatic diseases tended to increase after treatment. The plasma f-MHPG levels showed no significant changes after treatment in the responders, the nonresponders and the somatic disease group. The plasma f- and s-NE levels revealed no significant differences between each group. The plasma s-MHPG levels may be related to the treatment outcome of major depressive disorder.

CEREBRAL CORTEX G-PROTEINS AND cAMP FORMATION IN BIPOLAR AFFECTIVE DISORDER. L.T. Young*, P.P. Li, S.J. Kish, K.P. Siu, A. Kamble, O. Hornykiewicz, and J.J. Warsh. Clarke Institute of Psychiatry, Toronto, Ontario, Canada, M5T 1R8.

Substantial data from experimental animal and peripheral blood cell studies have pointed to a disturbance in transmembrane signal transduction at the level of the guanine nucleotide regulatory (G) protein in bipolar affective disorder which may be corrected with lithium treatment. Given the potential relevance of such disturbances in this disorder, we estimated brain G-protein levels and adenylyl cyclase activity directly in various brain regions from subjects with bipolar affective disorder. Membrane G-protein ($G_s\alpha$, $G_{i(1\&2)}\alpha$, $G_o\alpha$ and $G\beta$) immunoreactivities were estimated by Western blotting in postmortem brain regions obtained from 10 patients with bipolar affective disorder and 10 age and sex-matched controls. To examine whether there were functional correlates to the observed elevated $G_s\alpha$ levels, basal, GTPγS- and forskolin-stimulated cAMP production were determined by radioimmunoassay. Compared with control samples, $G_s\alpha$ (52 kDa species) immunoreactivity was significantly ($p<0.05$) elevated in prefrontal (+38%), occipital (+80%) and temporal (+62%) cortex but not in hippocampus (+24%), thalamus (-23%) or cerebellum (+22%). In contrast, no significant differences were found in the other G-protein subunits measured. Forskolin-stimulated cAMP production was significantly increased in temporal (+31%) and occipital (+96%) cortex. GTPγS-stimulated cAMP production was increased to a similar extent but failed to reach statistical significance. A significant correlation ($r=0.60$) was observed between forskolin-stimulated cAMP formation and $G_s\alpha$ (52 kDa) immunoreactivity when examined across these cortical regions. The findings of increased cerebral cortical $G_s\alpha$ subunit levels and adenylyl cyclase activity point to an important disturbance at the level of the G-protein in bipolar affective disorder which may explain the pathophysiology of this condition as well as the mechanism of action of lithium treatment.

669.10

PHASE DELAY AND DISORDERING OF NORADRENERGIC DIURNAL PATTERNS IN DEPRESSION. E.M. DeMet*, J. Piletz, H. Gwirtsman, and A. Halaris. Depts. Psychiatry, Univ. Calif. Irvine, CA 92717, Case Western Reserve Univ., Cleveland, OH 44109, and NIMH, Washington D.C., 20852.

Diurnal patterns of the noradrenergic metabolite 3-methoxy-4-hydroxyphenylglycol (MHPG) were studied in the plasma of 43 depressed patients and 12 controls. Daily rhythms were adequately fit by a sinusoidal function (24 hr fixed period) in both groups although the unexplained variance in patients was significantly greater than in controls. Disordered rhythms, while characteristic of the depressed patients, showed no evidence of state dependency. Peak MHPG levels, in controls, occurred at 2:54 PM. Patient values peaked 1.81 hr earlier than controls and this difference was significant. No group differences were found in either the time independent average levels or sinusoidal amplitudes of the MHPG rhythms. The effects of chronic desipramine treatment on diurnal patterns were examined in a subset of patients. No significant change was found in any variable after treatment regardless of the degree of clinical response. The results suggest that depressed patients typically have aberrant circadian noradrenergic regulation and to a lesser extent either an increased zeitgeber sensitivity or decreased circadian period. None of these abnormalities, however, appear to be directly linked to changes in mood state.

669.11

DISCRIMINATORY CAPABILITY OF PET MEASUREMENTS OF REGIONAL BLOOD FLOW IN FAMILIAL PURE DEPRESSIVE DISEASE. W.C.Drevets*, E.L. Spitznagel, A.K.MacLeod, M.E. Raichle. Washington Univ. Sch. of Med., St. Louis, MO 63110.

We reported increased blood flow (BF) in the left prefrontal cortex, amygdala, and medial thalamus, and decreased BF in the l. medial caudate in familial pure depressive disease (FPDD), a subtype of unipolar major depression (Drevets et al., J Neurosci., 1992). This and other evidence suggested a circuit involving the prefrontal cortex, amygdala, and related parts of the striatum, pallidum, and thalamus is involved in the pathophysiology of FPDD. Discriminant analysis of the covariance of activity in these structures correctly categorized FPDD subjects (n=9) in 89% of cases and controls (n=24) in 92% of cases (Wilks' lambda=.42, F=9.5, p<.0001). Of 4 additional subjects with FPDD (not previously studied) this covariance matrix classified 3 as FPDD. Of 8 bipolar depressives one was classifed as FPDD and 7 as normal. However, 3 of 6 normals scanned while thinking sad thoughts were incorrectly classified in the FPDD category. In the "sad thoughts" relative to the "rest" scan, BF increased in the l.prefrontal cortex and medial thalamus, but decreased in the amygdala (Wilks' lambda=.000012, F=35, p<.0001. This contrasts with FPDD, where amygdala BF is increased. If this experimental task reflects the cognitive and emotional state in FPDD, a possible explanation for these data is that abnormal modulation of the amygdala exists in FPDD.

669.12

PRENATAL AMPHETAMINE EXPOSURE INCREASES THE NUMBER OF NEURONS POSITIVE FOR NITRIC OXIDE SYNTHASE (NOS) IN THE LATERODORSAL TEGMENTAL NUCLEUS OF THE RAT. M. Nielsen, M. Lyon,* and W. O. McClure. Dept. of Biological Sciences, Univ. Southern California, Los Angeles CA 90089-2520, and *Dept. Psychiatry and Behavioral Sciences, Univ. of Arkansas for Medical Sciences, Little Rock AR 72205.

A substantial amount of evidence suggests that at least some of the schizophrenia(s) are related to errors in fetal development. To test the fetal development hypothesis we have exposed rat pups *in utero* to dopaminergic agonists and have examined the behavior and neuroanatomy of these animals when they mature to young adulthood. NOS-positive cells in the laterodorsal tegmental nucleus (LDT) were of interest, since these control phases of sleep which are deficient in schizophrenics. Twenty-three pregnant Wistar rats were injected on d 11-14 of pregnancy with d-amphetamine sulfate (5 mg/kg) or saline. Pups at 45-50 days of age were sacrificed by cardiac perfusion, after which cells of the LDT of selected horizontal sections were stained for NOS using NADPH and nitroblue tetrazolium. The number of NOS-positive cells observed in a field of 6.93×10^4 μm^2 increased by 12% in animals treated with amphetamine (control = 42.92 +/- 4.48, n=7; treated = 48.14 +/- 1.89, n=7; t=2.84(12), p=0.015). This increase agrees in direction but is smaller than that reported for schizophrenics (Karson et al. Psych. Res: Neuroimag. (1991) 40, 31-48). The data suggest that certain aspects of the fetal development hypothesis of human schizophrenia can be demonstrated in an animal model. (Supported by NIH and the Hedco Foundation).

669.13

THE EFFECT OF ELECTROCONVULSIVE STIMULATION ON HIPPOCAMPAL LONG TERM POTENTIATION *IN VIVO*. C.A. Stewart, I.C. Reid and L.J. Whalley*. Dept. of Psychiatry, Univ. of Edinburgh, Edinburgh EH8 9JZ, and *Dept. of Mental Health, Univ. of Aberdeen, Aberdeen, Scotland, UK.

Although electroconvulsive therapy (ECT) has been used as an effective treatment for severe depressive illness for 50 years, its mode of action, remains unknown. Apparent side effects of ECT include disruption to memory processes which have been documented in the medical literature. A recent study has suggested that electroconvulsive stimulation (ECS) in rats has profound effects on the induction of Long Term Potentiation (LTP) recorded from a hippocampal slice preparation (Anwyl et al, 1987, Brain Res.). Given the putative role of LTP in learning and memory, this finding provides a possible mechanism/explanation for the memory impairment associated with ECT.

In this study, the effects of repeated ECS on the induction and single ECS on the maintenance of LTP were examined in intact rats. Seizures were induced transcranially via ear-clip electrodes. Field potentials were recorded from the hilus of the dentate gyrus during low frequency stimulation of the perforant path in anaesthetised animals. A series of 10 ECS spaced over 20 days impaired LTP induction as measured by the excitatory post synaptic potential (EPSP) slope function (control 24.6 +/- 5.2%, ECS 11.1 +/- 2.8%) and the population spike height (control 337 +/- 75.2%, ECS 1.9 +/- 5.09%). Examination of the absolute EPSP slope and population spike values pre-tetanus indicated that the reduction in the amount of LTP obtained may have been due to the system being partially saturated. Preliminary experiments looking at the effect of a single ECS induced 25 minutes after tetanus suggest that the seizure reverses previously established LTP as assessed by EPSP slope and population spike. Further experiments are in progress to determine the precise time course of these effects and their behavioural consequences.

PLATELET 3-H-PAROXETINE AND I-125-LSD BINDING IN OBSESSIVE COMPULSIVE DISORDER. W.A. Hewlett* and F. Ching. Department of Psychiatry, Stanford University School of Medicine, Stanford, CA. 94305

Serotonergic agents have been used to treat patients with Obsessive Compulsive Disorder and abnormalities in serotonergic functioning have been reported in this disorder. To study characteristics of the serotonin uptake carrier and the serotonin-2 receptor in OCD patients, we compared the binding kinetics of 3-H-Paroxetine and I-125-LSD in platelets obtained from untreated patients and controls subjects. Patients were treated for 6 weeks with either clomipramine or clonazepam. Binding characteristics were then compared in the treated and untreated conditions for these subjects. There was no difference for patients and control subjects in Bmax or Kd for either radioligand. In addition, there were no differences in these parameters for subjects treated with clonazepam. There was an apparent difference in Kd for 3H-paroxetine when subjects were treated with clomipramine, but there was no difference in the Bmax for this ligand, and no differences in I-125-LSD binding characteristics. These results provide no evidence for abnormal functioning of the serotonin uptake carrier or the serotonin-2 receptor in OCD patients.

669.15

Treatment Implications of Baseline Anger and of Anger Response to MCPP in Generalized Anxiety Disorder (GAD). M. Germine, M.D., A.W. Goddard, M.D.*, D.E. Sholomskas, Ph.D., G.R. Heninger, M.D., D.S. Charney, M.D., and S.W. Woods, M.D. Department of Psychiatry, Yale University School of Medicine, New Haven, CT 06519

In a group of 10 patients with GAD a marked anger response to the serotonergic agonist MCPP has been noted, which appears to show relative specificity to GAD. Baseline anger is predictive of net anger response ($r=0.78$, $p=0.008$) and of net MCPP change in Panic Attack Symptom Score (PASS) ($r=0.83$, $p=0.003$). No significant correlations were noted between baseline anxiety and any of these measures. After the MCPP challenges and baseline ratings conducted over 3 weeks off medication, a clinical trial of open-label buspirone was conducted on 8 of the patients. One patient dropped out during the first week due to side effects. Four patients were judged to be clinical responders and three non-responders by a research psychiatrist blind to the anger data. The responders had a mean net anger response to MCPP of 46 ± 13mm (visual analog scale or VAS) compared to 0 ± 1mm in the non-responders ($p=0.002$) and VAS baseline anger scores of 4.5 ± 4.1mm vs 0.7 ± 1.2 ($p=0.12$). No significant realationship was noted between net VAS anxiety response to MCPP and response to buspirone. Together these results suggest a relationship between baseline anger, anger response to MCPP, and buspirone response in GAD. Although the neurobiological mechanisms underlying these relationships are not immediately apparent, these observations do suggest that baseline anger and/or anger response to MCPP may be useful predictors of clinical outcome, at least in GAD. Replication with larger samples is required.

ELECTROCONVULSIVE SHOCK (ECS) INDUCES LONG-TERM CHANGES IN REGIONAL BRAIN CYTOCHROME OXIDASE ACTIVITY. J.N. Nobrega *, R. Raymond and W.M. Burnham. Neuroimaging Research Section, Clarke Institute of Psychiatry, and Pharmacology Department, University of Toronto, Toronto, Ont., Canada.

Electroconvulsive therapy has clearly beneficial effects in severe depression. However, questions remain concerning its mechanisms of action and possible long-term deleterious effects on brain function. The present study used cytochrome oxidase (CO) histochemistry to examine long-term effects of ECS on regional brain metabolic activity. CO is a mitochondrial enzyme whose activity is tightly coupled to neuronal function (Wong-Riley, *TINS*, 1989, *12*, 94). Rats received a course of 8 ECS (once every 48 hr, 150 mA, .2 sec) and were sacrificed either 24 hr or 28 days after the last ECS or sham treatment. CO activity was quantitated in 99 different brain areas using calibrated densitometric standards. Twenty-four hr after the last seizure CO activity was generally elevated in ECS-treated brains, but in none of the regions examined did ECS vs. control differences reach statistical significance. In contrast, at 28 days CO activity in ECS brains was significantly increased in the bed n. of the stria terminalis (+25%), basolateral (+14%) and medial amygdala (+12%), dorsomedial (+20%) and ventromedial (+12%) hypothalamus, ventromedial thalamus (+9%), intrapeduncular n. (+20%), mammillary n. (+14%) and pontine n. (+16%). The observed general tendency for *increased* CO activity after ECS is consistent with an absence of gross pathology. The observations at 28 days suggest that ECS induces progressive metabolic changes which seem to develop independently of additional stimulation. Finally, the fact that changes were seen predominantly in limbic structures suggest a possible involvement of these areas in the therapeutic effects of ECT.

669.17

ANTERIOR CINGULATE GYRUS METABOLISM CORRELATES WITH RESPONSE TO BEHAVIORAL TREATMENT FOR OCD. J.M. Schwartz*, K.M. Martin, L.R. Baxter. UCLA School of Medicine, Los Angeles, CA 90024

Prior work by us using PET demonstrated that obsessive-compulsive disorder (OCD) patients who respond to either drug or behavioral treatment show a decrease ($p<.01$) in the metabolic rate (MR) of the head of their right (R) caudate nuc. (Cd) relative to the ipsilateral hemisphere (Hem) (Cd/Hem). Only drug responders showed a change in anterior cingulate gyrus (Cing) MR, with a decrease ($p=.03$) in R Cing/Hem (Baxter et al, Arch Gen Psychiatry, 1992).

Further data analysis in this ongoing study shows a significant rank order correlation between the percentage change in the Yale-Brown OC scale after drug-free behavioral treatment and the percentage change in left (L) Cing/Hem ($n=8$; $tau=-.62$, $p=.03$); this correlation was not significant for R Cing/Hem ($p=.38$). Drug treatment data for Cing/Hem did not approach significance on this correlation ($p>.45$, R & L).

Both drug and behavior treatment response may relate to alterations in the gating of cortical inputs by the Cd; behavioral treatment response may also involve activation of Cing, related to the work of behavioral self-control efforts.

670.1

SEROTONIN AND BETA-ADRENERGIC RECEPTOR BINDING IN FRONTAL CORTEX AND HIPPOCAMPUS OF SUICIDE VICTIMS. C.A. STOCKMEIER*, Y. ZHANG, H.Y. MELTZER, J. OVERHOLSER, P.R. ERNSBERGER, P.A. THOMPSON AND L. KHAITAN. Dept. of Psychiatry, Case Western Reserve University, Cleveland, OH 44106

Abnormalities in serotonin (5HT) and β-adrenergic receptor binding have been reported in frontal cortex of suicide victims. Brain samples were collected at autopsy from 12 violent suicide victims (gunshot or hanging) and 12 age and sex matched controls dying of natural or accidental causes or homicide. Psychological autopsy examinations revealed that 6 suicide victims had a history of depression. We used quantitative receptor autoradiography to measure the binding of [^{3}H]ketanserin, [^{3}H]8-OH-DPAT and [^{125}I]pindolol to 5HT-2, 5HT-1A and β-adrenergic receptors. In all samples, age was inversely correlated with 5HT-2 and 5HT-1A receptor binding in subregions of frontal cortex (area 8,9) and the hippocampus. Levels of 5HT or norepinephrine in frontal cortex were inversely correlated with postmortem delay. Postmortem delay had little effect on receptor binding. There were no significant differences between matched pairs of controls and all suicides or matched controls and suicides with a depressive illness for monoamine content or 5HT-1A, 5-HT-2 or β-adrenergic receptor binding in frontal cortex, or 5HT-1A or 5-HT-2 receptor binding in hippocampus. Further studies with larger sample size and attention to effects of drug treatment and prior depression are needed. Supported by PHS Grants MH45488 and MH41684.

670.2

MEASURES OF SEROTONIN FUNCTION AFTER SLEEP DEPRIVATION IN DEPRESSION. R.M. SALOMON, P.L. DELGADO, J. LICINIO, H.L. MILLER, G.R. HENINGER,* D.S. CHARNEY. VAMC Affective Disorders Program --116-A, Yale Univ. Sch. of Med., 950 Campbell Ave.,West Haven, CT 06516.

Sleep deprivation (SD) temporarily improves mood in 50% of medication-free depressed patients. The neurobiological mechanisms responsible for this improvement of mood are not currently understood. Most antidepressant medications are thought to enhance brain serotonin (5HT) function. This study assesses 5HT function during SD in depression. **Method**: 7 drug-free depressed patients received intravenous *l*-tryptophan (L-TRP) (100 mg/kg) after a night of undisturbed sleep (US) and again after a night of SD in a random sequence, rater-blind protocol. Repeated ratings of mood (Hamilton Depression Scale (HAM-D)) and blood for prolactin (PRL), cortisol, and growth hormone were collected at baseline prior to the L-TRP infusion and at 30, 60, 90, 120, 150, and 180 minutes after the infusion. **Results:** SD resulted in an improvement of mood (≥ 10 pt decrease in total HAM-D) in 4/7 (57%) of these drug-free depressed patients. The mean decrease in total Ham-D score for the 7 patients was 10 after SD but only 5 after US. Hormone data is available for 4 of the 7 patients. PRL response to L-TRP infusion was greater after SD than after US in 3 of 4 subjects. The fourth subject showed no appreciable prolactin rise after either of the tryptophan infusions. The mean ΔPRL (peak minus baseline) for the 4 subjects was 2.7 ng/ml after US and 9.6 ng/ml after SD. **Implications**: SD improved mood in about 50% of these depressed patients, consistent with previous literature. Preliminary data suggest that as with other AD treatments, SD may cause an enhanced prolactin response to L-TRP infusion. Data on the relationship between ΔPRL response to L-TRP infusion and the improvement of mood are currently being obtained.

670.3

INVOLVEMENT OF SEROTONIN$_2$-RECEPTORS IN THE LEARNED HELPLESSNESS MODEL OF DEPRESSION. S.C. Pandey*, M.P. Dubey, J. Sagen, J.M. Davis, and G.N. Pandey. College of Medicine, University of Illinois, Chicago, IL, 60612.

It has been shown that chronic treatment with most antidepressant drugs causes down regulation of serotonin-2 ($5HT_2$) receptors in rat brain. It has been also shown that $5HT_2$ receptors are upregulated in the frontal cortex of suicide victims and platelets of depressed and suicidal patients. To examine if the changes in $5HT_2$ receptors are similar both in brains and platelets during depression, we determined the $5HT_2$ receptors in cerebral cortex and platelets of learned helplessness (L.H) and control rats. Rats received uncontrollable shocks (2.5 mA) and were then tested for shock escape (L.H). Control rats received no uncontrollable shocks. After 10 days of training, rats were decapitated and brain regions were dissected out for determination of $5HT_2$ receptors by receptor binding technique using ^{125}I-lysergic acid diethylamide (LSD) as ligand. We observed that B_{max} of ^{125}I-LSD binding to $5HT_2$ receptors was significantly increased, while there was no change in K_D values in cortex and platelets of L.H rats as compared to control rats. These results thus suggest that upregulation of $5HT_2$ receptors in brain and in platelets is associated with learned helplessness behavior. Since $5HT_2$ receptors are increased both in brain and platelets, this again suggests that platelet $5HT_2$ receptors can be used as a biological marker for depression.

670.4

SEROTONIN 5-HT$_{1C}$ BUT NOT 5-HT$_2$ RECEPTOR NUMBER IS INCREASED IN HIPPOCAMPUS OF SUICIDE VICTIMS. *R.A. Henteleff*, V. Arango, and J.J. Mann.* Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

We have previously reported increased ^{125}I-LSD binding in the prefrontal cortex of suicide victims (Arango *et al., Arch Gen Psychiatry, 1990*). In order to determine whether this increase involves 5-HT$_2$ or 5-HT$_{1C}$ sites we determined the proportion of 5-HT$_2$ and 5-HT$_{1C}$ receptors in human cortex, choroid plexus and hippocampus. We assayed 5-HT$_2$ and 5-HT$_{1C}$ receptors by saturation binding isotherms using ^{125}I-LSD. Nonspecific binding was determined by 10μM mianserine. 5-HT$_2$ binding was masked by 3.2nM cisapride in order to determine 5-HT$_{1C}$ binding. We compared 5 pairs of suicide victims and controls matched for age, sex, postmortem delay and season of death. All subjects had clear toxicological screens. ^{125}I-LSD binding kinetics in both cortex and choroid plexus conformed to a single site model. Competition and saturation binding kinetics characterized the cortical site as the 5-HT$_2$ receptor and the choroid plexus binding site as the 5-HT$_{1C}$ receptor. No detectable 5-HT$_{1C}$ receptors were present in cortex. 5-HT$_{1C}$ receptor number (B_{max}) was significantly greater in the hippocampus of suicide victims compared to controls (54.9 ± 17.7 *vs.* 28.7 ± 10.3) fmol/mg protein, p=0.043, 2-tailed Wilcoxon matched pairs). In contrast, 5-HT$_2$ receptor number did not differ in suicides and controls (972.1 ± 122.9 *vs.* 1000.1 ± 348.5 fmol/mg, p=0.9). The affinity (K_D) of both receptor populations did not differ between groups. This study indicates that the increase in ^{125}I-LSD binding in the cortex of suicide victims is unrelated to 5-HT$_{1C}$ receptors and provides further evidence for the biochemical specificity and regional localization of the alteration in serotonin function. Supported by MH40210 and MH46745.

670.5

REDUCTION IN CORTICAL SEROTONIN TRANSPORTER SITE NUMBER IN SUICIDE VICTIMS IN THE ABSENCE OF ALTERED LEVELS OF SEROTONIN, ITS PRECURSORS OR METABOLITE. *T.F. Lagattuta*, R.A. Henteleff, V. Arango and J.J. Mann.* Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

A reduction in the number of serotonin (5-HT) transporter binding sites has been reported in the cortex suicide victims (Stanley *et al., Science, 1982;* Henteleff *et al., Soc. Neurosci. Abstr., 1991*). The 5-HT transporter is an index of the integrity of the 5-HT terminals. Levels of 5-HT, its precursors tryptophan (TRY) and 5-hydroxytryptophan (5-HTP), and its metabolite 5-hydroxyindoleacetic acid (5-HIAA) are also indices of serotonin neuron function and yet have not been reported concurrently with 5-HT transporter binding kinetics in the cortex of suicide victims. We therefore, assayed 5-HT transporter binding kinetics in prefrontal (PFC) and temporal cortex (TC) of suicide victims and controls using ^{3}H-paroxetine (^{3}H-parox), and measured levels of TRY, 5-HTP, 5-HT and 5-HIAA in the same brain areas by HPLC-ECD. Suicides (S) and controls (C) with clear toxicological screens (N=16 pairs) were matched for postmortem interval (PMI), sex, age and season of death and assayed in pairs. ^{3}H-parox binding (B_{max}), but not affinity (K_D) was lower in the suicide group in both areas (PFC: S = 102±12 fmol/mg protein, C = 157±25 p=0.022; TC: S = 136±12, C = 186±18, p=0.004), while 5-HT, 5-HIAA, 5-HTP or TRY did not differ between groups (p>0.05). No correlations were found between B_{max} or K_D and levels of 5-HT, 5-HIAA, TRY or 5-HTP. Levels of 5-HT, its precursors or metabolite did not correlate with age, but 5-HIAA and TRY correlated positively with PMI (range 4-24h) in the suicide group but not in controls. Females (N=12) had lower levels of 5-HIAA (p=0.065), 5-HTP (p=0.096) and TRY (p=0.076) than males (N=20) in PFC but not in TC. We conclude that fewer 5-HT transporter sites are a more sensitive indicator of 5-HT nerve terminal alterations in suicide than levels of 5-HT, its precursors or metabolites. (Supported by PHS grants MH40210 and MH46745.)

670.6

SEASON SELECTIVELY AFFECTS BLUNTED PLATELET 5-HT$_2$ RECEPTOR SIGNAL TRANSDUCTION IN DEPRESSED PATIENTS. *B.W. Rigatti*, K.M. Malone, D.M. Abbondanza, G.L. Haas, T.M. Kelly, J.A. Sweeney, T.A. Mieczkowski, J.J. Mann.* Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Seasonal effects on some serotonin (5-HT) indices in brain, platelet and CSF have been reported. Serotonergic abnormalities have been associated with depressive disorders and seasonal effects may be associated with the onset of episodes of depression. To determine the biochemical specificity of these effects, we studied the seasonal effects on the platelet 5-HT$_2$ receptor- and epinephrine-stimulated phosphoinositide (PI) hydrolysis second messenger system in healthy controls and patients with affective disorders.

Across all seasons, serotonin (0.2 mM) stimulated a 60.4 ± 5.1% increase in PI turnover in controls compared to 41.2 ± 3.5% in patients (p = 0.004). Epinephrine (EPI; 0.1 mM) associated increase in PI turnover was 34.3 ± 5.3% in controls compared to 17.6 ± 1.2% in patients (p = 0.01).

Seasonal effects were significant for 5-HT stimulated PI turnover for patients (p = 0.011) and healthy controls (p = 0.003). In patients, 5-HT stimulated PI turnover peaked during Summer (57.8 ± 6.6%) which was significantly higher than all other seasons. There was a 24.8% increase from Spring to Summer. Seasonal effects differed in controls (p = 0.005) because 5-HT stimulated PI responses were higher in Spring than Summer. No statistically significant seasonal effect was found for EPI-stimulated PI turnover in patients (p = 0.075).

We conclude: (1) PI hydrolysis signal transduction is blunted in depressed patients; (2) Season selectively affects 5-HT activation of PI hydrolysis in patients compared to EPI activation of PI hydrolysis; (3) Platelet 5-HT$_2$ and EPI stimulated PI hydrolysis in patients are maximally divergent from control values in Spring *versus* Summer. This finding may be related to the increased rate of depression and suicidal behavior in Spring. Supported by MH46745, MH48514 and MH40695.

670.7

EFFECT OF ALCOHOL-DEPENDENCE ON 5-HT$_{1A}$ BINDING IN SUICIDE.
V. Arango, M.L. Miller, M.D. Underwood, R.W. Smith, P.J. McDevitt, T.M. Kelly and J.J. Mann.* Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Serotonin has been implicated in the regulation of alcohol preference and intake. Serotonin alterations have been associated with suicidal behavior. Using quantitative autoradiography we sought to determine whether postsynaptic 5-HT$_{1A}$ binding is altered in the prefrontal cortex of alcohol-dependent suicide victims by studying nine Brodmann areas (8, 9, 11, 12, 24, 32, 45, 46 and 47) of alcohol-dependent suicide victims and nonalcoholic controls with negative toxicological screens for other drugs. Alcohol-dependence was determined by conducting a psychological autopsy. Subjects were matched for postmortem delay, age and gender (N=4 pairs). In addition, a group of nonalcoholic suicide victims and matched controls were also studied (N=14 pairs). Slide-mounted coronal sections (20μm) from the right hemicerebrum were incubated with 2nM ^{3}H-8-OH-DPAT as described previously (Arango *et al., Soc. Neurosci. Abstr.*, 1991). 5-HT$_{1A}$ receptor distribution across cortical layers was similar in all groups, forming five isodensity bands corresponding to layer I, layer II, outer layer III, layers III-IV, and layers V-VI. Layer II had the highest level of binding. The nonalcoholic suicide group had 20% more 5-HT$_{1A}$ binding than the controls in area 46, but not in the other areas (p = 0.024). The alcoholic suicide group had elevated binding compared to controls in areas 46, 8, 9, 11, 12, 24 and 32. The binding in both suicide groups and controls was negatively correlated with with postmortem delay. Females had greater 5-HT$_{1A}$ binding than males. We conclude that: 1. 5-HT$_{1A}$ binding is increased in some brain regions of suicide victims; and 2. alcoholism and suicide was associated with a more widespread alteration of 5-HT$_{1A}$ binding. This study provides further evidence for an association of serotonin and both alcoholism and suicide. Further studies should investigate other brain areas and other 5-HT$_1$ receptor subtypes. (Supported by PHS grants AA09004, MH40210 and MH46745.)

670.8

ALTERATIONS IN ^{3}H-KETANSERIN BINDING IN ALCOHOLIC SUICIDES.
M.L. Miller, M.D. Underwood, R.W. Smith, T.M. Kelly, J.J. Mann and V. Arango.* Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Serotonin alterations are associated with alcohol-dependence. We recently reported that 5-HT$_{1A}$ binding alterations in the prefrontal cortex are more widespread in alcoholic suicides than in nonalcoholic suicides (Arango *et al., Soc. Neurosci. Abstr.*, 1992). Using quantitative autoradiography we sought to determine whether similar alterations in ^{3}H-ketanserin (^{3}H-KET) binding were present in alcohol-dependent suicide victims. Coronal sections of the right hemicerebrum at a level anterior to the genu of the corpus callosum (20μm) were taken from alcohol-dependent suicide victims and nonalcoholic controls who had negative toxicological screens for all other drugs. Each coronal section at this level included Brodmann areas 8, 9, 46, 45, 47, 11, 12, 32 and 24. Alcohol-dependence was determined through a psychological autopsy. Subjects were matched for postmortem delay, age, gender, race and season (N=5 pairs). Slide-mounted sections were incubated with 2nM ^{3}H-KET and nonspecific binding was defined by 1μM mianserin. Binding to nonserotonergic sites was masked by 1μM prazosin and 1μM tetrabenazine. The distribution of ^{3}H-KET binding across cortical layers was similar in both groups, appearing as 5 isodensity bands corresponding to layers I-II, layer III, layer IV, layer V and layer VI. Layers III, IV and V had the highest level of binding. The alcoholic suicide group had decreased binding compared to controls in Brodmann area 47 (Suicides: 23.2 fmol/mg tissue; Controls: 33.8 fmol/mg tissue, p=0.016). The binding in both groups was positively correlated with postmortem delay in some brain areas. Binding in males and females did not differ. We conclude that ^{3}H-KET binding is decreased in some brain regions of alcoholic suicide victims, an effect that differs from suicide victims that are not alcohol-dependent. These preliminary results provide further evidence for the involvement of serotonin in alcohol-dependence. (Supported by PHS grants AA09004 and MH46745.)

670.9

^{3}H-CYANOIMIPRAMINE BINDING IS REDUCED IN SUICIDE VICTIMS.
R.W. Smith, V. Arango, M.L. Miller, M.D. Underwood and J.J. Mann.* Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

We previously reported decreased ^{3}H-paroxetine binding to the serotonin transporter in membrane homogenates from suicide victims compared to controls (Henteleff *et al., Soc. Neurosci. Abstr.*, 1991). Conflicting reports exist in the literature as to whether binding to the serotonin transporter on serotonin nerve terminals is reduced in brain cortical regions of suicide victims (Arango and Mann, *Int. Rev. Psychiatry*, 1992). Using the selective radioligand ^{3}H-cyanoimipramine (^{3}H-CNIMI), we sought to determine whether binding is altered in slide-mounted sections (20μm) from the prefrontal cortex (Brodmann areas 8, 9, 46, 45, 47, 11, 12, 24 and 32) of suicide victims compared to controls. All cases had negative toxicological screens. Subjects were matched for postmortem delay, age, gender, and where possible, race and season (N=13 pairs). Tissue was preincubated in 50mM Tris-HCl buffer with 130mM NaCl, 5mM KCl (pH 7.4, 30 min, 23°C) and then incubated (24 h, 4°C) in the same buffer containing 30μM PMSF and 0.4nM ^{3}H-CNIMI. Nonspecific binding was determined by 10μM sertraline. After a 17 week exposure, films were developed and quantified by image analysis. The highest level of binding in both groups was localized to the outer layers of the anterior cingulate gyrus (Brodmann area 24), sixfold higher than the dorsal prefrontal cortex (areas 8 and 9). In area 46 (lateral aspect of the hemisphere) the suicide group had a 42% reduction in binding, compared to controls (Suicides: 5.36 fmol/mg of tissue; Controls: 9.50 fmol/mg of tissue, p=0.031). Binding did not differ between groups in any of the other areas examined. Binding was positively correlated with postmortem delay (p<0.05) but not with freezer storage, age or sex (p>0.05).

We conclude that ^{3}H-CNIMI binding sites: 1) have a specific distribution in prefrontal cortex; 2) are reduced in a specific area of the prefrontal cortex in suicide victims; 3) correlate positively with postmortem delay; and 3) are not different in males and females. The reduction in binding is consistent with the hypothesis of a serotonergic deficiency associated with suicide. (MH40210 and MH46745.)

NEUROTOXICITY: BIOLOGICAL

671.1

PATHOLOGIC CHANGES IN THALAMUS, HIPPOCAMPUS AND CORTEX OF RAT FOLLOWING THIAMINE DEFICIENCY INDUCED SEIZURES.
Shuxing Zhang* and P.J. Langlais. Dept. of Psychology, SDSU, and VA Med. Ctr., San Diego, CA 92182.

Rats recovered from an acute bout of pyrithiamine induced thiamine deficiency (PTD) display learning and memory deficits and severe destruction of medial thalamus and mammillary bodies. Milder damage to limbic and cortical areas has been difficult to detect because of long recovery periods (3-6 months). In the present study male Sprague-Dawley rats were treated daily with a thiamine free diet and pyrithiamine hydrobromide (0.25 mg/kg, i.p.). Separate groups were given a large dose of thiamine (10 mg/kg, i.p.) 5, 6, or 8 hrs following onset of seizures, placed on regular diet for one week, and the brains perfused transcardially. In animals reversed after 5 hrs of seizures, neuronal loss and gliosis was limited to anteromedial, paracentral and posterior nuclei of thalamus. Gliosis without neuronal loss was present in medial mammilary body (MB) nuclei. Dark, pyknotic and vacuolated pyramidal neurons were evident in hippocampal CA 3-4 and to a lesser extent in CA 1-2 sectors. In animals reversed after 6 hrs of seizures, the increase in damage was remarkably greater within thalamus than in MB or hippocampus. Animals reversed after 8 hrs of seizures had near total destruction of thalamus, hemorrhagic lesions within MB but no appreciable increase in severity of hippocampal changes. Animals reversed after 5 hrs of seizures demonstrated dense concentration of degenerating fibers within cortical layers 3 and 4 of frontal and parietal areas, and CA3-4 hippocampal sectors. Supported by NIH grant NS2948101 and VA Merit Program Award to PJL.

671.2

INCREASED EXTRACELLULAR GLUTAMATE IN THALAMUS AND HIPPOCAMPUS OF ACUTELY THIAMINE DEFICIENT RATS.
P.J. Langlais*, S.W. Henderson and S.X. Zhang. Dept. of Psychology, SDSU, and V A Med. Ctr., San Diego, CA 92182.

An excitotoxic basis for thiamine deficiency encephalopathy has been suggested by the demonstration that MK-801 prevents thalamic lesions in pyrithiamine treated (PTD) rats (Langlais & Mair, *J. Neurosci.*, 10:1664-1674, 1990). The current study measured extracellular fluid levels of excitatory amino acids (EAAs) before and during the onset of PTD induced seizures and pathologic lesions. Male Spraque-Dawley rats were treated with daily pyrithiamine (0.25 mg/kg, i.p.) and thiamine deficient diet. Microdialysates were simultaneously collected from probes acutely inserted via guide cannula into right medial thalamus and left hippocampus. Hourly samples were collected during separate 5-7 hour sessions from unanesthetized and freely moving animals. Basal levels were obtained at a pre-lesion stage (9-11 days of PTD treatment). No significant change from basal levels were observed in a second set of dialysates collected later in PTD treatment (11-12 days) and prior to onset of seizures or pathologic change. In samples collected during the onset of seizures (days 14-15), the levels of glutamate and aspartate in dialysates began to rise within 1-2 hrs and from 4-5 hrs after onset of seizures were elevated to 300-700% of basal levels in medial thalamus and 200-300% in hippocampus. In dialysates collected 8-10 hrs after seizure onset, levels of the EAAs fell to 10-30% of basal levels. Neuronal loss within thalamus containing the probe was noticeably less severe than on the undialyzed side, presumably due to the removal of EAAs. Supported by NIH grant NS2948101 and VA Merit Program Award to PJL.

671.3

EFFECTS OF NICOTINE ON RETINAL DEVELOPMENT.
S. He, T-X. Jiang, C.-M. Chuong, D.R. Hinton*.
Department of Pathology, USC School of Medicine, Los Angeles CA 90033

Prenatal exposure of rats to high doses of nicotine via maternal infusion can impair nervous system development in association with decreased fetal viability and growth. Persistent alterations in certain parameters of neural cell development also occur at lower doses of nicotine which do not impair intrauterine growth. The retina serves as an excellent model for developing nervous tissue because of its ease of access and well-described developmental sequence.

Timed pregnant rats were implanted on embryonic day (E)15 with minipumps containing nicotine bitartrate or sodium bitartrate (control). Serum levels of nicotine in experimental animals averaged 200 ng/ml. Fetuses were sacrificed at days E18 and E21. Eyes were dissected, fixed in 4% paraformaldehyde and embedded into glycol resin for morphologic examination. Animals from experimental groups showed atrophy and vacuolization of the nerve fiber layer of the retina when compared to controls. These changes were mild at E18 and prominent at E2l. Ganglion cell number did not appear to be affected.

Cultures of retinoblastoma cells (Y79), and primary cultures of human astrocytes and retinal pigment epithelium were tested for viability, proliferation and cell number in the presence of varying amounts of nicotine. There was no effect noted at levels of nicotine below 250 μg/ml.

Chick retinas from embryonic stage 34 of development were cultured on membranes for 72 hours in the presence of varying amounts of nicotine. Explant cultures showed normal development and maintenance of outer retinal structure at levels up to 320 ng/ml. Neurite outgrowth was assessed by culturing stage 34 dissociated chick retinal cells on poly-L-lysine coated plastic. Although the number of cells extending neurites was similar, nicotine treatment at 100 ng/ml and above resulted in significant shortening of neurites.

These experiments suggest that nicotine is acting on retinal tissues by affecting differentiated neuronal functions such as neurite outgrowth.

671.4

BRAIN EDEMA IN HEPATIC ENCEPHALOPATHY (HE) AND HYPERAMMONEMIA. W. Hilgier and J.E. Olson*.
Wright State Univ. Sch. Med., Dayton, OH 45401.

Brain edema in HE has been associated with circulating ammonia which is metabolized to glutamine in the brain. We measured alterations in blood chemistry and brain regional specific gravity and osmolyte contents in models of simple hyperammonemia and liver failure induced by daily administrations of ammonium acetate (AAc) or thioacetamide (TAA), respectively. Serum and brain ammonia increased to similar levels (≈200% and 70% of control, respectively) in both experimental groups. GOT and GPT activities increased 10 fold in TAA but not AAc model. In both groups, specific gravity decreased in white matter, gray matter and basal ganglia indicating edema formation. Moreover, we observed a concomitant decrease in potassium, glutamate, and taurine contents, whereas glutamine was elevated in all brain regions. In AAc injected rats, gray matter specific gravity and potassium and taurine contents returned to control levels 24 hours after the third injection. In HE, ammonia-induced changes of brain amino acids may result in brain edema while potassium loss represents a mechanism of water homeostasis. Supported by NS 23218 and Kettering Medical Centre, Medical Education.

671.5

CENTRAL EFFECTS OF T-2 TOXIN, A TRICHOTHECENE MYCOTOXIN. J. Wang, J.R. Wilson* and D.W. Fitzpatrick. Departments of Foods and Nutrition and Psychology, University of Manitoba, Winnipeg MB R3T 2N2 Canada.

The effect of T-2 toxin on the brain was examined. To examine the dose-dependent effect of T-2 on neurotransmitter, rats were orally dosed with T-2 @ 0.1, 1.0 or 2.5 mg kg^{-1} BW; killed 2, 6 and 10 hrs post dosing; and brain nuclei were analyzed. T-2 treatment increased 5-hydroxy-3-indoleacetic acid (HIAA) and serotonin (HT) throughout the brain, produced transient increases in nucleus raphe magnus (NRM) norepinephrine (NE) and a decrease in substantia nigra (SN) NE. No regional changes in epinephrine (E), dopamine (DA) or dihydroxyphenylacetic acid (DOPAC) were observed. Few treatment differences were observed, with 0.1 mg kg^{-1} T-2, 2% of the LD_{50}, affecting brain monoamines. To investigate the effect of dietary T-2, rats were fed diet containing 2.5 or 10 ppm T-2; killed after 7 or 14 days; and brain nuclei were analyzed. NRM's HT, HIAA and NE increased in a dose dependent manner and a transient DA increase was observed. In the SN, animals fed 10 ppm T-2 had increased E after 7 days, and decreased NE after 14 days. Paraventricular nucleus of the hypothalamus and medial forebrain bundle, DOPAC concentration were lower in T-2 animals. To examine the effect of T-2 on the blood brain barrier, rats were dosed with T-2 @ 0.2 and 1 mg kg^{-1} BW intraperitoneally and 2 hrs post dosing, permeability was determined using C^{14}-mannitol and C^{14}-dextran with H^3-water the diffusible reference. In all brain regions examined, permeability increases were observed for mannitol, a small molecular weight saccharide, but not dextran. The observed affect of T-2 on the blood brain barrier, brain monoamines and the resulting neurochemical imbalance may account for the physiological and behavioral manifestation of trichothecene intoxication.

671.6

ALCOHOL REDUCES NERVE GROWTH FACTOR RECEPTOR IMMUNOREACTIVITY IN NEONATAL RAT CEREBELLUM. D.P. DOHRMAN, J.R. WEST, C.R. GOODLETT and N.J. PANTAZIS*. Dept. of Anatomy, Univ. of Iowa Medical School, Iowa City, IA 52242.

Nerve growth factor receptor (NGFR) is expressed during a restricted time (postnatal days 6-20) in the rat cerebellum. NGF, a potent neurotrophic agent, may play a critical role in the development of cerebellar Purkinje cells. Alcohol exposure during development depletes cerebellar Purkinje cells in the rat, with the most severe depletion occurring when alcohol is administered at a time which approximates NGFR expression on Purkinje cells. This raises the possibility that alcohol depletes Purkinje cells by disrupting the interaction between these cells and neurotrophic factors, such as NGF. Since NGF activity is mediated via NGFR, this study examined whether alcohol alters the expression of NGFR in the cerebellum.

Rat pups (4 day) were divided into 3 groups. The alcohol group was artificially reared and fed ethanol via a gastrostomy tube from days 4-10. The gastrostomy control group was artifically reared, but fed no alcohol. The suckle control group was reared normally and received no alcohol. At day 10, all animals were perfused and cerebellar sections were immunostained for NGFR with 192-IgG antibody.

The two control groups had identical results and revealed that Purkinje cells expressed NGFR, with the greatest expression at this age present in more posterior cerebellar lobules. Purkinje cells in more mature areas of the cerebellum displayed prominent NGFR in their dendritic fields, whereas less developed cells had NGFR on their somas and dendrites. The external granule layer also expressed NGFR, but only in the proliferative zone; no NGFR was evident in the premigratory zone.

Alcohol reduced NGFR immunoreactivity in the Purkinje cell layer and dendrites in the molecular layer. The data support the hypothesis that alcohol reduces neuronal cell numbers by interfering with expression of NGFR, thereby disrupting neurotrophic support of neuronal cells. (Support: NIH AA05523; AA07313)

ALCOHOL INHIBITS PROLIFERATION OF NEURONAL-LIKE CELLS (PHEOCHROMOCYTOMA, PC12) IN CULTURE. J. LUO, C.R. GOODLETT, J.R. WEST* and N.J. PANTAZIS. Dept. of Anatomy, Univ. of Iowa Medical School, Iowa City, IA 52242.

Animal studies have shown that fetal alcohol exposure depletes selected populations of neuronal cells in the CNS. Although killing of cells by alcohol has often been suggested as a potential mechanism for this loss, alcohol can also reduce cell numbers by inhibiting (slowing) cell proliferation. This latter possibility was the focus of this study. Because it is difficult to determine mechanisms of alcohol action in animals, an *in vitro* neuronal cell model (PC12) was used, incorporating a novel approach (synchronized cultures of PC12 cells) to examine alcohol's effect on cell proliferation.

PC12 cells were synchronized by feeding the cells with media (RPMI) containing low serum (0.08% fetal calf serum, FCS; 0.17% horse serum, HS). This low serum treatment growth-arrested the cells and the cells accumulated in the G1 phase of the cell cycle. Three days later, growth-arrested cells were fed normal serum (5% FCS, 10% HS) which stimulated synchronized growth of the cells (i.e., the vast majority of cells were at the same point in the cell cycle and progressed synchronously through the cycle). The alcohol group also received ethanol (400 mg/dl) along with the normal serum, whereas the control group received no alcohol. The alcohol concentration in the culture media was maintained by placing the cultures in sealed containers which contained an alcohol bath. Cell numbers were determined by hemacytometer at selected time points after addition of normal serum.

Results show a steep rise in cell division in these synchronized cultures which begins approximately 30 hours after addition of normal serum. Alcohol treatment delays this rise in cell division by several hours. This study suggests that inhibition of proliferation is one potential mechanism by which alcohol can reduce cell numbers in proliferating cell populations. (Support: NIH AA05523; AA07313)

EFFECT OF NICOTINE ON NEURAL CREST CELL MOTILITY AND NEURITE ELONGATION IN VITRO T.X. Jiang, C.K. He, D.R. Hinton and C.M. Chuong* Dept. Pathology, Univ. Southern California, Los Angeles, CA 90033.

It has been shown that prenatal exposure to nicotine influences the development of the nervous system. To analyze the specific effects and mechanism of nicotine (10 ng - 10 ug/ml) on neural development, we used primary neural crest cell cultures and dorsal root ganglion explants for the evaluation of the effect of nicotine. In trunk neural crest explant cultures, crest cell were plump, spindle shaped, with long axis of cells randomly arranged, and the advance margin was very uneven, suggesting active cell motility. In contrast, in the presence of nicotine, crest cells were flat, polygonal in shape, arranged regularly in palisades and the advance margin was even, suggesting lower cell motility. Time lapse video confirmed the difference in cell motility. In dorsal root ganglion cultures (chicken embryo stage 32), nicotine showed significant inhibition of neurite length around 100 ng/ml. At 10 ug/ml, there was complete inhibition. However, the number of dying cells and the degree of fasciculation were similar between control and nicotine treated explants. There is no apparent difference in immunofluorescent staining patterns of adhesion molecules N-CAM and Ng-CAM. This suggests that nicotine is specifically inhibiting neurite elongation. The results suggest that nicotine has inhibitory effect on neural cell motility and neurite elongation in vitro. We are currently studying the mechanism of these effects and evaluating the effect of nicotine on neural development in vivo.

NEUROANATOMICAL ANALYSIS OF CEREBELLA FROM MARIJUANA-EXPOSED RHESUS MONKEYS. M.Halks-Miller*, Megan Yao, & Gordon Pryor. Dept. of Neuroscience, SRI International, Menlo Park, CA 94025.

Several investigators have reported neuroanatomical changes in both rat and primate brains after exposure to either THC or marijuana (MJ) smoke. Our studies were designed to use unbiased stereologic methods to assess the putative changes in primate brain after long-term exposure to MJ smoke. Fifteen male rhesus monkeys were divided into three groups and exposed to either placebo smoke (P), moderate MJ smoke (M), or high MJ smoke (H). These subjects were implanted with an array of intracerebral glass electrodes before MJ exposure. Three untreated control monkeys were also included for study. After completion of the behavioral and electrophysiologic testing, all animals were sacrificed by per cardiac infusion with aldehyde fixatives. The cerebellum was chosen for initial study because of the high concentration of cannabinoid receptors in its molecular layer. The cerebella were sagittally sectioned, weighed, and blocked for light and electron microscopy. One cerebellar hemisphere was used for analysis of the volume compartments: molecular layer, granular layer and white matter. Within the molecular layer three volume compartments (vessels, large dendrites, and neuropil) were also evaluated. Synaptic number within the neuropil was estimated using the unbiased dissector method. Purkinje cell number was similarly evaluated. Synapse number was then normalized to number of Purkinje cells. The three test and the untreated control groups were compared by analysis-of-variance (ANOVA) methods for possible marijuana-induced changes in the neuroanatomical parameters described above. These tests failed to reveal any differences among the marijuana-treated and control groups. These studies do not support the premise that chronic exposure to marijuana smoke leads to permanent structural changes in primate cerebellum.

BOTULINUM NEUROTOXIN SEROTYPES A, B AND E EXHIBIT PROTEOLYTIC ACTIVITY. B. R. DasGupta* and W. Tepp. Food Research Institute, Madison, WI 53706

Botulinum neurotoxin (NT) serotypes A-G are encoded by genes found either in the chromosome, plasmid or a phage hosted by Clostridium botulinum. The ~150 kDa single chain NT after posttranslational proteolytic processing (nicking) is a dichain protein made of ~50 kDa L- and ~100 kDa H chains that correspond to the N- and C-terminal segments of the parent protein; -S-S- bond(s) links L and H chains. The NT binds via H chain to the presynaptic membrane at the neuromuscular junctions. The L chain after entering the secretory cells inhibits neurotransmitter release by an activity presumed to be enzymatic, the substrate of which is unknown. We report that the NT types A, B and E incubated at pH 5-8 show self-digestion--evidence is time dependent discrete bands in SDS-PAGE. The self-digestion is promoted following nicking and DTT reduction. The dichain type E NT cleaved actin (rabbit muscle) into discrete fragments. The L chain of type E NT, separated from the H chain, digested actin more effectively than the parent NT. These new data indicate, consistent with earlier reports (Biochime 71, 1193, '89; J. Physiol. (Paris) 84, 220, '90; Soc. for Neuroscience Abst. 16, 609, '90; 17, 1526, '91; FASEB J. 6, A227, '92; J. Neurochem. 57, 1413, '91) that the NT is a protease and suggest that the NT types C and D represent phage encoded proteases. The peptide bonds cleaved by the proteolytic activities of the three NT types are under study. Funded by NS17742.

TETANUS TOXIN ENTERS NEURONS THROUGH ACIDIC ENDOSOMES. L.C. Williamson*, W. Y. Clarke, S.C. Fitzgerald and E. A. Neale. Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Tetanus toxin (TnTx) acts preferentially on inhibitory synapses to block neurotransmitter release. In murine spinal cord cell cultures, TnTx inhibits Ca^{++}-dependent evoked release of glycine. To test whether TnTx enters neuronal cytoplasm via acidic endosomes, toxin action was assayed in cultures pretreated with monensin to neutralize acidic compartments. Monensin (0.5 μM) completely blocked the effect of TnTx, presumably by interfering with its movement from endosomes into the cytoplasm. Monensin effects were reversible and the drug had no effect on toxin binding. If an acid environment were required for toxin translocation across endosomal membranes, lowering the external pH should allow the entry of toxin directly through the cell membrane, by-passing the endosome. Cultures were exposed to TnTx at 4°C to achieve toxin binding without endocytosis, and then were pulsed for 6 min in the cold with medium at pH 7.25 or pH 4.9. Monensin was added and the cultures warmed. Inhibition of evoked glycine release was observed in toxin-exposed cultures in the presence of monensin when cultures were pulsed at pH 4.9. However, there was no inhibition of evoked glycine release in cultures pulsed at pH 7.25. These findings indicate that TnTx requires an acid environment to penetrate cellular membranes. 3-(2,4-Dinitroanilino)-3'amino-N-methyldipropylamine (DAMP) accumulates in acidic compartments and can be visualized by immunohistochemistry as punctate staining in neurons and glia in spinal cord cultures. Monensin reduced DAMP accumulation in neurons and glia. If, in the presence of acid, TnTx forms pores in membranes, it could disrupt the pH gradient in endosomes and likewise prevent DAMP accumulation. In cultures exposed to toxin, DAMP immunoreactivity was reduced in neurons although immunostaining in glia was similar to controls. These data suggest that TnTx enters the neuronal cytoplasm through an endosome pathway.

CYTOTOXIC ACTION OF PALYTOXIN IN AORTIC SMOOTH MUSCLE CELLS IN CULTURE. R.E. Sheridan*, B.F. Doxzon and S.S. Deshpande. Neurotoxicology Branch, Pathophysiology Division, USAMRICD, Aberdeen Proving Ground, Maryland 21010-5425, USA.

Palytoxin (PTX) produced by coelenterate species (genus *Palythoa*) is a potent marine toxin which depolarizes neurons, skeletal, smooth and cardiac muscles. In addition to direct myotoxicity, PTX induces intense vasoconstriction and hemorrhage which contribute to lethality (Toxicon,12, 427, 1974). A7r5 clonal cells derived from fetal rat aorta have many characteristics of smooth muscle (Exp Cell Res. 98, 349, 1976). We have used the A7r5 cell line to further delineate the mechanism of toxic action of PTX. A7r5 cells were grown in 35 mm dishes to confluency (4-10 days) in DMEM supplemented with 5% fetal bovine serum under standard conditions. Exposure of cells to PTX (10^{-8}M) for 15 min at room temperature followed by wash and incubation in culture medium at 37°C (≥30 min) led to swelling, clumping of cytoplasm, vacuolation and shrinking of heterochromatin. These cells were nonviable as confirmed by inclusion of trypan blue and release of LDH. Concentration-response determination for PTX (3 X 10^{-9} to 4 X 10^{-8}M) using the vital dye assay gave an EC50 value of 7.1 X 10^{-9}M. PTX-induced cytotoxicity could not be reversed by washing. Prior incubation of cells with ouabain (10^{-4}M) or verapamil (10^{-5}M) for 30 min reduced the cytotoxic effects produced by PTX. Whole-cell patch clamp recording from single A7r5 cells showed that PTX (3 X10^{-9} to 10^{-8}M, 25°C, 15 min) depolarized cells and increased membrane conductance to Na^+ and K^+ (>5-fold) as we previously reported in guinea pig ileum cells (Soc. Neurosci. Abst. 17, 1522, 1991). The precise mechanism responsible for the cytotoxic effects of PTX on A7r5 cells is presently unclear, but seems to involve Na^+ and/or Ca^{2+} overload. In light of the involvement of smooth muscle in PTX poisoning, A7r5 cells could serve as a useful model to test specific drugs for protection against PTX toxicity.

671.13

A NEW FOOD-RELATED NEUROTOXIN: OKADAIC ACID. M. T. Fernandez, V. Zitko, S. Gascón and A. Novelli*. Dept. Functional Biol., Biochem. and Mol. Biol. Section, Oviedo Univ., Sch. of Med., 33006 Oviedo, Spain; Marine Chem. Div., Biol. Station St. Andrews, N.B. E0G2X0, Canada.

Okadaic acid (OKA), a marine toxin of algal origin, is a potent inhibitor of protein phosphatases 1 and 2A, and in humans is responsible for the *diarrhetic shellfish poisoning*. We have recently reported that OKA at concentrations as low as 0.5 nM produced neurotoxicity in primary cultures of cerebellar neurons (Fernandez et al., Life Sci.1991,49,PL-157). It has been also reported that okadaic acid may affect a subtype of excitatory amino acid (EAA) receptor (Wang et al., Science 1991,253,1132). We now present further evidence indicating that neurotoxicity by OKA occurs independently from the activation of EAA receptors. Thus, changes in the neurotoxic effect of these two types of toxins with neuronal age in culture were not parallel, and EAA receptor antagonists did not protect against neurotoxicity by OKA. OKA neurotoxicity was not enhanced by glucose-deprivation, as it occurred for EAAs, and OKA did not potentiate neurotoxicity by EAAs. Biochemically, OKA did not stimulate cGMP increase nor did enhance stimulation of cGMP by EAAs.

BRAIN CONTENT OF GLYCOSPHINGOLIPIDS AFTER ORAL ADMINISTRATION OF MONOSIALOGANGLIOSIDES (GM1) DERIVATIVES. A. Polo, G. Kirschner[1], A. Guidotti and E. Costa*. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Med. School, Washington, DC 20007 and Fidia Research Laboratories, Abano Terme, Italy

Natural (GM1, GD1a, GD1b, and GT1b) and semisynthetic [GM1 with [N-acetyl sphingosine (LIGA4), and GM1 with N-dichloroacetyl sphingosine (LIGA20)] glycosphingolipids protected against glutamate-induced neuronal death when added to primary neuronal cultures or when given parenterally to rats exposed to hypoxic brain lesion. Glycosphingolipids also prevented intraneuronal destabilization of $[Ca^{2+}]_i$ homeostasis without blocking the function of glutamate receptors (FASEB J., 1990, 4: 2789). Thus, a protracted ganglioside treatment could be attempted as a therapeutic strategy to prevent neuronal damage in chronic neurodegenerative diseases (e.g. Alzheimer's, epilepsy, Parkinson's) in which glutamate could be neurotoxic. To develop such a strategy, sphingolipids, absorbed orally, are needed. To this end, we have administered p.o. to rats 70 μmol/kg of glycosphingolipids tritium labeled in the 3C position of sphingosine: GM1; LIGA4; LIGA20; GM1 inner ester (AGF2); GM1 isopropyl ester (AGF44). Six hours after oral administration the increase in the content of authentic glycosphingolipids in brain measured after tetrahydrofuran extraction and separation on HPTLC was as follows: AGF2 0.012 μM < AGF44 0.032 μM < GM1 0.050 μM < LIGA4 0.55 μM < LIGA20 0.86 μM. The brain concentration remained elevated for at least 12-24 hrs, whereas the concentration in plasma declined with time. Because LIGA4 and LIGA20 are readily absorbed and slowly metabolized, repeated oral administration of these glycosphingolipids produced brain concentrations between 1 and 4 μM which can protect against glutamate neurotoxicity. In contrast, AGF2 and AGF44, even after 7 days of treatment, were able to accumulate in brain to concentration of only 0.2 to 0.4 μM.

672.2

TEMPERATURE DECREASE MAY MEDIATE PROTECTION BY MK-801 AGAINST SEROTONERGIC TOXICITY. G.M. Farfel* and L.S.Seiden. The University of Chicago, Dept. of Pharm. and Physiol., Chicago, IL 60637.

Several amphetamine analogues, when administered in high dose regimens, have been shown to cause long-lasting depletion of CNS serotonin (5-HT) which can be attenuated pharmacologically or by lowering ambient temperature. We have found MK-801 (MK) blocks depletion of 5-HT induced by methamphetamine (MA) and MDMA, but not p-chloroamphetamine (PCA) or d-fenfluramine (FEN). MK, when combined with MA, has been observed to cause hypothermia which is not seen with either drug alone. The purpose of this study was to assess whether MK protects against 5-HT toxicity by induction of hypothermia. Our results indicate that MK is more potent at inducing hypothermia when combined with MA or MDMA than with PCA or FEN, indicating hypothermia may be the basis for its neuroprotection. Single-housed male Sprague-Dawley rats (n=4-6/group) were given saline (SAL; 1 ml/kg IP) or MK (2.5 mg/kg IP) followed 15 min later by SAL (1 ml/kg IP or SC), MA (10 mg/kg IP in 4 injections 1 h apart), MDMA (40 mg/kg SC), PCA (10 mg/kg IP) or FEN (12.5 mg/kg IP as 1 injection or 2 injections 1 h apart). Some rats also received a second injection of SAL or MK. Core body temperature (TEMP) was measured every 15 min for at least 4 h, and ambient temperature was maintained at 20-22 ° C. Neither SAL alone nor MK + SAL produced significant effects on TEMP (± 1 °C). MA + SAL caused a significant increase in TEMP which peaked 2.6 °C above baseline after the fourth MA injection. MDMA + SAL caused a decrease in TEMP (-1.3 °C) at 30 min which returned to baseline by 90 min. PCA + SAL caused a TEMP increase of less than 1 °C. Co-administration of MK with MA or MDMA caused TEMP to decrease 3.6 and 3.5 °C, respectively, within 2 h of the first injections and lasting more than 3 h. MK + PCA caused a 2.2 °C decrease in TEMP 1 h after the injections which returned to baseline within 2 h, while MK + FEN caused a 2.1 °C decrease in TEMP 3 h after the first injection which also lasted less than 2 h. Since MK protects against serotonergic toxicity induced by MA and MDMA but not PCA nor FEN, these data suggest that protection against serotonergic toxicity by MK is mediated by a decrease in TEMP of more than 2.5 °C which lasts for at least 3 h. (Supported by DA-00085).

672.3

RELEASE OF GLUTAMATE FROM CULTURED STRIATAL GLIA: EFFECTS OF GLUTAMINE, KYNURENATE AND KAINATE EXPOSURE. J.F. Bowyer[1*], G.W. Lipe[1] and D.L. Davies[2]. [1]Div. of Neurotoxicol., NCTR/FDA, Jefferson, AR 72079-9502 and [2]Dept. of Anat., Univ. of Arkansas Med. Sciences, Little Rock, AR 72205.

In striatal slice preparations, the release of glutamate can be evoked by application of exogenous glutamine; potential sources for this glutamate release include neuronal glutamate terminals and glia. In an endeavor to assess the role of glia in this release, glutamate release from neuron-free glial cultures derived from 3-day-old rat striatum was measured by HPLC. The present study examined the interaction of exogenous glutamine with kynurenate, kainate and hypotonic buffer. For analysis of glutamate release, cultures were washed twice with Krebs-Ringer bicarbonate buffer, and then incubated for 30 min at 37°C. Inclusion of 500 μM glutamine in the buffer increased glutamate levels (from <0.2 μM to 0.44 μM). In the presence of kynurenate (1 or 2 mM) and 500 μM glutamine, the [glutamate] rose to 0.75 μM while kynurenate alone yielded no change. However, when cultures were pre-incubated (4 hr) in 50 μM kainate glutamate release was slightly decreased with or without exogenous glutamine. Hypotonic buffer significantly elevated glutamate release, and 500 μM glutamine potentiated this effect. These effects in glial cultures are similar to those previously observed in striatal slices, and they indicate that under some circumstances, glia may contribute to glutamate release in striatum.

672.4

NIACINAMIDE BLOCKS THE TOXICITY OF 3-ACETYLPYRIDINE IN CEREBELLAR GRANULE NEURONS IN VITRO. M. Weller, A. M. Marini and S. M. Paul*. Clinical Neuroscience Branch, National Institute of Mental Health, Bethesda, MD 20892.

3-Acetylpyridine (3AP) is a potent experimental neurotoxin which preferentially damages the inferior olivary nucleus when administered in vivo. To our knowledge its effects on neuronal viability have not been investigated in vitro. Cerebellar granule cells in vitro are susceptible to 3AP toxicity with an ED50 of 220 μM after 90 hours of exposure. Higher concentrations of 3AP result in a more rapid toxicity. Neuronal cell loss is completely prevented by prior application of niacinamide at concentrations ten times lower than 3AP. The toxicity of 3AP is enhanced by pretreatment with N-methyl-D-aspartate (NMDA) but not significantly attenuated by the NMDA receptor antagonists MK-801 and APV-5. Deprenyl, mazindol, and tetrahydrofolic acid have no influence on 3AP-induced neuronal death. This characteristic pharmacological profile of 3AP is probably due to the erroneous substitution of 3AP for niacinamide in the formation of niacinamide adenine dinucleotide phosphate (NADP) by neuronal cytosolic nucleosidases.

672.5

BLOOD-BRAIN BARRIER BREAKDOWN, DEMYELINATION AND REMYELINATION AFTER NMDA-INDUCED LESIONS OF RAT LATERAL HYPOTHALAMUS. H. Brace, M. Latimer and P. Winn (SPON: Brain Research Association) Dept. Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU

Excitotoxic lesions of the rat lateral hypothalamus (LH) promote demyelination of fibers *en passant* (Stellar et al. Brain Res. 1991, 541:29) but whether this involves blood-brain barrier breakdown (Coffey et al. Neurosci. 1990, 35:121), the time course of events, and the extent to which the myelination recovers are all uncertain. Rats received unilateral NMDA lesions of the LH (1.0ul 0.09M NMDA, pH 7.3, phosphate buffer vehicle) and were sacrificed at various times after surgery. 20um sections were cut and stained with cresyl violet or Gallyas silver stain for myelin. Lesions were characterised by cell loss in the LH and adjacent structures. At 7 days lesions were large and gliosis was evenly spread but not dense. Vascular cuffing and large cells with acentric nuclei were present in the damaged tissue. These cells were not present after 14 days. Gliosis increased further by 21-28 days and crystals, thought to contain calcium, could be seen. Demyelination was found after 7 days, contiguous with but not outside the area of neuronal loss. At the edges of the damaged area myelin was abnormal: myelinated fibers had a "braided" appearance and some had swollen into large, balloon-shaped droplets. At 14 days the edges of the demyelinated area were better defined: myelin was still braided but there were fewer (and smaller) swellings. After 21 days small dots of myelin appeared in the damaged area, often clustered around blood vessels. Remyelination continued and by 2 months strands could be seen passing through the LH. These data suggest that NMDA lesions of the rat LH promote neuronal loss and demyelination; that at 7 days after surgery the blood-brain barrier is absent locally; and that remyelination occurs over time.

672.6

INTRASTRIATAL INJECTIONS OF QUINOLINIC ACID CAUSE SPATIAL LEARNING DEFICITS IN RATS. C.L. Curtis, G.J.Ross III, E.A. Hyde, R.E. Szymanski, J.S. Hull and G.L. Dunbar*. Brain Research Laboratory, Dept. of Psychology, Central Michigan University, Mt. Pleasant, MI. 48858.

Intrastriatal injections of quinolinic acid (QA) cause increases in locomotor and seizure activity. We examined if these QA lesions also would affect spatial learning abilities. Rats were given intrastriatal injections (1 μl) of either 200 nmole QA (n=16) or saline (n=8). Spontaneous motor activity of each rat was observed for 1 hr at 2- and 24-hr after surgery, and for 10 mins on postoperative days 5 and 10. All rats were tested in the Morris water maze on postoperative days 5-15. Body weight was recorded daily and amount of food and water consumed was calculated on postoperative days 1-5 and 10. Half of the QA rats died within 48 hr after the injection. Half of the remaining QA rats required force feeding and all of the QA rats showed significant decreases in food and water consumed. All QA rats showed barrel rotations and tonic-clonic episodes, but no significant differences in spontaneous motor activity levels were observed after postoperative day 5. All QA rats were significantly impaired on every measure in the Morris water maze task. These results indicate that QA-induced cognitive impairments remain even after most locomotor abnormalities subside.

672.7

N-METHYL-D-ASPARTATE RECEPTOR-MEDIATED NEUROPROTECTION IN CEREBELLAR GRANULE CELLS REQUIRES NEW RNA AND PROTEIN SYNTHESIS. A.M. Marini*, P. Damschroder-Williams, and S.M. Paul. CNB, NIMH, Bethesda, Md 20895.

Cultured cerebellar granule cells are glutamatergic neurons which express all of the glutamate receptor subtypes. Previous studies have shown that cultured cerebellar granule cells are susceptible to the neurotoxic effects of the excitotoxin glutamate and the chemical neurotoxin, 1-methyl-4-phenylpyridinium (MPP^+). Although the toxicity of glutamate and MPP^+ are time- and concentration-dependent in cultured cerebellar granule cells, the mechanisms of toxicity are different. Whereas glutamate mediates its toxicity by the activation of N-methyl-D-aspartate (NMDA) receptors, MPP^+ kills neurons by intracellular uptake into vulnerable neurons. Paradoxically, preincubation of cultured granule cell neurons with subtoxic concentrations of NMDA or glutamate markedly antagonizes the neurotoxicity from subsequent exposure to toxic concentrations of either MPP^+ or glutamate. The neuroprotective effects of NMDA and glutamate against MPP^+ toxicity are observed at concentrations as low as 1 μM, blocked by specific NMDA receptor antagonists and require at least 30 min to fully develop. Preexposure of the neurons to subtoxic concentrations of NMDA also resulted in significant protection against toxic glutamate concentrations (50-1000 μM). Moreover, NMDA-receptor mediated neuroprotection is prevented by the RNA synthesis inhibitor, actinomycin D, or the protein synthesis inhibitor cycloheximide. Thus, activation of NMDA receptors by glutamate results in either neurotoxicity or neuroprotection, depending on the glutamate concentration and apparent degree of receptor stimulation. NMDA receptor-mediated neuroprotection in these neurons requires new RNA and protein synthesis and appears to be mediated by the expression of a neuroprotective protein(s). Taken together, these data demonstrate the presence of an active NMDA receptor-mediated and transcriptionally-directed neuroprotective mechanism in cerebellar granule cells.

COMPLEMENT mRNAs INCREASE IN THE RESPONSE TO NEUROTOXIC BRAIN LESIONS. I.Rozovsky, D. Willoughby, T.E.Morgan, G.M.Pasinetti, M.N. Dugich-Djordjevic, T.H. McNeil*, and C.E. Finch. Andrus Gerontology Center,University of Southern California, Los Angeles, CA 90089.

Recently complement receptor, activated complement products, regulatory complement proteins, and complement mRNAs were demonstrated in normal human and rat brains. We also showed up-regulation of complement mRNAs in AD brain in association with AD type lesions, and in experimental rat brain lesions. Data from our lab show that resident brain cells synthesize and regulate complement component mRNAs in response to brain injury. Kainic acid (KA) induced seizure activity resulting in eventual neuronal loss in CA3-CA4 hippocampal pyramidal neurons was used as a model of selective neurodegeneration. By *in situ* hybridization analysis the major increase of C1qB mRNA signal in CA3 hippocampal layer was observed 48 hours after KA induced seizure activity . Northern blot hybridization analysis of total RNA isolated from microdissected hippocampus showed elevation of C1qB mRNA signal 48 hours after the onset of KA induced seizure activity: 6 fold increase in CA3 layer, 4 fold - in dentate gyrus- CA4 layer, and less than 2 fold- in CA1 layer. This differential up-regulation of C1qB mRNA correlates with different sensitivity of hippocampal neurons to KA actions. Granule neurons of the dentate gyrus can be selectively destroyed by intrahippocampal injections of colchicine. By *in situ* hybridization C1qB and C4 mRNA signals increase in colchicine lesioned hippocampus (ipsilateral to the lesion). The highest increase of the signal was observed 10 day post lesion distributed mainly in areas adjacent to granule neurons layer, subiculum and outer molecular layer of CA1. These results suggest possible role of complement and complement mediated inflammation in association with local cell death. (Supported by AG 00093-10).

KAINATE INDUCED SEIZURES UPREGULATE EXPRESSION OF bFGF mRNAs IN THE RAT HIPPOCAMPUS. M. Khrestchatisky*, K. Bugra, H. Pollard, L. Ferhat, G. Charton, I. Moreau, A. Autour, A. Represa, D. Diabira, P. Chinestra, G. Barbin and Y. Ben Ari. Unité INSERM 29, 123 Bd de Port Royal 75014 Paris , France.

bFGF stimulates proliferation and subsequent differentiation of a variety of mesenchymal cell types. In vitro, this factor demonstrates neurotrophic activity. In the central nervous system bFGF, seems to be constitutively expressed, and in the rat hippocampus in situ hybridization reveals low levels of bFGF expression in field CA2. These findings support the notion that this potent neurotrophic factor may be involved in CNS development and maintenance and that it could act as a survival factor in the adult CNS. To test this hypothesis, we have studied the regulation of the bFGF gene following neuronal hyperactivity induced by kainic acid (KA) in vivo and in vitro. Our in vivo models include intraperitoneal and intra-amygdala injections of KA while the in vitro experiments were conducted with hippocampal slices. bFGF mRNA expression was monitored using in situ hybridization and reverse transcriptase coupled PCR. We have observed that three hours following seizure activity, bFGF mRNA expression was increased in fields CA1 and CA2 when compared to control animals and that this upregulation was transient.

672.10

ZINC ENHANCES KAINATE NEUROTOXICITY IN THE RAT HIPPOCAMPUS K. SHIRAISHI[1]*, S. NAKAZAWA[1], H. ITO[2]
Department of Neurosurgery[1], and Anatomy[2], Nippon Medical School, Tokyo, Japan

Zinc is one of the N-methyl-D-aspartate(NMDA) antagoniosts and has recently been known to potentiate non-NMDA currents in *Xenopus* oocytes expressing mRNA of a glutamate receptor clone(GluR3). Histochemical studies proved that the zinc distribution was localized in the hippocampus, CA3-4, where kainate binds specifically. We designed to examine whether the neuropharmacological effects of zinc could exist and to find areas where they would develop in the rat brain. S-D rats, weighing 300-320 gm, were anesthetized with chloral hydrate 350 mg/kg. The left external carotid artery was exposed, and a small catheter was introduced into the common carotid artery to inject zinc chloride to the internal carotid artery without disturbing the blood flow. Zinc chloride (7.0 mM, pH 6.50, volume 1.0 ml/kg) was injected for 10 minutes. One hour after the injection, *in vitro* quantitative autoradiography of kainate revealed an increase of binding of kainate in the left hippocapus CA3-4. In another rats, 1.0mg/kg kainate, which is not sufficient to induce neuronal damage, was intraperitoneally injected after the carotid infusion. One day after the insult, Nissl preparations showed neuronal damage in the left CA3-4. According to these results, we thought zinc enhanced the kainate neurotoxicity in the rat hippocampus.

KAINIC ACID LESION INDUCES DIFFERENTIAL RESPONSE OF [125I]IGF I AND [125I]IGF II RECEPTOR BINDING SITES IN THE RAT HIPPOCAMPAL FORMATION. D. Seto*, S. Kar and R. Quirion. Douglas Hospital Research Center, Depts. of Pharmacology and Therapeutics and Psychiatry, McGill Univ., Canada H4H 1R3.

The insulin-like growth factors I and II (IGF I and IGF II) are mitogenic polypeptides with structural and functional homologies to hormone insulin. Both peptides address a wide spectrum of neuronal and non-neuronal cells and their physiological response are presumed to be mediated by respective cell surface receptors i.e., IGF I and IGF II receptors. Besides their involvement in growth and development, evidence suggests that these growth factors in the adult nervous system act as maintenance factors in addition to modulation of hormone/neurotransmitter releases. In the present study following systemic injection of kainic acid to the adult rat (10 mg/kg; i.p.), [125I]IGF I and [125I]IGF II receptor binding sites were evaluated to investigate their possible differentiation in cellular localization and response to injury. [125I]IGF I receptor binding sites were found to be concentrated in the granular layer of the dentate gyrus and the pyramidal layer of the CA1-CA3 regions whereas the underlying strata showed only moderate to low density of labelling. Following kainic acid treatment, [125I]IGF I binding was substantially decreased in all layers of the CA1-CA3 regions whereas in the dentate gyrus, granular cell layer showed only a moderate decrease in the labelling. As for IGF I receptors, relatively high densities of [125I]IGF II sites were primarily localized in the pyramidal cell layer of the CA1-CA3 regions and in the granular cell layer of the dentate gyrus whereas other layers exhibited only low binding densities. Systemic adminstration of kainic acid induces a moderate decrease of [125I]IGF II binding especially in the pyramidal cell layer of the CA1 region. In the granular layer of the dentate gyrus however, no apparent alteration in the density of IGF II binding sites was noticed. Thus, it appears that IGF I and IGF II receptor binding sites in the hippocampal formation are differentially affected following peripheral kainic acid injection. This is most evident in the granular cell layer and provide further evidence for the differential localization of these two receptor classes in this region of the rat brain.(Supported by FRSQ and MRCC).

Oxidative Stress and Antioxidant Response in Rat Piriform Cortex Associated with Kainic Acid-Induced Seizures. M.E. Layton, J.K. Wagner, S.R. Nelson, F.E. Samson and T.L. Pazdernik*. Dept.of Pharm.,Tox. and Therapeutics and R. L.Smith Res. Ctr., Kansas University Medical Center, Kansas City, Kansas 67337 USA.

Seizures induced by kainic acid (KA; 12 mg/kg ip) cause extensive neuropathology in the piriform cortex. To measure oxidative stress in brain during KA-induced seizures, thiobarbituric acid-reactive substances (TBARS), a general index of lipid peroxidation, and the antioxidants ascorbic acid (AA) and uric acid (UA) in intracerebral microdialysates were analyzed. In controls (N=7) and in KA-treated rats (N=7), TBARS levels in the piriform cortex 90 minutes after injection were 22 ± 4.6 and 30 ± 3.6 ng/mg protein, respectively ($p < 0.03$). In contrast, TBARS levels in the frontoparietal cortex, a region of the brain not damaged by seizures, were not significantly different in controls (18 ± 6.7 ng/mg protein) versus KA-treated rats (20 ± 3.7 ng/mg protein; N=7). Control microdialysate AA levels in the piriform cortex were 0.9 ± 0.4 μM and increased dramatically to 15.9 ± 6.0 μM during KA-induced seizures ($p = 0.0001$, ANOVA with repeated measures; N=3). Control microdialysate UA levels of 2.4 ± 0.5 μM increased to 4.7 ± 0.5 μM during KA-induced seizures ($p = 0.0001$; N=3). Thus, KA-induced seizures produced oxidative stress in the form of increased lipid peroxidation in a brain region known to be extensively damaged by seizures, but not in an undamaged region. These data suggest that oxidative stress may contribute to seizure-associated neuropathology, whereas increased AA and UA in brain extracellular fluid may represent an antioxidant response to the oxidative stress. SUBSTANCE P INJECTIONS AND POLYMER IMPLANTS PROTECT AGAINST EXCITOTOXIN-INDUCED D_1 DOPAMINE RECEPTOR LOSS IN RAT STRIATUM
P.R. Sanberg*, D.F. Emerich, P. Aebischer, S.M. Amisetti, W. Ouellette, T.K. Koutouzis, D.W. Cahill and A.B. Norman. Div. of Neurosurgery, Univ. of South Florida, Tampa, FL; Brown Univ., and CytoTherapeutics, Inc., Providence, RI.

Recently, it was demonstrated by Pert & colleagues (O'Neill et al Soc.Neurosci.Abstr. 16,194,1990) that substance P (sub P) and a heptapeptide fragment potentially protected against NMDA-induced toxicity of hippocampal neurons *in vitro*, and NMDA-induced lethality *in vivo*. The present study examined whether sub P could protect against quinolinic acid(QA)-induced lesions of the striatum, as measured by a loss of striatal D_1 dopamine receptors.

Sub P (200 nmol/10 ul) was injected unilaterally into the lateral ventricle of rats. About 25 min. later, an intrastriatal injection of QA (100 nmol/ul) was given. Controls received vehicle only. Animals were sacrificed approx. 5 days later and the striata were frozen and examined for D_1 dopamine receptors. The D_1 receptors were assayed using ^{3}H-SCH23390, and saturation analysis determined Bmax and Kd. Results showed that QA alone induced about a 40% loss of D_1 receptors. Sub P alone produced no significant change, but sub P prevented the QA-induced loss of striatal D_1 receptors.

In another study, sub P was extruded into Evac polymer rods for slow release. One 4mm rod segment was implanted unilaterally into the striatum of each rat. One week later, animals received a stereotaxic injection of QA (50, 75 or 100 nmol/ul) 0.5 mm medial to the implanted rod. Controls received QA alone. Three weeks later, the striata were analyzed for D_1 dopamine receptors. Results showed a dose-dependent loss of D_1 receptors following QA alone. Sub P rods protected the striatum from QA-induced D_1 receptor loss at the time point studied. These results support the neuroprotection role of sub P on excitotoxicity.

NEUROTOXICITY: MISCELLANEOUS TOXINS

673.1

IMMUNOCYTOCHEMICAL LOCALIZATION OF CATALASE IN RAT BRAIN.
S. Moreno and E. Mugnaini*. Lab. of Neuromorphology, Univ. of Connecticut, Storrs, CT 06269-4154.

Peroxisomes are cytoplasmic organelles first described in mouse proximal kidney tubules and now well characterized and known to be present in virtually every eukaryotic cell. They are responsible for the removal by catalase of hydrogen peroxide produced in the peroxisomal oxidative pathways and are involved in several metabolic processes, such as lipid ß-oxidation, aminoacid metabolism and biosynthesis of plasmalogens, major myelin constituents. The importance of peroxisomes in the nervous system is emphasized by numerous genetic diseases associated with impaired function of peroxisomes, or their numerical reduction, and neurological disturbances. Little is known, however, about neural peroxisomes (also called microperoxisomes, because they are smaller than those in kidney and liver cells). We have studied the distribution of peroxisomes in the adult rat brain by means of a new, extremely sensitive, immunocytochemical procedure (J.C. Adams, in press), utilizing an affinity-purified polyclonal antibody against catalase. Two main categories of neurons showed an intense positivity: (a) large neurons located in the mesencephalic nucleus of the trigeminal nerve, red nucleus, cerebellar and vestibular nuclei, the reticular formation, and all the cranial and spinal motor nuclei; (b) small interneurons of the cerebral cortex and the hippocampal formation, the cerebellar Golgi cells, and the principal neurons of the thalamic reticular nucleus. In both white and gray matter, most astrocytes and oligodendrocytes were distinctly immunostained. Ependymal cells showed a high staining intensity, while no reaction was evident in endothelial cells. A moderate degree of staining was found in most neurons throughout the brain. These data suggest that catalase expression is only partly correlated with cell size. High catalase content in certain small neurons and the macroglial cells may reflect particular cellular metabolic processes, such as those related to firing, myelin synthesis or metabolite transport.

Benzylamines Reduce Hydrogen Peroxide Induced Neuronal Degeneration In Vitro: Correlation Between Structure and Cytoprotection.
C.A. Luttman, P.T. Keith, J.R. McCowan, J.H. Wikel, M.J. Yu and R.D. Saunders* Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285

Generation of reactive oxygen species plays a pivotal role in neuronal degeneration during ischemia/reperfusion and traumatic injury. During brain ischemia, H_2O_2 may accumulate to levels which are toxic to neurons. Agents which prevent phospholipid oxidation may prevent membrane degradation and subsequent neuron death. We tested the ability of a homologous series of 3,5-dialkoxy-4-hydroxy-benzylamines in preventing H_2O_2-induced neuronal degeneration in vitro. Acute exposure of neuronal cultures to 50 uM H_2O_2 for 15 min resulted in few morphological changes, but "delayed" widespread neuronal degeneration occurred during the ensuing 24 hours. Treatment of the cultures with benzylamines reduced the cytotoxic effect of H_2O_2. In general, increasing the length of the carbon side chain was associated with increased cytoprotection. However, substituent bulk (MR) and substituent length (L1) may represent independent parameters in the context of H_2O_2 toxicity- i.e. derivatives with equivalent L1 values were equally effective despite having different MR values. These compounds were only partially effective and may not address other mechanisms occurring in the cascade of H_2O_2 toxicity (i.e. enzyme inactivation). Our data provide evidence that agents which prevent oxidation of membrane phospholipids may prove beneficial during pathological conditions where hydrogen peroxide is produced in vivo.

673.3

A GLUTAMATE HYPOTHESIS FOR TARDIVE DYSKINESIA.
P.E. Andrén* and L.M. Gunne. Dept. of Psychiatry, Ullerâker, Uppsala Univ., S-750 17 Uppsala, Sweden.

Several animal models have been developed for the study of tardive dyskinesia (TD) based on hyperkinetic states induced in long-term neuroleptic-treated animals. These models for TD have been contrasted against models for Parkinson's disease (where an upregulation of dopamine transmission within certain brain areas is characteristic of TD, while a downregulation is linked with parkinsonism). This dualistic view of contrasting models has been presented for years, despite numerous reports from the clinic, claiming that TD and parkinsonism often occur together.

The GABA hypothesis for TD has been linked with decreased GABA activity in the internal segment of globus pallidus (GPi), substantia nigra reticulata (SNr) and the subthalamic nucleus (STN). Interestingly, a downregulation of GABA terminals has recently been demonstrated in these brain regions of the hypokinetic, parkinsonian brain. The changes within the GABA-system may thus reflect or sometimes antedate the occurrence of tardive parkinsonism (TP) rather than TD. The changes within the GABA neuron system may account for signs of TP, whereas the origin of TD must be sought elsewhere.

Studying an admittedly limited number of Cebus monkeys with TD we found a reduced deoxyglucose uptake both in GPi and its thalamic target area (though not in the SNr). The animals were treated with fluphenazine-decanoate for several years and sacrificed four months after the last depot injection. The reduced glucose utilization in these areas may reflect a reduced synapse activity, possibly resulting from glutamate excitotoxicity. The STN-fugal neurons terminating in GPi and SNr are known to be glutamatergic and this system of glutamate neurons is upregulated in the parkinsonian brain and also during long-term neuroleptic treatment. This chronic upregulation might have excitotoxic effects on the GABA pathways from GPi and SNr to the thalamus. A destruction of those thalamic afferents could result in a hyperkinetic state and may be an underlying mechanism explaining the choreic elements of TD. This would thus give rise to a glutamate hypothesis for TD.

673.4

LEVODOPA TOXICITY IN CELL CULTURE.
A.N Basma, W.J Nicklas, F.C. Kauffman* and H.M. Geller. Depts. of Neurology and Pharmacology, UMDNJ-RWJ Med.Sch., Piscataway, N.J.08854.

Parkinson's disease continues to progress in patients treated with Levodopa (L-dopa), and this progression has been ascribed to the continued loss of dopaminergic neurons in the substantia nigra. It has been suggested that L-dopa and dopamine can generate reactive molecules that might contribute to the acceleration of the loss of dopaminergic neurons. Using cultured E15 rat mesencephalic neurons and the pheochromocytoma PC12 cell line as model systems, L-dopa was cytotoxic with $LD_{50's}$ of 140 and 400 μM in dopaminergic and GABAergic mesencephalic neurons, respectively, following a 2 day exposure and 60 μM in PC12 cells after a 4 day exposure. The mechanism of toxicity of L-dopa was investigated to see whether there was a correlation between cytotoxicity and autoxidation of L-dopa itself or dopamine formed from the L-dopa. Carbidopa, an inhibitor of aromatic L-amino acid decarboxylase, did not protect against L-dopa cytotoxicity in either PC12 cells or neurons, and clorgyline, an MAO-A inhibitor, did not enhance L-dopa toxicity in PC12 cells suggesting that cytotoxicity was not due to dopamine formed from L-dopa. Catalase or superoxide dismutase alone provided partial protection against L-dopa toxicity in PC12 cells. However, the combination of these enzymes totally protected against cytotoxicity. Therefore, L-dopa cytotoxicity in PC12 cells and mesencephalic neurons is most likely due to its autoxidation. Furthermore, these preliminary findings would suggest that although L-dopa is beneficial in the treatment of Parkinsonism, it could also be deleterious to neurons in the brain of patients because of its capability to be autoxidized, generating reactive molecules.

2'-AMINO SUBSTITUTED MPTP DEPLETES BRAIN SEROTONIN AND NOREPINEPHRINE WITHOUT AFFECTING DOPAMINE IN C57BL/6 MICE. A. M. Andrews, N. A. Garrick*, and D. L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

Both 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) and 1-methyl-4-(2'-methylphenyl)-1,2,3,6-tetrahydropyridine (2'-CH_3-MPTP) are known dopaminergic neurotoxins. Experiments with another 2'-substituted derivative of MPTP, namely 1-methyl-4-(2'-aminophenyl)-1,2,3,6-tetrahydropyridine (2'-NH_2-MPTP), produced considerably different results following systemic administration (4 x 20 mg/kg i.p.) to C57BL/6 mice. Amine neurotransmitters and their metabolites were quantitated by HPLC-ECD in mice sacrificed 1 and 3 weeks post-treatment. While 2'-CH_3-MPTP (2 x 20 mg/kg) caused dopamine(DA) and its primary metabolites to become substantially reduced (~80%) in key brain areas such as striatum, 2'-NH_2-MPTP produced marked depletions (~70%) in serotonin (5-HT), 5-hydroxyindoleacetic acid (5-HIAA), and norepinephrine (NE) in frontal cortex and hippocampus. Smaller decreases in 5-HT, 5-HIAA, and NE were seen in brain stem and striatum as well. 2'-NH_2-MPTP had no effect on dopaminergic neurochemistry. Our current studies are investigating whether 2'-NH_2-MPTP or a metabolite has a different specificity than other MPTP analogs for aminergic transport systems.

NEW EVIDENCE FOR A LOSS OF SEROTONERGIC NERVE TERMINALS IN RATS TREATED WITH FENFLURAMINE. R.I.Westphalen and P.R.Dodd*
Clinical Research Centre, Royal Brisbane Hospital Foundation,
Bancroft Centre, Royal Brisbane Hospital, Herston Q 4029, AUSTRALIA.

Evidence to classify fenfluramine as a serotonergic neurotoxin comes from reports that show decreases in markers of serotonergic nerve terminals (vesicular 5-HT and 5-HT uptake sites on pre-synaptic nerve terminals) in rats treated with fenfluramine. However, suggestions that the antigen (5-HT) was repositioned by fenfluramine (fenfluramine-induced 5-HT release) rendered the immunocytochemical evidence questionable. Therfore, studies which used the 5-HT uptake sites as markers of serotonergic nerve terminals gained attention. These studies found decreased radio-ligand binding to 5-HT uptake sites, and a reduced rate to which synaptosomes from animals treated with fenfluramine take up radio-labelled 5-HT. However, the present study demonstrates that this evidence is also exhibited in an animal model of reduced 5-HT uptake site density on otherwise functional serotonergic nerve terminals (Rx), established by injecting male Wistar rats with an irreversible 5-HT uptake site antagonist, *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ). Therefore, a decrease in 5-HT uptake site density and maximum 5-HT uptake rate into synaptosomes may not portray a loss of 5-HT containing nerve terminals, highlighting the fact that it had not been demonstrated conclusively that fenfluramine administration leads to a loss of serotonergic nerve terminals.

When maximal loading of [^{14}C]5-HT into synaptosomes (α) was measured, it was found that animals treated with fenfluramine gave a significantly lower value than those in the Rx group ($p < 0.02$). Rx animals did not differ significantly from controls. Therefore the measurement of α allowed a distinction to be made between a loss of uptake sites on an intact neurotransmitter system, and a loss of uptake sites as a consequence of terminal loss.

It was concluded that the combination of decreased uptake site density (B_{MAX}) and/or uptake rate (V_{MAX}) with decreased synaptosomal loading of neurotransmitter (α) give evidence of a loss of pre-synaptic nerve terminals. The present study thus indicates fenfluramine-induced destruction of serotonergic nerve terminals.

673.7

DEXFENFLURAMINE (DFEN) REGIMENS THAT REDUCE BRAIN SEROTONIN (5HT) MARKERS DO NOT AFFECT EITHER GFAP OR MICROGLIA IN RAT FRONTAL CORTEX. N.E. Rowland, W.J. Streit, A. Kalehua, B.H. Li, S.L. Semple-Rowland* Depts Psychology & Neuroscience, Univ of Florida, Gainesville FL 32611.

Male Sprague-Dawley rats were administered DFEN (0-12 mg/kg, twice daily, per os) for 4 days and were sacrificed either 18 hr, 66 hr, or 2-3 weeks after the last injection. Higher doses of DFEN produced a marked and long-lasting depletion of brain 5HT content and uptake sites (by paroxetine binding). 5HT immunohistochemistry showed the previously-described swollen 5HT-reactive axons at short survival times in frontal cortex. As a measure of possible degenerative changes, we also studied responses of glial cells in the vicinity of swollen 5HT-reactive processes. No evidence for an astrocytic reaction was obtained in either sections or Western blots of tissue extracts immunostained for glial fibrillary acidic protein (GFAP). In double-stained sections, there was no GFAP reaction even adjacent to 5HT-immunoreactive swollen processes. Likewise, sections stained for reactive microglia (Griffonia simplicifolia) showed no change in the number or intensity of microglia at any time after DFEN.

Supported by a grant from IRIS (Servier).

A DIHYDROPYRAZOLE INSECTICIDE, RH 3421, BLOCKS VOLTAGE-DEPENDENT SODIUM CHANNELS IN PRIMARY CULTURES OF RAT DORSAL ROOT GANGLION NEURONS. J.M. Frey*, D. Highfield, S.M. Murray, and G .R. Christoph. Central Research and Development, E.I. Du Pont de Nemours and Company, Newark, DE 19714.

Certain dihydropyrazoles have potential utility as insecticides. Previous neurophysiological data on invertebrate preparations indicate that RH 3421, methyl 1-[*N*-(α,α,α-trifluoro-*p*-tolyl) carbamoyl-3-(4-chlorophenyl)-4-methyl-2-pyrazolin-4-ylcarboxylate, blocks voltage-dependent sodium channels (Salgado, V.L. Pestic. Sci. 1990, 28, 389-411). To characterize the potential neurotoxic effects of dihydropyrazoles in mammalian preparations, RH 3421 was independently synthesized and was applied by pressure ejection to individual neurons during tight-seal, whole-cell voltage clamp experiments. Sodium currents were isolated by including calcium and potassium channel blockers in the bath and pipet solutions. In order to de-inactivate sodium channels (50% inactivation voltage *ca.* -70 mV), a 5-sec conditioning prepulse to -110 mV was delivered prior to each depolarizing voltage step. Sodium currents recorded under these conditions had typical current-voltage characteristics and peak amplitudes of 4-10 nA elicited by voltage steps to -10 mV from holding potentials of -60 mV or -90 mV. RH 3421 (up to 10 μM) decreased the peak sodium current in a concentration-dependent manner, with greater effect at less negative holding potentials. Blockade was not reversed by washing during the 45-min duration of the typical experiment. Membrane hyperpolarization, however, did partially reverse compound-induced sodium current blockade. These results directly support Salgado's conclusion that dihydropyrazole insecticides cause voltage-dependent blockade of sodium channels and extend the findings to mammalian neurons.

673.9

SOMAN INDUCED CHANGES IN THE CAT VISUAL SYSTEM FOLLOWING PYRIDOSTIGMINE. A.W. Kirby*, A.T. Townsend, C. Pope, G.evans, R. Murhpy and R. Collins. USAARL, Fort Rucker, AL 36362.

Soman is an organophosphorus compound, an irreversible inhibitor of cholinesterase (ChE), and a potential nerve agent. Pyridostigmine (pyrido) is a carbamate, a reversible inhibitor of ChE, and the pretreatment drug of choice for protection against nerve agent exposure. Last year at this meeting we reported changes in visual function following soman. These studies were done to evaluate the protection to the visual system when pyrido pretreatment is used.

Adult cats were prepared surgically under halothane anesthesia and maintained throughout the experiment with urethane. Following base line visual evoked response (VER) collection, enough pyrido was given to inhibit 30-80% of blood ChE. Soman (4 μg/kg) then was given.

This dose of soman resulted in about 80% inhibition of blood ChE and 80-90% VER reduction with no recovery over the next 24 hours. A 60% inhibition of blood ChE with pyrido did not alter the VER. Following soman, reduction of the VER was about 30% compared to 80% without pyrido, and blood ChE returned to about 60% within several hours. Even with less pyrido pretreatment, significant recovery occurs within several hours.

COMPARISON OF ORGANOPHOSPHATE INTERACTIONS WITH ACHE AND MUSCARINIC RECEPTORS. T.R. Ward, D.J. Ferris, H.A. Tilson, S. Padilla* and W.R. Mundy. Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC 27711

Toxicity of organophosphate compounds (OPs) has long been associated with their ability to inhibit acetylcholinesterase (AChE). Recently reports have surfaced indicating direct interaction of OPs with muscarinic acetylcholine receptors in the CNS. We investigated the sensitivity of muscarinic receptor binding to [3H]quinuclidinyl benzilate (QNB) and [3H]cis-methyldioxolane (CD) to competition with a series of OPs in washed homogenates of frontal cortex from adult male Long Evans rats. The OPs' IC50s for competition with radiolabeled ligands were compared to the IC50s for the inhibition of AChE activity. The OPs studied were diisopropylfluorophosphate (DFP) and echothiopate (EC), the insecticides parathion (PT), malathion (MT) and disulfoton (DI), and their activated forms paraoxon (PO), malaoxon (MO) and demeton S (DE). QNB (a muscarinic antagonist which binds to all receptor subtypes) binding was not affected by these compounds at concentrations under approximately 100 μM. CD (a muscarinic agonist which binds to only 8-10% of the total muscarinic sites) binding was inhibited with IC50s of: PT >100 μM, PO 0.021 μM, MT 91 μM, MO 0.74 μM, DI 55 μM, DE 16 μM, DFP 4.3 μM, EC 0.011 μM. AChE activity was inhibited with IC50s of: PT >100 μM, PO 0.004 μM, MT >100 μM, MO 0.029 μM, DI >100 μM, DE 2.3 μM, DFP 0.42 μM, EC 0.005 μM. The ability of OPs to inhibit AChE activity correlated well with their ability to compete with CD binding (r=.99). These results suggest that OPs can interact directly with a subset of muscarinic cholinergic receptors in the CNS at biologically relevant concentrations.

673.11

CHANGES IN CELLULAR CALCIUM HOMEOSTASIS AND TOXICITY OF 2,2'-DICHLOROBIPHENYL IN RAT CEREBELLAR GRANULE CELLS. P.R.S. Kodavanti, D. Shin, H.A. Tilson* and G.J. Harry. Neurotoxicology Division, HERL, U.S.E.P.A and DART/STB, NIEHS, Research Triangle Park, NC 27711.

Some polychlorinated biphenyls (PCB) affect locomotor activity and brain dopamine function in laboratory animals. The exact mechanism of these effects, however, is not known. Since neurotransmitter uptake and release are dependent on the maintenance of normal calcium homeostasis of the nerve cell, we have studied the effects of a potentially neurotoxic PCB congener, 2,2'-dichlorobiphenyl (DCBP), on Ca^{2+}-homeostasis using cerebellar granule cells. Perturbations in calcium homeostasis have also been closely associated with cell death caused by a variety of toxicants. Free Ca^{2+} measurements (fluo-3 fluorescence) and cytotoxicity (LDH leakage) assays were performed in cerebellar granule cells (10-14 DIV). Ca^{2+} sequestration was studied in mitochondria and microsomes, whereas Ca^{2+} extrusion was studied in synaptosomes, prepared from adult rat cerebellum. In cultured cerebellar granule cells, DCBP was cytotoxic at 200 μM and higher concentrations after 1 hr of exposure. However, 50 μM DCBP increased cerebellar granule cell free Ca^{2+} two-fold following 20 min incubation. This increase was not transient, and a steady rise was observed with time. DCBP was also very potent in inhibiting ^{45}Ca-uptake by mitochondria (IC50 = 6.21 μM) and microsomes (IC50 = 7.68 μM). Synaptosomal Ca^{2+}-ATPase was also inhibited by DCBP (IC50 = 81 μM). These results indicate that at concentrations where cytotoxicity is not observed, DCBP increases intracellular free Ca^{2+} and inhibits Ca^{2+} sequestration by intracellular organelles as well as Ca^{2+} pumps in synaptic plasma membrane. Since DCBP is very potent in inhibiting these events, the possible neurotoxicity of this PCB might be associated with perturbations in cellular calcium homeostasis. (Supported by EPA award CR 818550-01-0).

EFFECTS OF NEONATAL MONOSODIUM GLUTAMATE ON PEPTIDE mRNA EXPRESSION IN RAT ENDOCRINE AND VISUAL CNS STRUCTURES. S. E. Bachus*, W. S. Young, III, & M. Palkovits. Lab of Cell Biology, NIMH, Bethesda, MD 20892.

Since we found that electrolytic arcuate-premammillary lesions modulate levels of mRNA for galanin (GAL), vasopressin (VP), angiotensin (AII) and cholecystokinin (CCK) in hypothalamic magnocellular neurons (Neurosci. Abst. 17:1186), we investigated whether arcuate lesions caused by neonatal monosodium glutamate (nMSG) produce similar effects. In addition, because nMSG causes optic nerve atrophy, we measured CCK and substance P (SP) mRNA levels in the visual system structures, the dorsal nucleus of the lateral geniculate (DLG) and superficial layers of the superior colliculus (SCs). Rat pups received 4 mg/kg MSG, or 0.9% saline, s.c., on days 0, 2, 4, 6 and 8, and were sacrificed on day 35. Peptide mRNAs were measured with hybridization histochemistry using ^{35}S-oligodeoxynucleotide probes (Meth. Enzym. 169:702).

Arcuate levels of mRNAs for neuropeptide Y (NPY), GAL, and neurokinin B were depleted by nMSG, and levels for proopiomelanocortin (POMC) were reduced to 30% of control ($p<.0005$). (Similar results using immunohistochemistry for NPY, GAL and POMC gene products were reported by Meister et al., Exp. Brain Res. 76:343). GAL mRNA was doubled in the paraventricular nucleus ($p<.0005$) and increased by 17% in the supraoptic nucleus ($p<.05$) by nMSG. Magnocellular CCK, VP, and AII mRNA levels were not affected. In the SCs, while the density of label was comparable, the area was smaller after nMSG, so that the total label was reduced to 30% of control for SP ($p<.001$) and to 28% for CCK ($p<.001$). In the DLG, nMSG increased the density of CCK mRNA by 21% ($p<.005$), but because the area was reduced, the total label was reduced to 66% of control ($p<.001$). Thus, in addition to alterations of peptide gene expression in hypothalamic nuclei, the nMSG-induced damage to optic fibers affected peptide gene expression in subcortical visual areas.

673.13

DIMETHYL SULFIDE AS A PHARMACOLOGICAL ANALOGUE FOR HYDROGEN SULFIDE. R.J. Reiffenstein*, A.F. Almeida and S.H. Roth. Department of Pharmacology, University of Alberta, Edmonton, AB, Canada T6G 2H7, and University of Calgary, Calgary, AB, Canada T2N 4N1.

Despite the extensive use of rats to study the toxic effects of hydrogen sulfide, deficiencies exist. Coma, which is a common symptom of humans exposed to hydrogen sulfide is not often seen in rats because the dose curves for coma and lethality are very steep. Though other animal models are used these problems remain. In an attempt to resolve them, a comparison of hydrogen sulfide has been made with dimethyl sulfide (DMS) which is chemically similar but less potent and can produce coma. To reduce the animals used, the cumulative method of Reed and Muench (Am.J.Hyg. 27, 493,1938) was used to derive ED50 and LD50 values.

The intraperitoneal injection of DMS elicits a comatose state in Sprague Dawley rats (200-300g body weight) that is dose dependent with an ED50 of 813 mg/kg. The period coma lasted less than 25 minutes and the animals appeared to recover fully. Animals that died did so several hours later of relatively abrupt respiratory failure. Using a 24-hour post injection time mark, the LD50 for DMS is 537 mg/kg showing a decreased toxicity of greater than thirty fold as compared with hydrogen sulfide. It is noted that the LD50 is lower than the ED50 under these conditions.

Agents purported to have antidotal effects for sulfide poisoning, namely dithiothreitol (DTT) and sodium nitrite were studied for their ability to reverse coma and to prevent death. Sodium nitrite, 75 mg/kg administered at onset of coma decreases duration of coma, but DTT (50mg/kg) had no effect whether administered at onset of coma or 20 minutes prior to DMS. Pretreatment with DTT caused a small reduction in lethality (LD50-661 mg/kg). Supported by Medical Research Council of Canada.

N-BUTYL BENZENESULPHONAMIDE TOXICITY IN PRIMARY NEURONAL CULTURES. I. Wakayama, V.R. Nerurkar and R.M. Garruto*. Laboratory of Central Nervous System Studies, NINDS, National Institutes of Health, Bethesda, MD 20892

We previously demonstrated that N-butyl benzenesulphonamide (NBBS) is neurotoxic both *in vivo* and *in vitro*. *In vivo*, NBBS-inoculated rabbits develop a specific myelopathy with axonal and dendritic changes in spinal motor neurons after monthly intracisternal inoculations of a 100 µg dose for up to 12 months. *In vitro*, using continuous cell lines of neuronal (Neuro-2a) and glial (C6-glioma) origin, we demonstrated that, at a concentration of 10 µM and 50 µM NBBS respectively, cell growth and DNA synthesis were inhibited.

To further determine the mechanisms of NBBS neurotoxicity, particularly on cytoskeletal derangement, we studied the toxicity of NBBS on primary hippocampal cultures. Ten days after plating when neurofilament and other cytoskeletal proteins were fully expressed in the perikarya and in neurites, dissociated mouse hippocampal neurons were exposed to NBBS at different concentrations (10 µM, 25 µM and 50 µM) for 2 to 4 days. Immunostaining using antibodies against phosphorylated neurofilament and α-tubulin revealed that staining intensity of both neurofilament and α-tubulin was markedly reduced in distal neurites, while staining in the perikarya and proximal neurites was preserved. Neuritic outgrowth was also inhibited in NBBS-treated neurons compared to untreated neurons. These findings suggest that cytoskeletal derangement and redistribution in neurites begin distally and eventually lead to structural changes and neuronal death.

NEUROTOXICITY: METALS

EARLY PRENATAL AND POSTNATAL LEAD EXPOSURE INDUCES ASTROGLIAL REACTIVITY. A. Selvin-Testa, C.F. Loidl, J.J. López and J. Pecci-Saavedra*. Inst. de Biología Celular. F. de Medicina, U.B.A. Buenos Aires, 1121, R. Argentina.

In previous results we observed that 3 months of lead exposure -started when pups were 7 days old- caused hypertrophic astrocytes in the rat hippocampus. The aim of the present study was to compare the astroglial response in the cerebellum and the hippocampus, two regions with late postnatal development. Experiments were done with rats whose parents were lead intoxicated during 4 months (1g% lead acetate solution -*subclinical dose*). Lead administration was continued during conception, gestation, the early postnatal life, and following weaning, for 3 months. Immunohistochemistry methods were used for identification of the cytoskeletal intermediate filaments, GFAP and vimentin. Reactive vimentin and GFAP immunostaining astrocytes were observed in the different layers of the hippocampus. They showed an increase in size, changes in shape, and a great increment in number and in the immunoreaction. Besides, vimentin-hypertrophic-hyperplastic astrocytes only appeared in the cerebellar white matter. Lead exposure during the period of rapid brain growth could modify the complex neuron-glia interaction altering the neuronal microenvironment and so disturbing the brain function. (Work supported by the CONICET and U.B.A, Agentina).

LEAD POISONING AND DMSA: EFFICACY OF CHELATION TO ATTENUATE LEAD-INDUCED BEHAVIORAL CHANGES. P. W. Stewart, J. D Goldblatt, M. E. Lennon, R. G. Burright, P. J. Donovick*. Psychol. Dept., S.U.N.Y. Binghamton, Binghamton, N.Y. 13902.

We investigated the effect of 2,3 dimercaptosuccinic acid (DMSA), a relatively new chelating agent for lead poisoning, on activity, aggression and blood-lead levels in non-lead and lead-exposed male, young adult, Binghamton Heterogeneous Stock mice. The effect of water temperature (5C - extreme stress vs. 25C - moderate stress) in a water swim test was examined to determine how it might interact with lead and DMSA to affect behavior. Literature suggests lead-induced behavioral changes more reliably occur in aversive conditions, we therefore hypothesized that lead exposure would result in hyperactivity in mice relative to controls, but only in the extreme stress condition. Lead-exposed mice were also predicted to be more aggressive in aggression tests relative to controls - a prediction consistent with clinical literature associating lead exposure with aggression in young children. DMSA was expected to reduce blood-lead, and thus might be expected to attenuate lead induced behavioral changes. Results indicated that 5C water stress caused all animals, regardless of lead or chelation status, to reach an apparent behavioral asymptote (ceiling) in the activity chamber. Surprisingly, the effect of lead and DMSA on swim activity actually appeared additive in the 25C water stress chamber. Isolation-induced intermale aggression testing showed that lead-exposed pairs of mice were less aggressive than control pairs. However, a three-way interaction indicated that the non-lead, non-chelation group had significantly elevated aggression, but only for those pairs with a history of exposure to the 25C water swim condition. Although DMSA failed to attenuate lead-induced behavioral changes in this study, results should be weighed relative to the clinical benefits that DMSA reportedly provides.

674.3

DIFFERENTIAL EFFECTS OF EARLY CHRONIC LEAD (Pb) EXPOSURE ON NEONATAL RAT BRAIN NMDA, PCP AND ADENOSINE A_1 RECEPTORS. M.F. Jarvis*, W. J. Brooks., J. C. Leboutillier, J. N. Nobrega, T. L. Petit. Dept. of Psychology, Univ. of Toronto, Ontario and Rhone-Poulenc Rorer Cent. Res. Collegeville, PA 19426.

In order to further characterize the neurotoxic effects of chronic Pb exposure, autoradiographic techniques were used to examine the effects of early Pb exposure on NMDA, PCP, and adenosine A_1 receptors in neonatal rat brain. Rat pups nursed mothers exposed to 4% $PbCO_3$ in thier diet, or a Na_2CO_3 control diet from postnatal day 1 (P1) to P25. At P25, rats were sacrificed and the distributions of [^{3}H]CGP 39653 binding to NMDA receptors, [^{3}H]TCP to PCP receptiors and [^{3}H]CHA to adenosine A_1 receptors in brain were assessed. Chronic Pb exposure was found to produce an increase (+ 20-30%) in the density of ligand binding to NMDA and PCP receptors in specific regions of the hippocampus. However, [^{3}H]CHA binding to A_1 receptors was found to be generally decreased (20-60%) throughout the neonatal rat brain. The present observations are consistent with recent behavioral and electrophysiological data indicating that Pb may directly alter the NMDA/PCP receptor complex in the rat forebrain and may also suggest a direct effect on inhibitory neuromodulation via adenosine A_1 receptors.

674.4

LEAD ELEVATES THE INTRACELLULAR CALCIUM ION CONCENTRATION OF NEURONS: A F-19 NUCLEAR MAGNETIC RESONANCE STUDY OF NEURONS IN MICROCARRIER CULTURE. F.A.X.Schanne, D.K.Batter* and J.A.Kessler. Depts. of Pediatrics, Pathology, Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461

Exposure to lead (Pb) early in development leads to significant neurobehavioral deficits in humans and animals. The objective of this study was to determine the effect of Pb on the intracellular calcium ion concentration $[Ca^{2+}]_i$ of developing neurons. Neurons were isolated from the cortex and hippocampus of fetal rat brains on day 18 of gestation. Neurons were attached to Cytodex #3 microcarriers and maintained in Eagle's Minimal Essential Medium supplemented with 10% fetal calf serum at 37°C, 5% CO_2. Neurons were loaded with the divalent cation indicator 1,2-bis(2-amino-5-fluorophenoxy)ethane-N,N,N',N'-tetraacetic acid (5F-BAPTA) and the $[Ca^{2+}]_i$ was measured using ^{19}F NMR. This method provides for the simultaneous identification and measurement of Ca^{2+} and a variety of heavy metals, including Pb^{2+}. The untreated or baseline $[Ca^{2+}]_i$ of neurons measure on days 4 to 6 *in vitro* ranged from 128 to 184 nM. Upon treatment with Pb^{2+} (5μM) the $[Ca^{2+}]_i$ rose 50 to 60% within 1 hr in cortical neurons and greater than 80% in hippocampal neurons. These data indicate that Pb^{2+} elevates $[Ca^{2+}]_i$ in developing neurons in culture. Given the importance of $[Ca^{2+}]_i$ in the expression of neuronal structure and activity we propose that these changes in $[Ca^{2+}]_i$ may contribute to Pb-induced alterations in neural morphology, plasticity and responses to neurotransmitters.

674.5

SELECTIVE TOXICITY TO CENTRAL NORADRENERGIC NERVOUS SYSTEM IN POSTNATALLY LEAD EXPOSED RATS. S.G. Song, D.O. Seo, J.H. Cheong, C.Y. Shin, M-U. Choi*° and K.H. Ko. Department of Pharmacology, College of Pharmacy and Department of Chemistry, College of Natural Science, Seoul National University, Seoul 151, Korea.

Possibility whether postnatal lead ingestion can cause selective toxicity to central noradrenergic nervous system in rats was tested. Three groups of wistar rats; 1) Control, 2) Low dose and 3) High dose groups, were prepared. Right after parturition from dams rat pups received drinking water containing either 0% (control), 0.05% (low dose) or 0.2% (high dose) of lead acetate. At 2, 4, 6 and 8 weeks of age, dopamine β-hydroxylase (DBH) activity and Na-K ATPase activity were measured in 5 areas of rat brain; Telencephalon, Diencephalon, Midbrain, Pons/Medulla and Cerebellum. DBH activities were assayed by modified method of Coyle and Axelrod (1972) using S-adenosyl-[^{14}C]-methionine as substrate. DBH activity was determined as a criterion of lead poisoning to central noradrenergic nervous system and ATPase activity as a criterion of nonspecific lead poisoning to any kinds of tissues. In lead exposed rats, DBH activities were higher but Na-K ATPase activities were lower than those observed in age-matched control animals. Selective toxicity of lead poisoning to central noradrenergic nervous system was evaluated by the changes of DBH activities without concomitant changes of ATPase activities. Brain areas where selective toxicity of lead seems to be induced were telencephalon and pons/medulla (2 weeks of age) and telencephalon, diencephalon and pons/medulla (4 weeks of age), midbrain and pons/medulla (6 weeks of age), cerebellum (8 weeks of age) in low dose group, and midbrain (6 weeks of age), cerebellum (8 weeks of age) in high dose group.

LEAD-INDUCED ALTERATIONS IN CYTOSOLIC PROTEINS BY CULTURED ASTROCYTES EXPOSED TO LEAD. L. Shemancik, D. Cory-Slechta, B. Weiss,* and J. Finkelstein. Env. Health Sci. Center and Strong Children's Res. Center, Univ. of Rochester, Rochester, NY 14642

Astroglial cells accumulate Pb and are less sensitive to detrimental effects than neurons. A possible mechanism by which astrocytes adapt to Pb may be upregulating the expression of particular genes. We have previously demonstrated that exogenously added Pb resulted in enhanced synthesis of a 23kD acidic cytosolic protein by astrocytes. To begin to address the question of the mechanisms underlying the regulation of the 23kd protein by Pb, astrocytes were cultured in actinomycin D prior to the addition of the metal. Astrocytes, both pretreated or untreated, were exposed to 0, 5, and 50μM Pb acetate for 24 hours and pulse-labeled [^{3}H]-leucine. Proteins were separated by SDS-PAGE and subsequently analyzed by fluorography. Treatment with actinomycin D precluded synthesis of the 23kD protein. The differences in size and charge of the cytosolic proteins in Pb-exposed and untreated astrocytes were futher characterized by two-dimensional electrophoresis. After a 24 hour treatment period with 0 or 50μM Pb acetate, cells were pulse-labeled and cytosolic proteins were analyzed by two-dimensional electrophoresis and fluorography. The 23kD protein was resolved into 7 different charged species in Pb treated astrocytes. The untreated control revealed faint but definite spots corresponding to all but the most acidic of the 23kD proteins. To determine the relative abundance of the various proteins in Pb-treated and untreated astrocytes, cytosolic proteins were also analyzed by silver stain. Two spots corresponding to the 23kD proteins were notably more abundant in Pb-treated cells and an acidic trail of proteins ranging from 5.2-5.9pI was apparent in the same molecular weight region, thereby suggesting that the 23kD protein may accumulate and undergo post-translational modifications in response to Pb. These results suggest that Pb may affect both transcriptional and translational events in astrocytes.

COMPARISON OF FE(III) AND PB(II) SIGNATURES IN CULTURED ASTROGLIA: A NEW ASSAY FOR SCREENING NEUROTOXINS. **M. E. Legare, W. H. Hanneman, R. Barhoumi, R. C. Burghardt, and E. Tiffany-Castiglioni*. Dept. Vet. Anat. and Public Health, Texas A&M University, College Station, TX 77843.**

A battery of in vitro assays was developed to detect the presence of neurotoxic metals, particularly Pb, in cultured astroglia. In order to produce such a battery, it was necessary to distinguish unique neurotoxic effects of Pb (a Pb signature) from the toxic effects of other compounds. The Pb signature we obtained was compared to the signature produced in astroglia by the epileptogen Fe(III). Cellular responses to metal exposure were quantitated by the use of vital fluorescent probes and interactive laser cytometry. We found distinct signatures for Pb and Fe. Whereas Pb stimulated an increase in intracellular glutathione content on day 6 of treatment, Fe had no effect. Furthermore, cell-cell communication via gap junctions, which was unaffected by Pb treatment, was increased in Fe-treated cells. In addition mitochondrial membrane potential was decreased in Pb treated cells but increased in Fe-treated astroglia. We are also comparing metal effects on Ca metabolism.

674.8

ONTOGENETIC ALTERATIONS OF ODC ACTIVITY IN DEVELOPING BRAIN REGIONS AFTER POSTNATAL EXPOSURE TO LEAD-ACETATE. N.H. Zawia*and G. J. Harry, DART/STB/NIEHS, P.O. Box 12233, RTP, NC 27709.

Ornithine decarboxylase (ODC), the rate limiting enzyme of the polyamine pathway, can serve as an important tool to examine the effects of toxicants on early developmental phases of the nervous system. ODC activity follows a distinct ontogenetic pattern in individual brain regions, peaking at periods of maximal cell proliferation. We have studied the effects of inorganic lead on characteristic developmental profiles of ODC activity in the cerebellum, neocortex and hippocampus. Two exposure models were used with Long Evans hooded rats: 1) lactational exposure via 0.2% lead-acetate in the drinking water of the dam from PND1 to PND20 (23 mg/kg daily dam dose); 2) daily dosing of pups by gavage (600 mg lead acetate/kg of body weight) from PND2 to PND5. Animals were killed on PND 5,10,15 and 20, and distinct brain regions were dissected, and then frozen at -70^{0}C until assayed for ODC activity. Lactational exposure to Pb-acetate resulted in a dramatic (2 fold) stimulation of cerebellar ODC activity which was maintained up to PND 10 but dropped to control levels by PND 15. This induction of ODC activity was only observed in the cerebellum. In contrast to animals receiving low doses of Pb-acetate (lactational exposure), animals on direct Pb-acetate dosing exhibited an inhibition of ODC activity in all the brain regions examined. This loss of activity is suspected to be associated with cell loss due to high lead dosing. These data suggest that low lead exposure can interfere with proliferative events in the postnatally developing cerebellum and suggest that lead may produce generalized perturbations in neuronal development.

674.9

HEMOGLOBIN NEUROTOXICITY IN CORTICAL CELL CULTURE IS ATTENUATED BY NIMODIPINE. R.F. Regan*, S.S. Panter, and J.R. Hess Letterman Army Institute of Research, Presidio of San Francisco, CA 94129-6800.

The neurotoxicity of human oxyhemoglobin (HbAo) was investigated in murine neuronal and glial cell cultures. A twenty-four hour exposure to 100.0 μM HbAo, approximately 1.0% of the hemoglobin concentration present in whole blood (calculated on the basis of heme concentration), resulted in death of over 80% of neurons. Glia were not injured. Neuronal death was blocked by the ferric iron chelator deferoxamine (10.0 μM). Nimodipine was neuroprotective in a concentration-dependent fashion between 1.0-30.0 μM. Thirty micromolar nimodipine reduced cell injury about 90% compared with control untreated cultures. The related dihydropyridine nifedipine was also effective but was significantly less potent. Neuronal death was reduced about 50% by 100.0 μM nifedipine. The benzothiazipine calcium channel antagonist diltiazem, however, was ineffective at its maximum non-toxic concentration (30.0 μM). Both nifedipine and nimodipine significantly inhibited iron-dependent brain lipid oxidation, as measured by the generation of thiobarbituric acid reactive substances; however, nimodipine was a significantly less potent inhibitor of lipid oxidation than nifedipine. These observations suggest that hemoglobin is a potent neurotoxin in cortical cell culture. This neurotoxicity is dependent on iron and may be mediated, in part, by mechanisms sensitive to dihydropyridines.

674.10

Alteration in the ^{3}H dopamine uptake by synaptosomes exposed to ascorbic acid and Fe^{2+} is associated with a decrease in membrane fluidity and α-tocopherol level. Prevention by a Ginkgo biloba extract (EGb 761). C.RAMASSAMY*[c], J.PINCEMAIL[a], C.DEBY[a], Y.CHRISTEN[b] and J.COSTENTIN[c] [a] Centre Pathologie de l'Oxygène 4000 Sart-Tilman, Belgium. [b] IPSEN 30 rue Cambronne 75015 Paris cedex 15, France. [c] Neuropsycho pharmacologie U.R.A. 1170 C.N.R.S. 76803 St-Etienne Rouvray, France.

After 1h incubation in a Krebs Ringer medium (95% O2, 5%CO2) synaptosomes prepared from mice striata or cortex loss their ability to uptake respectively ^{3}H dopamine or ^{3}H serotonin. This effect was depending on the simultaneous presence of ascorbic acid (from 1μM) and Fe^{2+}(1μM). This decrease appeared as a consequence of a lipid peroxidation induced by the couple ascorbic acid/Fe^{2+} (Asc/Fe^{2+}) : it was associated with a decrease (≈70%) in the level of α-tocopherol (measured by HPLC), which constitutes an index of lipoperoxidation. It was also associated with a decrease in membrane fluidity (measured by fluorescence polarization of the probe 1,6-diphenyl-1,3,5-hexatriene) that might also result from a lipoperoxidation process. In the presence of EGb 761 (10μg/ml) or quercetin (which structure looks like that of some components present in the EGb 761 extract) all these alterations were completely prevented. We conclude that the synaptosomal lipoperoxidation elicited by (Asc/Fe^{2+}) through a decrease in membrane fluidity alter the activity of the amine uptake complexes. These alterations were prevented by EGb 761 which operated either by its free radical scavengers or its ferrous ions chelating properties.

674.11

THE EFFECTS OF VARIOUS LEVELS OF ASCORBIC ACID ON THE RESPONSE OF THE ODS RAT TO TRIMETHYLTIN. **A.W. Bannon, A.J. Verlangieri, and M.C. Wilson*. University of Mississippi, Dept. of Pharmacology, School of Pharmacy, University, MS 38677.**

Trimethyltin (TMT) is an organotin that can produce specific damage to the hippocampus. Behavioral deficits (e.g., memory) observed following TMT administration are often correlated with damage to the hippocampus. The influence of ascorbic acid (AA) levels on the response to TMT was investigated in ODS rats. Like man, this strain of rat does not synthesize AA. Rats were maintained on three levels of ascorbic acid: (1) 0.1 mg/ml (Low AA); (2) 0.2 mg/ml (Basal AA); and (3) 1.0 mg/ml (High AA). Following a determination of baseline performance in a radial arm maze (RAM) task and measuring locomotor activity, all rats received a single oral dose of 7.5 mg/kg TMT chloride. The rats were then allowed a 14-day recovery period. After this period, rats were retested in the RAM and activity levels were reevaluated. By the end of baseline testing in the RAM, performances of all AA groups were similar. During baseline, the mean activity score of the High AA group was significantly lower than the other groups. Following TMT dosing, fewer acute effects of TMT (e.g., aggressiveness) were observed in the Low AA group, as compared to the Basal and High AA groups. As for RAM testing following TMT, all groups were affected, with the greatest initial deficits being observed in the High AA group. Also, compared to baseline locomotor activity, the High AA group displayed a significant increase in locomotor activity. Significant group differences were not found in the histological data, but the trend was that rats maintained on "high" levels of AA exhibited more hippocampal damage than rats maintained on "low" levels of AA. This trend was consistent with the behavioral results. (Supported in part by the Res. Inst. Pharm. Sci.)

674.12

HYDERGINE TREATMENT REDUCES THE ENHANCED CHOLINESTERASE STAINING OBSERVED IN THE DENTATE GYRUS OF TRIMETHYLTIN EXPOSED RATS R.L. Cannon*, R.C. Hamdy +, and M.L. Woodruff Depts. of Anat., and Int. Med. +, J.H. Quillen Sch. of Med. East Tenn. St. Univ. Johnson City, TN 37614

Trimethyltin (TMT), is a neurotoxin that destroys cells in the hippocampus including those that receive cholinergic (ACh) input. This destruction models that found in Alzheimer's disease (AD). Increased acetylcholinesterase (AChE) staining and choline acetyltransferase (ChAT) activity in the outer molecular layer (OML) of the dentate gyrus have been reported in TMT treated rats. Hydergine (HYG) is used to attenuate some of the cognitive and behavioral deficits observed in conditions such as AD. HYG has been shown to effect the ACh system of the hippocampus. The purpose of this study was to examine the effect of HYG on (1) TMT induced hyperactivity and (2) on AChE staining in the hippocampus. Forty eight adult male Long-Evans rats were assigned to 8 groups. Six groups were orally gavaged with 6mg/kg TMT chloride, three of these received one of 3 doses of HYG, 0.2, 1.2 or 3.0 mg/kg in an ethanol vehicle by gavage daily for 28 days. One was given vehicle, one handled and one TMT group untouched. The remaining rats served as controls with half being gavaged with vehicle. The animals were then observed in an open field for ten minutes a day for 3 days. Line crossings and rearings were noted. The rats were sacrificed and their brains sectioned at 20 μm for thionin or 40 μm for AChE stain. Statistical analysis of behavior and densitometry results indicate HYG reduced open field activity, and AChE stain density. These findings suggest that Hydergine may be effective in treating damage by neurotoxins.

674.13

TRIMETHYLTIN-INDUCED c-fos EXPRESSION: ADOLESCENT vs NEONATAL RAT HIPPOCAMPUS. G.J. Harry* and N.H. Zawia, DART/STB, NIEHS, P.O. Box 1233, RTP, NC 27709.

In the adult animal, the immediate early genes (IEG) such as c-fos, c-jun, and other activity-dependent genes such as ornithine decarboxylase (ODC) are induced within minutes to hours in response to perturbations to the cellular environment. We have examined the induction of these genes following acute exposure to a known neurotoxicant, trimethyltin (TMT). TMT-induced alterations, morphological, physiological, and biochemical, in selective neuronal populations in the hippocampus have previously been observed within 16-24 hours following an acute exposure. Using Northern blot analysis, we have examined the induction of these genes within the hippocampus, frontal cortex, and the cerebellum at 0.5, 1.5, and 5 hours following acute exposure to TMT (4 mg/kg, s.c.). In the neonatal (PND 4) rat hippocampus, the basal expression of c-fos, c-jun, and ODC was high and appeared to be unaltered at all time points examined following TMT exposure. However, in the adolescent (PND 35) rat, TMT exposure produced a dramatic induction of c-fos mRNA in the hippocampus within half an hour. No changes in the expression of this gene were seen in the cerebellum and the frontal cortex at either age. Expression of actin mRNA was not altered by TMT exposure at either age. The age-dependent immediate early gene response to TMT may be due to a differential regulation of these genes, however, it may be representative of a localization to the hippocampal granule cells of the facia dentata which are relatively immature at PND 4. These results suggest that immediate early genes may be involved in the response of the brain to TMT in an age-dependent and region-specific manner.

NEURODEGENERATIVE EFFECTS OF TRIMETHYL TIN INVOLVES SEVERAL TRANSMITTERS AND NEUROTROPHINS. H. Lindström, C. Wetmore, J. Luthman*, E. Lindqvist and L. Olson. Department of Histology and Neurobiology, Karolinska Institute, 104 01 Stockholm, Sweden.

Acute exposure to trimethyl tin (TMT) in adult rats induces a behavioral syndrome which includes aggression, hyperirritability, tremor, convulsive episodes, hyperactivity and learning deficiencies. TMT (8 mg/kg i.p.) was injected in adult Sprague-Dawley male rats and previous findings of a selective hippocampal lesion were confirmed. Two weeks after TMT treatment a marked loss of CA3 pyramidal neurons was seen in hippocampus, concomitant with a pronounced gliosis as demonstrated by GFAP and vimentin immunoreactivity (IR). NGF mRNA was found to be expressed in neurons scattered throughout the pyramidal cell layer and in the hilar region of the dentate gyrus; BDNF protein IR and mRNA were abundantly expressed in pyramidal neurons as well as granule neurons of the dentate gyrus, as visualized using polyclonal antipeptide antibodies and oligonucleotide probes. Decreases in the BDNF protein IR and mRNA were seen after 4 hours and 2 weeks; NGF mRNA was decreased only following 2 weeks. A minor decrease in fibers with acetylcholinesterase IR was seen in the CA3 region. In addition, alterations in the GABAergic, tyrosine hydroxylase and serotonin IR were observed at various time points after the TMT injection (1, 2 or 12 weeks post-injection). Also, endogenous monoamine levels were affected, in particular regional 5-HT levels. Treatment with MK-801, a non-competitive NMDA receptor antagonist, tended to reduce the loss of acetylcholinesterase fibers and the gliosis. TMT has previously been shown to induce overflow of various neurotransmitters, including glutamate. It is therefore possible that at least one component of the neurodegenerative effect of TMT is similar to other neurodegenerative conditions that may involve increased extracellular glutamate levels and overstimulation of excitatory amino acid receptor. However, the present findings do not indicate that the NMDA receptor subtype is critically involved in the neurodegenerative actions of TMT.

IN VITRO NEUROTOXICOLOGY OF ORGANOTIN COMPOUNDS T.A. Thompson, S.M. Toggas, W.B. Severs* and M.L. Billingsley. Dept. of Pharmacology, Pennsylvania State University College of Medicine, Hershey, PA 17033

Organotin compounds induce neurotoxic changes; trimethyltin (TMT) causes selective patterns of neuronal destruction whereas triethyltin (TET) causes degeneration of myelin. In order to characterize mechanisms of TMT and TET toxicity, human SMS-KCNR neuroblastoma, HTB-14 glioma and mouse 3T3 fibroblast cell lines were exposed to graded concentrations of TET (0-200 μM), TMT (0-200 μM) and SnCl2 for 48 hrs. Cell viability was determined using the fluorescent dyes calcein-AM and ethidium homodimer. TMT caused a dose-related loss of cell viability in SMS-KCNR cells (LD50= 25 μM); HTB-14 and 3T3 cells were resistant to TMT. In contrast, TET was toxic to SMS-KCNR (LD50= 7 μM) and HTB-14 cells (LD50= 10 μM). All cells tested were resistant to SnCl2. Previous experiments coupling subtractive hybridization and molecular cloning demonstrate that a novel 88 residue protein, termed stannin, is expressed in TMT-sensitive cells. Immunoblot analysis indicated that SMS-KCNR cells and hippocampus expressed stannin, while HTB-14 cells gave a background signal, suggesting that stannin expression correlates with TMT sensitivity. Transfection experiments which cause stable heterologous expression of stannin in resistant cell lines are currently in progress.

MERCURY TOXICITY: BAND 3 PROTEIN MEDIATED TRANSPORT. K. Kiningham, E.J. Kasarskis*. Grad Ctr for Toxicology and Dept Neurology, VAMC and Univ. Kentucky, Lexington, KY 40536.

Inorganic mercury (Hg^{+2}) is a recognized cytotoxicant, however, the mechanism by which Hg^{+2} enters the cell has not been defined. Recently it has been reported that cations such as zinc, cadmium, and lithium are transported across cell membranes via the band 3 anion channel protein. Band 3 is a ubiquitous protein that mediates the exchange of anions, maintains acid-base balance, and provides a cytosolic binding site for glycolytic enzymes. By using erythrocytes as a model, we have shown that DIDS, a specific band 3 inhibitor, blocks Hg^{+2} uptake.

Erythrocytes were incubated at 37°C for 10 minutes in a solution containing 10 mM HEPES buffer, pH 7.4, ^{203}Hg, increasing concentrations of $HgCl_2$ (.01 μM to 100 μM) and a range of inhibitor concentrations (10 μM to 200 μM). Hg^{+2} uptake was inhibited in a dose-dependent manner with increasing concentrations of DIDS. At a concentration of 10 μM $HgCl_2$ and 200 μM DIDS, the percentage of ^{203}Hg associated with the cells was decreased by more than 50%. The results indicate that the band 3 protein is a transporter of Hg^{+2}, perhaps in the form of an anionic species such as $HgCl_4^{-2}$. The presence of band 3-like proteins in brain might represent the site through which essential and toxic elements enter cells in the central nervous system.

674.17

EFFECTS OF METHYLMERCURY ON RESPIRATORY ACTIVITY OF IMMATURE CEREBRAL CORTICAL NEURONS, CEREBELLAR GRANULE CELLS, PURKINJE CELLS, OLIGODENDROCYTES AND ASTROCYTES OF PRENATAL AND NEONATAL RAT IN-VITRO. S. Yee and B. H. Choi*. Div. of Neuropathology, Univ. of California, Irvine, Irvine, CA 92717

The sensitivity of the CNS to toxic effects of methylmercury (MeHg) has been well documented. However, the molecular events underlying cellular damage in various CNS cell types following MeHg poisoning remain unclear. To study the effects of MeHg on the respiratory activity of different CNS cell types, homogeneous cultures of astrocytes, oligodendrocytes, immature cerebral cortical neurons, cerebellar granule cells and Purkinje cells established from prenatal and neonatal rats were used to examine the oxygen uptake following exposures to various concentrations of MeHg (1-10 μM) in basic salt solution (MEM) using polarographic technique. Under control conditions, the respiratory rate of oligodendrocytes was relatively higher (6.70% O_2/sec/μg protein x 10^{-5}) than other cell types (5.45% O_2/sec/μg protein x 10^{-5}). MeHg caused significant reduction in the respiratory rate at all concentrations in all cell types within short periods of time. However, the most profound effect in the reduction of respiratory rate and of the time to reach cessation of the oxygen uptake was noted in oligodendrocytes, followed by cerebellar granule cells, immature cortical neurons, astrocytes and Purkinje cells, in successive order. Exposures to various concentrations of metal ions including tin and iron showed no significant effect in the respiratory rate. These results indicate that MeHg affects respiratory activity of the CNS cells in a specific but differential manner, and provide a significant insight into the molecular mechanism of MeHg neurotoxicity. METHYLMERCURY-INDUCED DISRUPTION OF RAT HIPPOCAMPAL SYNAPTIC TRANSMISSION AND LONG-TERM POTENTIATION. **Y.Yuan and W.D. Atchison*.Dept. of Pharmacol./Toxicol. and Neurosci. Prgm. Michigan State University, E. Lansing, MI 48824.**

Using extracellular microelectrode recording techniques, population spikes (PS) and long-term potentiation (LTP) were recorded to examine the effects of the neurotoxicant methylmercury (MeHg) on synaptic transmission in isolated hippocampal slices. PSs were induced in the CA1 region by stimulating (0.25 Hz) schaffer collaterals and LTP was induced by applying a brief high-frequency stimulation (HFS, 15 trains of 4 stimuli at 100 Hz in 100ms intervals). MeHg was applied to slices acutely by perfusion with artificial cerebrospinal fluid (ACSF). At 20-500 μM, MeHg first increased PS amplitude by 20-50 % and then decreased and blocked the PS completely. Time to increase and time to block PS were both concentration-dependent. In the absence of MeHg, application of HFS increased PS amplitude by 50-100 %, an effect which lasted for at least 2 hours. With simultaneous application of 20-100 μM MeHg and HFS, the PS amplitude was increased further by 20-50 % based on the already elevated PS amplitude by HFS. Subsequently, the PS amplitude was reduced and finally blocked in a similar way to that produced by MeHg on PSs recorded without HFS. If MeHg (100μM) was applied for 20 min before HFS, PS amplitude was decreased below the control level. However, LTP was still induced by HFS, suggesting that MeHg may not affect induction of LTP even though it did suppress the maintenance of LTP. Reversibility of effects of MeHg on PS and LTP were examined by washing slices with MeHg-free ACSF for 60-90 min. No recovery or only partial recoveries were observed. Thus, bath application of MeHg caused a biphasic irreversible effect on central synaptic transmission, as well as long-lasting increased central synaptic transmission. **Supported by NIH grant ES03299 and RCDA ES00178 to WDA.**

CUMULATIVE DOSE RESPONSE FUNCTIONS FOR LEAD ACETATE, TRIETHYLLEAD, AND METHYLMERCURY IN THE RAT HIPPOCAMPAL SLICE. S.B. Fountain* and J.D. Rowan. Dept. of Psychology, Kent State Univ., Kent, OH 44242.

The present study assessed the effects of lead acetate (PbAc), triethyllead (TEL) chloride, and methylmercury (MeHg) chloride on rat hippocampal slice excitability using a cumulative dose response function (cDRF) procedure. Slices were prepared using standard techniques and maintained at the interface of a pool of artificial CSF and an O_2/CO_2 atmosphere. Stimulating and recording electrodes were positioned in the Schaffer collaterals and CA1 cell body layer, respectively. When a stable waveform was recorded, an input/output (I/O) profile was obtained as a baseline measure by administering a series of increasing stimulus intensities. Exposure was accomplished by switching from normal to agent-bearing medium reservoirs supplying the slice chamber. Tests of excitatory and inhibitory systems in area CA1 of the hippocampal slice were conducted using a paired-pulse technique (25 msec interpulse delay) every 5 min over a period of 2 hr postexposure. During the monitoring period, the cDRF procedure monitored changes in excitatory and inhibitory systems beginning with a low dose of an agent, then successively higher doses were introduced every 30 min. Slices were exposed to 0.1, 1, 10, and 100 μM PbAc, TEL, or MeHg in successive 30-min periods. Slices were exposed to only one agent. Significant suppression of excitability was observed at the 10 μM dose of TEL and at the 100 μM dose of PbAc and MeHg. In addition, MeHg produced significantly greater suppression than PbAc at the 100 μM dose. The results favor the view that the hippocampal slice preparation may prove to be a valid method of neurotoxicity screening. EFFECTS OF ALUMINUM ON CALCIUM SEQUESTRATION MECHANISMS IN 7 DAY AND ADULT RAT BRAIN. W.R. Mundy*, P.R.S. Kodavanti, V. Dulchinos and H.A. Tilson. Neurotoxicology Division, U.S. Environmental Protection Agency, Research Triangle Park, NC 27711.

Aluminum (AL) is a neurotoxicant which acts on a number of targets in the central nervous system. Recent studies from our laboratory indicated that AL chloride interferes with Ca^{2+} homeostasis in the cerebellum. We have further examined the effect of AL on cellular Ca^{2+}-homeostasis in the developing and adult rat brain. ^{45}Ca-uptake was examined in mitochondria (M) and microsomes (ER), and Ca^{2+}-ATPase actvity examined in synaptosomes (SYN) isolated from the frontal cortex, hippocampus, and cerebellum of 7 day (developing) and 5 month (adult) male, Long-Evans rats. ^{45}Ca-uptake was greater in the hippocampus and cerebellum of adult rats compared to developing rats, but was similar in the cortex. AL (50-800 μM) inhibited ^{45}Ca-uptake in M and ER at both ages. Developing rats were more sensitive to AL inhibition of ^{45}Ca-uptake (IC_{50} 425-620 μM) compared to adult rats (IC_{50} 600-1100 μM) in M. AL inhibition of ^{45}Ca-uptake was similar for both ages in ER (IC_{50} 775-1500 μM). Ca^{2+}-ATPase activity was greater in SYN from all three brain regions in adult compared to developing rats. In contrast to ^{45}Ca-uptake, AL stimulated Ca^{2+}-ATPase activity. In the cortex and hippocampus, AL stimulated Ca^{2+}-ATPase activity to a greater extent (2-3 times) in developing rats than adult rats. However, AL-induced stimulation of Ca^{2+}-ATPase activity in the cerebellum was similar for both ages. These results suggest that some mechanisms of Ca^{2+}-homeostasis are not fully developed in the 7 day old rat, and that developing rats are differentially sensitive to the effects of AL compared to adults.

WIDESPREAD AUTOFLUORESCENT GRANULOMAS IN THE RABBIT CENTRAL NERVOUS SYSTEM (CNS) FOLLOWING INTRANASAL EXPOSURE TO A LIPOPHILIC ALUMINUM-CONTAINING COMPOUND (ALUMINUM FLAVONOL). R.N.Katz[1], P.F.Good[1], A.A.Kaputsin[2], A.Hsu[2], and D.P.Perl[1,2]* 1. Fishberg Research Center for Neurobiology, 2. Department of Pathology. Mt. Sinai Medical Center, New York, NY 10029.

We have previously shown that intranasal exposure to aluminum compounds may lead to uptake into the CNS along olfactory pathways (Perl and Good, Lancet 1:1028,1987). In those experiments it was noted that aluminum-organic compounds were more extensively distributed in the brain than $AlCl_3$. We now report that aluminum flavonol ($AlFl_3$) a lipophilic autofluorescent aluminum chelate compound, is widely distributed following intranasal exposure. A stable suspension of $Al(Fl)_3$ (75mM, 0.25 ml) was introduced directly into the nasal recess of 6 adult New Zealand albino rabbits, two animals each exposed for 2, 4 and 8 weeks. The rabbits remained asymptomatic throughout the experiment. In all animals, granulomas consisting of macrophages, lymphocytes and giant cells were encountered in pyriform cortex, basal forebrain, dorsal neocortex and hippocampus. Some animals also showed lesions in the midbrain and spinal cord. Neurofibrillary degeneration was not encountered in any of the animals although aluminum was detected in macrophages of the granulomas using laser microprobe analysis. We examined unstained tissue sections from the exposed animals using fluorescent microscopy and demonstrated prominent autofluorescence of the granulomas indicating the presence of $AlFl_3$. We conclude that aluminum compounds, particularly this unique lipophilic complex, may be rapidly taken up and transported throughout the CNS following intranasal exposure. These findings may have important implications to the potential risks posed by certain airborne neurotoxins. Supported by the American Health Assistance Foundation.

ALUMINUM-INDUCED INHIBITION OF CHOLINE UPTAKE INTO RAT BRAIN SYNAPTOSOMES. M.L. Caspers*, M.J. Fu and M.J. Dow. Dept. of Chemistry, Univ. of Detroit Mercy, Detroit, MI 48219.

Aluminum is a toxin which has been linked to several neurological disorders. The high affinity uptake of choline is the rate-limiting step in acetylcholine biosynthesis. Pretreatment of synaptosomes with $AlCl_3$ for 1 min prior to addition of [^{3}H]choline gives maximum inhibition of choline uptake. $AlCl_3$ can inhibit the high affinity uptake of choline in a dose-dependent manner, with 8.11% inhibition ($P<0.03$) noted at 1μM $AlCl_3$ and 15.69% ($P<0.02$) inhibition at 100μM $AlCl_3$. Double reciprocal plots of high affinity choline uptake versus [^{3}H]choline concentration indicate that 100μM $AlCl_3$ reduces the maximum rate of choline uptake from basal levels of 253 fmol/min/mg to 124 fmol/min/mg ($P<0.033$) whereas no change in the apparent K_M of the choline transporter is noted. Sodium citrate in ten-fold molar excess of $AlCl_3$ is unable to reverse this inhibition. Our data suggest that low concentrations of $AlCl_3$ can interfere with high affinity choline uptake and thus acetylcholine biosynthesis. (Supported by Alzheimer's Disease Research of the Amer. Health Assist. Found. and a gift from J. Rose.)

EXCESSIVE *IN VIVO* PHOSPHORYLATION OF NEUROFILAMENT SUBUNIT PROTEINS IN ALUMINUM NEUROTOXICITY. M.J. Strong*, D.M. Jakowec. Dept. Clin. Neurol. Sci., University of Western Ontario, Canada, N6A 5A5.

Aluminum-inoculated New Zealand white rabbits develop intraneuronal inclusions of phosphorylated neurofilament proteins (NF). To determine if these are aggregates of excessively phosphorylated NF, littermates of New Zealand white rabbits, age 5-6 weeks, were inoculated with either 1000, 750, 500, 250 or 100 μg $AlCl_3$ in 0.9% NaCl or 0.9% NaCl alone, killed 48 hours later and the NF-enriched fraction (Triton X-100 insoluble) from spinal cord isolated . Adjacent sections were formalin-fixed, serially sectioned and either silver stained or immunostained (SMI 31; 1,10,000). Time course dephosphorylation studies with alkaline phosphatase (E. Coli.; enzyme: substrate 1:50) and two dimensional electrophoresis were performed.

Inclusions did not occur with inoculums of 100 or 250 μg $AlCl_3$, but thereafter developed in a dosage-dependant manner. Immunoreactivity on Western blots to phosphorylated NF-H epitopes was abolished by 20 minutes incubation of purified NF with alkaline phosphatase in the control, 100 μg and 250 μg inoculums and by 30 minutes for 500 μg, but remained present at 90 minutes for both the 750 and 1000 μg inoculums. On two dimensional electrophoresis, the NF-H isolated from rabbits with spinal pathology demonstrated a loss of immunoreactivity to the poorly phosphorylated tail region (pI 6.1, @170 kda) and the transitional band to the higher molecular weight, highly phosphorylated isoform (pI 5.8, 210 kda). These results demonstrate a dose-dependant induction of NF inclusions in spinal motor neurons in which NF-H and NF-M subunit proteins are highly phosphorylated. Whether this reflects phosphorylation of all carboxy-terminal KSVP sequences, or of phosphorylation at novel sites, and whether this process is integral to the induction of inclusions is the subject of current experiments.

KEY WORD INDEX

The *Abstracts* volume 18 Key Word Index is printed on the following pages. This subject index uses a permutation process to create an index entry for every key word in the abstract title. Key words are placed at the beginning of the center column of the index and the program numbers in the right column. Text reading left and right of the key word is retained for understanding in context. A slash (/) shows the end and the beginning of the author's title. Space limitations do not permit the full abstract title to be printed. Words with limited search value are not listed as key words. The BioSciences Information Service Subject Index is used by many scientific organizations and has become the standard in computerized scientific indexes.
