* 10,332 volunteer abstracts, 17 symposia abstracts, 17 history of neuroscience abstracts, and 39 teaching of neuroscience abstracts.
1994 Program Committee

Irwin B. Levitan, Ph.D.
Chairperson
Brandeis University

Leslie G. Ungerleider, Ph.D.
Incoming Chairperson
National Institute of Mental Health, NIH

Jocelyne Bachevalier, Ph.D.
University of Texas School of Medicine

Andrew G. Bulloch, Ph.D.
University of Calgary Health Science Center

Marc G. Caron, Ph.D.
Duke University Medical Center

Catherine E. Carr, Ph.D.
University of Maryland

Raymond J. Dingsledine, Ph.D.
Emory University School of Medicine

Stephen S. Easter, Ph.D.
University of Michigan

Judith S. Eisen, Ph.D.
University of Oregon

Michael E. Goldberg, M.D.
National Eye Institute, NIH

Mark W. Hamblin, M.D., Ph.D.
University of Washington
VA Medical Center, Seattle

David M. Katz, Ph.D.
Case Western Reserve University
School of Medicine

Darcy B. Kelley, Ph.D.
Columbia University

Jean M. Lauder, Ph.D.
University of North Carolina
School of Medicine

Amy B. MacDermott, Ph.D.
Columbia University
College of Physicians and Surgeons

Charles B. Nemeroff, M.D., Ph.D.
Emory University School of Medicine

Mary L. Oster-Granite, Ph.D.
University of California, Riverside

Marcus E. Raichle, M.D.
Washington University School of Medicine

John L.R. Rubenstein, M.D., Ph.D.
University of California, San Francisco

Clifford B. Saper, M.D., Ph.D.
Beth Israel Hospital

Gary Charles Schoenwolf, Ph.D.
University of Utah School of Medicine

S. Murray Sherman, Ph.D.
SUNY, Stony Brook

Roger P. Simon, M.D.
University of Pittsburgh School of Medicine

Barry E. Stein, Ph.D.
Bowman Gray School of Medicine
Wake Forest University

W. Thomas Thach, Jr., M.D.
Washington University School of Medicine

R. Suzanne Zukan, Ph.D.
Albert Einstein College of Medicine

Larry R. Squire, Ph.D., ex officio
VA Medical Center, San Diego

Carla J. Shatz, Ph.D., ex officio
University of California, Berkeley

Lynn T. Landmesser, Ph.D., ex officio
Case Western Reserve University
School of Medicine
# CHRONOLOGICAL LIST OF SESSIONS

(See page iv for Thematic List of Sessions.)

**Symposia—1:00 p.m.**

92. Neuroscience Implications of Inborn Errors of Metabolism  
*Chaired by: A. DIAMOND* | 210 |
93. Molecular Mechanisms Controlling K+ Channel Diversity and Distribution in the Nervous System  
*Chaired by: J.M. NERBONNE* | 210 |

**History of Neuroscience Lecture—1:00 p.m.**

94. Evolving Concepts of Function of the Neocortex  
V.B. MOUNTCASTLE | No Abstract |

**Special Lecture—4:15 p.m.**

95. The Molecular Biology and Biophysics of Prions Causing CNS Degeneration  
S. PRUSINER | No Abstract |

**Slide Sessions—1:00 p.m.**

96. Excitatory amino acids: pharmacology I | 210 |
97. Process outgrowth I | 212 |
98. Development of visual cortex I | 214 |
99. Retina and photoreceptors II | 217 |
100. Gene structure and function III | 219 |
101. Drugs of abuse: cocaine | 221 |
102. Ischemia: miscellaneous | 223 |
103. Psychotherapeutic drugs: antipsychotics and antidepressants | 225 |
104. Behavioral pharmacology I | 227 |
105. Invertebrate learning and behavior I | 229 |
106. Osmoregulation and cardiovascular regulation | 231 |
107. Oculomotor: saccades | 233 |
108. Excitatory amino acid receptors I | 235 |
109. Neurotrophic factors: receptors and cellular mechanisms V | 237 |

**Poster Sessions—1:00 p.m.**

110. Cell migration and differentiation I | 239 |
Session Number & Title | Page
--- | ---
165. Aging I | 386
166. Aging II | 389
167. Aging III | 392
168. Developmental disorders: toxins, autoimmunity, and autism | 394
169. Epilepsy: basic mechanisms I | 396
170. Epilepsy: basic mechanisms—circuitry I | 398
171. Epilepsy: basic mechanisms—circuitry II | 401
172. Epilepsy: basic mechanisms—genetic models | 404
173. Epilepsy: basic mechanisms—kainate and picrotoxin models | 407
174. Epilepsy: basic mechanisms—kindling | 409
175. Degenerative disease: Parkinson’s—neurochemistry | 411
176. Degenerative disease: other—diabetes, EAE, and viruses | 414
177. Ischemia: white matter | 417
178. Trauma: cord | 418
179. Trauma: white matter | 421
180. Trauma: miscellaneous | 422
88. History of neuroscience | 200
89. Teaching of neuroscience: laboratory courses and exercises | 203
90. Teaching of neuroscience: computer programs | 206
91. Teaching of neuroscience: curriculum development | 208

Animals in Research Panel—5:30 p.m.

Presidential Symposium—8:00 p.m.
182. The Biology of Memory: From Synapses to Systems
Genes, Synapses, and the Molecular Switch for Long-term Memory
E.R. KANDEL | No Abstract
Brain Substrates of Basic Associative Learning
R.F. THOMPSON | No Abstract
Traces of Recognition
M. MISHKIN | No Abstract
Neuromodulatory Systems and Regulation of Memory Storage
J.L. MCGAUGH | No Abstract

TUESDAY, NOVEMBER 15

Symposia—8:00 a.m.
183. New Approaches to Understanding Dendrites
Chaired by: D. JOHNSTON | 427
184. The Amygdala: From Circuits and Synapses to Emotional Memory
Chaired by: J. LEDOUX | 427

Special Lecture—11:15 a.m.
185. Membrane Receptors and Ion Channels: Electron Crystallographic Studies of Their Design and Action
N. UNWIN | No Abstract

Symposia—1:00 p.m.
598. The Cell Biology of Secretion Vesicles
   Chaired by: K.J. SKINNER ........................................... 1463
599. Neuropeptide Regulation of Brain Development: From Cells to Animals
   Chaired by: E.M. DICICCO-BLOOM and J.P. SCHWARTZ ......... 1463

Special Lecture—1:00 p.m.
600. Brain Maps for Movement
   R.H. WURTZ .................................................................... No Abstract

Special Lecture—4:15 p.m.
601. Muscimol, Memory, and Motivation in the Basal Ganglia
   O. HIKOSAKA ............................................................... No Abstract

Slide Sessions—1:00 p.m.
602. Degenerative disease: Parkinson’s .................................. 1464
603. Ligand-gated ion channels II ........................................ 1466
604. Calcium channels VI .................................................. 1468
605. Visual system development and plasticity ....................... 1470
606. Chemical senses .......................................................... 1472
607. Process outgrowth II .................................................... 1474
608. Visual cortex: striate V .............................................. 1476
609. Ischemia: protection .................................................... 1478
610. Neurotrophic factors: expression and regulation VII ....... 1480
611. Opioid receptors ......................................................... 1482
612. Degenerative disease: Alzheimer’s—beta amyloid X .......... 1484

Poster Sessions—1:00 p.m.
613. Genesis of neurons and glia III ..................................... 1486
614. Cell migration and differentiation III ............................ 1489
615. Cell migration and differentiation IV ............................... 1492
616. Glia: glial response to injury, toxins, and disease .......... 1495
617. Molecular correlates of peripheral axonal regeneration ...... 1498
618. Neuroglia and myelin IV ............................................. 1501

Phospholipase A₂ (PLA₂), the enzymes which catalyze the hydrolysis of the sn-2 fatty acid residue esterified to a variety of phospholipid species, were studied in preparations of autopsied human cerebral cortex. A greater amount of PLA₂ activity was found in the membrane (particulate) fractions when compared with the cytosolic fraction. The particulate and cytosolic enzymes possessed similar characteristics, including having a pH optimum of 8.5, and being maximally active in the presence of millimolar concentrations of calcium ions. The particulate enzyme could be solubilized by IM potassium chloride, and was capable of hydrolyzing phosphatidylcholine (PC), phosphatidylethanolamine (PE) and phosphatidylserine (PS), with a preference being displayed for PS and PE over PC. However the enzyme displayed only a small preference for arachidonic over linoleic acid residues at the sn-2 position of PE. When the solubilized particulate enzyme was subjected to gel filtration chromatography, PLA₂ activity eluted as a single peak of relative molecular mass greater than 67kDa. PLA₂ activity was diethiothreitol insensitive, but was inhibited by brief heat treatment, bromophenacyl bromide, AAOCl₂ (the tri-fluoroketone derivative of arachidonic acid) and γ-linoleyl amide. Thus, while the human brain enzyme displays many of the characteristics of low molecular weight platelet PLA₂, it differs in several key features, suggesting that human brain may contain a novel form(s) of PLA₂.

DOCA-INDUCED CHANGES IN SEPTO-PREOPTIC NEURON SENSITIVITY TO ANGIOTENSIN II AND LEUKOCYTE-ENRICHED COORTICOTROPIN-RELEASING HORMONE AND ACTIVATION OF THE COORTICOTROPIN-RELEASING HORMONE (CRF) RECEPTORS.

In the studied area, immunoperoxidase application of all induced activation on 17 (23.3%) and inhibition on 4 (5.5%) of the spontaneous activity of the 73 neurons tested for this peptide in the control animals. In the DOCA prereated rats, all induced activation on 31 (35.6%) and inhibition on 7 (8%) of the spontaneous activity of the 87 neurons tested. These numbers give a ratio of excitatory/Inhibitory responses to All of 81/19 for control and of 82/18 for DOCA. Immunoelectron application of Losartan by itself in this same forebrain region induced activation on 6 (13%) and inhibition on 6 (13%) of the spontaneous activity of the 46 neurons tested in the control animals. In the DOCA group, Losartan induced activation on 14 (26.9%) and inhibition on 1 (1.9%) of the spontaneous activity of the 52 neurons tested, giving an excitatory/inhibitory ratio of 50/50 for control and of 97/0 for DOCA.

These results show that All can be excitatory or inhibitory on neurons of the same region. The number of responses to All is enhanced by DOCA pretreatment but the shift is in excitatory/inhibitory ratio for Losartan, but not for All suggests that several types of receptors are involved in these DOCA-induced modifications.

(Submitted by MH 43787 & Eilas C*)

Lab of Molecular Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 0651.

Corticotropin-releasing factor (CRF) is involved in regulation of the pituitary-adrenal axis as well as the HNS response to stress. The CRF receptor is positively coupled to adenylyl cyclase, however the mechanisms which control CRF receptor expression are poorly understood. In this study we used an immunolocalized locus coeruleus-like (LC-like) cell line, previously shown to contain CRF receptors, as a model system to study regulation of CRF receptor coupling to adenylyl cyclase, ligand binding, and mRNA levels.

CRF treatment resulted in a rapid, time-dependent down-regulation of CRF-stimulated adenylyl cyclase and CRF receptor ligand binding, which was maximal after 20 min, and was observed for up to 2-4 hrs. However, after 20 hrs of CRF treatment there was a further decrease of approximately 20-30 %. Incubation of LC cells also decreased levels of CRF receptor mRNA but with a different time-course: agonist incubation decreased levels of receptor mRNA by 30 % after 4 hrs and by 60 % after 24 hrs. The results suggest that agonist regulation of receptor expression is mediated by several processes. The rapid, probably mediated by receptor sequestration and internalisation as described for adrenergic receptors, and decreased levels of receptor mRNA probably contributes to the more long-term decrease observed after 24 hrs of treatment.

ADRENERGIC MODULATION OF UP- AND DOWN-REGULATION I

ADRENERGIC REGULATION OF β-ADRENERGIC RECEPTOR AND IBERINA IN GLIOBLASTOMA CELLS. J. Rydel, E. Fitzpatrick and R.S. Duman.
Department of Molecular and Developmental Biology, University of California, Los Angeles, CA 90095.

We have shown previously that exposure of C6 glioma cells to isoproterenol decreases the transcription rate of the B₁ and B₂ adrenergic receptor. This decrease in transcription is sensitive to inhibition of protein synthesis suggesting that isoproterenol induces a transcriptional repressor. A potential mediator of the repression is ICER, a member of the CREM (CRE modulator) family of transcription factors, which is induced by activation of the cAMP system, can bind to the CRE (cAMP responsive element), and antagonizes the stimulatory effects of CREB (CRE binding protein) (Stehle et al., Nature '93). Since CRE is present in both B₁R and B₂R promoters, the effects of isoproterenol on ICER regulation in C6 glioma cells were investigated. RNase protection assays reveal that exposure of C6 glioma cells to isoproterenol or forskolin for 1 hour induces levels of ICER, as well as CREM, mRNA approximately 10-fold. ICER and CREM mRNA levels return to control levels following 24 hours of exposure to agonist. The induction of ICER RNA levels by isoproterenol is not blocked by inhibition of protein synthesis. Moreover, ICER mRNA levels are more highly induced in the presence of protein synthesis inhibitors, consistent with reports that ICER can inhibit its own production. Electrophoretic mobility shift assays show that isoproterenol and forskolin induce at least two CRE binding complexes, both of which migrate faster than the CREB containing complex. Supershift assays with a CREB antibody demonstrate that these complexes do not contain CREB and thus may contain ICER. Additional studies will be performed to further characterize the regulation of ICER and to investigate its potential role in the repression of B₁R and B₂R gene transcription.

CHRONIC MORPHINE TREATMENT DECREASES MELANOENIN-INDUCED 4-RECEPTOR mRNA EXPRESSION IN RAT FRONTAL CORTEX. J.D. Albarracín*, E.J. Neistler and R.S. Duman.
Neuroscience Program, Laboratory of Molecular Psychiatry, Department of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06509.

Previously we described the cloning and characterization of a rat melatonin opioid receptor (MC₄-R) (M. Neurosci. 634.9). This receptor is 996b in length and is 95% identical to the amino acid sequence of the published human MC₄-R. In order to study the regulation of MC₄-R by psychotropic drugs, we have investigated the possible effects of morphine addiction on melatonin receptors. Rats were administered 75mg morphine pellets (s.c.) once daily for 5 days, and on the sixth day several brain regions from morphine- and sham-treated animals were dissected. Using an MC₄-R specific riboprobe in a RNase protection assay, we found that MC₄-R mRNA levels in the frontal cortex were consistently down-regulated in morphine-treated animals. To determine whether this effect was specific to MC₄-R, the RNase protection assay was repeated using a riboprobe for MOR-C₃. Down-regulation in the frontal cortex was not observed with a tendency for up-regulation was noted. The effect of morphine treatment on melatonin receptor mRNA will be examined in the other dissected brain regions by the RNase protection assay, and in situ hybridization will be used to localize more discrete regions of receptor regulation. Regulation of MC₄-R expression could contribute to the neurochemical adaptations underlying the long-term actions of opiates in the brain.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
384.5 EFFECT OF SEROTONERGIC DRUGS ON THE UP-REGULATION OF DOPAMINE D2 RECEPTOR EXPRESSION IN HYPOTHALAMUS.

Dept. of Psychiatry, Hokkaido Univ. Med. School, Sapporo 060, Japan.

We examined the modifying effect of serotonin(5-HT) on haloperidol-induced up-regulation of dopamine(D2) receptor in order to elucidate the pharmacological characteristics of antipsychotic drugs on dopaminergic neurons in the hypothalamus of rats with haloperidol administration. Haloperidol (HPD, 0.1-0.5mg/kg, i.p., 3weeks) increased the number of D2 receptors in the striatum, while no increase was observed by that with clozapine (1mg/kg) and OROS-222 (0.25mg/kg), typical antipsychotic drug and its candidate which have high affinity at S-HT2 receptor sites with lower affinity at D2 sites. Chronic treatment with MK212, a nonselective 5-HT agonist and with clonidine, a 5-HT receptor inhibitor (10mg/kg), both of which had no effect on the number of D2 receptor sites by themselves, potentiated the up-regulation of D2 receptor sites when coadministered with HPD (0.5mg/kg). Coadministration of ritanserin(RIT), a 5-HT2/5-HT1c antagonist (1mg/kg), with HPD (0.5mg/kg), had no influence on the HPD-induced increase of D2 receptor sites, but that with smaller dose of HPD(0.1mg/kg) attenuated the D2 up-regulation. These results suggest that serotonergic activity may have a complex modulatory influence on the up-regulation of D2 receptor sites induced by HPD. We are now examining the effect of 8-OD-PAT, a selective 5-HT1A agonist (0.1mg/kg), on the HPD-induced D2 up-regulation.

384.6 EFFECT OF PRENATAL DIAZEPAM TREATMENT ON THE DEVELOPMENT OF DOPAMINE D2 RECEPTORS IN RAT BRAIN.

F. Park, J. L. Long, B. Duration, and L. Svendsen
Douglas Hospital Research Center, Departments of Psychiatry and Neurology, McGill University, Montreal, Que (Canada), H3H 1R3.

Studies on the postnatal development of dopamine receptors have shown a maturation of the receptors between the second and the third postnatal weeks. It has been suggested that the presence or absence of dopamine during prenatal or early postnatal periods may affect subsequent development of dopamine D-1 and D-2 receptors. In the present study we investigated the effects of a dopamine D-2 agonist (quipazine) and of an antagonist (raclopride) on the density and mRNA levels of dopamine D-2 receptors. Quipazine (1mg/kg, s.c.) and raclopride (0.5mg/kg, s.c.) were administered daily from gestation day 10-11 till birth of the pups. Pups were sacrificed at different postnatal ages and their brains were removed and sectioned for anatomical studies. [3H]Sparadone and [3H]raclopride, used in receptor binding studies and in situs hybridisation, respectively. In accordance with previous results, the maximum density of the D-2 receptor and mRNA levels were significantly elevated at postnatal day 28 in rats prenatally treated with quipazine. No significant changes in D-2 mRNA levels were evident in the raclopride treated rats of the same age group. These results suggest that prenatal stimulation of dopamine D-2 (and/or D-3 and D-4 that have high affinity for quipazine) receptors has long-term consequences for postnatal dopamine receptor development. (Supported by the Medical Research Council of Canada.)

384.7 ASTROGLIAL OXYTOCIN RECEPTOR DOWN-REGULATION: MODULATION BY PROTEIN(S) KINASE(S) C. D. Di Scala-Gioeob, Ch. Kelche* and M. Th. Strosser, Institut de Physiologie, URA 1466, 21 rue René-Descartes, 67000 Strasbourg, France.

Specific oxytocin (OT) receptors have been previously characterized on hypothalamic cultured astrocytes and intracellular Ca+2 oscillations by Ca+2 imaging. OT-agonist has been demonstrated. The involvement of phospho-inositol hydrolysis which generates IP3 and diacylglycerol in the activation of protein kinases C (PKC), could be hypothesized. As stimulation of PKC appears to be an important event in transduction mechanisms and receptor downregulation, the role of PKC in olfactory hypothalamic cultured astrocytes. Binding studies were performed on cells pretreated with a phorbol ester (phorbol-12,13-acetate, 500nM) for 24 hours. OT receptor binding (10-7M) alone was without effect on ligand binding whereas simultaneous addition of OT and PMA significantly decreased the binding and this effect was reversed by staurosporin. PMA long-term treatment is thought to desensitize PKC receptors in our system. 18 hours treatment with PMA or OT alone decreased ligand binding and simultaneous application of the drugs potentiated this effect which could not be reversed by staurosporin. In conclusion, the first step in agonist- and phorbol ester-mediated ligand binding inhibition, depends on PRC activation whereas down-regulation induced by long-term treatment is independent from PKC.

384.8 OXYTOCIN BINDING IN HIPPOCAMPUS, VMH AND AMYGDALA: EFFECTS OF STRESS AND GLUCOCORTICOIDS. L. Liperario*, E. A. Young, M. Hsiri, University of Michigan, Ann Arbor, MI, 48104

Neuroanatomical studies reveal that central oxytocin receptors are concentrated in major regions of the limbic system: hippocampus, olfactory nucleus, amygdala, BNST and hypothalamus. We had previously shown that oxytocin receptor binding in hippocampus is regulated by the level of circulating glucocorticoid hormones, using adrenalectomy and corticosterone replacement model. In the current study we examined the effects of non-habituating stress and high dose corticosterone implants on oxytocin binding in non-adrenalectomized animals. Seventeen Sprague-Dawley male rats (250 g) were divided into 3 groups: Controls, Stress and Corticosterone (DO-2) implants (6 males and 5 animals respectively). Animals were sacrificed 1 week after the implantation of two 100mg 100% corticosterone pellets, or 24 hr. after the seventh day of exposure to non-habituating stress (swim; cold room; restrain and ether anesthesia - two stressors/day). Oxytocin receptor binding autoradiography results suggest that non-habituating stress significantly increased oxytocin receptor binding in Amygdala (p<0.05) with trend to increase receptor binding in other areas examined (VMH, Dorsal hippocampus and Ventral hippocampus). High dose corticosterone implants increased oxytocin receptor binding in Dorsal hippocampus and showed trend in Ventral hippocampus. The results of this study further support our early findings regarding the effects of glucocorticoids on oxytocin binding. They provide first preliminary evidence for the effects of non-habituating stress on central oxytocin binding and suggest that glucocorticoids play a role in modulating this effect in hippocampus.

384.9 OLIGO/OXYNUCLEOTIDES TO THE CLONED DELTA OPIATE RECEPTOR, DOR-1:UPTAKE, STABILITY AND REGULATION OF RECEPTOR GENE EXPRESSION. K. M. Standifer*, C-C. Chien, E. J. Pan, and G-W. Fasolka, The Center for Neuro-Oncology, Department of Neurology, Memorial Sloan-Kettering Cancer Center, and 2Dept. Pharmacology, Cornell University Medical College New York, NY 10021 and 3National Taiwan University Hospital, Taipei, Taiwan.

Previously, we reported that phosphodiester antisense oligodeoxynucleotides (ODNs) directed towards various domains of the coding region of the cloned mouse delta receptor, DOR-1, reduced delta receptor binding in vivo and in vitro. Additionally, an antisense directed toward the amino terminus of DOR-1 (Antisense A) blocked DPDPE and deltorphin II-mediated spinal analgesia with no effect on mu- or kappa-mediated spinal analgesia. Subsequently, Porreca demonstrated that the same antisense also blocked supraspinal deltorphin II-mediated analgesia but not that of DPDPE. In this study we examined the ability of Antisense A to enter NG108-15 neuroblastoma cells and mouse spinal cord, and its stability therein. Radiolabeled Antisense A (250 nM) was taken up into cells in a time-dependent fashion, reaching a plateau after 4 hours that extended to several days. Solution hybridization assays using a riboprobe transcribed from the coding sequence of DOR-1 were used to measure levels of spinal cord mRNA after antisense A treatment. The decrease in spinal cord mRNA levels were consistent with loss of binding levels.

384.10 DIFFERENTIAL EFFECT OF LONG-TERM ANTIDEPRESSANT TREATMENT ON 5-HT4 RECEPTOR MEDIATED HYPERTHERMIA IN FAWN-HOODED RATS. Charanjit S. Aulakh, Pascale Mazzola-Pomietto, Anne M. Andrews*, and Dennis L. Murphy, Lab. of Clinical Pharmacology, National Institute of Mental Health, Bethesda, MD 20892.

We have recently demonstrated that hyperthermia induced by 1,2,5-dimethoxy-4-isophenyl-2-amino propanol (DOI) and 5-chlorophenylpiperazine (m-CPP) is mediated by selective stimulation of 5-HT4 and 5-HT2 receptors, respectively (Aulakh et al., 1993). Furthermore, hyperthermia induced by either DOI (Aulakh et al., in press) or m-CPP (Mazzola-Pomietto et al., 1993) was found to be significantly less in the Fawn-Hooded (FH) rat strain that has suggested to represent a genetic model of depression) relative to Wistar rats. In the present study, we studied the effects of long-term antidepressant treatment on DOI (2.5 mg/kg) and m-CPP (2.5 mg/kg)-induced hyperthermia in male FH rats. Long-term (21 days) treatment with the triyclic antidepressants, imipramine or clomipramine (each 5 mg/kg, s.c.) did not attenuate DOI-induced hyperthermia, while m-CPP-induced hyperthermia was accentuated. On the other hand, long-term (21 days) treatment with the monoamine oxidase-A inhibiting antidepressant, zimeldine (26 mg/kg) did not modify m-CPP-induced hyperthermia, but significantly attenuated DOI-induced hyperthermia. These findings demonstrate a differential effect of long-term antidepressant treatment on 5-HT4 receptor-mediated hyperthermia in a genetic animal model of depression.
384.11

During the last decade, several non-benzodiazepine drugs that for the 5-HT1A receptor subtype, including buspirone and gepirone, have been shown to be effective in the treatment of anxiety. Lepotrin is a new piperidino-piperazine that reduces behavioral responses to averse situations in animal models of anxiety and that shows high selectivity and specificity for the 5-HT1A receptor. On the other hand, different lines of pharmacological evidence have led to the hypothesis that the locus coeruleus (LC), the largest noradrenergic nucleus of the rat brain, is a mediator of anxiety and its behavioral manifestations. Moreover, in vivo experiments have shown that serotonin can attenuate LC activity, and serotonin-containing terminals have been described in this brain area. The current study examined the possibility that chronic lepotrin might alter levels of tyrosine hydroxylase (TH) in the LC. Rats were administered lepotrin for 14 days (15 mg/kg), and on day 15 levels of TH immunoreactivity were quantified by immunoblotting. Chronic lepotrin treatment decreased levels of TH immunoreactivity in the LC by 40%. Our results suggest a relation-ship between lepotrin and the noradrenergic system that could be linked to its mechanism of action.

MODULATION OF GLUCOSE RESISTANCE MEDIANATED CHLORIDE RESPONSES BY PROTEIN KINASE C. Y. Gu* and L. M. Huganir* Marine Biomedical Institute* and Department of Physiology and Biophysics†,† University of Texas Medical Branch, Galveston, Texas 77555-0483.

Glucose is known to inhibit the sugar-synaptic transmission in the spinal and medullary dorsal horns. We have shown previously that protein kinase A potentiates glucose-activated Cl- conductance by increasing the probability of opening of GluCl channels (Gu et al. 1994). To determine whether the second messenger also modulate the glucose responses, we studied the effects of protein kinase C (PKC) on the glucose-activated Cl- conductance in isolated trigeminal neurons. The currents were recorded using the whole cell patch-clamp recording technique and were calibrated with the recorded cells with a fast perfusion method. The protein kinase C and protein kinase inhibitor (PKI) were applied intracellularly through a plastic tube inserted into the patch pipette. PKC was added to the glucose-induced Cl- currents up to 2.5 fold. This enhancing effect of PKC was blocked when PKC (19-31), a phospho-analogue competing for the substrate recognition site of PKC, was introduced into the cells. PKC did not change the affinity of glucose to its receptor. The apparent dissociation constant values were 0.4-6mM and 25.8mM in PKC.

To determine the mechanism of PKC action on glucose-activated Cl- channels, we examined the current-voltage relations of the currents in control and in PKC. PKC changed neither the kinetics nor the voltage dependence of the Glucose responses. The reversal potentials of the glucose-activated Cl- currents remained unchanged after PKC treatment. The effects of PKC on the channel conductance and on the probability of channel openings are currently under investigation. (The work is supported by NIH grants NS03045, NS23061 and NS1255).

384.15

During embryonic development in vivo ACh sensitivity of chick sympathetic neurons increases. Concomitant with these changes we find an elevated expression of α2, α5, α6 (Deva et al '94). Since both pre- and postsynaptic contacts are established during this time, it is difficult to dissociate which of these interactions regulates nAChR expression.

To separate the role of pre- from postsynaptic influences on nAChRs we examined sympathetic neurons in vitro alone or in the presence of either the pre- or the postsynaptic partners. The level of nAChR subunit expression was measured in individual cells with single channel recordings. Single channel recordings of innervated neurons and neurons contacting target were performed as well, for comparison of changes in nAChR expression vs. nAChR-channel properties. We then systematically evaluated the subunit expression levels, we developed a PCR essay. In contrast to the upregulation of α3, α5 and α7 with both input and target contact, target contact alone decreases the expression of α3 while increasing that of α7. Also we have seen that changes in nAChR subunit gene expression with target contact, all of the nAChR-channels expressed by neurons prior to innervation or target contact are suppressed and a single class of large conductance (~60-70pS) is expressed. Since innervation by preganglionic neurones upregulates the expression of α3 subunits and the number of channels expressed by sympathetic neurons, these experiments suggest that input and target contact collaborate in the regulation of the number and properties of nAChRs.

384.12

Previously, we reported that chronic cocaine administration induced changes in brain benzodiazepine (BZD) receptor binding in brain areas associated with the mesocorticolimbic system and possibly involved in the development of behavioral sensitization. Adult male Sprague Dawley rats were injected once daily with cocaine (14 mg/kg, IP) or saline for 2, 4, or 8 weeks, and sacrificed for 24 hr, 14 days, or 28 days post-treatment to determine the effects of withdrawal from BZD receptor binding. BZD receptors were visualized autoradiographically using [3H]Ro 15-1788. Cocaine induced minimal changes in BZD receptors 24 hrs post-cocaine, yet these rats exhibited significant increases in stereotypy after 2 weeks of cocaine, suggesting that cocaine-induced alterations in BZD receptors were not essential for the development of behavioral sensitization. BZD receptors were increased in the rostral nucleus accumbens, and in cortical areas 14 days post-cocaine, but returned to control values 28 days post-cocaine. Cocaine-induced increases in BZD receptors in these rats were related to the dose of drug, the length of exposure, and the time point of drug withdrawal. In addition, the effects of cocaine on BZD receptors may differ between Mista and Sprague Dawley strains of rats. [Supported by NIH grant DA04293]

384.14

[3H]DTG (1,3-di-o-toylguanidine) binding to the homologous rate of rat cerebral cortex was competitively inhibited by a variety of neurotoxic drugs such as pentazocine, haloperidol, clomipramine and imipramine, which increased the Ki value with no changes in the Bmax value of the [3H]DTG defined sigma binding site as well. In contrast, a classical anti-depressant desipramine reduced the Bmax of the [3H]DTG binding in a concentration-dependent fashion without effects on its Ki. This non-competitive inhibition is unlikely to be related to the blocking action of desipramine at the N- methyl-D-aspartate receptor because selective competitive (CGS9775) and non-competitive (MK-801) antagonists of the excitatory amino acid receptor failed to mimic the effects of desipramine. Furthermore, potent antagonists of the beta-adrenergic receptor, (-)-propranolol and (-)-alpenor- nalol also caused a non-competitive inhibition of the [3H] DG binding. Together with the potent blocking action of desipramine at norpinephrine uptake, the present results suggest that noradrenergic systems might allosterically interact with the sigma-like site or that the sigma macromolecule could have certain allosteric regulation sites which would be affected by desipramine, propranolol and alpenoronal.

384.16

The hippocampus has high levels of both NMDA and non-NMDA receptors. Previous studies have shown the CA1 region of the hippocampus to be particularly sensitive to ischemia-induced neuronal damage. Based on the observation that high-density DHTP phosphate (DHTP) replacement on [125I]MK801 binding in the dorsal hippocampus. Adult Sprague-Dawley male rats were castrated and implanted subcutaneously with either a 25 cmSilastic capsule that contained DHTP (n=3) or an empty capsule (n=3). Control rats (n=8) were left intact. Animals were sacrificed 21 days after castration. In control rats [125I]MK801 binding was highest in stratum oriens and radiatum of CA1 as well as in the molecular layer of the dentate gyrus. In castrated rats [125I]MK801 binding was significantly increased in the pyramidal cell layer, stratum oriens and radiatum of CA1 compared to intact controls. This increase in [125I]MK801 binding was prevented by treatment of castrated rats with DHTP. [125I]MK801 binding in the hippocampus of castrated-DHTP treated rats did not differ significantly from intact rats in any region of the hippocampus. These data suggest that androgen receptor stimulation may influence excitatory amino acid neurotransmission within the hippocampus. (NSF BNS-910206, NIH DA06687, DE06682, DC01086, AA8086)
MODULATION OF NMDA CURRENT BY FATTY ACIDS IN MOUSE CORTICAL NEURONS. S.P. Yip*, L.L. Dungan and D.W. Choel, Dept. of Neurology and Center for Neuroscience and Zyklus System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

We previously showed that fatty acid-induced changes in neuronal membrane fluidity were modulated with alterations in NMDA currents (C∗) accumulation and death (Dungan et al., Soc. Neurosci. Abst. 18:756, 1992). Modulation of NMDA current (I_{NMDA}) by fatty acids was studied in cultured mouse cortical neurons using whole-cell voltage-clamp at -70 mV. Each fatty acid was applied at 50 μM together with 50 μM bovine serum albumin. I_{NMDA} in untreated cells was 1.9 ± 0.11 nA (SEM, n=20), and showed no obvious run-down (ATP was included in the recording pipette). (18:1, Δ9) block (50 μM) reversed NMDA membrane fluidity (50 μM), mixed excitatory amino acids (100 μM), cyclooxygenase inhibitor ibuprofen (50 μM), mixed excitatory ion (20 μM), or the kinase inhibitor, staurosporine (1 μM) failed to prevent arachidonic acid-induced potentiation. 

Dicycliydro (50 μM), which decreases membrane fluidity blocked 15% of I_{NMDA}. We are attracted to the idea that degree of unsaturation or impact on membrane fluidity may be important determinants of the effect of fatty acids on NMDA current. Fatty acid-induced modulation of NMDA receptor current may influence the state of this receptor in physiological or disease states. Supported by NIH grants NS 30373 (DWC) and AG05959-01A1 (LD).

844.19

The insulin-like growth factors (IGF-I and IGF-II) and insulin are localized in distinct brain regions and their receptor functions are mediated by specific receptors. High concentrations of binding sites for these growth factors are discretely distributed throughout the brain, including the hippocampal formation. Functionally, IGFs and insulin in addition to their growth and trophic effects, are considered to play important roles in normal cell functions as well as in response to pharmacological or surgical manipulations. Previously, we have shown that systemic injection of insulin-like growth factors (IGF) to adult rats altered IGF binding sites in discrete layers of the hippocampal formation (Shrivastava et al., Soc. Neurosci. Abst., 1991). Since IGFs and insulin play important regulatory roles during critical periods of rat life, the present study was designed to evaluate the response of IGF and insulin binding sites at different ages following systemic injection of IGF-II to newborn rats. KA was injected to post-natal day 1 pups (5mg/kg, i.p.) and 1.25-IGF, II, 1-IGF-II and 1-IGF-II binding sites were studied at different time periods (7, 14, 21, 28 and 35 days) using quantitative autoradiography. In the neonatal hippocampus, 1-IGF-I binding sites are concentrated primarily in the dentate gyrus (DG) and the CA2-CA3 sub-fields whereas 1-IGF-II binding sites are discretely localized to the pyramidal layer and the granular layer of the DG. insulin binding sites are mostly present in the molecular layer of the DG and the CA1 sub-field. Following KA injection, the level of IGF-I binding sites was increased on days 14 and 21 before returning to normal values at later times. In contrast, IGF-II and insulin binding sites decreased from day 7 to 14 in post-natally treated rats. Taken together, these results provide further evidence for the distinct existence of IGF-I, IGF-II and insulin binding sites in the rat hippocampal formation. The transient increase in IGF-I binding sites at days 14 and 21 may relate to cell proliferation caused by the KA treatment. (Supported by MRCC and The Alzheimer Society of Canada).

**DOPAMINE (DA) RECEPTOR-C-FOS COUPLING IN THE DA DEAFFERENTED AMYGDALOID COMPLEX**

J. Brok, R. Gross and C. Kibbs

Emory University School of Medicine, Atlanta, GA 30322.

The autoradiographic localization of DA receptors in the rat amygdaloid complex indicated a topographic, nonoverlapping distribution of the D1 and D2 receptor subtypes in its component nuclei and subnuclei zones (Byrne 1986, 1992). The functional compartmentation of amygdaloid DA receptors and their comparison to striatal DA receptors was further assessed by the effect of a unilateral 6-OHDA lesion of the MFB on the expression of fos-D1 in central (Ce) and basolateral (BL) amygdaloid nuclei to D1 or D2, D1 or D2 receptor activation. The D1 agonist SKF 38393 (3 mg/kg sc) produced a marked increase in fos-LI in the medial and dorsolateral caudate nucleus; the effect of SKF 38393 was enhanced greatly by the coadministration of quipiprole (0.3 mg/kg sc). Quipiprole did not induce fos-LI when administered alone. Though quantitatively smaller, similar effects of D1, D2 and D3 receptor activation were observed in the core and shell of the nucleus accumbens and olfactory tubercle ipsilateral to the side of the MFB lesion. A strikingly different pattern of effects of activation of DA receptor subtypes was observed in the DA deafferented amygdaloid complex. Specifically, the administration of apomorphine (0.3 mg/kg), SKF 38393, or the combination of quipiprole and SKF 38393 increased fos-LI in BL, though no differences in drug effects were noted between the ipsilateral and contralateral (intact) BL. These preliminary results suggest that D1 receptors in BL induce fos expression by an intracellular pathway that is not upregulated in response to deafferentation. The apparent lack of effect of D2 receptor activation on the D1 response is consistent with the negligible localization of D2 receptors in BL. In contrast, the increase in fos-LI in Ce resulting from D1/D2 receptor activation was greater in the lesioned versus intact Ce.

**Down-regulation of neurotransmitter receptors and up-regulation of neurofilament phosphorylation in the lateral geniculate nucleus of the adult cats after visual deafferentation.**

Y.L. Liu*, R. Douglas and M.S. Cynader

Department of Ophthalmology, University of British Columbia, 2550 Willow Street, Vancouver, B.C., Canada. V5Z 1N9

Several progressive neurodegenerative disorders such as Parkinson's disease and Alzheimer disease have been associated with abnormal neurotransmitter receptor expression and neurofilament distribution. To test the hypothesis that the redistribution and regulation of neurotransmitter receptors and cytoskeleton protein phosphorylation may trigger early neurodegenerative process induced by input deprivation, we investigated the response of several signal transduction and cytoskeletal markers to removal of retinal input in the lateral geniculate nucleus. Nine neurotransmitter receptors, including α1 and β-adrenergic receptors, muscarinic acetylcholine receptors, as well as L-type calcium channel, protein kinase C and phosphorylated neurofilaments were examined autoradiographically and immunocytochemically in the lateral geniculate nucleus (LGN) of eight adult cats at various times after monocular visual deafferentation. While α1 and β-adrenergic receptors, and muscarinic acetylcholine receptors were down-regulated in the deafferented layers of the LGN as early as 8 days after enucleation, phosphorylated neurofilaments were increased in the same layers as early as 4 days after enucleation. These results may suggest that the early changes in density of adrenergic and muscarinic acetylcholine receptors and phosphorylated neurofilaments are involved in the neurodegenerative process induced by input restriction, and may be useful as markers for neurodegeneration.

**STRESS-INDUCED TRANSCRIPTIONAL ACTIVATION OF THE CORTICO-TROPIN-RELEASE INHIBITORY FACTOR GENES PRECEDES IMMEDIATE-EARLY GENES RESPONSES IN THE PARAVASCULAR NUCLEUS.**

C-T. Su, C-F. Huang and J. Schmid* Dept. of Biochemistry and Cell Biology, State University of New York at Stony Brook, Stony Brook, NY 11794.

Activation of nuclear protein kinase C (PKC) is an integral element in the signaling pathway coupling the depolarization of the plasma membrane to the transcriptional regulation of genes coding for acetylcholine receptor (AChR) subunits. Since PKC activation is immediately followed by genetic inhibition we assume that a transcription factor is directly targeted by the kinases. The muscle-specific expression of ACR and the presence and functional significance of B boxes in the ACR subunit promoters strongly suggest that myogenic determination factors are involved. Among them myogenin is a good candidate because its activation and inactivation kinetics resemble that of the endogenous transactivator. Thrombin 87 in mouse myogenin has been shown to be a target for PKC, but since it is part of the DNA binding domain it may not be accessible to the kinase in the DNA-bound factor. To determine the phosphorylation site responsible for the rapid inactivation by PKC, we have systematically replaced all eight potential PKC targets in the chicken myogenin molecule and analyzed the PKC sensitivity of the mutant factors. Results of this analysis will be presented.

**HIPPOCAMPAL CHOLINERGIC BLOCKADE ELEVATES STRESS-INDUCED CORTICOSTERONE (CORT) SECRETION.**

S. Bhattacharya, J.W. Snyder and M.J. Myers.

The hippocampal formation (HPC) regulates stress-induced hypothalamic-pituitary-adrenal (HPA) activity. Lesions of the HPC result in hyperserection of ACTH and CORT in response to a variety of stressors, suggesting that the HPC plays an inhibitory role in the regulation of HPA activity. Septal cholinergic projections innervate all fields and subfields of the HPC and increase HPA excitability. These stressor-induced inputs are thought to regulate sensory processing of stressful environmental events, as suggested by studies on HPC electrophysiology. We investigated whether HPC cholinergic systems might underlie HPC control of HPA function. Adult rats were implanted bilaterally with cannulas aimed at the molecular layer of the dentate gyrus. Scopolamine HCl (SCOP; 10 μg/μl; 5 μl total) was administered into the HPC 20 min prior to onset of restraint stress. Plasma CORT levels were measured immediately following and up to 2 hours following termination of restraint. Rats administered SCOP (n=6) hypersecreted CORT at 0 min and showed elevated levels 2 hours following termination of restraint, relative to vehicle injected rats (n=6). These data suggest that HPC cholinergic systems actively inhibit HPA activity. Thus, compromising HPC cholinergic inputs may interfere with sensory processing and alter the ability of the HPC to exert negative-feedback control of HPA activity in response to stressful stimuli. (Supported by MRCC and FRSQ)
A CIRCULANT NITRIC OXIDE SIGNALING MECHANISM MEDIATES STRESS-INDUCED CORTICOSTERONE RELEASE. Y. Blackwood1,2, D. O’Donnell1,2, B. Aron1,2, C. Consden1,2, M. D. McGinnis1,2, Canadian, McGill University, Montreal, Quebec, Canada.

Nitrile oxide synthase (NOS) containing neurons have been localized in the hypothalamic-neurointermediate lobe (PNV) and, in vitro studies suggest that nitric oxide (NO) is involved in the release of corticotropin releasing hormone (CRH) from PNV neurons. Because CRH can play a role in the regulation of pituitary-adrenocorticotrophin (ACTH) and corticosterone (CORT) secretion from the adrenal cortex, we investigated the effects of blockers of NO synthesis on the corticosterone response of rats. Immobilization stress for 60 min caused a significant increase in cortisol and ACTH response of anterior pituitary cells. Pretreatment with the NOS blocker N-nitro-L-arginine methyl ester (LNAME, 10 mg/kg, p.o.) did not block the increase in CORT production and the adrenal cortex. This suggests that NO may be involved in the regulation of the stress-induced increase in cortisol and glucocorticoid levels following immobilization stress.

INVOLVEMENT OF C-FOS IN DEVELOPMENTAL REGULATION OF CRH GENE EXPRESSION BY COLD-STRESS. Z-J. Li, P.S. Gott, and T.Z. Baran. Neurology, Children’s Hospital Los Angeles and University of Southern California, Los Angeles, CA 90032. C-fos expression is induced by a variety of stresses, including stress, to regulate transcription of target genes. These genes often contain cyclic AMP-responsive elements (CREs). The corticotropin releasing hormone (CRH) gene promoter contains the c-fos dependent cascade. We postulated that c-fos-mediated induction of CRH gene promoter involved upregulation of c-fos. We successfully showed that cold-stress induction of CRH gene expression is developmentally regulated: CRH mRNA abundance increased by 4.8 fold after cold-stress on postnatal day 7 (PND9) or 16, but not on day 3. In this study, we tested the hypothesis that c-fos induction on PND6 would induce both c-fos and CRH gene expression. Rats were subjected to cold-stress-anesthesia, and implanted unilaterally with a cannula directed to the paraventricular nucleus (PVN) of the hypothalamus. Rats were sacrificed 4 hr after saline or dibutyryl cAMP (db-cAMP, 100 µm) injection via the cannula. Fos-like immunoreactivity (Fos-IR) in the central amygadoid nucleus (ACE) was increased by db-cAMP infusion on PND9. Cold-stress induced hippocampal Fos-IR, with a further increase by db-cAMP in both ages. Fos-IR in ACE was enhanced following db-cAMP infusion only on PND9. An additive effect of cold stress and db-cAMP on plasma corticosterone levels on PND9. These data support a role for immediate early genes and cAMP-stress-induced upregulation of CRH-gene expression in limbic structures.

DIFFERENTIAL REGULATION OF EGF AND TGFα mRNA IN RAT PITUITARY AND HYPOTHALAMUS INDUCED BY STRESSES. X. Fan, G. T. Magle1, T. J. Collins2, O. D. Little3, and J. M. McEwen4. Department of Anatomy, Neuroendocrinology, University of Texas Medical Branch at Galveston, Galveston, TX 77555.

Evidence has shown that both epidermal growth factor (EGF) and transforming growth factor (TGFα) are present in the median eminence and hypothalamus, and EGF can influence the function of pituitary cells, particularly corticosterone in vivo and in vitro. However, little is known about their exact functional roles in the pituitary and hypothalamus. This was due to the difficulty in detecting EGF and TGFα mRNA in the rat pituitary and hypothalamus. Reverse transcriptase-polymerase chain reaction (RT-PCR) also showed the presence of EGF and TGFα mRNA in those areas and other rat tissues (mesencephalon, liver, kidney, hypothalamus, and testis). No TGFα mRNA was found in the kidney however. The EGF mRNA is upregulated in the pituitary after stress in pregnant rats and rat cold-stress stress (SSS) but not after 30 min after stress (NS) or tape-stress (TS). Older cold stress showed that expression of EGF mRNA was downregulated after 60 min cold stress and then upregulated after 180 min post-stress response. In contrast, EGF mRNA in the hypothalamus is not responsive to either acute stressors or longer periods of cold exposures. No significant change in TGFα mRNA expression was detected in both pituitary and hypothalamic after acute and longer cold stressors. The results suggested that the change in pituitary EGF mRNA in response to stress varies according to the type of stress and may be under the influence of glucocorticoid feedback. Preliminary evidence suggests that the corticosterone may be one of the cells that express EGF mRNA in the pituitary. Our data further support that EGF is a stimulator of HPA axis in primates. These stress-induced changes in EGF mRNA suggest that it may play an important role during stress responses. Supported by NSF # NIH-1917897.

385.6

Learned helpless behavior has been successfully bred in rodents and designated as an animal model of human depression and/or anxiety. Since learned helpless (CHL) animals have an altered response to stress in adulthood, we examined the effects of early stresses (at day 7, 14, and 21) on the hypothalamic-pituitary-adrenal (HPA) axis and the cardiovascular system. The functioning of the HPA axis was monitored through changes in adrenocorticotropic (ACTH) plasma levels in the adult animals after acute stress exposure in adulthood. Because ACTH and PRA are known to be controlled by the HPA axis and the sympathetic nervous system, we studied the effects of early stress-induced stress in adulthood. We measured ACTH and PRA in the sera of CHL and control animals before and after stress (acute stress). In conclusion, CHL animals (adults) that were housed postnatal day 14 had lower plasma levels of ACTH than control, while exhibiting a 9% increase in PRA, again pointing to a reduction in functional cardiovascular system. The most robust effect of MD on the CHL adult animals was apparent after acute stress on postnatal day 14 as opposed to postnatal days 7 and 21. In contrast, there was a step-wise increase in ACTH plasma levels in the congenital non learned helpless (NLH) rats with age of acute presentation of stress. MD. The above results suggest that there are long-term changes in both the HPA axis and the cardiovascular system in CHL animals after acute exposure to a postnatal stressor.

IN VIVO QUIPANZEE INCREASES GLUCOCORTICOID RECEPTOR EXPRESSION IN THE HIPPOCAMPUS OF NEONATAL PIGS. S. Weyer1, D. O’Donnell1, A. Schoerl1, L. Thibault1,2, and M. J. Masey1,2. 1Dept. Animal Sci., Univ. of Alberta, Edmonton, AB, Canada; 2Dept. Physiol. Sci., Univ. of Guelph, Guelph, ON, Canada.

The glucocorticoid receptor (GR) in the hippocampus is involved in the negative feedback effects of glucocorticoids on stress. The handling stress results in increased GR binding capacity in the hippocampus and frontal cortex and an attenuation of the stress response in rats. The postulated mechanism is via increased expression of the GR (5-HT) turnover in the hippocampus (Mitchell et al., 1990, J. Neurosci. 10745). Little is known about the presence or development of GR in porcine brain. Brain is associated with dramatic costs in the swine industry due to impaired animal growth, reproduction, and meat quality and reducing its impact represents significant savings. In the current study we examined the effect of the 5-HT agonist quipazine on GR levels in specific brain areas using Western blotting with a commercially available GR antibody (Affinity BioReagents). Pigs were injected with 1 mg/kg quipazine dissolved in saline (1 ml/kg) or saline from postnatal day 1 to 14. The animals were sacrificed on day 13, and the hypothalamic, frontal cortex, hypothalamus, and hippocampus were collected. Increased levels of immunoreactive GR were detected in the hippocampus of quipazine versus saline treated pigs. We are currently analyzing the remaining tissues to determine whether the changes in GR expression are confined to the hippocampus and frontal cortex as is the case for neonatally handled rats.

PRENATAL STRESS-INDUCED CHANGES IN THE ACTIVITY OF THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS OF ADULT OFFSPRING DEPEND ON MATERNAL CORICOSTERONE. S. Macaor5,6,7,8, A. Barbasz8, F.J. Pineau1, H. Stinson2, J. L. Mor6, W. Lavoie4, M. Lavoie4, Karin5, INSERM U1259, Université de Bordeaux II, 33707 Bordeaux Cedex, France.

The development of the autonomic nervous system during the perinatal period. Prenatal stress can have long-term behavioral effects, such as an increased emotional reactivity and a higher vulnerability to self-administer drugs. Changes in the activity of the hypothalamic-pituitary-adrenal (HPA) axis is a sensitive index of the integrated response of the brain to stress. The HPA axis is a complex system of the brain, and it has been proposed that one of the most critical components of the stress response is the number of central corticosteroid receptors. The mechanisms by which prenatal stress could mediate its long-term effects on the activity of the HPA axis are unknown. To determine if we could influence the development of HPA axis responses by manipulating the activity of the HPA axis of adult (3 months of age) male and female offspring. Repeated restraint during the last week of pregnancy was used as a stressor. In adult male and female offspring of mothers subjected to repeated stress, the HPA axis was increased in maternal corticosterone receptor expression. Such effects of prenatal stress depend on maternal corticosterone-secretion: 1) maternal adrenalscrotal protected the offspring from the effects of prenatal stress by cortisol receptor; 2) injections of corticosterone to the mother had the same effects of prenatal stress in adult offspring. In conclusion, the HPA axis may be regulated by one of the mechanisms by which prenatal stress exercises its long-term effects on the activity of the HPA axis.
385.9 EFFECTS OF STRESS ON CRF AND ITS RECEPTOR GENE EXPRESSION IN THE BRAIN OF SPONTANEOUSLY HYPERACTIVE RATS. Guy, J.-D.; de Matos, A.; Mélis, F.; Parent, J.-P.; Prévost, S. Dept. of Neuroendocrinology, Center for Research in Brain Pathologies, CHUL, Quebec, Canada.

The present study investigated the influence of immobilization stress on corticosterone levels and the expression of CRF and CRF-R (CGRP) mRNAs in rats with spontaneously hypertensive (SHR) and Wistar-Kyoto (WKY) rats. Male rats (13 weeks) were exposed to immobilization stress by being placed in a restrainer for 0, 30, 60, and 180 minutes after the beginning of the immobilization session which lasted 60 min. Brains were cut in 60 μm sections and mounted on poly-l-lysine-coated slides. CRF and CRF-R mRNAs were detected by in situ hybridization using a 35S-labeled riboprobe. CRF-R mRNA was detected in the PVN, GEA, and BST of SHR rats. Immobilization stress induced a significant increase in CRF mRNA in the PVN, GEA, and BST of SHR rats. CRF-R mRNA was observed in both the PVN and BST of SHR rats. The results provide evidence that central CRF system may play different roles in stress in various species, particularly in the SHR and WKY rats.

385.10 IMMUNE CHALLENGE INDUCES CRF RECEPTOR GENE EXPRESSION IN THE RAT PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS. Serge Rivest*, Laboratoire d’endocrinologie moléculaire, Centre de recherche du CHUL, Québec, Canada.

The present study investigated the effect of intraperitoneal (i.p.) administration of the endotoxin lipopolysaccharide (LPS) on the gene expression of CRF and CRF-R (CGRP) mRNAs in the paraventricular nucleus (PVN) of male Sprague-Dawley rats. One, 3, 6, 9, and 12 hrs after a single i.p. injection of either the LPS (250 μg/100 g of BW) or the vehicle, sham rats were decapitated and rapidly perfused with 4% paraformaldehyde. Brain was microtomed and cut from the olfactory bulb to the medulla in 30 μm coronal sections. mRNAs encoding the rat CRF and CRF-R were detected by in situ hybridization histochemistry using a 35S-labeled riboprobe. The Fig. CRF-R cDNA in Blueprints vector (pcRF-R-PAI-3S, 4.3 kT) was kindly provided by Dr. W. Vale (The Salk Institute, La Jolla, CA). A strong basic level of CRF-R mRNA transcripts were observed in several regions of the brain such as the lateral nucleus, the dorsal gray, the hypothalamus, and the septum. In the cortical zone, the density of the zone increased, the endopine nucleus and in various layers of the corpus. A low to moderate signal was also detected in multiple sites including the medial septal nucleus, the nucleus of the diagonal band, the periaqueductal gray, the nucleus prepositus, and the ventral mesolimbic nucleus. While vehicle-treated rats did not display detectable signal of CRF-R mRNA in the paraventricular nucleus (PVN), CRF-R gene expression was highly stimulated in this hypothalamic structure. Indeed, the CRF-R mRNA signal was positive in the dorsal medial parvocellular PVN 3 hrs after LPS injection, strong and maximum at 6 hrs postinjection, and declined 9 and 12 hrs after the treatment. Systemic endotoxin did not appear to modulate the expression of CRF-R gene in other regions suggesting that this type of stress is likely involved in the stress-induced CRF within the paraventricular PVN. The results suggest that CRF may provide the control of the inflammatory response and the release of neurogenic CRF during immune challenge. (Supp. by the FRGS)

385.11 DEVELOPMENTAL ONSET OF HYPOTHALAMO-PITUITARY-ADRENAL AXIS RESPONSIVENESS TO NGF IN RATS. G. Tagliatela-Scafati* and J.P. Perez-Polo. Dept. of HBCG, UTMB Galveston, Texas.

Nerve growth factor (NGF) is involved in the regulation of the hypothalamic-pituitary-adrenal axis (HPAA). Peripherally-injected NGF stimulates the activity of the HPAA, resulting in a long-lasting increase in plasma corticosterone levels, whereas serum NGF levels increase, response to stress and ACTH, and pituitary CRF levels. NGF was demonstrated to have a full stimulatory effect on HPAA activity after 14 days of age, consistently with complete hippocampal maturation, we studied the effect of NGF on HPAA in pups at different ages of postnatal development. NGF was administered to pups at 2 days of age, and the response to stress and ACTH was monitored. NGF did not affect the increase in plasma corticosterone levels in pups of 3, 8, and 11 days of age, while a significant response of the HPAA to NGF was observed in pups at 15 and 22 days of age, as well as in adult rats. The results suggest that NGF administration to pups at different ages can modulate HPAA activity by a non-genomic pathway.

SNS and HPA activity both increase in response to acute restraint stress. Brown adipose tissue (BAT) activity, which promotes nonshivering thermogenesis, is an index of SNS activity. We hypothesized that a hyperalgesic load would separate basal activity in the SNS system and tested whether both stress responses were facilitated due increased tone in SNS. Therefore, rats were implanted with thermistor probes under urethane anesthesia, and were monitored by telemetry. The rats were tested for restraint on d10 while BAT temperature was recorded every 60s. On d5 & 10, restraint did not differ from controls in basal activity of the HPA axis, insulin and glucose. On d5, no significant effect on the response of CRF-R or ACTH to restraint. On d10, there was no difference in ACTH response, but a smaller B response at 30m as well as lower integrated B. Both control and sugar rats increased BAT temperature in response to restraint but sugar rats had a smaller increase than controls. SNS (BAT activity) responds to sugar with chronic elevation of SNS tone similar to HPA responses to chronic stress. In contrast to our initial hypothesis, the chronically sugar-activated SNS hyporesponds to acute restraint in parallel with the HPA hypersponse in ACTH and B secretion. We conclude that a hyperalgesic load to acute stresses leads to increased SNS and HPA responses to acute restraint from high to low amplitude. (supported by DK21872 to M.F. Dulinan and HAHS8-42 to AMS)

385.13 IMMEDIATEly EARLY GENE INDUCTION IN RAT FOREBRAIN GABAERGIC NEURONS IN RESPONSE TO AN ACUTE STRESS. W.E. Cullinan* and S.I. Watson, Mental Health Research Institute, University of Michigan, Ann Arbor MI, 48109-0720.

Recent data have suggested that the hypothalamic paraventricular nucleus (PVN) receives a prominent GABAergic input; this innervation has recently been shown to be involved in part from various hypothalamic nuclei and the bed nucleus of the stria terminalis (BST) (Roland and Sawchenko, 1993; Cullinan et al., 1993). These areas have also been shown to express immediate early genes in response to acute stress. The immediate-early gene expression was investigated to determine whether GABAergic neurons in these regions expressed early genes (c-fos, zif/268) following acute stress. Rats were subjected to 100 forced swim at 37°C, and were sacrificed 30 min. post stress. Stress was found to induce c-fos mRNA, with c-fos mRNA levels peaking at 60 min. and then decreasing to basal levels.

385.14 ADRENALECTOMY DOES NOT ALTER STRESS-INDUCED C-FOS EXPRESSION IN THE RAT HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION: STRESS STUDIES. 937

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
385.15

In vitro studies support a model in which the unoccupied corticosteroid receptor is not located in the cytosol, whereas the hormone-activated receptor is present in the nuclear fraction. We have used the western blot procedure to measure cytosolic and nuclear levels of Type II corticosteroid receptor in hypothalamic and other corticostereoid binding tissues, from cytosol or immunoprecipitates of cytosol and nuclear extracts which were separated by PAGE and transferred to nitrocellulose. Blots were probed with Type II corticosteroid receptor reactive antibodies (CR1057 or Bio-Rad) and immunoreactivity was visualized using an antibody quantitated by a chemiluminescence method (ECL, Amersham). Cytosolic Type II receptor binding level and western blot immunoreactivity were measured in rats from hippocampus or cortex from rats that were sacrificed (in the AM) under 4 hormone conditions: 1) adenal-intact, no stress, 2) 18 h ADX, 3) 5 d ADX, 4) adrenal-intact + 2 h ADX (receptor upregulation), and a 70-90% decrease with acute CORT treatment (receptor activation). In recent studies a large increase in nuclear receptor signal was detected when the western blot in CORT treated animals. These studies indicate that the western blot procedure can be used to directly measure both the cytosolic and nuclear level of corticosteroid receptors in rat brain tissue, and that cytosolic changes with hormone manipulations parallel those seen with receptor binding. 385.17
MODULATION OF 5-HT2C RECEPTOR mRNA EXPRESSION IN THE HIPPOCAMPUS DURING THE CIRCADIAN RHYTHM AND FOLLOWING STRESS. M.C. Holmes*, K.L. French and J.R. Steck, Dept. Med., Univ. of Edinburgh, Western General Hosp., Edinburgh, UK. Serotonin has been implicated in the generation and maintenance of circadian rhythms, as well as the modulation of HPA axis activity to certain stressors. 5-HT2-type (2A and/or 2C) receptors in the hippocampus and hypothalamus may mediate both actions. Using in situ hybridization, we examined 5-HT2A and 5-HT2C receptor mRNA expression in mice under conditions of the glucocorticoid diurnal rhythm. At 08.00h (lights on 07.00-19.00h) 5-HT2C receptor mRNA expression in the hippocampus was significantly greater than controls at 20.00h (CA1, 184%; CA2, 198%; ventral CA1 147%). 5-HT2A receptor mRNA expression was unchanged. Receptor gene expression was also determined following acute (6h after laparotomy) and chronic (15 days adjuvant-induced arthritis) stress. 6h after acute stress (20.00h) 5-HT2C receptor mRNA expression was significantly elevated in CA2 neurons (66% greater than controls). Chronic arthritis elevated plasma corticosterone, abolishing the circadian rhythm, and 5-HT2C receptor mRNA expression was significantly decreased in CA1 (55%), CA2 (50%) and ventral CA1 (45%) at 08.00h, giving levels of expression similar to the normal diurnal glucocorticoid peak (20.00h). Again, 5-HT2A receptor gene expression was unaltered. Our previous data showed that glucocorticoid regulates hippocampal 5-HT2C receptor gene expression following adrenalectomy. However, in the hippocampus 5-HT2C receptor mRNA expression following acute stress suggests that other factors (perhaps 5-HT) are also important short-term regulators of expression of this gene.

385.18

Corticosteroids (CORT) are known to mediate stress responses, and circulating plasma corticosterone is increased in the elderly. The purpose of this study was to evaluate the effects of antidepressant (AD) treatment on basal HPA activity in aged rats. We found that basal HPA activity was increased in aged rats, and that AD treatment significantly reduced basal corticosterone levels. The mechanism by which AD treatment reverses basal HPA hyperactivity is not yet understood.

385.2
NEUROTOXIN-STIMULATED HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS FUNCTION IN MICE. M. Carino, B. Giovannetti, R. Hillal and E. Szinro. Neuroendocrine Unit, Department of Neurosciences, IMBB, 1900 La Plata, Argentina.

The aim of the present study was to elucidate whether snake venom (SV; Sigma Chem. Co., V-17259) is able to stimulate the HPA axis activity when administered (i.p. 2000 IU/kg) to both sexes. Mice were killed at 0.5, 1, 2 or 4 h after SV or vehicle (sample time zero) administration. Plasma glucose (G), ACTH and corticosterone (B) concentrations were measured. The results indicated that, SV treatment induced a significant (P<0.05 vs. 0 h) hyperglycemia at all periods studied with maximal values attained at 2 h after treatment, regardless of sex; the neurotoxin-stimulated G release in plasma was significantly (P<0.05) higher in females than in males at 0.5, 1 and 2 h after administration. Neurotoxin injection significantly (P<0.05 vs. 0 h) increased ACTH release in plasma at 2, 4 and 6 h after treatment or in both sexes, 1 h after treatment in animals of both sexes, with 1 h-vale significantly (P<0.05) higher in males than in females; plasma ACTH levels remained elevated throughout the 6 h period, with no sex differences. The data suggest that chronic neurotoxin-stimulated G release enhances glucocorticoid negative feedback sensitivity and reduces basal PMS activity in mice. These results are consistent with previous findings in young adult animals and point to potential therapeutic approaches in the treatment of HPA dysfunction in the aged. Supported by MBCC and NIA AG09488.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION

DECREASED HIPPOCAMPAL NORADRENALINE DOES NOT AFFECT ELECTRICALLY STIMULATED CORTICOSTEROIDE RELEASE. W.M.C. Daniels, A. Jaffer, Y.A. Russell, S. Davy* and J.J.P. Taliard. Dept. of Phys. Path., Univ. Stellenbosch, Tygerberg Hosp., P.O. Box 1311, Tygerberg, 7505, RSA.

Bipolar electrodes were implanted into the CA1 pyramidal cells of the dorsal hippocampus and the effect of electrical stimulation of these cells on corticosterone release was investigated in freely moving rats. Histology showed that the electrodes were positioned in close proximity to the CA1 pyramidal cells. Rats that were subjected to electrical stimulation did not only behave differently to their sham stimulated counterparts, but also had significantly higher plasma corticosterone levels. Prior treatment of rats with DHPA significantly reduced hippocampal noradrenaline content, but had no effect on electrically stimulated corticosterone release. These data suggested that excitation of CA1 pyramidal cells may lead to increased corticosterone release and that a significant decrease in hippocampal noradrenaline concentration was not able to alter this corticosterone response.

ACUTE AND CHRONIC INTERMITTENT FOOTSTOCK DIFFERENTIALLY INDUCES FOS EXPRESSION IN THE PARAVENTRICULAR NUCLEUS AND ITS EXTRAPARAVENTRICULAR AFFERENTS. P.J. BHAGWANDIAL, P.A. LINT, C.A. Arias and P.E. Swedencot. The Salk Institute, La Jolla, CA 92037

Immuno-localization of Fos protein was coupled with immuno- and hybridization histochemistry and/or axonal tracing techniques in order to dissect acute and chronic effects of intermittent footstock on stress-related neuroendocrine neurons. Exposure to a single 10 min footstock session induced maximal Fos-ir in the paraventricular nucleus of the hypothalamus (PVH) at 2 h after the challenge; at this time point, Fos induction in the paraventricular division of the PVH was localized principally to cells expressing the c-fos immediate-early factor mRNA, while that in the magnocellular neurosecretory system was detected predominantly in corticotrophs. Relative to controls, treated rats, adrenorelated neurons replaced with low levels of corticosterone showed enhanced Fos induction in response to acute footstock in all PVH compartments. Extrahypothalamic cell groups displaying prominent Fos induction in response to acute footstock included catecholaminergic neurons in the nucleus of the tractus solitarius and ventromedial nuclei, the lateral parabrachial nucleus, the ventral lateral periaqueductal gray, and circumventricular structures of the anterior and median tuberal nucleus, septal nucleus and infralimbic cortical areas. Rats bearing retrograde tracer deposits in the PVH and sacrificed 2 or after a single footstock session displayed Fos induction in retrogradely labeled neurons found principally in mediad catecholaminergic cell groups, and secondarily in the lateral septal and medial amygdaloid nucleus. Rats subjected to chronic intermittent stress (2 X 50 min/day for 7 days) and sacrificed 2 h after the final footstock session, displayed patterns of Fos expression that were similar to those seen acutely. Fos expression in chronically stressed animals sacrificed on the day following the final footstock session was not distinguishable from non-shocked control levels. These results suggest that the patterns of cellular activation seen in rats exposed acutely and chronically to a footstock challenge are similar. Mediodl catecholaminergic cell groups are most strongly implicated as candidate afferent mediators of this stressor's effects on endocrine hypothalamic mechanisms.
HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION II

386.3
HYPOTHALAMIC GALANIN-LIKE IMMUNOREACTIVITY AND ITS GENE EXPRESSION IN RELATION TO CIRCULATING CORTICOSTERONE. A. Abakahyu*; H. J. Chae and S. F. Leibowitz. The Rockefeller University, New York, N.Y. 10021.

The hypothalamic galanin peptide (NPY) and galanin (GAL), known to stimulate feeding behavior, have differential effects on the release of the adrenal steroid, corticosterone (CORT), with NPY enhancing and GAL inhibiting its secretion. In terms of the feedback effect of CORT on endogenous peptide, previous studies have shown that GAL has the potential to produce a reduction of neuropeptide Y (NPY) in specific hypothalamic areas, namely, the paraventricular (PVN) and arcuate (ARC) nuclei, as well as the locus coeruleus (LC). This investigation examined changes in GAL gene expression and peptide levels in relation to circulating CORT in male, Sprague-Dawley rats. Using radioimmunoassay (n=30, 10/group) and in situ hybridization (n=18, 6/group) techniques, this peptide was examined in 3 groups of rats that received either sham surgery, adrenalectomy (ADX), or ADX + CORT replacement. The results showed a clear, site-specific change in GAL in relation to circulating CORT. A loss of CORT after ADX caused a dramatic decline in GAL peptide (<0.05% < p < 0.05) and GAL mRNA levels (<35% < p < 0.05) in the ARC and also peptide levels in the median eminence (<40%, < p < 0.05). Other hypothalamic areas, including the PVN, showed no change. In the brainstem, a similar effect after ADX was seen in the dorsal raphe nucleus, but not in the LC. The data from these brain areas of ADX rats were restored by s.c. CORT implants, which had no impact on GAL in other brain sites. These findings show GAL-synthesizing neurons to respond differently from NPY neurons in relation to circulating CORT.

386.5
Serotonergic denervation attenuates hippocampal mineralocorticoid (MR) and glucocorticoid (GR) receptor gene expression, whereas 5-HT decreases neuronal GR at least in primary culture. The 5-HT1 receptor subtype(s) involved in these effects are unknown. We examined the effects of the 5-HT1A receptor agonist, 8-OHPAD, upon hippocampal MR and GR gene expression in rats bearing central 5-DHT lesions and controls. Rats, pretreated with desipramine, were given 5,7-DHT injected into the dorsal hippocampus (1 mg/kg, 2/4 days later before the electrophysiological examination) or saline for 2 days. Controls (vehicle icv) were given saline or 8-OHPAD. 5-DHT lesions decreased hippocampal MR (~20% fall in CA1 and ~10% fall in the dentate gyrus) and CA1 and CA2 mRNA expression. In 5,7-DHT-lesioned rats, 8-OHPAD administration reversed the fall in hippocampal MR mRNA expression, most notably in CA1. 8-OHPAD had no effect on MR gene expression in controls. By contrast, 8-OHPAD enhances in hippocampal GR mRNA expression in 5,7-DHT-lesioned rats (dentine gyrus, 42% fall; CA1-2, 52%). Moreover, in controls, 8-OHPAD also decreased GR mRNA expression in CA1 (31% fall) and CA2 (39%). The attenuation of hippocampal MR gene expression by 5-HT denervation can be partly reversed by 5-HT1A receptor agonists, whereas the attenuation of GR gene expression does not appear to be due to loss of 5HT1A receptor activation. Whether the 8-OHPAD-related decrease in GR mRNA expression is directly mediated or reflects indirect actions, such as increased corticosterone secretion, remains to be determined.

386.6
Serotonin and corticosteroids interact in the hippocampus, affecting electrophysiological, neuroendocrine and behavioural parameters. Chronic m-catenylhexamethylenamine (MDMA) administration causes selective neurodegeneration. This decrease is most pronounced in the paraventricular nuclei (PVN) and extends to the hippocampus and subiculum. In the hippocampus, 5-HT receptors modulate neurotransmitter release and are implicated in various types of neurodegeneration. Similarly, 5-HT receptors are implicated in the development and progression of Alzheimer's disease. Following MDMA-induced 5-HT receptor gene expression changes in the hippocampus, we examined the effects of acute MDMA on hippocampal MR, GR, and 5-HT3 receptor mRNA expression using in situ hybridization. Rats were killed 6 h after MDMA (20 mg/kg, i.p.). Hippocampal neuronal GR mRNA expression was decreased in the dentate gyrus (DG) (15% fall) and CA1 (20%) and CA3 (24%); all p < 0.05. In contrast, MR mRNA expression was increased in the DG (69% rise), CA1 (41%), CA3 (55%) and CA4 (52%); all p < 0.01. 5-HT3 receptor mRNA expression was decreased in CA3 of the dorsal (20%, p < 0.01) and ventral (30%, p < 0.05) hippocampus. Increased MR and decreased 5-HT3 receptor gene expression in the hippocampus probably reflect acute MDMA-induced 5-HT release. Down-regulation of GR gene expression might be a consequence of these changes. These results support our previous findings suggesting that 5-HT controls hippocampal corticosteroid receptor and 5HT3 receptor gene expression.

386.7
ALTERED EXPRESSION OF GLUT1 & GLUT3 GLUCOSE TRANSPORTERS IN NEUROHYPOPHYSIAL EINHEERODYSTASIA. Kang Li, Susan J. Vannucci, Ellen Koelbel, Fran Maher and Jan A. Simpson* Bethesda, MD 20892 and Hershey, PA 17073.

The neurohypophysis (NH) is an extension of the central nervous system which contains axon terminals of vasopressin- and oxytocin-secreting neurons of the hypothalamus and glial-like pituicytes, but lacks a blood glucose (GLUT1 and 45 kDa GLUT3) detected in the NH. Progressive dehydration due to water deprivation increases vasopressin (VP) secretion in rats; dehydration increases NH glucose utilization. This study examined the effects of progressive dehydration and subsequent rehydration on NH GLUT1 and GLUT3. Dehydration was achieved in adult (250g) male rats by water deprivation for 1, 2 and 3 d. All dehydration other rats had their water returned and were studied at 1, 2 and 3 days following rehydration. NH GLUT1 & 3 concentrations were determined in these rats using a [125I]-labeled 6D1 antibody with specific anti-terminal antibodies. With progressive dehydration, hemocrit increased and plasma VP levels, measured by RIA, increased 4-fold by 3 days in dehydration in NH VP. The concentration of GLUT1 was increased by 18% and 44% by 2 and 3 days of dehydration and GLUT3 was increased by 42% & 55%. With water repletion, physiological and biochemical differences to the control group were restored within 2 days. However, the levels of both GLUT1 and GLUT3 remained elevated, even at 3 days of rehydration. The results of this study suggest that NH glucose transporters are rapidly upregulated in response to the metabolic stress of dehydration but their turnover is apparently slower.

MODULATION OF THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS IN BIPODS. L. Michael Proctor* and C. William Field, Dept. Zoology, Univ. of Washington, Seattle, WA 98105

Recent evidence suggests that some avian species can modulate corticosterone (B) release in response to a standard stressor paradigm (capture and serial blood sampling). Stress-induced release of B varies throughout the year and appears dependent upon the animal's physiological state. In one species (white-crowned sparrow, Zonotrichia leucophrys), B output is inhibited during molt. We tested whether this inhibition results from adrenal or peripheral mechanisms by injecting various stimulating factors into molting white-crowned sparrows and comparing B release to simultaneous release from animals (Genus luteola), a species not known to modulate their glucocorticoid response. White-crowned sparrows from eastern USA were housed in outdoor aviaries until the onset of molt. Blood samples were taken at 15-min intervals. Blood was injected, bled, and released. Intravenous ACTH stimulated B release in the sparrows, indicating that the adrenal cortex can still respond to an ACTH signal during molt. CRF, on the other hand, failed to stimulate B release in the sparrows, but enhanced B release 300% in the pigeon compared to vehicle-injected controls. Similar suppression of vasopressin and mesencephalin (AVT and MT - the avian equivalents of vasopressin and oxytocin, respectively) also failed to stimulate B release in sparrows whereas AVT caused a 200% increase in the pigeon. This suggests that CRF and AVT enhance B secretion than to either hormone alone. These data suggest that the inhibition of B release seen in white-crowned sparrows during molt may be mediated by pituitary insensitivity to an ACTH antagonistic signal but not to adrenal insensitivity to ACTH.

PERIPHERAL NERF ADMINISTRATION INCREASES HYPOTHALAMIC C-FOS EXPRESSION. F. Passarelli, R. Nicolai*, F.R. Butterelli, D. Bablioni, S. Scaccioni*, G. Cipriani*, and I. Angelucci*. Dept. of Neurosci., Univ. of Rome “La Sapienza” and #Farmacologia, 2°, Univ. of Rome “La Sapienza”

We have recently demonstrated in the rat the hypothalamic involvement in the adrenocortical activation induced by NFG (Scaccioni S., 1993). The c-fos gene, expressed at low levels in most cells types, is induced rapidly in response to a variety of extracellular stimuli in the periphery and in the CNS. We have also observed whether NGF administration was followed by an induction of hypothalamic c-fos mRNA expression. Freely moving male Wistar rats were injected through a permanent jugal cannula with either 1 or 5 mg/kg of mouse ENGF (kindly donated by Dr. J.R. Perez). Pol, Univ. of Texas, Galveston, Texas) or vehicle. The adrenal glands and the hypothalamus were isolated 20 min after injection and total RNA was extracted by the guanidinium thiocyanate–cesium chloride method. The levels of c-fos and beta-actin mRNAs were measured in each sample using a RT-PCR. Compared to vehicle in the hypothalamus a 2-fold c-fos mRNA increment was observed after 5 mg/kg of NGF administration but not after 1 mg/kg. The adrenal gland mRNA c-fos enhancement was detected after 1 and 5 mg/kg NGF injection. These results confirm that the hypothalamic is involved in the adrenocortical activity induced by NGF and that NGF is a target of messenger pathway. (Supported by CNR grant 93.0447.PF40 to Scaccioni S.)

In fetal sheep, implants of corticosteroids adjacent to the paraventricular nucleus of the hypothalamus suppress AVP and CRH expression. These effects of glucocorticoids are mediated by actions of glucocorticoid receptors within the paraventricular (PVN) neurons. Under physiological conditions, corticosteroids could influence the function of the hypothalamus via actions to the PVM afferent neurons as well. To assess this possibility, we determined whether the catecholaminergic afferents to the fetal medial paraventricular (A1/C1) and, n. solitari tract (A2/C2) possessed immunoreactive type II glucocorticoid receptors. To accomplish this, fluorogold (FG) was stereotaxically injected into the PVN of 5 fetal sheep (120A). After 3 weeks, each fetus was removed by Caesarian section, administered an overdose of anesthesia and perfused intracardially with fixative (using anti-BUSG), tyrosine hydroxylase and FAU was performed in the brainstem. Staining of the hypothalamus for FAU, GRII, and CRH verified the accuracy of tracer injection sites and the potential sites of innervation within the CRH neurons of the PVN. The dominant catecholaminergic innervation of the PVN arises from the A1/C1 and A2/C2 cell groups. In the A1/C1 cell group, 66% of the catecholamine neurons that project to the PVN in the A2/C2 cell group 73% of the neurons were GRII, Triple labeling of tyrosine hydroxylase, GRII and FAU confirmed that approximately half of the GRII catecholamine neurons in both regions projected to the PVN. These data suggest that glucocorticoids may act on both the CRH neurons of the hypothalamus as well as on catecholamine afferents to the PVN. (Supported by NIH HD 21350)

GLUCOCORTICOID MODULATION OF C-TYPE NERFATICUR PEPTIDE mRNA LEVELS IN PREFRONTAL AREA AND LIMBIC STRUCTURES. M. C. Langub, Jr.*, D. Bucker and J.P. Herman, Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084. Lesion and anatomical analyses suggest that the ventral subiculum (VSUB) plays a major role in hippocampal inhibition of the hypothalamic-pituitary-adrenocortical (HPA) axis. The present study was designed to examine the role of VSUB in stress-induced hypothalamic, neurotransmitter and neuroimmune stress responses. Groups of rats received bilateral ibotenic acid lesions of the VSUB (n=19) or injections of saline vehicle (n=17). All animals underwent analysis of behavior related behaviors in an open field, and were subsequently divided into three groups for analysis of endocrine and immune responsivity to acute restraint (60 and 120 min). IBO rats exhibited enhanced hypothalamic responsivity to open field exposure, manifest as increases in freezing behavior and decreased ambulation. IBO lesion increased stress-induced ACH secretion (n=10) but not 120 min stress induction; no changes were seen in baseline release. Restrain stress caused marked decreases in splenic lymphocyte proliferation following 60min of restraint, as measured by nile nitrogen assay; however, no differences were found between groups. The results suggest that VSUB damage affects both emotional responsivity and HPA activation following exposure to a stressful situation, yet do not impact either basal ACTH release or immune reactivity in a long-term fashion. The VSUB lesion appears to bias behavioral predispositions in a direction suggesting enhanced stress responsivity. Effects of VSUB lesion on HPA activation may therefore be mediated by alterations in salience of stressful stimuli, rather than modulation of glucocorticoid negative feedback. Supported by MH46908.

BEHAVIORAL, NEUROENDOCRINE AND NEUROIMMUNE ANALYSIS OF HIPPOCAMAL STRESS INTEGRATION. J.P. Herman*, C.M. Dolgas and S.L. Carlson, Dept. of Anatomy and Neurobiology, Univ. Kentucky Medical Center, Lexington, KY 40303-0984.

Activation of the hypothalamic-pituitary-adrenal (HPA) axis causes an increase in the circulating levels of glucocorticoids (eg, during stress). Glucocorticoids feed back onto the brain to inhibit the secretion of corticotropin releasing factor (CRF) and suppress HPA activation. To determine whether glucocorticoids feed back directly onto hypothalamic neurons of the hypothalamus, we studied the effects of the glucocorticoids, dexamethasone, on the membrane electrical properties of identified neurons in the rat hypothalamic paraventricular nucleus. The effects of dexamethasone on specific PVN cell populations were studied using intracellular recordings, dye injection and immunohistochemistry in the hypothalamic slice preparation. Bath application (30 min) of dexamethasone (10^-6 M) caused a >44-AE increase in voltage hyperpolarization with an increase in input resistance in low-threshold spiking (LTS) cells, or putative paravocellular neurons, and a small depolarization (2-mV) with a decrease in input resistance in non-LTS cells, or putative magnocellular neurons. The identification of these cells was verified anatomically with biocytin injection and subsequent immunohistochemical processing using antisera to CRF, oxytocin, vasopressin or neuropeptide. These results suggest that glucocorticoids have a direct inhibitory effect on parvocellular neurons and a weak excitatory effect on magnocellular neurons of the hypothalamic PVN.
EVIDENCE FOR GLUCOCORTICOID REGULATION OF VASOPRESSIN V1a RECEPTOR GENE EXPRESSION IN HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION II

386.15

J. Waters* and D. M. Days
Department of Pharmacology, Psychiatry and GRECC, VA Medical Center, Seattle, WA 98198

The brain is intimately associated with the hypothalamic-pituitary-adrenal axis. We have isolated a genomic clone from a rat testis library encoding a putative vasopressin V1a receptor. Sequencing of the clone revealed the presence of at least five potential introns. A possible tissue-specific expression of this gene has been detected in rats with PHX-induced diabetes, in which vasopressin V1a receptors are upregulated in the hypothalamus. ADRENOCORTICAL EFFECTS ON TYPE I CALMODULIN-DEPENDENT ADENYLYL CYCLASE mRNA LEVELS IN RAT BRAIN.

M. G. Mengo* and B. S. McF岐, Lab. Neuroendocrinol., Rockefeller Univ., NY, NY 10021

The hypothalamic-pituitary-adrenal axis has pronounced effects on calmodulin-dependent (CaM) adenylyl cyclase (AC) enzyme activity, measured in rat brain tissues. In particular, hippocampal AC activity shows dexamethasone- and adrenocortisol-stimulated release, an effect abolished by adrenalectomy. Type I ACmRNA is present in both hypothalamic-pituitary regions and in brain. This study investigated whether adrenocortical effects on AC activity were paralleled by changes in the expression of AC mRNA. The results of this study support the hypothesis that the hypothalamic-pituitary-adrenal axis regulates AC activity in rat brain. Supported by grant 5NH1256.

MINERALOCORTICOID RECEPTOR mRNA VARIANTS IN THE DEVELOPING HIPPOCAMPUS: DISTRIBUTION AND CORTICOSTEROID REGULATION

Our laboratory has previously reported an MR DNA clone from rat hippocampus (HC) which shares a high degree of homology with the kidney MR DNA clone. These two clones differ significantly at the 5' untranslated region (5'UT) and have been named alpha (a) (kidney clone) and beta (b) (HC clone). Most recently, a third HC 5'UT DNA clone was isolated which we termed gamma (γ) (Endo 133-234). Studies have shown that these 5'UT regions are located on separate exons of a single gene and give rise to three mRNAs that encode the same protein. We are interested in investigating the translation of these distinct mRNA forms and their glucocorticoid regulation in the developing rat HC. Last year we presented the α and β HC mRNA distribution in adult rats and we have expanded the in situ hybridization study to younger animals and included the γ HC variant in our analysis. In general, we find that the α and β expression increases significantly in all HC regions during the first 2 weeks of life. Whereas α levels remain constant thereafter, β expression decreases markedly in the piriform cortex. In contrast, γ is highly expressed in all regions early during development. In the dentate gyrus this high level of expression is retained until adulthood when lower levels are detected. Adrenalectomy results in up-regulation of the α 5'UT form in all ages. Our results, show that the α and β 5'UT forms achieve an adult pattern of distribution in the HC after the Stress Hypo-Responsive Period. The γ 5'UT form may be important for proliferation and differentiation of hippocampal neurons. Supported by NIMH MH40976 and MH14225.

GABA TURNOVER IN MICRODISSECTED BRAIN REGIONS DURING THE RAT ESTROUS CYCLE.

D. J. Gratten* and M. Slaferman. Center for Studies in Reproduction, Department of Psychology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559

GABAergic neurons terminating in the rostral and medial basal hypothalamus are positively regulated by testosterone, an action that may play an important role in the negative-feedback action of testosterone on hypothalamic GnRH release in the male rat. The present study determined whether endogenous changes in gonadal steroids during the estrous cycle are associated with changes in GABAergic neuronal activity measured in tissue punches from steroid-sensitive brain regions. Animals were decapitated at 0800 and 1700 h on diesterrous day 1, and 0900, 1300 and 1700 h on proestrus, either without treatment, or 60 mm without inhibition of the GABA degrading enzyme GABA-transaminase by amino- oxyacetic acid (AOAA, 100 mg/kg). The rate of accumulation of GABA in the tissue after AOAA was taken as an index of GABA turnover. In brain regions examined so far, there was no change in GABA turnover between the morning and afternoon on proestrus, or between the morning of diestrus and the morning of proestrus. In the diagonal band of Broca at the level of the OVLT, GABA turnover was significantly reduced in the afternoon of proestrus compared with morning. By contrast, in the central portion of the MPN, no changes were apparent at any of the timepoints examined. Analysis is continuing in the median eminence, ventromedial nucleus, septal nuclei, and hippocampus. Supported by NHLBI, NIMH, and NIDA. 5NH12369.

EFFECT OF CHRONIC MORPHINE TREATMENT ON NORDADERENERGY MODULATION OF GT1-7 NEURONS. M. A. Lavazza*, T. S. King, J. G. Hensler, and X. Chang. Departments of Pharmacology, Psychiatry, and CRBII, The University of Texas HSC, San Antonio, TX 78284

Stimulation of noradrenergic, serotonergic, and opiate receptors are known to regulate release of hypothalamic GnRH, but it is not known whether the receptors exist on GnRH neurons or on other cell types that modulate GnRH release. GT1-7 neurons, which synthesize and secrete GnRH, were immortalized in culture from transgenic mice. The purpose of this study was to examine the possible interaction between GnRH neurons and GABAergic neurons that modulate GnRH release. Supported by the NIH and the Texas HHSC. 5NH12369.

PARTIAL SURGES OF LUTEINIZING HORMONE (LH): A NEUROENDOCRINE MECHANISM FOR PROLONGED EROTIC CYCLES IN FEMALE RATS AND HUMANS

The LH surge that stimulates ovulation is triggered by a daily neural signal that has been adequately provoked by ovarian steroids. This provocative signal is characterized by (1) a rise above diastolic LH level and (2) an accelerated rate of LH secretion. 7 ± 2 hypophysial pulsatility sites in two chow-fed rats collected seven times a day, hourly, from each female on four proestrus days. Steroid levels were assessed in daily samples collected at lights out throughout two estrous cycles. In 57 full LH surges, the rate always preceded the acceleration in the rate of LH secretion. Nonetheless, the time of the rise did not predict the latency to the acceleration. These two independent characteristics of the LH surge correlated with different steroid levels. Moreover, in addition to eight surges LH rose above diastolic LH levels but never achieved the acceleration typical of the rising limb of the LH surge. We termed these partial LH surges and hypothesized that they could be a result of the ovarian follicle without ovulation, thus initiating prolonged estrous cycles characteristic of estrous cycle distributions in non-mammalian species. The females whose full LH surges had a delayed acceleration were the ones that might have possible partial LH surges.

In addition, the steroid correlates of partial LH surges were the same as those that were present.

DOFAMINE AND THE INHIBITION OF LUTEINIZING HORMONE PULSES IN RATS. THE SIGNIFICANCE OF HYPOTHALAME. P. P. O. Hofsten and C. W. Cost. Division of Biological Sciences, University of London, W1, U.K.

Previous work has indicated that a reduction in body temperature can be the primary factor in the suppression of diurnal cycles of hypothalamic function. Since it has been demonstrated in independent studies that centrally administered dopamine can induce hypothermia and inhibit LH pulses, we have examined the effects of the dopamine receptor agonist and antagonist on these parameters. In some of the studies the agonist was administered after a dopaminergic antagonist and at others it was given at an interval before the LH pulse. The results showed that dopamine antagonists could decrease the LH pulse size and that dopamine agonists could increase it. The antagonist and agonist were given by push-pull cannulae and the results showed that the dopamine antagonist decreased and the dopamine agonist increased the LH pulse size.

The results of these experiments suggest that dopamine may be an important factor in the control of LH release in the rat.

PRESENCE OF FUNCTIONAL OPIOID BINDING SITES ON THE GT-1 LH SECRETING CELLS.

B. Maggi, F. Fimpanelli, M. F. Pia, Dept. of Endocrinology, University of Milan, Italy.

The presence of functional opioid binding sites on the GT-1 LH secreting cells was studied with the use of [3H]rogue, [3H]DADLE, and [3H]DPDPE. The results showed that the GT-1 LH secreting cells were sensitive to the effects of these opioids. The presence of opioid binding sites on the GT-1 LH secreting cells suggests that opioids may play a role in the regulation of LH release.
Castration decreases mRNA levels encoding glutamic acid decarboxylase (GAD), the rate-limiting enzyme for aminobutyric acid (GABA) biosynthesis, within regions of the brain containing GABAergic cells. Closer examination has revealed that the majority of GAD-labeled cells in the MPOA are coexpressive with the region previously described by Gorski and colleagues as the SDN-MPOA. The objective of the present study was to examine the effects of castration on expression of GAD mRNA specifically within this highly stereotyped-sensitive area of the brain. Brain sections from 2-6x6 mm blocks were taken from anesthetized rats, and 48 hours postcastration examined by confocal microscopy to evaluate GAD mRNA content, in an attempt to determine if GAD is upregulated in the absence of testosterone. We observed that the expression of GAD mRNA increased significantly in the PVN of castrated rats compared to controls. In the MPOA, no significant change was observed in GAD mRNA expression. We have concluded that the increased expression of GAD mRNA in the PVN is a result of castration, and that this may be due to the loss of inhibitory effects of testosterone on GAD mRNA expression. These findings have implications for understanding the mechanisms underlying the regulation of GABAergic neurotransmission in the brain. Further studies are required to determine the precise role of GAD in regulating GABAergic activity in these regions, and to identify potential therapeutic targets for the treatment of disorders involving GABAergic dysfunction.
388.5 SYNAPTIC BURST ACTIVITY IN HYPOTHALAMIC NEURAL NETWORKS. W. Muller* and D. Swadulla MPI biophysics. Chemie, D-37077 Goettingen and Pharmakol. Institut, Universitaetsstr. 22, D-39106 Erlangen, FRG.

Burst activity is important for the release of hormones from central neurons. In dissitributed (picrotoxin 20 μM) networks of hypothalamic neurons in culture, neurons exhibit 'rhythmic' burst activity that is blocked by the glutamate receptor antagonist CNQX (10 μM; D-cyclohexyl-2-amino-2-phenylglycine 2.3-μM). Using Ca2+ imaging on Fura-2/AM loaded cultures and patch clamp techniques we found synchronous increases in [Ca2+]i in a large majority of neurons (>85%) that corresponded to bursting activity recorded from a single neuron. In 20 μM CNQX, none of the neurons showed oscillations in [Ca2+]i.

In mammals corticotropin-releasing factor (CRF) regulates the pituitary release of adrenocorticotropic hormone (ACTH). In teleosts CRF is also thought to stimulate the release of ACTH, but in addition, seems to be involved in the regulation of immune activity. We localized CRF-like immunoreactivity in the brain and pituitary of hatchery-reared juvenile, 12 to 15 months, chinook salmon (Onchorhynchus tshawytscha). Fish were perfused with Bouin's fixative (10%) Submammary, brains from fore and sections at 30 microns were then incubated with polyclonal CRF antiserum for 48 h. Incubation for less than 48 h resulted in little or no staining. Precipitation of the antibody with CRF eliminated all observed staining.

388.7 cFOS AND cJUN ARE EXPRESSED IN CULTURED HYPOTHALAMIC TRH NEURONAL SYNTHESIZING NETWORKS BY GLUCOCORTICOIDS. L.G. Low and J.M.D. Jackman.* Division of Endocrinology Brown University, Rhode Island Hospital, Providence, RI 02903.

There is evidence that glucocorticoids (GC) regulate the hypothalamic-pituitary-thyroid axis. Although GC have been reported to reduce proTRH mRNA levels in the thyrotrpic area of the hypothalamus in vivo, it has not previously been feasible to determine the direct effect on hypothalamic TRH neurons in vitro. Accordingly, we have studied the effect of GC on proTRH mRNA levels in hypothalamic cultures (Jackman MD et al., 1994) and the possible involvement of the protooncogenes c-fos and c-jun in this process. A non-isotopic double label in situ hybridization histochemistry method was used to examine the possibility of colocalization of TRH with c-fos and c-jun mRNAs. We demonstrated that the mRNA for TRH is coexpressed with both c-jun and c-fos in hypothalamic cells. Treatment with dexamethasone (Dex) enhanced the cell signal for both TRH and c-fos/c-jun, and also increased the number of cells coexpressing their mRNAs. Following the use of Image Analysis, Dex 10-8M enhanced mRNA of TRH 133% (p<0.01; n=6), c-jun 131% (p<0.01; n=6) and c-fos 148% (p<0.01; n=6). We also applied 32-P-labeled RNA Blotting and Image Analysis to measure the steady state levels of c-fos and TRH mRNA. The data revealed an enhanced expression of c-fos 3.1 fold, c-jun 4.2 fold and proTRH 3 fold (n = 4, p<0.01). Nuclear run-on analysis of transcription was performed to measure the effect of Dex. The results showed that Dex 10-8M increased the transcription activity of c-fos 3.4 fold, c-jun 5 fold and proTRH 7.7 fold (n = 3, P<0.01). Conclusion: 1. Dex enhances the expression of proTRH mRNA as well as c-fos/c-jun mRNAs in hypothalamic neurons in vitro. 2. Dexamethasone increases the transcription activity of c-fos, c-jun and proTRH in hypothalamic in vitro. 3. The existence of c-fos/c-jun in TRH neurons and the increase of their transcription activity by Dex suggests that these protooncogenes may mediate the effect of glucocorticoids on TRH gene transcription.

The macrophage, a critical component of the immune response, is profoundly affected by stress. We have previously reported stress-induced interleukin 1 (IL-1), prostaglandin (PGE2), and Ig antigen alterations (Jiang, et al., 1990). We now report findings for increased interleukin 6 (IL-6) and tumor necrosis factor (TNFα) following exposure to stress (p<0.05, p<0.01, respectively). In addition, preliminary data show increased specific binding (Bmax) and/or increased binding affinity (Kd) for substance P (SP) to the peritoneal macrophages from stressed mice. The stress paradigm for all work involved subjecting male C57Bl/J6 mice to 5-minute swim tests in 10°C (+/−2°C) water twice daily for 4 days. Cytokine concentrations were determined by ELISA, and SP binding was assessed with fluorescein- and 125I-labeled SP. Specificity and affinity were determined by competitive displacement with unlabeled SP. Results from this work, together with recent findings for stress-induced increases in immunoreactive SP in the peritoneal wash fluid, suggest that perhaps SP interacts with cell-surface receptors to mediate the various functional alterations in macrophages following stress.

Exposure to inescapable tail shock (IS) results in decreases in anti-KLH Ig. The mechanisms responsible for this change are not well understood. The following studies assess the possible involvement of a putative endogenous antinociceptive benzodiazepine ligand in modulating IS-induced suppression of anti-KLH Ig.

Naturally occurring compounds (e.g. diazepam binding inhibitor, DBI) have been shown to increase immunosuppression and bind to both the central-type (CBR) and, the peripheral-type (PBR) benzodiazepine binding sites, & modulate the immune system. We examined the effect of CBR & PBR blockade during IS on the IS-induced reductions in anti-KLH Ig. Rats (13g) were immunized with KLH (200µg) i.p., injected with either RO15-1788 (RO 10 mg/kg; CBR antagonist) or PK1195 (PK 8 µg/kg; PBR antagonist) & exposed to 100 ± 6.6 mV of IS or returned to their home cages (HC). anti-KLH IgG levels were measured using ELISA. RO did not block the IS-induced decrease in anti-KLH IgGs, whereas PK did. Since prior work has suggested that glucocorticoids may play a role, we blocked IS-induced suppression with a CBR antagonist (RO15-1788). We found that IS-exposed rats had lower levels of anti-KLH Ig, compared to IS-exposed + RO15-1788. These results suggest that the IS-induced decrease in anti-KLH Ig may be mediated by the CBR system.

Stressors can result in changes in immune function. Exposure to inescapable tail shock (IS) results in long-term decreases in anti-KLH IgGs. The mechanisms responsible for this change are not understood, but evidence suggests an involvement of altered T cell subpopulations. The following studies examined these earlier observations. Rats were immunized with KLH (200µg IP) and exposed to IS (n = 6) or returned in their home cages (n = 6). Lymphocytes from the mesenteric lymph node (MLN), cerebral lymph node (CN) and spleen (SPL) were obtained 48, 72, 96, and 168 hrs after IS termination. The percent of CCR+. TCD4+, CCR+. TCD8+, CD45RC-. CD4+ (Th1-like) and CD45RC+. CD4+ (Th2-like) lymphocytes were assessed at each time point for each tissue using two color flow cytometry. The number of KLH specific splenic B cells was also measured 7 days (168 hrs) after KLH+IS using ELISPOT. IS resulted in a complex pattern of changes. The greatest shifts occurred immediately after IS + KLH and 96 hrs (4 days) after IS + KLH. IS resulted in an increase in CD4+ T cells and Th1-like cells per gram of wet tissue only in the spleen. Four days after IS + KLH, there was a decrease in Th1-like MS cells and an increase in Th2-like MS cells. Seven days after IS + KLH there was a reduction in the number of KLH specific splenic B cells. These changes in T cell phenotypes could be involved in causing the IS-produced reduction in the formation of KLH specific B cells and alterations in immunoglobulin levels and isotypes (IgG1 & IgG2). NIH-MH54954

Inescapable tail shock (IS) suppresses IgG response to KLH. Evident suggests that alterations in early processing events such as antigen transport & processing by macrophages may be involved. Someors can alter Ms function & can make Ms suppressive. The following studies examined the role of Ms in stress-induced decreases in anti-KLH IgGs. First, stress-induced changes in Ms numbers were investigated immediately after IS + KLH in the peritonal cavity, the mesenteric lymph nodes (MS), cervical lymph nodes (CN), & the spleen (SPL). Cells were labeled with anti-ED1 (Ms specific antibodies) & anti-CD11c (a anti-CD11c) followed by a second color flow cytometry. IS decreased ED1+ peritoneal cell number & ED1+ splenic cell number immediately after IS + KLH. In contrast, the number of ED1+ cells in both MS & CN increased after IS + KLH. If the number of IS+ED1+ cells reflects an increase in a suppressive Ms population, then inhibition of these cells should result in a potential increase in immune system function. Anti-CD11c (a) (12g) were injected intraperitoneally (IP) with either gandoline chloride (GdC3; 7.5 mg/kg, a phagocyte inhibitor), or saline. Twenty-four or 72 hrs after GdC3, rats were immunized with KLH (200µg) either IP, which includes the draining nodes (MS), or intravenously (IV), which bypasses the draining nodes. The Ig response to KLH, measured using ELISA, was found to be enhanced in IP immunized rats both 24 hrs & 72 hrs after GdC3. In contrast, GdC3 had no effect in IV immunized rats 24 hrs after GdC3, & slightly suppressed the Ig response in these rats 72 hrs after GdC3. It appears, therefore, that Ms can have a suppressive effect on Ig production in response to IP KLH & that IS-induced decreases in anti-KLH Ig production may be due to increased suppressive Ms in the MS. The importance of IS-induced decreases in peritoneal and SPL Ms is currently being investigated. NIH-MH540545.

389.8 CONDITIONED STRESS-INDUCED ALTERATIONS IN IMMUNE FUNCTION IN LACTATING RATS. N. Shapiro*, M.A. Porzene, G.D. Hoffman, B.S. Rabin. Deps. of Clinical Immunopathology & Neurobiology, University of Pittsburgh Med. Center, Pittsburgh, PA Stress-induced CNS and leukocyte alterations are increased in lactating females. We determined whether lactating rats were similarly resistant to stress-induced alterations in immune function. Sprague Dawley female rats were exposed to either 2 sessions of 16 footshocks (1.6 mA, 5 sec) where shock was paired with a tone (C+), or were left undisturbed in their homecages (HC). Half of the rats were bred and on day 10 of lactation half the C+ rats were exposed to the same footshocks, but shock was withheld (C−C+), while the other half were left undisturbed (C−HC). Diestrous rats received identical stress treatments as did lactating rats (L). Exposure to these treatments resulted in increased levels of plasma corticosterone (6.8-8.3 µg/dL). Stress levels were elevated in both C+ groups immediately following re-exposure, but C−C+ exhibited lower levels of steroid (34.8 µg/dL) than C−HC (50.1 µg/dL). Spleenocyte xTCR stimulated proliferation was suppressed in C−HC, but remained at nonstress levels in C−C+. Whole blood mitogen responses (PHA, ConA) were suppressed following conditioned stress, but LPS stimulated proliferation was enhanced in both C−HC and C−C+. Mesenteric lymph node (MLN) lymphocyte proliferation stimulated with anti-T cell receptor antibody (aTcR) or ConA was enhanced in C−HC, while this effect was less noticeable in C−C+. These data suggest that lactating rats are resistant to stress-induced suppression of splenocyte proliferation, as these alterations to blood lymphocyte immune function as are NLC controls, and exhibit greater stress-related enhancement of MLN proliferation.

MONOAMINERGIC, NEUROENDOCRINE AND IMMUNE RESPONSES TO STRESS: THE INFLUENCE OF LATERALIZATION. C. Deluze, B. Delpeigne, J.A. Antelis, L. Bouyer, S. Gessert

Stress responses including modifications of immune reactivity, neuro-endocrine functions, and brain functioning were hypothesized to depend on lateralization. To answer this question, we studied the stress responses in mice selected as left- and right-handers in a paw preference test.

First, restraint stress, known to affect immune reactivity, induced modifications in the mesolimbic dopaminergic (DA) system which are asymmetrically expressed and are related to behavioral lateralization. Indeed, the asymmetry of DA metabolism in the nucleus accumbens observed in left-handers correlated with paw preference scores, disappeared after stress. Conversely, an asymmetry in DA metabolism in the frontal cortex, appeared in stressed animals.

Second, the injection of lipopolysaccharide (LPS) is usually followed by a decrease in T-lymphocyte proliferation, an increase in ACTH and corticosterone plasma levels and an augmentation in brain monoaminergic metabolism and thus may be considered as a stress inducer. The modifications of brain monoaminergic metabolism were asymmetrically expressed and depend upon behavioral lateralization. Plasma corticosterone was enhanced in both left- and right-handers, but plasma ACTH was increased only in right-handed animals. T-lymphocyte proliferation was depressed only in right-handers.

These results show that an immune challenge, which may be considered as a stressor, induces modifications in the activity of the central nervous system, the HPA axis and the immune system, that depend on brain and behavioral lateralization. Therefore, the bidirectional pathways between the brain and the immune system appear to be subject to lateralization.

ADVERSE EFFECTS OF CHRONIC NICOTINE ON IMMUNE ORGAN ATROPHY IN AN ANIMAL MODEL OF ANOREXIA NERVOSA. A. Chiu, D.M. Anos, H.A. Funk, T.S. Reg* and P.P. Arvidson, Virginia Governor's School for Science & Technology, Hampton, VA 23669; Eastern Virginia Medical School, Norfolk, VA 23501; Veterans Affairs Medical Center, Hampton, VA 23667.

Anorexia nervosa (AN) is an eating disorder associated with excessive activity, weight loss and immunosuppression. Nicotine increases activity, decreases body weight and affects immune function. This investigation determined if nicotine administration affects weight loss and worsens the thymus and spleen atrophy associated with a popular animal model of AN. The model was produced by giving moderately food-deprived rats (1.5-2.5x body food access) free access to running wheels (22.5°/day). Three groups of rats (9-10 rats/group) were injected with either 0, 0.4 or 0.8 mg/kg/day of nicotine (free base; s.c.) for 11 days prior to and throughout the syndrome. Contrary to previous reports, nicotine administration affected weight gain and food intake and rate of weight loss in the model. However, nicotine worsened the thymus atrophy associated with the syndrome. This effect, which was specific to the thymus and did not occur with the spleen, was related to an exacerbation of the relative adrenal hypertrophy that occurs in the syndrome. It is proposed that nicotine stimulates glucocorticoid secretion, which adversely affects the immature T lymphocytes of the thymus but spares the mature lymphocytes of the spleen. These data raise the possibility that, while nicotine may not affect weight loss in AN, it may adversely affect immune function, which is already compromised in the disorder.

389.10

The present study was performed in order to determine whether stress-induced catecholamines release may be correlated with the inhibition of influenza virus-specific (and/or poliovirus-specific) immune responses and specific-induced lymphoproliferation. Unconditioned Thoroughbreds were subjected to sham, psychological or various intensities of exercise stress. Jugular blood was collected at four different time points, before and during each stress test. Triglyceride cultures of 2x10° peripheral blood mononuclear cells were incubated at 39°C with control medium and with various concentrations of norepinephrine and epinephrine. Mitogen. Proliferation was measured by incorporation of tritiated thymidine incorporated into days 0 and 7. Blood samples obtained at the aforementioned 4 time points were also assayed for catecholamines using high performance liquid chromatography. Non-specific lymphoproliferation was significantly decreased during slow or exercise stress. Specific lymphoproliferation declined (P < 0.05) in all but the sham stress test and was increased (P < 0.05) at the end of psychological stress. Circulating concentrations of norepinephrine and epinephrine were increased (P < 0.05) by all stress tests. Thus, stress-induced changes in lymphoproliferation were not related to increased catecholamine concentrations that resulted from psychological and physical stressors.

IMMUNOSUPPRESSIVE TREATMENT RESTORES EXPLORATORY BEHAVIOR IN AUTOIMMUNE MRL-lpr MICE. Boris Šakić*, Henry Szechtman and Judith A. Denburg. Deps. of Biomedical Sciences and Medicine, McMaster Univ., Hamilton, Canada L8N 3S5.

Various behavioral deficits of unknown etiology accompany systemic autoimmune diseases in humans. Autoimmune MRL-lpr mice show a variety of behavioral deficits in comparison to undiseased age-matched controls. This report describes an animal model of behavioral dysfunction in autoimmune disease. We have recently observed impaired exploration of a novel object in the MRL-lpr group. Moreover, this behavioral deficit significantly correlated with high serum autoantibody titers (a reliable symptom of autoimmunity). In the present study we test the relationship between exploratory behavior and autoimmunity by treating young MRL-lpr and MRL lpr/+ mice for 6 weeks with immunosuppressive drug, cyclophosphamide (100 mg/kg/week, i.p.). It was expected that such a treatment would prevent development of autoimmune symptoms and restore normal exploratory behavior in MRL-lpr mice. Indeed, chronic immunosuppressive treatment almost completely abolished the onset of autoimmune disease and increased the duration of novel object exploration in the MRL-lpr group. Thus, in MRL-lpr mice there may be a causal relationship between autoimmune factor(s) and impaired exploration of novel objects. (IBS is a OMH Postdoctorate Fellow; supported by funds from NERSC)
389.15 INTERLEUKIN-1 INHIBITS SEXUAL BEHAVIOR OF FEMALE BUT NOT MALE RATS. B. Yirmiya*, R. Avissar, O. Donchin, and E. Cohen; Department of Psychology, Bar-Ilan University of Jerusalem, Mount Scopus, Jerusalem 91505, Israel.

In response to infection and injury, a variety of cells release the cytokine interleukin-1 (IL-1), which produces immunologic and neuroendocrine behavioral effects. The present study examined the hypothesis that the previously reported suppressive effects of IL-1 on reproductive hormones and goal-directed activity are also associated with decreased inhibition of sexual behavior. The effects of IL-1 on sexual motivation and sexual receptivity in female rats were examined using the partner preference (PP) paradigm and the last of lusotus questionnaire. The effects of peripheral (i.p.) administration of IL-1 were examined after the sexual phase of intact cycling females. Administration of IL-1, at a dose of either 2 or 10 μg/kg, significantly decreased copulation (soliciting) and receptive behaviors. The suppression of sexual behavorination was further demonstrated in ovariectomized rats, following hormonal induction of estrus: IL-1 (2 μg/kg) injected 2 hr before testing significantly decreased PP scores as well as copulatory and receptive behaviors. Intracerebroventricular administration of IL-1 (10 ng/rat) suppressed PP scores and copulatory behavior in intact cycling females. The effects of IL-1 on male sexual motivation and performance were assessed using the PP paradigm and by counting the number of mounts, intromissions and ejaculations during a 15 min testing period. IL-1 had no effect on any component of male sexual behavior. The inhibition of female sexual behavior by IL-1 may be an adaptive mechanism, which prevents conception during an infection and therefore reduces the risk of prenatal infection.

Interferons are known to be antiviral and are up-regulated in lupus-like autoimmune diseases such as that seen in NZB x NZW F1 (B/W) hybrid mice. This study focused on the role of interferon-alpha (IFN-α) in the behavioral abnormalities seen in these mice by examining brain from female B/W mice for IFN-α mRNA. Using reverse transcription followed by polymerase chain reaction amplification (RT-PCR), IFN-α was detected in brains both before and after the onset of severe immunologic abnormalities (12 and 24 weeks). In situ RT-PCR was used to localize specific brain regions producing IFN-α. Following fixation and paraffin embedding, brains of 12 week old mice were sectioned in the sagittal plane, cryoprepared to permeabilize membranes and DNAase to destroy genomic DNA. mRNA was converted to cDNA in an RT reaction and IFN-α cDNA was amplified by PCR. A digoxigenin-labelled nucleotide was incorporated into the amplified product and detected immunocytochemically. Negative and positive controls were run with each sample. Positive signal for IFN-α mRNA was found in middle layers of the cerebral cortex, and extending along most of the anterior-posterior axis. Signal was seen in membranes surrounding the brain and in occasional cells throughout the CNS. Dysmorphology of the cerebellum was also apparent. To determine the specificity of this pattern of signal, brains of mice injected with the IFN inducer Poly IC were examined. These mice displayed IFN-α mRNA signal in neurons throughout the brain. Thus, it appears that the in situ RT-PCR technique is sensitive and specific. The production of IFN-α mRNA in the CNS may explain some of the behavioral alterations in autoimmune mice. Supported by MH49043, MH10643, MH15442 and HD04024 and by the Developmental Psychology Endowment fund of the Department of Psychiatry.

Stress is a complex phenomenon involving a highly coordinated activation of the endocrine, immune and central nervous systems. We have reported the central pattern of c-fos expression induced by intermittent footshock and the activation of central c-fos expression system suggests that the psychological dimension of footshock may be an important component in stressor c-fos expression. We have assessed the ability of conditioned fear to induce c-fos expression in the brain and to alter immune activity in male, B6D2F1 rats. Rats were given three sessions of intermittent footshock (UCS) with a tone as the conditioning stimulus (CS). A week later, animals were either re-exposed to the CS (cCS) and immediately sacrificed or not exposed to the tone (CS-). We found that footshock induced c-fos expression can be classically conditioned and that the cCS animals were immunosuppressed, relative to the CS- group. The conditioned expression occurred in the same brain regions observed following the UCS, whereas the cCS group showed minimal brain c-fos expression. Conditioned immune effects were also found in that the cCS group had significantly enhanced splenic NK cell activity, relative to CS animals. Splenect and blood cell lymphoproliferative responses to mitogen were also elevated in the cCS, relative to the CS group, thus conditioned fear can induce c-fos expression in a distinct central circuit as well as produce an immunomodulation. Presently, we are investigating the relationship between the strength of the conditioned response and the immune alterations observed during c-fos expression and the concomitant effects of conditioned fear on central c-fos expression and immune cell activity. Supported by MRC of Canada.

Interleukin (IL)-2 potentiates a variety of immune responses and influences cerebral nervous system activity. We reported that IL-2 induced expression of central monoamine activity that were similar to those provoked by uncontrollable stressors and that IL-2-induced immunomodulatory mechanisms were mediated by hypothalamic-pituitary-adrenal (HPA) systems. In the present study, we determined whether IL-2 would interact with a stressor to alter neuroendocrine and immune activity. BALB/c mice received either Ringer's Solution or IL-2 (200 ng, i.p.) and were immediately exposed to a novel environment for 0, 30 or 60 minutes. Seven fold elevations of plasma corticosterone concentrations were evident in IL-2 treated mice exposed to the stressor for 50 or 60 minutes compared with those measured immediately after IL-2 injection. These elevations were significantly greater than those observed in vehicle-treated animals exposed to the stressor for comparable periods. Corticosterone levels did not differ among vehicle and IL-2 treated mice that were returned to their home cages for 0, 30 or 60 minutes following injection. IL-2 also potentiated corticosterone elevations following exposure to restraint stress. Mice received vehicle or IL-2 were either not stressed or were immediately restrained for 30 minutes. Corticosterone levels were determined 0, 30 or 60 minutes after stressor termination. In vehicle-treated mice, levels were significantly increased immediately following restraint but returned to control levels within 30 minutes of stressor termination. In IL-2 treated mice, corticosterone levels were markedly elevated 0 and 30 minutes after stressor termination and returned to non-stress levels within 60 minutes of stressor termination. Additionally, the enhancing effects of IL-2 on an antigen-specific IgM PFC response were not evident in mice exposed to a mild stressor immediately after IL-2 administration. This treatment also resulted in a suppression of splenic T Cell proliferation and IL-2 production that was similar in magnitude and duration to that seen in mice exposed to restraint stress. It is suggested that neuroendocrine and immune consequences of a lymphokine (i.e. IL-2) are influenced by the stressor background on which it is superimposed. Supported by NIMH, MRC of Canada.

389.20 TO THE MECHANISMS OF PRENATAL EPYGENIC TRANSFER OF MATERNAL "ANTI-BRAIN" AUTOIMMUNE. N.K. Yabl- 

THEMECHIYCH,* A.R. Polataiev. Chernobyl-Test Ctr., Mosco-

cow, Russia.

Transfer of the specific autoimmune reactions from a mother, to her child (described earlier) is probably connected with an appearance of some effects of the nervous system. It is necessary to know the mechanisms that allow maternal immune system to play a "matrix" role in the immune peculiarities of a child. It can be supposed that the modulation of the maternal autoimmunity of female offspring of child lymphocytes (LC) by the maternal AB: (2) the "transplacental" activation of the immune system of child lymphocytes (LC) expressing autoantigens (autoimmune phenomena); (3) the maternal transmission of the immunosuppressive effect of the maternal LC (including memory cells); (4) the transfer of the maternal maternalization of the long (for years) persistence in a child. In expansion of this hypothesis (passively or actively immunized by the S100 proteins during pregnancy), the "mirror" phenomenon of the maternal AB is one of the explanations for the hypothesis (1) is groundless. In opposite real evidences for hypotumia (2) and (3) were receiv-

ed. Thus, the theory is probably based on the combination of the maternal maternalization of the child's autoimmune mechanisms and a direct transfer of the maternal maternalization of the LC with their subsequent persistence in a child.

Several lines of evidence indicate that surgical sterilization for breast cancer during the first half of their menstrual cycle show a 3-fold increase in metastatic growth. We present evidence in rats in support of the hypothesis that this phenomenon is attributable to metabolic development that is induced by the surgical procedure. The effect is also illustrated by elevated estradiol/low progesterone levels at the time of surgery. Suppression of innate immunity is suggested to underlie the increased susceptibility to metastasis, rather than a direct effect of sex hormones on the tumor. Syngeneic mammary tumor cells (MB16106) were injected intravenously into pre- and post-PH (control) rats during three different phases of the estrous cycle. The metaphase efficiency of this tumor, which is confirmed here to be highly controlled by natural killer (NK) cell activity, was higher during estrus phases that are hormonally homologous to the high-risk periods in women. Estrogen treatment alone caused similar effects in ovariolesteromized rats and progesterone partially blocked these estradiol effects, whereas neither hormone affected the proliferation rates of the tumor in vivo. The tumoral activity per blood NK cell was diminished during the high-risk estrous phases. These findings indicate an animal model for further studying the clinical phenomenon and suggest hormonal and immunological mechanisms mediating it. SEXUALLY DIMORPHIC EFFECT OF PRENATAL DHEA TREATMENT ON T-CELL FUNCTION. S. G. Shiota, I. Haras and F. Reda* Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104

We have hypothesized that sexual differentiation of the immune function occurs preferentially and is driven by similar events as seen in the sexual differentiation of the brain. Therefore, pregnant dams were treated with different doses of dehydroepiandrosterone (DHEA), a weak androgen, 100 μg/kg drinking water from day 8 of gestation until parturition when DHEA treatment was discontinued. Body weights of young, prepubertal (day 35 of age) male and female pups from the DHEA groups were significantly lower than those of controls, and showed a dose response effect even at this age (control males 133.6±2.6 g; DHEA males (250 ng/ml): 97.4±5.5 g; DHEA males (250 ng/ml): 93.2±2.2 g; DHEA males (250 ng/ml): 114.3±7.5 g; control females: 253.0±25.7 g; DHEA females: 26.2±26.6 g; DHEA females (250 ng/ml): 103.6±30.6 g). In contrast, both absolute thymic weights and thymic weights normalized to body weight were significantly higher in the offspring of the DHEA females (250 ng/ml) compared to those of individual animals representing different litters. There was no significant sex difference in the proliferative response to Con A in the control animals, although control males showed a tendency toward a higher response. Prenatal treatment with DHEA (2.5 mg/ml) significantly reduced proliferation in the male offspring (control: 210,468±53,357 cpm; DHEA: 90,897±2,594 cpm) while DHEA females were not affected significantly and showed an increased response than a diminished response (controls: 150,682±28,818 cpm; DHEA: 220,868±1,21,145 cpm). This data suggest that prenatal DHEA treatment permanently alters thymic function and T-cell dependent functions, particularly in the male offspring.

Glucocorticoids (GCs) are widely used in therapy for their antiinflammatory and immunosuppressive properties but their use in cytokine-related pathologies needs a thorough understanding of their role in modulating cytokine actions. The present study was designed to clarify the effect of GCs on the action of IL-1β on the serotonergic system. Changes in serotonin metabolism (hydroxyindoleacetic acid [SHIAA]) were recorded in freely moving rats by in vivo voltammetry using chronically implanted carbon fiber electrodes in the medial preoptic area (MPA) in the presence of 50 ng/kg DEX (40 μg/ml) induced an increase in 5 hydroxyindoleacetic acid (5-HIAA) levels; a rapid-short, term rise was followed by a lasting increase possibly due to newly synthesized IL-1. The synthetic GC dexamethasone (DEX) increased 5-HIAA levels in MPAs (50 mg/kg sc, 50 min before IL-1β) prevented the effect of IL-1β starting from 150 min, suggesting that it only inhibited the second increase. In adrenalectomized rats IL-1β had no effect but when pretreated with DEX (40 μg/ml) the effect of IL-1β was restored. The GC receptor antagonist RU38486 (25 mg/kg sc, 60 min before IL-1β) completely prevented IL-1β activation of the serotoninergic system. The results indicate that, although GC is effective inhibitors of IL-1 synthesis, their presence is necessary for IL-1β-induced activation of the serotonergic system. Thus GC may allow a number of corticosteroid-mediated actions triggered by IL-1 in the course of inflammation.

We have previously demonstrated significant and selective changes in numbers and percentages of lymphoid subpopulations and leukocyte subpopulations in the rat. These changes were rapidly induced by mild acute stress (2 h restraint), and consisted of a decrease in numbers and percentages of lymphocytes, and an increase in numbers and percentages of neutrophils. B cells, NK cells, and monocytes showed greater stress-induced decrease than T cells. Helper T cell number showed the lowest magnitude of decrease with stress. These stress-induced changes were rapidly reversed upon the cessation of stress.

In the present series of studies we demonstrate that adrenalectomy significantly reduced the magnitude of the stress-induced changes. Furthermore, administration of glucocorticosterone sodium phosphate inhibitor, eliminated the stress-induced changes in PBL. However, catecholamine receptor antagonists (phenolamine [alpha antagonist] and propranolol [beta antagonist]), failed to inhibit the stress-induced changes in PBL. Acute administration of corticosterone to adrenalectomized animals resulted in a close replication of the stress-induced changes observed in adrenal intact animals. Furthermore, acute administration of glucocorticosterone receptor agonists showed that the Type II receptor agonist (RU28362) replicated all the stress-induced changes in PBL (except the decrease in NK cell percentage). The Type I receptor agonist (aldosterone) had no effect. These results suggest that corticosterone is a major mediator of the stress-induced changes in leukocyte distribution. (MH 47674, MacArthur Foundation.)

TYPE II GLUCOCORTICOID RECEPTOR (GR) GENE EXPRESSION PARTICIPATES IN THE DEVELOPMENT OF NEUROENDOCRINE-IMMUNOLOGICAL SEXUAL DIMORPHISM: EFFECT OF ABNORMAL GR FUNCTION IN TRANSGENIC ANIMALS BEARING TYPE II GR ANTISENSE RNA. B. Marchetti*, M.C. Morais and N. Baden. Dept. of Pharmacology, University of Catania, Italy, and Molecular Psychogenetics, CHUL, Quebec, Canada.

Clinical and experimental evidence indicates that gonadal steroids can modulate immunological functions and that a sexual dimorphism exists in the immune response to different xenobiotics in the male and female, however, involved in sex-dependent immune responses are not completely understood. We have recently (Endocrine Journal 2:181, 1993) demonstrated that type II GR gene expression within the thymus is markedly modulated by physiological alterations of the sex steroid hormone milieu. The aim of the present study was to determine the role of type II GR gene expression in the development of neuroendocrine-immunological sexual dimorphism using a transgenic animal model created by partially knocking out gene expression with type II GR antisense RNA. In intact mice, a sexual dimorphism in the post-natal development of type II GR gene expression paralleled the development of sexually dimorphic immune responses, initiating 9 days after birth, reaching a peak of activity at 25 days of age, and declining around puberty. The development of a sex-dependent apoptotic potential after thymocyte treatment in vitro with corticosterone followed a similar pattern. In transgenic animals, the abolishment of a sexual dimorphism of type II GR gene expression was accompanied by a lack of sexually dimorphic immune responses and marked inhibition of the specific suicide program within the thymus, suggesting a key role for type II GR gene expression in the molecular mechanisms underlying the development of sexual dimorphism of immune responses.

The hypothalamus (HYF) and thymus gland (THY) both contain bio- and immunoreactive CRF and CRF mRNA (Redei, 1992; 1993). Hypothalamic secretion of CRF is a well-established final common pathway for direct and indirect immunomodulation, but the role of CRF in THY function is not well understood. We have compared the in vivo release of CRF during a 6 hr perfusion of preoptic area-medial hypothalamic (POA-MH) HYF and the THY, individual POA-MBH and THY were removed from male rats (350-450g) and placed in parallel perfusion chambers containing Earls’ balanced salt solution (pH 7.4) at 37°C. POA-MBH and POA-MBH+HYF were perfused at a rate of 2 μl/min, while the rate of the lobe of the thymus was lowered to 0.2 μl/min. After a 60 min preincubation period, fractions were collected (500x10/10 min) collected over 2 hr for basal release of CRF assessed by RIA (kg 6 g/ml) and after CRF was increased in the medium for a third time during the 90 min. At the end of the incubation each POA-MBH and THY was weighed and assessed for total CRF. As expected there was an 18 fold higher CRF secretion in HYF compared to THY. However, an injection of total secretion using a numerical integration of the release curve (trapezoidal approximation) revealed that total THY secretion was approximately 10 times greater than POA-MBH+HYF. Experimental lesions of the HYF which resulted in THY inhibition and subsequent increased response to inulin stimulus did not result in significant changes in CRF secretion by the thymus. Supported by NIH MH46808.

Numerous studies have reported the production of a variety of neuropeptides or peptide hormones by the immune system. CRF appears to play a role in cell proliferation, differentiation, and function. Recent studies indicate that CRF may also be involved in the regulation of the immune system. In this study, we have investigated the localization of CRF in the primary and secondary lymphatic organs of the rat. We have found that CRF is present in all the lymphatic organs studied, including the thymus, spleen, and lymph nodes. The results of this study suggest that CRF may play a role in the regulation of the immune system.

390.8 IMMUNE AND ENDOCRINE IMPLICATIONS OF LONG-TERM INTRACEREBROVENTRICULAR CORTICOTROPIN-RELEASING HORMONE ADMINISTRATION IN THE RAT. J.H.M. Reul*, M.S. Laberot, G.J. Wingers, E. Arzt and E. Holzbecher, Max Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich, FRG.

The brain, endocrine and immune systems communicate as an integrative network, which is critical for maintaining homeostasis during disease and other stressful situations. To investigate the physiological consequences of chronic hypophalmic-pituitary-adrenocortical (HPA) axis hyperactivity, rats were injected with corticotropin-releasing factor (CRF) for 1 week with CRH via an osmotic minipump and HPA axis and immune system function were studied. As compared to the vehicle, CRH produced elevated a.m. plasma ACTH and corticosterone levels, increased anterior pituitary POMC mRNA expression, thymus involution and adrenal enlargement. Regarding immune function, CRH treatment had markedly different effects on splenocyte proliferation and cytokine expression. Long-term CRH-created rat or rat-derived cells were examined for new responses in situ. Histologically, lymph node and thymus sections revealed no obvious morphological changes. However, chronic CRH exposure resulted in a marked increase in CD4+ and CD8+ T cells in the spleen and thymus. These results suggest that chronic CRH exposure may contribute to the development of chronic immune dysfunction and may have long-term implications for the maintenance of homeostasis.
391.1

EFFECT OF BACTERIAL ENDOTOXIN ON HIPPOCAMPAL AND PREDICTIVE NEUROTRANSMISSION, BODY TEMPERATURE, BEHAVIORAL ACTIVITY AND FREE CORTICOSTERONE LEVELS. A.C.E. Lindorfer*, C. Flachkampf, F. Holzhofer and J.M.H.M. Reul, Max Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich, FRG.

Evidence has accumulated for a bidirectional communication between the central nervous system and the immune system. However, on the level of the brain the mechanisms involved in the processing of signals from the immune system largely remains to be resolved. We started a study on the effects of i.p. lipopolysaccharide (LPS, bacterial endotoxin) administration on hippocampal and preoptic serotonergic and noradrenergic neurotransmission in freely moving rats. In addition, we monitored hypothalamic-pituitary-adrenocortical (HPA) axis activity by measurement of free corticosterone levels in the dialytes. Behavioral activity was scored by measuring the time during which rats were active and body temperature was assessed via biotelemetry. I.p. LPS treatment produced a dose-dependent increase in the extracellular concentrations of serotonin in the hippocampus but not in the preoptic region. In addition, the endotoxin caused a dramatic decrease in preoptic levels of noradrenaline, elevations in body temperature and HPA activity, and a decrease in behavioral activity. We conclude that signals from the immune system exert different effects on brain neurotransmission. These distinct changes in neurotransmitter may be involved in the regulation of specific neuroendocrine, autonomic and behavioral responses after an immune challenge.

(VW grant 1/68 430)

391.2

It has been shown that injection of lipopolysaccharide (LPS), a powerful bacterial endotoxin, results in a dose- and time-dependent expression of the proto-oncogene c-fos in the brain (Wan et al, B.B.K. 1:25; 51993). We have extended these studies and report here on the transmitter specificity of hypothalamic neurons that are activated following LPS injection.

LPS (100 µg) was administered i.v. to male 5-6 d rats. Two hours later the rats were perfused and the brains processed for c-fos immunocytochemistry (rabbit anti-fos, Santa Cruz). Immunocytochemical and histochemical methods showed that many of the c-fos positive neurons were also positive for tyrosine, vasopressin and NADPH-dihydrosaprase (NADPH-d). Double labelled cells were predominantly located in the paraventricular and supraoptic nuclei of the hypothalamus and analysis showed that NADPH-d > OXY = AVP in numbers of c-fos co-localized. Raw cell counts showed that LPS decreased NADPH-d staining, increased OXY, and had no effect on AVP. The LPS-induced changes in NADPH-d suggested a functional role for nitric oxide (NO). Consistent with this finding, preliminary results indicate that inhibition of NO synthase by i.c.v. injection of L-NAME potentiates the induction of c-fos protein by LPS. Supported by KBC and NIMH.

391.3

Centrally administered IL-1 results in a large increase in serum IL-6. However, the role of the brain's role in this response is yet to be characterized. The mechanisms of this induction and the signal conveying the information from the brain to the periphery are not known yet. To help characterize IL-6 pathway of IL-6 induction, IL-6 levels, measured as hybridoma growth factor on 7TD1 cell line, were evaluated in rat serum and cerebrospinal fluid (CSF) at different times after intracerebroventricular endotoxin (LPS, 2.5 µg/rat). In the same experiments, IL-6 mRNA expression, measured by Northern blot analysis, was evaluated in peripheral (in adenals and lymphocytes) and in the brain (in hypothalamus, hippocampus and striatum). In serum, the highest IL-6 levels were reached at t = 2 h after which they rapidly decreased. In the same time-course was showed in IL-6 mRNA in adenals and lymphocytes. A different pattern was present in the central nervous system: the CSF, IL-6 was detectable starting from t = 2 h, reached a plateau at t = 4-8 h and remained detectable until t = 16 h. IL-6 mRNA expression in the brain areas showed a similar time-course, reaching a maximum at t = 4-8 h. The results indicate that IL-6's synthesis is differently regulated in the brain and in the periphery.

391.4

QUINOLIC ACID IMMUNOREACTIVE CELLS IN THE BRAIN AFTER INTRACEREBRAL INJECTION OF LIPOPOLYSACCHARIDE. M.G. Esposito, J.R. Nofflet and M.A. Hannabold*. Georgetown University, Biology Department, Washington, DC 20057-1028.

Quinolic acid (QUIN) is a neuropharmacological tissue metabolite. Antibodies to quinolic acid were used to study its cellular localization in the brain 1 to 30 days after intracerebral injection of lipopolysaccharide (LPS). Quinolic acid immunoreactive (QUIN-IR) cells were observed in numerous regions of the forebrain, corpus callosum, neocortex, meninges and choroid plexus 10h after LPS application. The immunoreactive neurons were larger than lymphocytes, ranged from round to round-shaped in control and increased their number and morphology, and were often observed around the vasculature. The overall number of QUIN-IR cells increased at 48h, and peaked in number at 72h. In saline injected control animals, only rare QUIN-IR cells were observed at 72h surrounding the injection site. The number of QUIN-IR cells was reduced in the peri-injection region by 4 days after LPS injection, but did not return to control levels until 15 to 30 days later. Tissue destruction was observed in the cortex, hippocampus and corpus callosum, and progressed in severity during the days one and four. No clear correlation with QUIN-IR was found with the monoclonal antibodies EN1, ED1, F480, OX34 or OX41. The tissue damage observed around the injection site correlated more closely with a central mass of infiltrating leukocytes than with the separately scattered QUIN-IR cells observed in and around the damaged region. These results suggest that QUIN, derived from a select population of leukocytes, may contribute to some of the secondary neuronal death subsequent to CNS infections.

We propose that QUIN, rather than being simply a neurotrophic byproduct of tryptophan metabolism, may be a cytokine or immune modulator involved in the initial reactions to pathogens.

PROHORMONE CONVERTASES PC2 AND PC1 IN RAT NEUTROPHILS AND MACROPHAGES. A. M. Ballabio, C. Chabot*, C. Cottier, J. A. Spoiler* and E. B. Espinoza*. Dept. of Biochem. and Mol. Biol., Dept. of Physiology and Dept. of Med./Rheumatology. LSU Medical Center, New Orleans, LA 70112.

Prohormone- or proencephalin-converting enzymes PC2 and PC1 have been observed exclusively in cortical and subcortical regions. While the presence of these enzymes in cells of the immune system was demonstrated. PC2 was detected in peripheral and liver-infiltrated polymorphonuclear leukocytes (PMN) but not in alveolar macrophages (AM) or peritoneal mononuclear cells (SMC). PC2 is expressed by circulating PMN in vivo and in vitro but not in PMN, and a 66 kDa protein was the only PC1 form detected. Proenkephalin-derived peptides (PEN2) were observed in PMN. AM, and SMC by peptidase assay. 33, 25, 18, 21, 14 and 13 kDa in the liver cells and a doublet of 35 and 32 kDa in the livers. PC2 and PEN2 increased in liver PMN and peripheral PMN 90 min after intravenous (i.v.) infusion of LPS, suggesting an increased expression. However, in vitro assays showed that the proenkephalin peptide FMRF was not increased the basal secretion of PC2 proteins and PEN2 in PMN. These results indicate that PC2 proteins are released from PMN, together with PEN2, and that LPS in vivo may act through an indirect mechanism. Low levels of PC3 and PEN2 were detected in the am of rats treated for 90 min with SAL or LPS. However, a significant increase of PC3 and PEN2 appeared 30 h after LPS infusion. These results show for the first time that PC2 and PEN2 are differently expressed in PMN and AM, respectively, which were paralleled by the presence of different post-translation products of PENK. In addition, the in vivo effect of LPS on PC2, PEN2 and PEN5 levels in PMN and AM revealed the effect of LPS on proenkephalin levels in endocrine tissues, suggesting that similar mechanisms may control the turnover of PENK in neuroendocrine and in immune cells.

Pikriyova, Jilek and Winiwarter (CRC Press, 1992) described a very comprehensive mathematical model of the immune response to antigen. This model consists of 12 simultaneous first order differential equations and 8 auxiliary equations ("switches"). Eight cell types and 4 molecular messengers are represented. Here we describe an extension of the Pikriyova model which includes for NEI modulation. These equations are derived from our experimental investigation of the adrenal axis response to variable in doses of endotoxin (EN, E, C) to 50 and 100 µg/kg per b.w. administered to male SD rats (50-600 g) 30 min after IP injection of endotoxin. Rats received either saline or EN at the indicated doses and blood was withdrawn at 0, 0.5, 1 and 4 hrs later. Plasma ACTH and corticosterone (C) was assayed by RIA. Relative increase of EN resulted in parallel increased release of B at all intervals. However, ACTH release after 10 µg EN resulted in the greatest (2000) increment from time 0 when compared to other EN treatments. The maximum was only a 3X increase, whereas 50µg resulted in a 10X increase. Inverse changes in ACTH after EN may be explained at the N-P level, whereas the B response may be a direct cytokine effect that controls ACTH release. Overall, the mathematical model of the NEI Axis integrates these and other findings from our experiments to stimulate NEI regulation. Supported by NIH MH48608.

It is generally believed that during a viral infection, cytokines stimulate the release of endogenous adrenal steroids which in turn can feedback inhibit stress on evolving immune responses. Although ample data demonstrates that cytokines stimulate HPA axis activity, few studies have directly examined adrenal steroid secretion during viral infection. Accordingly, we examined steroid secretion at multiple time points in the am and pm of mice infected with lymphocytic choriomeningitis virus (LCMV). Since our previous studies have indicated that adrenal steroid secretion levels are similar between infected and control animals, we examined corticosterone levels at the receptor level, we also measured cytotoxic type II adrenal steroid (glucocorticoid) receptor binding in immune tissues. LCMV-infected mice exhibited modest elevations in corticosterone secretion on Days 3 through 7 post infection. In corticosterone values were greater than am values in all cases. Cytotoxic type II receptor binding in spleen and thymus of LCMV-infected animals was significantly decreased in the pm compared to non-infected animals, indicating that infection-induced increases in corticosterone in the pm were activating receptors in these tissues. Interestingly, however, significant decreases in cytotoxic type II receptors were also observed in the am of spleen of infected mice. These receptor decreases occurred in the absence of marked elevations in corticosterone and suggest that local factors (eg cytokines) elaborated during the immune response to LCMV may directly influence adrenal steroid receptor expression. Our studies on the interferon inducer, poly I:C, indicate that interferons may mediate these adrenal steroid-immune interactions in LCMV infection by augmenting corticosterone production and receptor expression in the presence or absence of hormone. Supported by MH41764 and MacArthur Foundation.

391.8 IMMUNE CELLS MEDIATE CHROMAFFIN AND SYMPATHETIC GANGLION CELL CATECHOLAMINE SECRETION. S.Jones, R. Litwin, J. Pintner1, J. Roberts, J. Walter1, and P. DaPoletto. Loyola Med. Center and Hines VA hospital, Maywood IL, Univ. Health Sci./The Chicago Med School (Mt. Sinai Hospital USA and Neuropharmacology, Univ Antwerp, Belgium).

Cytokines, such as tumour necrosis factor (TNF) and interferon-gamma (IFN-gamma) are secreted by activated T cells in response to mononuclear cell conditioned media (Life Sci.33,447-451) suggests that immune cells may mediate stress hormone secretion. In the present study, porcine chromaffin (C) and ganglion (G) cells were used to test the possibility that porcine cytokines and bovine immune cells could stimulate secretion. Blood, spleen, adrenal and superior cervical ganglion were obtained from local slaughter houses. Mononuclear cells isolated from blood or spleen were incubated (37°C) overnight in RPMI media without serum; cells were removed and conditioned media (CM) frozen and kept at -20°C. Purified C and G cells were isolated using collagenase and maintained in culture at 37°C. Secretion experiments were performed with 5:7-days for C (cultured in DMEM/F12, 10% FBS) and at 4 days for G (cultured in F12, 5% Horse serum). For secretion experiments, growth media was replaced with CM or control RPMI for 90 min, at 37°C. For C, Epiphrine released into conditioned media was measured by HPLC while G secretion involved assessment of preformed 5HT. Secrecy in response to CM is expressed as % of total cell content.

Recently we demonstrated that primary immunization with sheep red blood cells (SRBC) decreases hypothalamic and cortical serotonin (5-HT) levels in F344 rats while increasing extracellular 5-HT levels (Dardier et al., Brain Res., 1994). Pretreatment with an immunosuppressive drug, cyclophosphamine prevented these effects suggesting that a T lymphocyte product, but not a macrophagic one, may be involved in this serotonergic activation induced by SRBC. In the interleukin-6 (-IL-6) drug might be a good candidate for being a link between the immune system and the serotoninergic system. To characterize further this hypothesis, we have investigated the effects of keyhole limpet hemocyanin (KLH, 200 µg i.p.) on both hypothalamic IL-6 levels and the hypothalamic-pituitary-adrenal (HPA) response (plasma ACTH and corticosterone concentrations). The presence of specific antibodies for KLH (IgM) in the serum was also assayed by using an ELISA method at 3, 4 and 5 days following KLH injection. The hypothalamic IL-6 level significantly decreased by -26% (p<0.05) while IL-6A-IIA levels increased by +43% (p<0.01) while IL-6 levels increased as compared to controls 4 days following the primary immunologic response to KLH. In the cortex and hippocampus, no changes were observed in the serotonergic markers studied. Antibodies directed to KLH were present since Day 3 following KLH injection. Plasma ACTH levels in KLH treated rats were higher than responses in controls at all points, while corticosterone levels were peaked at Day 4 post-immunization. This data confirms our previous report showing that long-lasting changes occur in the hypothalamus as well as in the HPA axis when the production of specific antibodies is maximal following primary immunization.

391.10 N-2-HYDROXYETHYL)HEXADECANAMIDE IMPROVES NEUROLOGICAL DEFICITS ACCOMPANYING EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS IN RATS. A. Lom1, R. Carrella, and S. Mazzari. Researche S.C.P.A., Centro di Ricerca Biomedica, Ospedale Civile, 31033 Castelfranco Veneto, Italy.

Mac cells (MCS) present in the normal CNS have been proposed to regulate interactions between the immune and nervous systems. In addition, it has been suggested that MCS are involved in the pathogenesis of experimental allergic encephalomyelitis (EAE). Recently, the endogenous N-Acylamide N-2-hydroxyethyl)hexadecanamide, has been proposed to behave as a local autacoid or a mediator capable of negatively modulating CNS activation. In agreement with this concept, treatment of the animals (ALX) with N-2-hydroxyethyl)hexadecanamide (LG 21101) prevents MC-dependent edema formation and substance P-induced MC activation in the mouse ear pinna (Mazzari et al., this meeting). Here we have evaluated the effect of MC modulation by LG 21101 in the development/progression of EAE in B10.PL mice after immunization with I-A-n Cad, the Thy1.1-tergulated, acetylated peptide of mouse myelin basic protein (Rajewski et al., Science 250, 1213, 199). After treatment with LG 4.0 (10 mg/kg) given beginning on the day of immunization delayed the onset (6 day post-immunization) as well as the frequency of animals displaying the neurological syndrome. In addition, when treated was begun on day 4 post-immunization (F1), LG 21101 significantly reduced the severity of EAE. The exogenous N-Acylamide alleviated the clinical scores at day 8 P.I. up to day 31 P.I. (p< 0.05 versus vehicle, n = 19-20). These findings not only support a physiological role for N-2-hydroxyethyl)hexadecanamide, but also suggest that this type of molecule may represent a novel therapeutic approach to the management of inflammatory conditions of the nervous system modulated by MCS, including autoimmune CNS diseases.

391.11 THE CD4 CORECEPTOR MEDIATES EFFICACY OF T CELL ANTIGEN RECEPTOR INTERACTIONS WITH AUTOLOGOUS MYELIN BASIC PROTEIN. M.D. Mannpie1 and G. White. Department of Microbiology and Immunology, East Carolina University School of Medicine, Greenville NC 27834-4534.

Guinea pig (GP) myelin basic protein (MBP) is approximately 100-fold more active than rat (R) MBP as measured by induction of experimental autoimmune encephalomyelitis (EAE) in Lewis rats. A Ser for Thr substitution at position 80 comprises the distinguishing structural difference between the antigenic regions of GMPB and RMBP, respectively. To test whether the CD4 co-receptor has a differential role in T cell responses to these two proteins, we measured the inhibitory effect of the anti CD4 antibody W3/25 on in-vitro proliferative responses of MBP-specific T cell lines. W3/25 only partially inhibited proliferative responses to GMPB but fully inhibited the response to RMBP. This differential susceptibility to the inhibitory effects of W3/25 was observed across broad concentration range of antibody and antigen as well as across a broad range of T cell densities. T cell subpopulations or downregulating the CD4 expressed responses to GMPB but did not respond to RMBP. These results suggest that the response to autologous RMBP, unlike GMPB, is completely dependent upon CD4. In addition, T cell proliferative responses to GMPB that were obtained in the presence of W3/25 were fully antagonized in a concentration dependent manner by RMBP. These results indicate that MBP is a specific antigenic when CD4 is neutralized by an anti-CD4 monoclonal antibody. This work was supported by a grant from the National Multiple Sclerosis Society.

In situ hybridization of 35S-labeled cRNA probes was used to investigate the distribution of cDNAs encoding human p60 and p80 subtypes of the tumor necrosis factor receptor (TNF-R) in normal and herpes simplex virus (HSV) infected trigeminal ganglia in the mouse. Riboprobes were derived from previously described human equivalent length cDNA species provided by Immunex Corporation. Trigeminal ganglia were infected via cerebrocortical inoculation using a McKrae strain of HSV three days prior to analysis. In situ hybridization produced a moderately intense autoradiographic signal over subgroups of neurons and neuroglial cells in both normal and HSV infected ganglia. In general, the signal intensity and the moderately characterized neuronal labeling within trigeminal ganglia did not change in response to acute HSV infection. However, infection was accompanied by an intense white blood cell infiltrate, and many of these non-resident cells did display signal for both TNF-R subtypes. Signal over control sections hybridized with sense p60 and p80 TNF-R cRNA was comparable to background. The presence of TNF-R mRNA over neurons and astrocytes in the HSV infected trigeminal ganglia suggests a role for TNF in normal trigeminal functioning, and supports studies implicating TNF in the pathogenesis of immune-mediated peripheral neuropathies.

13.11 ISOLATION OF C1q PROTEIN FROM RAT BRAIN FOLLOWING INJURY
Departments of Pathological Sciences, Elzeo Andrus Gerontology Center, South Calif., Los Angeles, CA 90089.

There is increasing evidence for a role of complement (C) components in the neurodegenerative process. The presence of activated C is associated with senile plaques and neurofibrillary tangles (Ekenboom et al., 1992). In this laboratory, we have been developing a model of acute brain injury in the rat. Following trauma, we find a distinct metabolic activation of complement components in the injured brain (Johnson et al., 1992; Lampert-Echterns et al., 1993). Animal studies showed an increase in C3 in CRH after systemic calcium (Ca) or saline injections (Piasnetti et al., 1993; Johnson et al., 1992). Although CRH is not always accompanied by an increased translation of protein in brain or spinal cord, these complement studies provide evidence that CRH activates the complement system in brain. The present studies utilized protein chromatography and Western blots to identify CRH protein increases in brain after injury. Animal findings are consistent with the hypothesis that complement activation may be an important mediator of brain injury.

13.12 NEURAL-IMMUNE INTERACTIONS: RESPONSES TO IMMUNOLOGIC CHALLENGE
Department of Microbiology and Immunology, The University of Connecticut Health Center, Farmington, CT 06030.

The brain is considered an immunologically privileged site due to the blood-brain barrier (BBB). However, this barrier has been shown to be permeable to a variety of materials under certain conditions. The BBB may contribute to the development and progression of disease through the transport of effector molecules from the systemic circulation to the brain and vice versa. In this study, we investigated the effects of immune system activation on BBB permeability using the experimental autoimmune encephalomyelitis (EAE) model. EAE is an autoimmune disease of the CNS that is induced by injection of CNS antigens into susceptible animals. In this study, we used the Lewis rat model of EAE, which develops a chronic inflammatory response in the CNS after immunization with myelin basic protein (MBP).

13.13 RECRUITMENT OF MAST CELLS INTO THE CNS DURING DEVELOPMENT AND RESPONSE TO INFECTION IN THE MICE
Department of Neurology, Tufts University School of Medicine, Boston, MA 02111.

Mast cells are a type of innate immune cell that are distributed throughout the body and play a key role in inflammatory responses. In the central nervous system (CNS), mast cells are found in the meninges, blood-brain barrier (BBB), and peripheral nerves. Mast cell activation results in the release of histamine, tryptase, and other mediators that contribute to the inflammatory response. In this study, we investigated the recruitment of mast cells into the developing and adult CNS using intravital microscopy. We found that mast cells are recruited into the CNS during development and that their numbers increase following CNS injury. These findings have implications for understanding the role of mast cells in neurological diseases.

13.14 NERVE GROWTH FACTOR IMMUNOREACTIVE MAST CELLS IN HUMAN PERIPHERAL NERVE
Department of Neurology, Tufts University School of Medicine, Boston, MA 02111.

Mast cells are a type of innate immune cell that are distributed throughout the body and play a key role in inflammatory responses. In the central nervous system (CNS), mast cells are found in the meninges, blood-brain barrier (BBB), and peripheral nerves. Mast cell activation results in the release of histamine, tryptase, and other mediators that contribute to the inflammatory response. In this study, we investigated the recruitment of mast cells into the developing and adult CNS using intravital microscopy. We found that mast cells are recruited into the CNS during development and that their numbers increase following CNS injury. These findings have implications for understanding the role of mast cells in neurological diseases.

ACTIVATION OF THE BLOOD COMPLEMENT SYSTEM IN THE HUMAN SUBARACHNOID SPACE P.J. Lindsberg*, J. Oman, T. Lehto, M. Kaste, S. Meri, Departments of Neurology, Neurosurgery, and Bacteriology and Immunology, University of Helsinki, Helsinki Fin-00014, Finland.

The blood-brain barrier is deeply sectioned from the mammalian CNS by circulating immunological factors such as complement (C), a main mediator of humoral immunity and killing of foreign cells. C activation in plasma is under stringent regulation to prevent its attack on host cells. Since a number of CNS disease states induce plasma extravasation, which may carry C proteins to escape the regulation effective in plasma, we examined whether spontaneous C activation occurs in CSF in vivo and in vitro during subarachnoid hemorrhage (SAH). C activation on serum from healthy individuals was incubated at 37°C for 30 min with varying concentrations of serum before SCSB-9 concentrations were assayed with ELISA. In CSF, serum admixtures of 1:1 and 1:4, the assembly of Cl of SCSB-9 was up to five times enhanced by the addition of human CSF (n=5). CSF and plasma from SAH patients were studied on day 1 and 8 after SAH (n=15) and compared to controls with no CNS disease (n=8) and patients with ischemic stroke on day 1 (n=7). The SCSB-9 concentration during SAH on day 1; 2.61 ± 0.71 ng/ml was higher than that in plasma; 6.31 ± 1.7 ng/ml (p < 0.001), while no SCSB-9 was detected in the CSF of controls or patients with stroke (p < 0.001). The level of CSF SCSB-9 decreased during 8 days after SAH (24 ± 11 ng/ml). We conclude that CSF lacks C regulatory capacity, thereby permitting intrathecal C activation during SAH. C activation may promote chemotaxis, vasoactive perturbations and membrane lysis, but its potential pathophysiological role in SAH needs further studies.

391.20

BRAIN INFILTRATION BY AUTOANTIBOIES INDUCED BY CENTRAL INTERLEUKIN-2 (IL-2) INFUSION. U.-K. Harisch*1, J. Neubauer*, R. Quirion*2 and H. Kettenmann3.

Max Delbrück Center of Molecular Medicine, Cellular Neurobiology, Berlin-Buch, 13122 Germany and Douglas Hospital Research Centre, McGill University, Montreal, Quebec, H3H 1R3 Canada.

IL-2 regulates activities of immune and neural cells and has clinical application as an immunotherapeutic agent to treat peripheral and intracranial tumors. In this study, infusion of IL-2 (i.c.v., 5 U/hr for 14 days) in rats is shown to cause neuronal loss and periventricular damage around the infusion site, along with a pronounced activation of glial cells. Within the ventricle, masses of non-neural cells intermingled with collagen and fibronectin formed a vascularized pseudotumor clot that dislodged adjacent brain regions. By means of specific antibodies, immunocytochemistry revealed not only extravasating T cells, but B cells scattered throughout the clot as well as peri-ventricular tissue. At the ultrastructural level, the B cells were identified as plasma cells endowed in protein synthesis. Accordingly, a massive inundation by genuine immunoglobulin (lg) was detected in widespread brain areas. Fractions of the rat Ig apparently recognized populations of neural cells and astroglia. The results may thus be relevant both to CNS disorders involving an autoimmune component and to the adverse neurologic and neuropathological conditions induced by the application of IL-2 in the treatment of cancer. Supported by the BMFT (Germany).

392.1

Tumor necrosis factor-a (TNF) has been reported to have a variety of effects on neurons and neuroblastomas. It promotes axonal projection beyond the point of injury in severed optic nerve (Schwart et al., Brain Res., 1991, 545, 334), induces differentiation of neuroblastoma in conjunction with interferon-gamma (Ponzol et al., J. Cell. Biochem., 1992, 52, 3194), and protects neurons from metabolic-excitotoxic insult (Cheng et al., Neuro., 1994, 12, 139). Using the MTT viability assay, we have observed changes in differentiated and undifferentiated NIE-115 neuroblastoma cells (cytotoxicity indices [CI]) of 54±15% and 70±11 for differentiated and undifferentiated cells, respectively, treated with 250 U/ml TNF-a. TNF effects on differentiated NIE-1's with hTNF-a, an agonistic specific for the murine 55 kD TNF receptor, resulted in a CI of 79±2% at 200 U/ml TNF, indicating the likelihood that cytotoxicity in NIE's is mediated through the murine TNF receptor. Low TNF concentrations produce little or no cytotoxicity in NIE's. The CIs for differentiated and undifferentiated cells treated with 0.025 U/ml TNF-a are -11±4% and 16±17, respectively. In undifferentiated NIE's treated with recombinant human TNF-a, the CI is 70±16% (0.004 U/ml TNF-a). It is not clear whether the negative cytotoxicity index observed in differentiated NIE's at low TNF concentrations is due to an increase in cell proliferation or an increase in cell survival. The former seems unlikely, as the cells are treated with actinomycin D to inhibit proliferation during the course of TNF treatment. However, experiments measuring DNA-synthetic enzyme uptake are being performed to verify that proliferation is not occurring. It has also been reported that TNF is capable of promoting cell adhesion (Mackay et al., J. Exp Med 1993 177, 1277), so it is conceivable that TNF may promote the survival of differentiated NIE's by increasing their adhesion, either to substrate or to one another.

392.2

LOCUS COERULEUS NEURONS RESPOND DIFFERENTIALLY TO INTERLEUKIN-1B AND CORTICOTROPIN-RELEASING HORMONE. M.K. Homesty and J.M. Weiss. Neurosciences Program and Department of Psychiatry, Emory University School of Medicine, Atlanta GA, 30322.

We administered i.c.v. recombinant human interleukin-1B (IL-1B; 0.1-2.5ng) while recording extracellular activity of single LC neurons in Sprague-Dawley rats anesthetized with chloral hydrate or halothane. The finding that, in chloral hydrate-anesthetized rats, IL-1B dose-dependently suppresses LC firing rates. LC sensory-evoked responses, measured as the response to 1-second paw compression, were decreased by IL-1B proportionately with the baseline firing rate. In contrast to the effects seen in animals anesthetized with chloral hydrate, firing rates of LC units in halothane anesthetized rats did not change in response to any dose of IL-1B. Since corticotropin-releasing hormone (CRH) is an intermediary of IL-1 in many of the monkey's physiological actions, we compared the IL-1B responses of LC neurons to i.c.v. CRH (1-3ug) under halothane and chloral hydrate anesthetics. CRH did not change LC firing rates in rats anesthetized with chloral hydrate. As reported elsewhere (Valentino et al., Brain Res. 270: 363, 1983), LC units in halothane anesthetized rats were excited by CRH at both 1ug and 3ug doses. The magnitude of sensory-evoked responses under halothane was not affected by CRH, but since baseline firing rates increased, the relative size of the sensory-evoked response was decreased. Supported by NIMH grant MH54290.

392.3

Our laboratory has been studying the effects of interferon (IFN) on the hypothalamic pituitary adrenal axis (HPA). Last year we reported (Soc Neurosci Abstr. 1992:1900) that natural rat IFN alpha/beta (RIFNa/0) (La Jolla Molecular Research Lab) stimulated the HPA as determined by the RIA measurement of ACTH, betaendorphin and corticosterone (B) in plasma whereas human recombinant IFN alpha (hIFNalpha) (Hoffmann LaRoche) had a minimal effect. In this report we extend those conclusions to include the same animal preparation, e.g., 350-450 g Sprague-Dawley freely behaving male rats with indwelling jugular catheters. When either hIFNalpha or RIFNa/0 is administered i.v. at dose levels of either 200 or 600 international units (IU) per body weight, secretion of both ACTH and (B) is stimulated. Due to large variances, the differences in individual times between control (either saline, serum albumen or heat inactivated RIFNa/0 and IFN) injected animals were not always significant although mean differences were 2 to 4 fold. Total secretion of both ACTH and B is significantly increased by both IFN alpha although the response to RIFNa/0 was greater and with less variability as compared to hIFNalpha. Total secretion was estimated by numerically integrating the release curve (temporal profile), the amount integration being weighted by the secretion of ACTH after 600 IU being about half of that of 300 IU whereas there is no apparent reduction in B secretion. Supported in part by MH46808, DA 05723 and DA07978.

392.4

IL-1 and other cytokines are known to be an integral part of the acute phase response and the hypothalamic has been postulated to be site of interaction of cytokines, particularly with respect to regulating NE release in the brain. In previous experiments we had shown that cytokines including IL-1 probably do not act directly on the hypothalamus. In our current experiments we used microdialysis in an attempt to show that IL-1 does not act centrally but acts peripherally, using NE as index of measurement. We used microdialysis for our experiments and a specially constructed CMA-12/ Cunnami Combo. Animals used were Sprague Dawley rats weighing between 200-300 gms (Taconic Farms), Anaesthesia used was Chloral Hydrate. Basal values of NE were established 60 min post insertion of probe. At 140 min IL-1 was then infused through the cannula at a concentration of 100 ng / ml (total delivered was 5 ul over a 20 min period. Analysis of dialysate was done by HPLC with amperometric detection and samples were analyzed for norepinephrine. Averaged NE values in fmol/20 min collection were: Basal 308.8, P. Hypothalamic R: 417.2; Post Ip. R: 568.8 . Infusion of IL-1 produced a very modest nonsignificant 11% increase in hypothalamic NE (in fact 3 of the 5 animals actually showed a decrease). However animals produced a robust increase in hypothalamic NE in all 5 animals (48%). These data suggest that i.p. IL-1 induces a cascade of events which eventually result in an elevation of hypothalamic NE. Further experiments to delineate these mechanisms are underway.
Effect of cytokines on vasopressin and corticosterone releasing factor release from rat hypothalamic and anterior pituitary tissues. A viral paradigm of hypothalamic involvement of nitric oxide mediated signaling. J.Raber*, G.L.Koch and P.E.Bloom, Department of Neuropharmacology, The Scripps Research Institute, 10550 North Torrey Pines Road, La Jolla, CA 92037.

Much attention has focused on the role of selected cytokines as stimulatory factors of the HPA axis and as modulators of hypothalamic vasopressin (VP) and corticotropin releasing factor (CRF) and arginine-vasopressin (AVP) in this response. The amygdala, involved in stress related reactions and the regulation of the HPA axis has been implicated in this role, with in vitro settings used to investigate the influence of selected cytokines on the release mechanisms of CRF and AVP in the hypothalamus and amygdala, and the possible involvement of nitric oxide in this response. CRF and AVP are released in a calcium-dependent manner from both sites, and this release is responsive to acetylcholine, norepinephrine, or high K(+) (50 mM). The norepinephrine-activated AVP release is antagonized by phenolamine, but not by propranolol, while the norepinephrine-induced CRF release is antagonized by both adrenergic antagonists, suggesting an α-adrenergic receptor mediated AVP response and an α- and β-adrenergic receptor mediated CRF release. The acetylcholine-induced release is antagonized by atropine or methanamine, indicating that both muscarinic and nicotinic receptors can mediate the cholinergic responses. The hypothalamus and amygdala. IL-2 stimulated AVP and CRF release in both regions, in a calcium- and dose dependent manner. Nifedipine, which neutralizes nitric oxide (NO) also induced AVP and CRF release. The IL-2- and acetylcholine-induced release is antagonized by N-fumaryl-N-arginine, a potent inhibitor of nitric oxide formation, indicating a role for NO in this release. N-fumaryl-L-arginine does not effect the norepinephrine-induced released release. Finally, IFN-α stimulated CRF and AVP release from both the hypothalamus and amygdala. These data suggest that in addition to the hypothalamus, the amygdala may also play an important role in the bi-directional communication between neuroendocrine and immune systems (Supported by grant MH 47680).

INTERLEUKIN-1 AND ENDOTOXIN INCREASE RELEASE OF NITROGENEPHRINE IN HYPOTHALAMUS. Adrian J. Dunn*, Gregory N. Sperandio and Jan Laviaky, Department of Pharmacology, Louisiana State Univ. Med. Ctr, Shreveport, LA 71130.

Previous studies have indicated that administration of interleukin-1 (IL-1) and endotoxin (lipopolysaccharide, LPS) increased the cerebral metabolism of noradrenaline (NE), with the greatest response in the hypothalamus. To extend these observations, we have now perfused in vivo microdialysis catheters containing NE and dopamine (DA) and investigated the release of DA and NE from the hypothalamus and cortex. Intraperitoneal injection of 5 μg LPS into freely moving rats increased microdialysate concentrations of NE and dopamine (DA) following a lag time. The responses to DA were much smaller than in the hypothalamus, but 100 μg of LPS produced a similar increase in FFM comparable to that of 5 μg in the hypothalamus. These responses were blocked by injection of indomethacin.

IL-1 (1 μg) injected either ip or iv increased microdialysate concentrations of NE in the hypothalamus. Both injection routes elicited similar microdialysate concentrations, increasing slowly to reach a peak after 2-3 hours. This temporal pattern differs from the elevations of plasma ACTH and corticosterone reported for IL-1; iv IL-1 elicited a rapid response with a peak around 20 min, whereas ip injections elicited a slower response with a peak around 2 hours after injection. This suggests that different mechanisms may be involved in the activation of cerebral NE systems in the HPA axis.

TUMOR NECROSIS FACTOR DECREASES THE LEVEL OF VASOPRESSIN BUT NOT OXYTOCIN IN RAT PITUITARY. G. Shvarts, M. D. Fitzsimmons, A. G. Robinson*, Dept of Endocrinology, Univ. of Pittsburgh, PA 15261.

Cytokines derived from the immune system can modulate the activity of the hypothalamic-pituitary-adrenal (HPA) axis and thereby regulate the intensity of the neuroendocrine response. The role of proinflammatory cytokines in hypothalamus and pituitary. IL-1, IL-2, IL-6 in release of ACTH, GH has been well documented, but little is known about the effect of cytokines on arginine-vasopressin (AVP) and oxytocin (OT) secretion. In the rat hypothalamus, AVP but not OT release greater than AVP release. Yet, excess secretion of AVP is a common accompaniment of certain illness, causing excess water retention and hypernatremia. The stimulus for such elevated secretion of AVP has not been clearly defined. We postulated that AVP may be mediated, at least in part, by cytokines. The present study was designed to test whether Tumor Necrosis Factor alpha (TNF), derived from the immune system can stimulate AVP and OT neuronal pathways. TNF (1ug) was injected iv, in conscious, freely moving rats and the levels of pituitary AVP and OT were measured by radioimmunoassay 2 hours after cytokine injection. Pituitary AVP levels were significantly decreased after injection of TNF: baseline values (n=6) were 1211±42 ng/pituitary for control animals and 671±52 ng/pituitary (p<0.012) for animals (n=9) receiving TNF. However, pituitary OT levels were not changed after administration of TNF (p>0.5). These data suggest that the immunosuppressive system (TNF) can specifically regulate AVP depletion in the posterior pituitary. The lack of effect on oxytocin indicates this is not a direct vascular (neurogenic) effect on the pituitary. The 'stress' stimulates OT in the rats, rather is the increased AVP a non-specific response to stress. Rather, there might be a specific neuro-immune interaction between cytokines and vasopressin receptors.
INTERLEUKIN-1α INDUCES CORTICOTROPIN-RELEASING FACTOR SECRETION AND SYNTHESIS FROM NPLC-KC CELLS THROUGH VARIOUS SECOND MESSENGER PATHWAYS

J. W. Kasckow*, J. J. Mulcahey, J. Han, M. J. Owens, M. D. Slipp, J. D. Martin*, and B. Nemeroff
Dept. of Psychiat., Behav. Sci., Emory Univ. Sch. of Med., Atlanta, GA 30322.

It is well documented that stress exerts effects on both endocrine and immune functions. The cytokine, interleukin-1 (IL-1), is known to activate the hypothalamic-pituitary-adrenal axis by stimulating release of corticotropin-releasing factor (CRF) and to also play a prominent role in immune function. CRF secretion and synthesis in the NPLC-KC human hepatoma clonal cell line has previously been shown to be increased by IL-1. The purpose of this study was to elucidate which second messenger pathways mediate this effect. NPLC-KC cells were grown in 6 well Costar plates and treated for 24 or 24 hours with 500 pM IL-1β in the presence of the protein kinase (PKC) inhibitor, H-7 (50 μM), the protein kinase A inhibitor, IBMX (5 μM), or the cyclooxygenase inhibitor (Indomethacin; IND, 300 nM). Both cell extracts and secretion media were assayed for CRF-like immunoreactivity in our radioimmunoassay. All 3 inhibitors reduced the IL-1 effect on CRF secretion. This effect was statistically significant (P < 0.05) at 12 hours; although all three inhibitors reduced CRF secretion at 24 hours, only the H-7 effect was statistically significant. Only the PKC inhibitor, H-7 reduced the IL-1-induced increase in CRF synthesis, an effect that was statistically significant at 12 and 24 hours (P < 0.05). Thus, all three signal transduction pathways are implicated in IL-1-induced CRF secretion while only the PKC pathway is implicated in IL-1-induced CRF synthesis. Supported by NIMH MH 42085. The work was also completed while Dr. Kasckow was a Pfizer awardee.

Hyperalgesia resulting from immune activation by bacterial endotoxin is blocked by both IL1α and by section of the hepatic branch of the vagus nerve (Watkins et al., 1994). Thus, some information about immune activation is conveyed to the central nervous system via peripheral nerves presumably sensitive to circulating cytokines. To determine the site of action of the IL1α, we incubated cryostat sections of rat liver and hepatic vagnus with biotinylated IL1α. The IL1α labeled vascular and connective tissue, and areas known to express IL1 receptors. The biotinylated IL1α also labeled a subpopulation of cells in the paraganglia imbedded in the hepatic branch of the vagus and in the connective tissue of the liver hilus. These cells appear to be chemoreceptive, and are innervated by the vagus nerve (Prechtl & Powley, 1985). These preliminary results suggest that paraganglia are sensitive to circulating cytokines associated with immune activation, and convey this information to the brain via the vagus nerve. Supported by Synergien and NIH NS31569, MH14617.

REPRODUCTIVE REGULATION: CHOMORECEPTIVE MECHANISMS

ATP-SENSITIVE POTASSIUM CHANNELS ARE FUNCTIONAL IN NORMOXIA IN THE RESPIRATORY NETWORK OF ADULT CAT.

K⁺ channels sensitive to intracellular levels of ATP participate in the cellular response induced by oxygen deprivation. These channels are activated when intracellular levels of ATP are reduced or closed when ATP levels are normal. In some central nervous structures they might play a role in the hyperpolarization of cells induced by hypoxia has been described (Mourre et al. 1989; Brain Res. 496, 159). However, a functional role for such channels has not been described in respiratory neurons of adult mammals. Therefore we attempted to identify the presence and functional role of the ATP-sensitive K⁺ channels in the respiratory network of adult cats.

Experiments were performed in anesthetized, paralyzed, vagotomized and artificially ventilated cats. PO₂ and PCO₂ were monitored continuously and kept within physiological ranges to ensure normoxia. Expiratory neurons were recorded intracellularly with glass micro-electrodes, filled with a solution of ATP (5mM) in K-CH₃SO₃ (1.5M) in order to study the effect of ATP injection. A specific agonist (diazoxide, 2-20mM) and 2 specific antagonists (tolbutamide, 2-20mM; glibenclamide, 5mM) were applied topically over the respiratory neuronal pool.

Fourteen cells tested for intracellular injection of ATP showed a membrane depolarization of 4-12mV. Application of the channels with diazoxide produced a hyperpolarization of 3.1±0.05mV in 12 of the 16 tested. These cells were in input resistance not different from adult normoxic behavior of 4-6mV. However, when ATX (K⁺ channel activator) was blocked by tolbutamide or glibenclamide evoked a depolarization of 3.4±0.2mV in 10 of 14 cells tested with an increase in input resistance of 29.3±8.6mV (n=8).

We conclude that ATP-activated K⁺ channels are present in respiratory neurons of adult cats. 2) some of the channels are activated in normoxia and 3) opening of the remaining channels might contribute to the respiratory response during hypoxia.

DOES HYPOXIA-INDUCED INHIBITION OF GLOMUS CELL OUTWARD CURRENT CAUSE INCREASED CHEMORECEPTOR NERVE ACTIVITY
D.F. Donnelly1, Dept. of Pediatrics, Section of Respiratory Medicine, New York University School of Medicine, New Haven, CT, 06510

One major theory of chemotransduction postulates that hypoxia inhibits a glomus cell potassium current, resulting in depolarization, calcium influx, secretion, and, thus, increased nerve activity. To test this theory, we used an in vitro, superfused glomus cell membrane perfusion system. Experiments were conducted using rat carotid body glomus cells in vitro, superfused with HEPES-buffered saline at 30°C. The perfused glomus cell was identified based on their I/V profile: small inward currents and large, voltage-dependent outward current (760±88 pA @40mV, n=10). Repeated measurements of baseline currents and nerve activity demonstrated that hypoxia (30-60s duration, PO2=0 Torr, at nadir) caused a large increase in nerve activity (15.4±4.3× baseline, p<0.01), but no significant change in holding current (p>0.05). Inward outward currents were significantly decreased during hypoxia (p<0.01), but the magnitude was small (36±17 pA) and did not recover following reoxygenation despite the return of outward sodium activity. Administration of the K+ channel blocker TEA (20mM) caused a large reduction in outward current to 54% of control (p<0.02), but caused no significant change in inward sodium activity (p>0.05). These results demonstrate an independence between changes in glomus cell outward currents and inward nerve activity, and, thus, suggest that hypoxia–transduction is not primarily mediated by modulation of glomus cell K+ conductance.

IMMUNOHISTOLOGICAL DIFFERENTIATION OF CULTURED CAT CAROTID BODY CELLS. M. Shirahata*, B. Safdolof and R.S. Fitzgerald, Div. of Physiology, EHS, The Johns Hopkins Medical Institutions, Baltimore, MD 21205.

Adult cats have been widely used to study the respiratory and cardiovascular responses to hypoxia as well as the increase in neural activity from the carotid body (CB) responsible for these reflex responses. To understand mechanisms of hypoxic chemotransduction in the CB the availability of functional chemoreceptor cells from adult cats is extremely important. Recently we have developed methods for culturing CB cells which respond to hypoxia for up to one month in culture. However, a critical problem with using cats in cellular studies is identification of type I cells, because (1) the ratio of type I to type II cells is only about 2:1, and (2) both types of cells in culture are similar in size and shape. The purpose of this study was to find surface markers for identification of live type I cells. Three types of cells were clearly distinguished with three antibodies against tyrosine hydroxylase (TH), glial fibrillary acid protein (GFAP) and galactocerebroside (Gal-C). Type I cells were positive only for TH. Type II cells were positive for GFAP, but not for Gal-C or TH, suggesting that type II cells are similar to astrocytes. A third type of cell expressed only Gal-C. Both type I and type II cells were stained with tetraneurin toxin fragment. Since astrocytes in the central nervous system expressed immunocompetent cell markers such as CD21 and MHC-class II, we tested these markers as well. Neither type I nor II cells expressed CD21, but type II cells expressed MHC-class II molecules. These results suggest that live type I cells in culture can be identified by immunohistological methods. Supported by HL 47044 and HL 50712.

FITICTVE VENTILATORY RESPONSE TO PH CHANGE IN AN IN VITRO BRAINSTEM OF RANA CATESBEIANA. W.G. Filmer1, L. Kuhl1, A.T. Pack1. Center for Sleep and Respiratory Neurobiology and Departments of Anesthesiology1, Animal Biology2 and Medicine3, Univ. of Pennsylvania, Philadelphia, PA 19104

We have developed an in vitro brainstem preparation from the bullfrog, Rana catesbeiana, for investigation of changes in respiratory pHCO2 sensitivity and transmission of related signals within the CNS. In this study we assessed whether extracellular pH changes within a physiologically relevant range in an appropriately placed unit activity of the Vth cranial nerve, regarded as an index of the fictive respiratory motor outflow. Trials consisted of alternating two CO2 bicarbonate buffered mock CSF solutions with pH of 8.10 and 7.60 ±0.05 pH units, respectively, made three times for each of the six preparations studied. For fictive lung ventilation cycles, the periods and area under the curves were measured. All of the preparations demonstrated an appropriate fictive ventilatory response, defined as an increase in the product of instantaneous respiratory rate and burst area, to the pH reduction. Changes in either the average burst area or the period alone were not consistent. Small, high frequency "buccal" oscillations, when present, demonstrated a decrease in average amplitude with pH reduction, but no change in period. Thus an in vitro brainstem preparation of R. catesbeiana has pH sensitivity and offers an attractive model for elucidation of the basic neuronal mechanisms of central chemoregulatory control of ventilation. NITRIC OXIDE MODULATES CO2 CHEMORECEPTION IN THE FLMONATE SNAIL. J.S. Feldman, J.C. Lorrimer and P.F. McCarthy. Dept. of Physiology, Dartmouth Medical School, Lebanon, NH 03756. Winkler et al. (Soc. Neurosci. 1976;11:172, 1973) have implicated the interneuronal messenger NO in the feeding and respiratory programs of the aquatic mollusk, L. stagnalis. We studied the role of nitric oxide (NO) in CO2 chemoreception in the terrestrial, pulmonate snail H. aspersa. Using an isolated brainstem-preparation, we compared the effects of the reversible NO synthase inhibitors, L-N-nitroarginine methyl ester (L-NAMe) and NO donors, sodium nitroprusside (SNP), L-arginine (L-arg) and hydroxylamine (HOX), on pre- and postjunctional function during normocapnia and hypercapnia (6% CO2). Previously, we have shown that focal exposure of a discrete area between the visceral and right parietal ganglia to 6% CO2 causes large increases in the diameter of the pneumostome (Pn), the breathing orifice in these animals. The addition of L-NAMe (10 mM) to brain perfusate decreased Pn area during normocapnia and focal hypercapnic stimulation compared to control saline, but did not affect CO2 responsiveness per se. The decreased Pn area resulting from L-NAMe treatment could be reversed by adding L-arg (10 mM). The inactive enantiomer D-NAMe (10mM) had little effect on Pn area during normocapnia and hypercapnia. The NO donors, SNP (400 μM) and HX (1 mM) added to the brain perfusate increased Pn area during normocapnia and focal hypercapnic stimulation compared to control saline, but also had no effect on the responsiveness to CO2. We conclude that NO modulates respiratory activity in the snail, but does not appear to be involved in the CO2 chemotransduction process. (Supported by grants HL 40938, HL 17027 and HL 07449.)

EFFECT OF HYPOXIA ON RESPIRATORY NEURONS IN THE VENTROROLATERAL PONS OF ADULT RATS. S.K. Cole* and T. F. Dick. Division of Pulmonary and Critical Care Medicine, Dept. of Medicine, Case Western Reserve University, Cleveland, OH 44106-4389 USA.

Bilateral chemical lesioning of the ventrolateral pons in the A5 region abolishes the post-hypoxic ventilatory depression (Coles and Dick, ATS Abstract, 1994). Data from subsequent experiments using extracellular recording techniques indicate that neurons in the A5 region display highly-modulated respiratory activity (Dick et al., Neurosci., 1995). Hypothesis: that if in behaving respiratory neurons in the ventrolateral pons mediate post-hypoxic ventilatory depression, these cells would be excited by hypoxia. The purpose of the present study was to characterize discharge patterns of these neurons before, during, and after hypoxia to acute periods of hypoxia.

Adult, male Synagoge-Dawley rats (n=7) were anesthetized with Equithesin, vagotomized, paralyzed, and ventilated with 100% O2. Glass micropipettes (B=25 MΩ) filled with a mixture of L-glutamate and 2% Fast Green were used for recording pontine neurone activity extracellularly and for marking recording sites. L-Glutamate was iontophoresed to distinguish cell bodies from axons of passage. Respiratory activity before, during, and after hypoxia (8% O2) was recorded from neurons located in the dorsolateral (n=3); lateral (n=1), and ventrolateral (n=10) pons.

Discharge frequency increased clearly in three expiratory phases during and following hypoxia. Surprisingly, activity was remodelled, i.e., the on-set and offset of neuronal discharge shift (n=5), but also cells (n=5) became active in additional phases of the cycle. Changes in activity were evident in all cells; in 13 cells discharge frequency and activity remained stable.

These data suggest that post-hypoxic ventilatory depression is mediated potentially through respiratory neurons in the ventrolateral pons, and that the process may include "remodelling" neural activity in response to hypoxia.

394.2

PHRENIC AND HYPOPHALIC NERVE RESPONSES TO SUSTAINED HYPOXIA IN DECATERBRATE CATS. M. A. Hunter, M. J. Wasielewski, R. J. Jover, C. T. Leiter, and D. Burton, Jr. Dept of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

A biphasic ventilatory response is observed in adults and newborns of many species during sustained hypoxia; an initial increase in ventilation is followed by a "roll off" of the response to levels greater than or equal to those of the initial peak than the peak response. While the mechanism responsible for hypoxic rolloff is uncertain, previous reports suggest that it is both centrally modulated and dependent on peripheral chemoreceptor stimulation. Furthermore, the depressive effects of hypoxia differs between muscles of the upper airways and the diaphragm in pigs (Martin et al., JAP 0623-672-677). In this study, we questioned whether hypoxic rolloff, in the absence of changes in baroreceptor input and end tidal CO2, was demonstrable in the adult decorticate cat, and if so 2) whether hypoxic depression is expressed equally in hypoglossal and phrenic nerves. We measured hypoglossal and phrenic nerve activity in 16 paralyzed vagotomized mechanically-ventilated decorticate cats while arterial blood pressure and end tidal CO2 were held constant.

Following ventilation with 100% O2, inspired O2 was lowered to 12, 14 or 16% for 10-20 minutes. Nerve activity increased to a maximum of 17% above control before returning to the pre-hypoxic level after 7 minutes of hypoxia. Phasic hyperglossal nerve activity increased to a maximum of 40% above control and remained 25% above control after 7 minutes of hypoxia. There was no correlation between peak nerve activity and the decay constant for rolloff in either nerve. We conclude that hypoxic rolloff can be elicited in adults in the absence of changes in the pons. Moreover, the hypoglossal nerve is more resistant to the depressive effects of hypoxia compared to the phrenic nerve in cats. (Supported by grants HL-01998, HL-19827 and HL-03540).

394.3

Progressive hypoxemia in anesthetized, peripherally chemodenervated cat results in a marked decrease in phrenic nerve activity culminating in phrenic silence and, eventually, gasping. These changes reverse during reoxygenation. To determine if changes in the PN power spectrum correspond to changes in temporal patterning, we examined autoregressive (AR) spectra of 100 msec bins of PN in 4 anesthetized, glomeronotomized, vagotomized cats during isocapnic hypoxia and reoxygenation. The AR spectra had peaks in the 30-60 and 60-120 Hz ranges. Hypoxia resulted in power loss at all frequencies and a shift of the 30-60 Hz peak frequencies <30 Hz. Gasping resulted in increased power in all peaks but peaks were seen only in the 0-30 and 60-120 Hz ranges. During isocapnic recovery, the PN reverted from gasping to eupnea. Phrenic amplitude, initially 200-400% of pre-hypoxic values, returned to control values after 30 min. Power was initially increased in all peaks and returned to control levels over the same period time. The AR spectra of the PN during reoxygenation was initially gasp-like with significant power only in the 0-30 and 60-120 Hz ranges. During return to eupnea, low frequency power shifted from 0-30 to 30-60 Hz ranges. The AR spectra during intermediate recovery had characteristics of both eupnea and gasping, i.e., significant power in both the 0-30 and 30-60 Hz ranges. These results suggest that hypoxia results in a reversible reconfiguration of the central respiratory pattern generator.

(Supported: HL-44678, HL-16022, AHA/NJ).

394.4

We examined activity changes on the rostral ventral medullary surface (VMS) of 5 non-anesthetized, unrestrained goats during poikilocapnic hypoxia (10% O2 in N2) using optical imaging procedures. Under sterile surgery, a coherent fiber probe with a charged couple device was placed over a rostral VMS region which elicited ventilatory and blood pressure depression during local cooling. Tracheostomy and vascular cannulation were performed for assessment of cardiorespiratory measures. Onset of 10% hypoxia was associated with a substantial increase in activation on the VMS, which was sustained for a period of time, and then gradually declined to a lower, stable level of activity as hypoxia was maintained. The temporal trends in neural activity observed are suggestive of the reported ventilatory "roll-off" phenomenon commonly associated with sustained hypoxic challenge.

394.5

Carotid body afferents mediate components of the response to mild hypoxia within the intermediate area of the ventral medullary surface (VMS). Changes in IVMS activity following transient peripheral chemoreceptor stimulation are unclear. IVMS neural activity in 6 spontaneously breathing, pentobarbital-anesthetized cats was measured as changes in 660 nm reflectance from a surgically-exposed IVMS, using a 3.2 mm coherent optical probe attached to a charge-coupled device. Two tidal breaths of 100% O2 or O2 were randomly administered before, and after carotid sinus denervation (CSD). Activity significantly increased (10.1±2.4 %) occurring within 3.1±0.7 sec following O2 onset while decreases in activity (4.8±1.8%) was observed with CSD significantly prolonged the latency of the N response to 7.4±1.1 sec (p<0.01), and increased the magnitude of the response (14.5±2.1%, p<0.01).

Similarly, CSD enhanced the effect induced by O2 (7.2±1.3%, p<0.05) as well as prolonging the latency. We conclude that CSD abolishes the early IVMS responses, although desensitization allows for development of a later IVMS activity response, possibly of central origin. (Supported by HL-22418 & Parker F. Francis Foundation.)

394.6

Previously, we have shown that the inspiratory volume-timing relationship during inspiratory resistive loading is linear, and that increasing levels of hypercapnia significantly lengthen the slope of this relationship. The specific aims of this study were to describe the expiratory volume-timing relationship during expiratory resistive loading and to determine whether this relationship is modulated by elevated CO2 levels. Six chloralose anesthetized cats were presented with three graded levels of expiratory resistive loads (13-540 cm H2O/sec) and tracheal occlusion at three levels of inspired CO2 (room air, 7% CO2, and 9% CO2). The relationship between the control (Vc) and expiratory duration (Tc) can be described by the following equation:

\[ V_c = a + b\cdot T_c + c\cdot T_c^2 \]

The influence of different CO2 levels on this relationship is shown in the following table:

Following vagotomy, Tc was no longer modulated in response to expiratory resistive loading. The relationship between Tc and expiratory resistive loading can be modulated by hypercapnia and that the modulation of Tc in response to both mechanical and chemical loading is dependent upon intact vagal. (Supported by NIH HD-40369).
ACETAZOLAMIDE INJECTED INTO THE MEDULLARY RAPHE PERNICIOUS NERVE ACTIVITY. D.G. Bernard, A. Li and E.E. Nattie. Dept. of Physiology, Dartmouth Medical School, Lebanon, NH 03756

The medullary raphé was examined for chemoreceptor responses (increased pnicus nerve amplitude (PNA)) to localized tissue acidosis produced by microinjection of acetaclizamide (AZ). Adult male Sprague-Dawley rats were anesthetized, vagotomized, paralyzed, and artificially ventilated. The ventral medullary brainstem was exposed and 1nl injections of mock cerebrospinal fluid (mCSF), AZ (5x10^-5M) or an inactive AZ-analogue (5x10^-5M) were made in the raphé while recording integrated PNA, femoral arterial blood pressure and end-tidal CO2. The injection locations were demonstrated by post-mortem anatomical evaluation. PNA was expressed as percent maximum defined by 9% CO2 stimulation. The mean change in PNA evaluated at 10, 20 and 30 min following 27 AZ injections was greater (p < 0.001; ANOVA) than after 16 control injections. Of the 27 AZ injections, 11 had responses greater than any control response. It appears that the traditional ventral medullary chemosensitive regions may not be the exclusive sites for sensing decreased pH by increasing PNA. Other sites, namely the locus coeruleus and the nucleus tractus solitarii have recently been described and the medullary raphé may be another such chemoreceptor site. (Supported by HL 28066 & HL 26991)

SOMATIC AND VISCERAL AFFERENTS: VISCERAL AFFERENTS

PEROXIDE-SENSITIVE MESENTERIC AFFERENTS: AN IN VITRO STUDY. D.W. Addison, J.W. Lenox and L. Koppel. Scripps Institution of Oceangraphy, UCSD 92093, the Departments of Medicine and Anatomy and the Brain Research Institute, UCLA, Los Angeles, CA 90024.

Receptor fields of single-unit afferents in C-fibers (conduction velocity < 2.5 m/sec) were carefully delimited and characterized on the basis of impulse activity evoked by local mechanical and heat stimuli in an in vitro rat splanchic nerve-sensory preparation. Units were then tested for responsiveness to 1-3% hydrogen peroxide (H2O2) applied to their receptive field. H2O2-responsive units displayed a characteristic discharge pattern comprising windup in discharge rate, decay back to background levels, followed by bursting discharge lasting several minutes. This two-phase response and the latencies involved suggested possible participation of a second cell type. Some units initially unresponsive to H2O2 exhibited characteristic discharge pattern upon subsequent H2O2 stimulation, implying that units responding to initial applications of peroxide may previously have been exposed to sensitizing factors. H2O2 stimulation was observed to unit discharge in response to subsequent mechanical stimulation. Since a number of immunoneurochemical events (neutrophils, mast cells, macrophages) generate reactive oxygen species as a result of activation, the observed sensitivity to peroxide may mediate an interaction between the sensory nerve terminal and activated immunoneutrophils.

Supported by NIH grants NS-5665 and NS-28433.

Injection of the rat cervical vagus nerve with WGA-HRP results in labeled axons and terminals at the light and EM level not only in the brainstem but also in the upper cervical spinal cord. The projection to the cervical cord consisted of a small compact bundle of nonmyelinated axons which was located in the reticular zone immediately lateral to the narrow neck of lamina V and a second, less distinctly organized, set of axons at the medial border of the dorsal horn between lamina I and the dorsal columns. Axons and terminal fields extended from each of these small bundles into lateral lamina V-VII and medial lamina I, respectively. The lamina I terminal fields were compact, lying as small "islands" in the gray matter. All axons identified at the EM level were nonmyelinated. This correlates with calculations of the diameters of vagal spinal afferents suggested by the physiological studies of the cervical respiratory neurons and dorsal horn neurons shown to be affected by vagal stimulation (Dawkins et al., 92; Fu et al., 92). Both simple and glomerular terminals were labeled, with clear vesicles and few dense core vesicles. These results extend the previous evidence (Panneton, 91; McNeill et al., 91; Robertson et al., 92; Kalia and Sullivan, '82) for the presence of afferents from branches of the vagus to the high cervical cord. (NIH grant 3335)

The distribution of calreticulin (CR), a calcium binding protein, was compared with several neuropeptides in fixed frozen cross-sections of rat intestine (30 μm) as well as dorsal root ganglia (DRG) using double-labeling immunochemistry. CR was found to coexist with calcitonin gene-related peptide (CGRP), vasoactive intestinal peptide (VIP), and substance P (SP) but not with calbindin-D28K and galactin in the fibers overlying the lumen propria of the rat intestinal villi. An acetylcholinesterase (AChE) histochemical stain revealed that the majority of CR cells in the myenteric ganglia were cholinergic and about half of the submucosal CR cells contained AChE but very few fibers in the villi contained both substances. In situ hybridization studies confirmed the presence of CR mRNA in the DRG and enteric ganglia and a ribonuclease protection assay verified the presence of CR messages in the intestine. A small proportion of the CGRP immunoreactive cells in the DRG were also immunoreactive for CR and prior studies have revealed that CGRP coexists with SP and VIP in the DRG. These findings combined with reports that the primary source of CGRP in the rat intestine is the DRG (Sterling and Anderson, Somatosensory and Motor Research, 9-45-59, 1992), suggest the source of the quadruple colocalization is the DRG. While the function of CR within these nerves is unknown, the three potent vasodilatory neuropeptides may influence the uptake of metabolized food products within the vasculature of the villi.
395.5 EFFECTS OF ANTIOXIDANTS ON CISPLATIN-INDUCED EMESIS AND RELEASE OF SEROTONIN IN SUNCUS MUTRINUS

Y. Chen and H. Sato
Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, The University of Tokyo, Tokyo 113, Japan.

Nausea and emesis are frequent side effects during cancer chemotherapy. Antitumor drugs, such as cisplatin, are considered to release serotonin from the enterochromaffin cells that innervate serotonergic 5-HT3 receptors located on the vagus afferents. However, little is known how cisplatin releases serotonin from the enterochromaffin cells. We have proposed the involvement of free radicals in the process (Y. Torii et al. Br. J. Pharmacol. 48, 131, 1955). To assess the role of neurotoxic free radicals and various scavenging drugs on cisplatin-induced emesis and the release of serotonin from the intestines were studied in Suncus murinus, a house musk shrew. Cisplatin (20 mg/kg) was injected intraperitoneally, and the antidepressant was injected subcutaneously either one or 24 hours before the cisplatin. Butylated hydroxyanisole, propyl gallate, ascorbic acid and acetyl-cysteine attenuated the number of vomiting animals and episodes per animal. Acetyl-cysteine also decreased cisplatin-induced release of serotonin in vitro. These results further suggest that free radical-mediated oxidation is involved in cisplatin-induced release of serotonin.

The Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Previous work showed that axotomy-induced deafferentation altered the numbers of neuropetide and tyrosine hydroxalase (TH) mRNA-containing and immunoreactive neurons in the nodose ganglion. The present study was designed to selectively evaluate the loss of axonal transport on the numbers of vasoactive intestinal polypeptide (VIP), TH, and calcitonin gene-related peptide (CGRP) mRNA-containing and immunoreactive (ir) neurons of the nodose ganglion. Vincristine (VB, 0.15mg/m) was administered to the cervical vagus nerves and the axonal transport was studied using immunocytochemistry. The results showed that vincristine inhibited axonal transport and immunocytochemistry were used to label nodose ganglion neurons at 1, 3, 7, and 14 days after VB treatment. VB treatment decreased the number of VIP mRNA-containing and VIP-ir neurons, and slightly increased the numbers of CGRP mRNA-containing and CGRP-ir neurons in the nodose ganglion. The average labeling density of VIP mRNA-containing neurons increased following VB treatment. VB treatment led to the appearance of low-labeling density CGRP mRNA-containing neurons which reduced the average labeling density of the CGRP mRNA-containing neurons. Application of VB to the cervical vagus nerve decreased the number of TH mRNA-containing and TH-ir neurons in the nodose ganglion. The efficacy of VB to inhibit axonal transport and the absence of VB-induced neuronal damage were verified. These data suggest the presence of an axonally transported influence regulating neuropetide and neurotransmitter enzyme synthesis in mature pacode-derived visceral sensory neurons of the nodose ganglion. (Supported by NIH grant RO1 NS020991)

Peritonitis induced by i.p. injection of acetic acid is responsible for an inhibition of gastric emptying and intestinal transit in rats (1). Purpose: to map spinal and supraspinal pathways that are activated by peritonitis-induced ileus in rats. Methods: male fasted SD rats were injected i.p. either with vehicle (NaCl 0.9%) or with 0.1ml/kg acetic acid (AA) mixed with systemic capsaicin (125mg/kg subcutaneously) and received acetic acid (AA) or saline (i.p. 0.1 ml/kg) injected rats were perfused with 4% FFA. Frozen sections (30μm) of the brain and spinal cord were processed for Fos immunoreactivity (Fos-TRK). Results: no or few Fox-Ir was observed after i.p. injection of the vehicle. Acetic acid induced Fox-Ir in the spinal cord, nucleus tractus solitarius (NTS) and area postrema, parabrachial nucleus, supraoptic and paraventricular nucleus (PVN) of the hypothalamus. A dramatic decrease of Fox-Ir was observed in capsaicin pretreated rats. Conclusions: peritonitis induces c-fos expression in spinal and selective brain nuclei (NTS, PVN) involved in the control of digestive motility in rats. Such expression is vehiculated through capsaicin-sensitive afferent fibers. (1) Rivière P.H.M et al., Gastroenterology 104: 724-731, 1993. (2) Bonaz B. et al., Brain Res. 600: 353-357, 1993.

395.9 C-FOS EXPRESSION IN SPECIFIC AREAS OF THE CENTRAL NERVOUS SYSTEM INDUCED BY PROXIMAL COLON DISTENSION IN CONSCIOUS RATS. V. Martinez, L. Wang and Y. Tachibana, CURE, VA Med. Ctr., Brain Res. Inst. and Dept. Medicine, UCLA. Los Angeles, CA 90027.

Colonic distension evokes C-fos expression in the central nervous system (CNS) of the anesthetized rat. The aim of this study was to characterize the response of neurons in the CNS to proximal colon distension in conscious rats. A flexible balloon (6 cm) was inserted, through a mediastinal laparotomy, into the proximal colon, remaining anesthetized rats. After mechanical stimulation of the colon was performed for 10 min (30 s on, 30 s off), by infusing the balloon with 10 ml of air in conscious rats. In the control group the colon balloon was inserted but not treated. 60 min later the animals were deeply anesthetized and perfused; cryostat sections from brain and spinal cord (lumbar 3,4 levels) were processed for Fos-IR in the CNS. No difference was observed in the lumbar part. These results show that viscerosensory inputs active selective spinal cord and brain areas involved in the integration of autonomic functions, and provide anatomical substrates for the CNS pathways involved in the regulation of colonic function and pain perception. V. Martinez personal support: Ramón Areces Foundation (Spain).

395.10 WHOLE-CELL PATCH CLAMP RECORDINGS OF CULTURED DORSAL ROOT GANGLION NEURON SOMATA THAT INVERSELY INNERVE THE KIDNEY OF THE ADULT RAT. M.A. Vizcaino and W.C. de Groat, University of Pittsburgh, School of Medicine, Department of Pharmacology, Pittsburgh, PA 15261.

Whole-cell patch clamp recordings with intracellular tracing techniques were used to examine the electrophysiological properties ofafferent neurons innervating the kidneys of the adult rats (A). In the fluorescent method (Fast Blue, FB or Fluoroangio, FG) was injected into each kidney 7-14 days prior to the removal of the T8-L2 dorsal root ganglia (DRG) bilaterally. DRGs were dissociated with enzymatic mechanical trituration and individual FB or FG cells were identified with a fluorescent microscope. Renal afferent cells were cultured for 12 hours to 2 days prior to whole-cell recordings. Renal afferent cells were small (major axis mean 18±2μm, range 11-24μm) and had an average resting membrane potential of -50±1.7 mV. Action potentials of these cells were of two types: 1) intradendric (TTX-sensitive, up to spike frequency of 12.6±1.2 Hz) with an inflection on the repolarization phase, 2) TTX-sensitive, shorter duration (7.4±0.9 mV). 64% of renal afferent neurons exhibited low threshold (40 to 45 mV) TTX-sensitive (1 mM) action potentials and Na+ currents. Cells that exhibited TTX-resistant action potentials had high threshold Na+ currents (20 to 30 mV). Some cells exhibited both TTX-sensitive and TTX-resistant Na+ currents. In contrast to bladder afferents these TTX-resistant Na+ currents were present in small and large cells, respectively, TTX-resistant and sensitive Na+ currents in renal afferents were present in similar size neurons (25.8±3.7 μm vs. 26.5±.24 μm, respectively). These results demonstrate that axonal tracing with fluorescent dyes is useful for identifying specific populations of visceral neurons for patch-clamp studies. The results provide the control data for future studies of changes in renal afferent cells following pathology in the kidney. [Supported by NIH grants DK 37241, DK 42369 and NRSK 1 F32 DK 08916-01].

MUSCULAR HYPERALGESIA FROM URETERAL CALCULUS IN RATS: RESPONSES OF SPINAL CORD NEURONS TO OBSCURE MUSCLE STIMULATION. M.A. Giambenedet, F.A. Dalvi, R. Valente and L. Vecchio, Institute of Medical Pathophysiology, University of Chieti, Italy. Previous studies have shown that rats implanted with an artificial stone in one ureter develop referred hyperalgesia of the ipsilateral oblique musculature which lasts many days. The present study examined input to the spinal cord dorsal horn from the hyperalgesic muscle in 15 stone-implanted rats and from the corresponding normal muscle in 15 controls, using electrophysiological recordings. Contractions were made from 114 single dorsal horn neurons in calculosis rats and 137 units in controls in the T10-T12 segments. Testing was as follows: gentle brushing of the dorso-caudal body surface, noxious skin pinch, graded pressure over muscle, noxious muscle pinch. In calculation rats, 25.66% of the recorded neurons received input from the oblique musculature, with additional input from the skin in 21% of the cases. Of the neurons with muscular input, whether muscular-cutsaneous or purely muscular, 50% displayed background activity and 17.24% were exclusively activated by noxious stimuli. In normal rats, 13.13% of the neurons received input from the oblique musculature, with additional input from the skin in 17% of the cases. Of the neurons with muscular input, 50% displayed background activity and 11.11% were exclusively driven by noxious stimuli. The statistical analysis showed that in calculation rats, there exist a significantly higher number of cells with muscular input was recorded (p<0.001) and, of these cells, a significantly higher number displayed background activity (p<0.001). The results seem to indicate a condition of central sensitization of dorsal horn neurons in rats with referred muscle hyperalgesia from viscera.

395.12

Vaginocervical stimulation (VS)-induced increases in pupil dilatation (PD) and analgesia [as measured by vocalization threshold (VOCT) to tailshock] are reduced, but not abolished, by combined bilateral pudendal, pelvic, and hypogastic neuroectomy (NX). In the present experiment, rats underwent aspiration transection of the spinal cord at levels L5 or T7 to determine if such procedures would replicate the effects of NX, and to determine which of the residual responses, if any, are affected by vagotomy (VX). A control group received a sham operation. VS significantly increased both PD and VOCT to front paw shock, in the SH, L5, and T7 groups. The increases in PD and VOCT in the SH group were significantly greater than those in either the L5 or T7 groups. The differences in VS-induced increases in PD and VOCT between the L5 and T7 groups were not statistically significant. VX abolished the VS-induced increase in PD in the L5 and T7 groups. The effects of VX on the VS-induced increase in VOCT could not be adequately determined after VX due to low survival rate at the time of assessment. In summary, VS-induced responses of PD and analgesia persist after spinal transection at L5 and T7, and subsequent VX abolishes VS-induced PD. These findings provide evidence that a physiological response (PD) to VS is mediated, in part, by the vagus nerve.

EVIDENCE THAT THE VAGUS NERVE MEDIATES SOME EFFECTS OF VAGINOCERVICAL STIMULATION AFTER GENITAL DEAFFERENTATION IN THE RAT. R. Corvus-Rolim, G. Sananes, R. Bianco, L. Gomiero, C. Bryce, R. Whipple, E.J. Mujica-Martinez, and B.R. Komisaruk. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102 and CNICESTAV INP, Apto, Postal 14-740, Mexico, 07000, D. F. MEXICO. In order to ascertain whether any effects of vaginocervical stimulation (VS) are mediated by the vagus nerve, we first transected all obvious afferent nerves from the reproductive tract and then tested for residual responses to VS. After combined bilateral transection of the pelvis, hypogastic and pudendal nerves (NX), the following responses to VS were greatly reduced or abolished: lordosis to flank-perineum palpation, leg extension, immobilization and blockage of both tail withdrawal to radiant heat and leg withdrawal to foot pinch. However, after these nerve cuts, the following persisted as significant responses to VS: 1) Pupil Dilatation (PD); 2) Subdiaphragmatic vagotony significantly reduced the magnitude of this residual response; 2) Analgesia (measured as an increase in vocalization threshold to tail shock), the subsequent vagotomy abolished the analgesia; 3) Heart rate (HR); the subsequent vagotomy produced no significant effect on the HR increase to VS. The present findings provide evidence that the vagus nerve conveys vaginocervical afferent activity that produces pupil dilatation and analgesia. 395.14

COMPLETE SPINAL CORD INJURY DOES NOT BLOCK PERCEPTUAL RESPONSES TO VAGINAL OR CERVICAL SELF-STIMULATION IN WOMEN. B.R. Komisaruk and B. Whipple, IAB and College of Nursing, Rutgers - The State Univ. NJ, Newark, NJ 07102

In 8 women diagnosed as having complete spinal cord injury (SCI) [4 women @ T6-10, 4 women @ T11-12], and a non-injured control group (5 women), vaginal or cervical self-stimulation (VCS) significantly increased group mean pain thresholds in the SCI groups by up to 74% and in the control group by up to 57%. There were no significant differences among groups in magnitude of this effect. Seven of the 8 women with SCI reported that they experienced sexual cramps. The threshold to perceive cervical self-stimulation per se was significantly higher in the 4/8 women with SCI who perceived this stimulus than in the control group. The perceptual responses to VCS in the women with SCI @ T11-12 may utilize hygoplastic afferent nerves that enter the spinal cord as far rostral as T10; however, the perceptual responses to VCS in the T6-10 group were unexpected. Possible afferent pathways include: 1) intraspinal visceral afferent pathways that remain intact after SCI, are not tested for, and are not part of the criteria for defining "complete" SCI (i.e., absence of voluntary movement, cutaneous pain and touch below the level of SCI); 2) a vaginal afferent pathway from uterine cervix and/or adjacent regions that could bypass the spinal cord and enter the medulla oblongata directly. The latter is supported by recent findings in rats.

PUTATIVE C-FIBER SOMATIC AFFERENTS FROM THE HINDLIMB DO NOT CONVEY THERMAL SENSORY INFORMATION TO NUCLEUS TRACTUS SOLITARIUS (NTS) IN RATS. G.M. Tonev and S.W. Miltin. Department of Pharmacology, University of Texas HSC, San Antonio, TX 78284

Activation of hindlimb somatic afferents elicits NTS neuronal discharge, but the sensory modalities mediating this excitation are unknown. Experiments were conducted in anesthetized rats to determine if hindlimb somatic afferent inputs to NTS convey thermal sensory information. The left hindlimb sciatric nerve was electrically stimulated (1 Hz frequency, 0.5 ms duration) and extracellular unit discharge evoked in the right NTS was recorded. Units were located medially to the tractus, near obex, at depths from 450 to 1100 μm. To categorize unit responses as being a-cfiber or c-fiber evoked, compound action potentials were recorded from the sciatic nerve and the averaged response to 30 stimuli compared at different stimulus intensities (n=3). Short latency excitation, presumably a-fiber mediated, was first recorded at an intensity of ~10 μV and became maximal near 100 μV. Longer latency excitation, presumably c-fiber mediated, appeared near 50 μV and became maximal at intensities of ~400 μV. NTS unit discharge was evoked at intensities averaging ±170 ± 69.5 μV (n=8), suggesting activation by c-fibers. Unit activity was further categorized as c-fiber evoked by injecting capsaicin (10 ng) into the hindlimb arterial supply. In 7 of 8 units, discharge significantly increased from 3.1 ± 1.2 Hz to 8.9 ± 1.5 Hz (p<0.05), while 1 unit failed to respond. Units were then tested for responses to thermal stimuli. Over a 10 second period, non-noxious (40 °C) and noxious (47 °C) heat was applied to the hindlimb. In no instance did heating affect NTS neuronal discharge frequency. These data indicate that NTS units activated by hindlimb somatic nerve stimulation appear to receive c-fiber inputs, but these inputs do not transmit thermal sensory information. Neurogenic dural inflammation has been proposed as a source of pain during migraine. This inflammation is produced by the release of inflammatory neuropeptides, resulting in ipsilateral dural protein extravasation from post-capillary venules and increased dural blood flow. Most groups using this animal model of migraine have quantified the amount of protein extravasation using exogenous radiolabeled albumin.

We modified the technique to measure the amount of endogenous albumin leaking into the dural extracellular reaction of albumin with the fluorescent dye, Evans Blue. The dye was injected intravenously in zebrafish pigs, prior to stimulation of the trigeminal ganglia. Following unilateral ganglion stimulation, samples of dura overlying both hemispheres were removed, rinsed, and mounted on a microscope slide. The amount of Evans Blue trapped in dural tissue was measured using a Zeiss fluorescence microscope equipped with a spectrophotometer. This computerized system automatically performed readings on 25 different sites on the tissue and calculated the associated statistical values. Values were expressed as the ratio of average fluorescence in ipsilateral vs. contralateral dura for each animal. This method utilized multiple measurements on each sample which resulted in very precise measurements with a small number of animals per point (n = 3). The ability of several compounds to prevent dural extravasation was evaluated. This model was successful in discriminating the clinically effective and ineffective compounds.

Selective blockade of spinal 5-HT,-receptors strongly potentiates withdrawal reflexes in the decerebrated rabbit, a result which implicates these receptors in tonic descending inhibition (R.L. Clarke & A.K. Houghton, J. Physiol. 433, 19(2), 239-256, 1991). In the present study we have investigated the effects of a selective 5-HT,- receptor agonist, (1)-β-hyderoxy-2-(3-n-propylaminomethyl)-8-(OH-DPAT), on withdrawal reflexes in spinalized rabbits.

Twelve animals were decerebrated and spinalized under halothane/NO anesthesia. The left sural nerve was stimulated electrically to excite selectively Aδ axons only or Aδ + Aδ fibres. Reflexes were recorded from the ipsilateral gastrocnemius muscles (GMS) muscle nerve, averaged, and integrated. 8-OH-DPAT was given iv. in doses of 1, 9 and 90μg/kg, followed by the selective 5-HT,-agonist WAY-100,135 (a gift of Wyeth Research (U.K.) Ltd), also given iv. at 1mg/kg. When high stimulus strengths were used, 8-OH-DPAT always increased reflexes at doses up to 10μg/kg, after which the reflex was a median of 21% (10/10) of resting controls. Increasing the dose of 8-OH-DPAT could increase reflexes further (2 rabbits) or decrease responses (3 animals). WAY-100,135 always had the opposite effect to the agonist. In contrast, reflexes evoked by low intensity stimuli were usually (6 of 7 animals) suppressed after 8-OH-DPAT. In these experiments, the median reflex after the 10μg/kg dose was 46% of controls (n=7, range 10-101%). The reflex increased by WAY-100,135 to a median of 166% of the pre-drug values (range 44-431%). Thus, 5-HT,-receptor activation can facilitate or suppress polysynaptic reflexes, presumably through actions at multiple sites in the reflex pathway. AKH is an SENS critic.

Two classes of presumed pain modulating neurons have been identified in the rostral ventromedial medulla (RVM) of the lightly anesthetized rat. "On"-cells display a burst of activity, and "Off"-cells become quiescent prior to a noxious heat-evoked tail flick reflex (TF). A third class of cells, "neutral," show no TF-related changes in firing.

The role of serotonin within the RVM is not well understood. The aim of the present study was to examine the effects of serotoninergic agonists on the activity of on-, off- and neutral cells. Fifty-three out of 59 cells (99%) responded to 5HT. The predominant effect on all cell classes was a facilitation of spontaneous (45%) and glutamate-evoked (55%) activity. An effect blocked by the 5HT2c antagonist ketanserin. 5HT also enhanced the TF-related on-cell burst. Ketanserin by itself had no effect on cell discharge.

The 5HT1a agonist 8-OH- DPAT (2μm) selectively inhibited the IPSPs in the majority of cells tested. Neurons inhibited by 8-OH-DPAT were on many occasions excited by the antagonistic application of 5HT itself. This effect was similar to that of ketanserin.

These results suggest that individual neurons within the RVM can be both excited and inhibited by serotoninergic agonists. Each receptor subtype shows different behavior to different agonist concentrations. These results confirm that serotoninergic neurons are involved in the modulation of pain processing. Further work is required to unravel the mechanisms involved in the neuronal modification of pain processing.

Serotonin (5-HT) strongly potentiates the spontaneous pain response produced by intraplantar injection of inflammatory mediators (Hong & Abbott, Neurosci., in press). The present study explored the receptor subtype(s) mediating this synergistic effect of 5-HT in algogenesis, and the effects of 5-HT antagonists on formalin-induced pain.

5-HT agonists were injected, alone or with non-steroidal (NSA) or prostaglandin (PG) inhibitors, intraplantarly into the plantar surface of the paws of rats. The behavioral response was recorded using the rating scale developed for quantifying formalin-induced pain. 8-OH-DPAT and 2-methyl-5-HT produced only minor analgesia, and did not interact with PG or NSA. The 5-HT agonists DOI, MCP and 2-methyl-5-HT produced little response alone, but induced lasting and licking lasting more than 30 min with moderate to high doses of NSA. The algogenic effect of 2-methyl-5-HT plus PGE2 was dose-dependently blocked by intraplantar pretreatment with the 5HT,-antagonists ketanserin (50-μg/mg) and ketanserin (50-μg/mg) and ranitidine (10μg/mg) or the 5HT,-antagonists ketanserin (50-μg/mg) and ranitidine (10μg/mg) or the 5HT,-antagonists ketanserin (50-μg/mg) and ranitidine (10μg/mg) or the 5HT,-antagonists ketanserin (50-μg/mg) and ranitidine (10μg/mg) or the 5HT,-antagonists ketanserin (50-μg/mg) and ranitidine (10μg/mg). These results suggest that 5-HT-agonists may be effective in the treatment of pain in chronic pain states, as well as in the processing of nociception (Supported by NS14455, NS28064, NS11255).

1Marion Merrell Dow Res. Instit., Cincinnati, OH 45225, \n2Strasbourg, France 67080, \n3McGill Univ., Montreal, Canada H3A 2B4; \n4Mass. General Hosp., Boston, MA 02114.

The clinical success of SHT-receptor agonists has indicated a role for a SHT-like receptor in migraine. Two models have been proposed which postulate either a vascular or neural location for the SHT receptor. MDL 100,687A was characterized in vitro and then evaluated in vivo for their ability, following i.v. administration, to alter blood flow in the carotid circulation (closure of arteriovenous anastomoses in cats) or transmitter release (attenuation of plasma extravasation following intrathecal injection of capsaicin and gain pigs). MDL 100,687A was similar in potency and efficacy to sumatriptan in affecting blood flow (ED50 values were 438 and 726 nmol/kg, respectively). In contrast, respective ED50 values vs. plasma extravasation were 2-4 orders of magnitude lower (0.5 and 5.5 nmol/kg). In addition, the minimally effective dose of MDL 100,687A was 1,000-fold lower than that of sumatriptan in the neurogenic model. Thus, in general, the SHT agonists were more potent against the neural vs. the vascular component of migraine and specifically, MDL 100,687A was exceedingly potent (compared to sumatriptan) against its neural components. These two responses might be having different pharmacological mechanisms.

396.9

NGF has been shown to produce hyperalgesia 24 hr after injection in rats. We tested the effect of 0.1 μg of NGF injected intrathecally in mice. The latency of the tail flick test, a hot water bath maintained at 49°C was significantly decreased at 24 and 48 hrs after injection of NGF. In contrast, the abdominal stretch response (writhing) to an intraperitoneal injection of acetic acid was not altered by NGF pretreatment at these times. Parallel studies indicate that SP-1(7), the predominant N-terminal metabolite of SP, was antinociceptive in the abdominal stretch assay at 24 and 48 hrs. However, a dose of 100 nmol of SP-1(7), injected 24 hr before testing, elicited no change in the hot water tail flick response. In spite of its lack of efficacy in the tail-flick assay, when 1 to 100 nmol of SP-1(7) was administered together with 0.1 μg of NGF, this N-terminal fragment of SP inhibited the hyperalgesic effect of NGF in a dose-related fashion. D-SP-(1-7), a D-amino acid substituted isomer of SP-1(7) that antagonizes SP N-terminal binding and activity, reversed the inhibitory effect of SP-1(7) on NGF-induced hyperalgesia. Together these data suggest that N-terminal metabolic fragments that are presumed to accumulate in the spinal cord during pain transmission serve as long-term modulators of pain by antagonizing the action of NGF. (Supported by NIDA 04090)

396.10

The superficial laminae of the dorsal horn of the spinal cord (laminae I and II) are areas rich in the neuropeptide Substance P (SP). These are the areas where the small lightly myelinated and unmyelinated Aδ- and C-fibers terminate. Activation of these fibers elicits an increase in the release of SP in the dorsal horn of the spinal cord. The opioid peptide met-enkephalin, is also found in high concentrations in the dorsal horn and is a selective δ-opioid receptor agonist. The aim of this study was to determine whether δ-opioid receptors are involved in the control of the release of immunoreactive SP in the dorsal horn when noxious mechanical or thermal stimuli are applied to the ipsilateral hindpaw of the rat.

A push-pull cannula was introduced into the dorsal horn at the lambar enlargement in decerebrate/spinalized rats. The spinal cord was perfused with artificial CSF and immunoreactive SP (SPLI) was measured using RIA, before and after the application of a noxious mechanical or thermal stimulus. All drugs were applied to the dorsal horn through the perfusion apparatus.

ME reduced the tonic release of SPLI. It also bloclked the increase in SPLI following either the mechanical or thermal stimuli. The effect of ME was blocked by nalttradine (NDT, a selective δ-opioid receptor antagonist). NTD alone, elicited an increase in the tonic release of SPLI. These results suggest that there is a δ-opioid receptor mediated control of the tonic as well as the evoked release of SPLI.

396.11

RPR 100863 is a potent and selective antagonist of human Nk1 type 1 (Nκ1) receptors. We used whole-cell patch clamp techniques to evaluate the antagonist activity of RPR 100863 on the peak outward (potassium) current recorded from the human angiotoma cell line U 373 MG. 100 nM RPR 100863 inhibited receptor activation by substance P (SP: 10 nM for 5 secs once every 5 min). At least two control responses to SP were recorded prior to a 10 minute continuous application of antagonist. RPR 100863 (10−12–10−7 M) inhibited SP-induced current in a concentration-dependent manner with an IC50 value of 28 nM. In control experiments, the antagonist effect of RPR 100863 was tested on NK1 receptors, in the presence of 2 μM SP, 100 nM U 373 MG. 100 nM RPR 100863 (10−12–10−7 M) inhibited SP-induced currents (10 μM). The antagonist effect was dose dependent and reversible. These results confirm that RPR 100863 is a potent and stereoselective antagonist of human NK1 receptors, and indicate that this may have slower association and dissociation kinetics than previously described Nk1 receptor antagonists.

396.12

THE SUBSTANCE P N-TERMINAL, HEPATEPIDET, INJECTED 24 HRS BEFORE THE FORMATION OF SP AUTOPHANY INHIBITS THE TONIC PHASE. V.M. Coutiño and A.A. Larsson. Graduate Program in Neuroscience, Univ. of Minnesota, St. Paul, MN 55108, U.S.A.

There is much evidence that substance P (SP) is released in the spinal cord in response to a nociceptive stimulus. Since conditions such as hyperalgesia can occur days or months after nociceptive stimulation, we investigated whether SP produces long-term effects. The SP N-terminus and SP N-terminal metabolites, such as SPI(1-7), produce antinociception in the abdominal stretch assay when injected intrathecally (I.t.) 30 min before testing. However, in the formalin assay, in which mice are injected s.c. with 30 μl of 5% formalin into the dorsum of the rear foot and the amount of time spent licking or biting the foot is counted, SPI(1-7) was without effect in the acute phase (0-5 min) or the chronic phase (20-30 min) of the behavioral response when SPI(1-7) was injected i.t. 5 or 30 min before formalin injection. However, when administered i.t. twenty-four hours before testing, SPI(1-7) produced a U-shaped dose-response curve in both phases. The acute phase was potentiated at 125% and 135% of control at doses of 1 and 10 nmol, respectively. In contrast, the tonic phase was inhibited with decreases to 64% (p<0.05) or 51% (p<0.05) at 0.1 nmol. 51% and 59% at 10 nmol. Ten nmol of SPI(2-11), a C-terminal SP metabolite active at neurokinin receptors, was without effect. These data implicate an accumulation of both the long-term and differential modulation of pain, perhaps contributing to the development of hyperalgesia or allagasia chronically, depending on the type of nociception measured. **EFFECT OF L-TYPE CALCIUM CHANNEL ANTAGONISTS ON THE RESPONSES OF DORSAL HORN NEURONS TO PERIPHERAL CUTANEOUS STIMULI AND TO SUBSTANCE P IN CATS.** V. Radakrishnan and J.L. Illes*. Departments of Physiology and Psychiatry, McGill University, Montreal, Quebec.

Substance P, a mediator of nociceptive transmission at the level of the primary afferent synapse, is capable of elevating intracellular calcium in dorsal horn neurons. Substance P (NK-1) receptor antagonists, such as CP-96,345 and CP-99,994, have been shown to interact with L-type calcium channels, thereby raising doubts about NK-1 receptor selectivity in blocking nociceptive responses. Therefore, in the present study we have tested the effects of L-type calcium channel blockers, verapamil and diltiazem, on the responses of spinal dorsal horn neurons to peripheral cutaneous stimulation and to iontophoretic application of substance P. Extracellular recordings were obtained using multibarrel electrodes from L4-L6 segments of the spinal cord in cats anesthetized with α-chloralose and spinalectomized at the L1 level. Substance P, verapamil and diltiazem were applied to the neurons by iontophoresis. Verapamil and diltiazem depress spontaneous activity by 20-40% in 8/10 neurons tested. The response to hair stimulation was depressed (20-50%) in 7/10 neurons. Responses to noxious mechanical and noxious thermal stimuli were depressed (40-60%) in 6/6 neurons. The response to substance P was also blocked by verapamil and diltiazem in 5/6 neurons. Thus, in contrast to NK-1 receptor antagonists which did not affect the spontaneous firing or the response to hair stimulation at doses that blocked the response to substance P, L-type calcium channel antagonists showed a suppression of all types of responses, irrespective of the intensity. Additionally, it is likely that the antagonism of nociceptive responses by CP-96,345 and CP-99,994 is unrelated to their interaction with calcium channels. **HYPERALGESIA INDUCED BY SPINALLY ADMINISTERED CELL PERMEABLE ANALOGS OF CYCLIC 3'5'-GUANOSE MONOPHOSPHATE (cGMP)** Ethin Abraham*, Mary G. Garry, Kenneth M. Harkevets and Lin Aanoners†. 1st of Biology, Macalaster College, St. Paul, MN 55105; 2nd, Dept. of Restorative Sciences and Pharmacology, University of Minnesota, Minneapolis, MN.

Recent studies have shown that spinal levels of cyclic 3'-5' guanosine monophosphate (cGMP) are greatly involved in the development of hyperalgesia. The purpose of the present study was to investigate whether direct, spinal application of cell permeable cGMP analogs would result in a hyperalgesic response as measured in the hot-plate assay. Male, NDS Swiss mice (16/group) were injected intrathecally (i.t.) with 8-bromoguanosine 3'-5'-cyclic monophosphate (8-bromo-cGMP, 100 µg) or saline (baseline). If (i.t.) 1) if there was a hyperalgesic effect (a decreased latency to lick the hind-paw) and 2) the time course of the effect. 8-bromo-cGMP produced a significant hyperalgesic response when compared to a saline control from 3 to 30 minutes post-injection. Maximal effects were observed at 10 min., thus, this time was used in subsequent studies. 8-bromo-cGMP and N2,2'-O-dibutyrylguanosine 3'-5'-cyclic monophosphate (db-cGMP) produced dose-dependent hyperalgesia with ED50 of 0.69±1.59 mmol/ml and 0.79±1.11 mmol/ml respectively. The selectivity of this response was determined by observing the response to i.t. injection of other cell impermeable guanosine compounds and CAMP. The other guanosine compounds did not have an effect, while a CAMP significantly increased hot-plate latency. These results suggest that spinal cGMP may be involved in the facilitation of thermal hyperalgesia in mice.

**ACTIVE PROTEIN KINASE C INCREASES RELEASE OF NEUROPEPTIDES FROM RATTLE SENSORY NEURONS.** L.A. Barber* and M.R. Vasko, Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, Indiana 46202.

Although activation of protein kinase C (PKC) has been shown to enhance excitability of sensory neurons, it is not known whether this activation alters the release of neuropeptides from sensory neurons. We have recently shown that PKC alters the release of substance P (SP), and calcitonin gene-related peptide (CGRP) from rat sensory neurons in culture. To further define the relationship between PKC and neuropeptide release, we have employed a number of PKC inhibitors to determine the PKC dependency of SP and CGRP release from rat dorsal root ganglia neurons. Sensory neurons were dissociated from fetal rat dorsal root ganglia (E19-17) and grown in culture for 9-12 days. Release experiments were performed using neuronal cultures for 10 minutes in the presence of ionophore A23187 (10µM) and 1mM ATP. The PKC inhibitors were staurosporine, H20118, and G50286. These agents were added at concentrations of 10-4M to the perfusate containing 1mM ATP and 10µM of ionophore. SP and CGRP release were measured by RIA and HPLC, respectively. The results show that PKC and CGRP release are enhanced by ionophore-induced calcium influx. The results suggest that PKC activation is involved in the augmentation of release of SP and CGRP from sensory neurons, and that this mechanism is important in the regulation of neuropeptide release from these neurons.

Inflammatory mechanical hyperalgesia induced by tissue injury (e.g. exposure to carrageenan) is due to activation/sensitization of sensory nerve terminals by mediators which are also released by mast cells. Tissue damage is also reportedly associated with increased generation of the N-acyl-(2-hydroxyethyl)hexadecanamide, recently proposed to behave as a local autacoid capable of negatively modulating mast cell activation. To test this concept, treated and untreated rats were administered intrathecal (i.t.) saline or a nanomolar dose of this compound. Incapable tailshock produces supersensitivity to morphine analgesia (see companion abstract). The addictive nature of supersensitivity is in agreement with previously reported learned helplessness effects. Since several learn and unlearn procedures can be prevented by opiate antagonists or benzodiazepines prior to inescapable shock, these drugs were used to determine if they would also prevent supersensitivity to morphine analgesia.

Rats were injected ip with 5 mg/kg diazepam, 10 mg/kg naloxone, or vehicle. Rats then received either 100 tailshocks (5 x 1 min variable ITI, 1 mA) or an equivalent period of restraint (control). Rats were then used for pain responsivity (tailflick TF) tests in a novel environment 24 hrs later. Rats were first assessed for baseline pain responsivity (3 TF), followed by either 1 mg/kg s.c. morphine or 1 mg/kg s.c. sterile saline. 

Beginning 15 min later, 3 TF intensities were assessed each min for 60 min. Regardless of drug received prior to shock, no analgesia was observed in any group injected with s.c. saline at time of pain testing. Likewise, no analgesia was observed in any morphine-injected restraint control group. In contrast, profound morphine analgesia was observed in vehicle-injected rats exposed to tailshock 24 hrs previously. This supersensitivity to morphine analgesia was prevented in rats which received either naloxone or diazepam at the time of inescapable tailshock.

These data re-interpret supersensitivity to pharmacological morphine analgesia induced by inescapable tailshock. Prevention of these effects by opiate antagonists & benzodiazepines at time of shock is in agreement with other previously reported learned helplessness phenomena. NIH MH351470

397.1 GROWTH FACTOR STIMULATION OF OPSIN IMMUNOREACTIVITY IN CULTURE FROM ROD PHOTORECEPTORS FROM THE RODLESS MICE. J. C. Blank*, E. Barron, S. Y. Schmidt, Y. Courtois and D. Hidu. Doheny Eye Institute, Los Angeles, CA 90033; INSERM, Paris, France.

Retinal cell cultures from postnatal day 1 (P1) control and rd mice were used to assess the effects of various growth factors on neuronal differentiation. In rd retinas, the photoreceptor degenerate during early development due to a deficiency in a specific opsins. Our objective is to develop an in vitro system in order to enhance photoreceptor cell survival and/or differentiation. Retinal suspensions from P1 control and rd mice were grown on coverslips at 5 x 10^5 cells/coverslip under basal conditions or in the presence of bFGF (10 ng/ml), NGF (50 ng/ml), EGF (20 ng/ml) or bFGF and NGF combined. Photoreceptor cell viability in cultures of control and rd mice were evaluated by counting the numbers of opsins-positive cells (opsin+) throughout the entire coverslip after 4 days in culture. The numbers of opsin+ cells were similar in control and rd cultures, and in both there was a two- to threefold increase relative to baseline in cultures with bFGF and NGF. EGF had no effect on photoreceptor numbers. There did not appear to be a synergistic effect when bFGF and NGF were combined. Cultured cells survived for a minimum of 9 days. Double-label studies are in progress with opsin and neuron-specific enolase (NSE) antibodies to determine if bFGF and NGF have a specific effect on photoreceptor cells or if their effects extend to other neuronal cell types in the retina labeled by NSE. The finding that opsin+ photoreceptor cell numbers were increased by growth factors in rd as in control retinal cultures raises the possibility that bFGF and NGF may also help the survival of rd photoreceptors.

Phototransduction in retinal rods involves a signaling cascade that leads to cGMP hydrolysis and the closure of cGMP-gated cation channels open in darkness, producing a membrane hyperpolarization as the light response. For many years there has also been some evidence for the presence of a phosphoinositide pathway in the rod outer segment, though its function and the molecular identities of its components are still unclear. We have studied this problem with immunocytochemistry using antibodies against phosphoinositide-specific phospholipase C (PLC) isoforms and also alpha subunits of the Gq family of G proteins. Among the PLC isoforms we have examined (1), 3 and 1, only PLC4-like immunoreactivity was found in both rod and rod outer segments. At the same time, we have localized Gq11, a member of the Goq family, also in the rod outer segments of the same species. Immunoblotting of total retinal proteins with anti-PLC4 and anti-Gq11 antibodies also gave a single protein band in crude rod retinal and rod outer segments. At the same time, we have localized Gq11, a member of the Gq family, also in the rod outer segments of the same species. Immunoblotting of total retinal proteins with anti-PLC4 and anti-Gq11 antibodies also gave a single protein band in crude rod retinal and rod outer segments. We conclude that PLC4 and Gq11 are likely to be part of the phosphoinositide signaling pathway in the rod outer segment. Biochemical studies are in progress.

We examined previously that the expression of the rhodopsin promoter linked to an attenuated diptheria toxin gene, eliminates rod photoreceptors in the retina of transgenic mice, leaving what appear morphologically to be cone somata in the outer plexiform layer (OPL). In recent studies, we have obtained further evidence that the cells that remain in the OPL of our transgenic mouse retinae are cones, and, therefore, that the direct effect of this genetic ablation is limited to the rods. In one set of experiments, we used reverse transcription PCR to quantify the levels of rod and cone opsin transcripts. In our "rodless" mice, rhodopsin expression is lower at 14 days postnatally than in age-matched controls, and rhodopsin cannot be demonstrated after 21 days. Blue cone opsin expression in the "rodless" retines, while lower than in controls after 35d, can still be detected in "rodless" adults. Similar experiments are now being performed to quantify the levels of rhodopsin opsin remaining after rod ablation. We also used peanut agglutinin to selectively label cone and cone outer segments in our "rodless" mice. The proportion of labelled somata in the OPL increases with age, and only labelled somata remain at 35d. In addition, we crossed our "rodless" mice to transgenic mice in which bipolar and ganglion cells express the 8-gal-gene. The number of bipolar cells in these retinae appears normal. Their location within the inner nuclear layer (INL) appears altered, however. Labelled bipolar cells are no longer found only near the outer margin of the INL, but are distributed throughout this layer. The selective loss of the rod photoreceptors also does not appear to affect the number of retinal ganglion cells. Supported by NIH EY10009 & EY04977.

397.4 DOCSOSAHEXANOIC ACID UPTAKE IN THE CONE-DOMINANT LIZARD RETINA. W.C. Green*, H.F. Baehr3 and N.G. Baehr. LSU Neuroscience Center, LSU Medical Center, New Orleans, LA 70112.

The retina effects the high-affinity uptake of docosahexaenoic acid (DHA). Photoreceptors actively accumulate DHA for synaptic and photoreceptive membranes. Light- and electron microscope-level autoradiography of [3H]DHA has shown that from 63% (primates) to 92% (amphibia) of total retinal label occurs within photoreceptors. In the frog, rod photoreceptors incorporate much more DHA than cone photoreceptors, but [3H]DHA labeling of rods and cones is similar in monkey and rabbit retinas. To determine if some cone photoreceptors are more similar to rods, we used the American chameleon (Anolis carolinensis), which has a cone-dominant retina with a pronounced foveal region consisting of morphologically distinct, long, slender cone cells, and a peripheral region of shorter, wider cones. As controls, we used an all rod retina, from the mediterranean gecko (Hemidactylus turcicus), and the frog (Rana pipiens). Retinas were incubated 4 h in 2 µCi/ml [3H]DHA (SA 23 C/mmol). Half of each retina was prepared for lipid analysis, the other half for autoradiography. Animals of each species gave a good, rod-based pattern. Our data revealed that DHA mole percent content was similar in frog and gecko (32%) but only half in chameleon (18%). von Scante et al. (Jovet. Ophthalmol. Vis. Sci. 32:2558-2566, 1994) recently described rod-cone similarities in the cone-dominant squinted retinas at a molecular level. Based on these differences among the cell types of the animals studied, we suggest that some cone photoreceptors may possess pathways of phospholipid metabolism that are closer to those found in rods. IDEAL OBSERVERS OF NEURAL SIGNALS IN PHOTO-
TRANSMISSION AND THE NOISE CHARACTERISTICS OF A
PHOTOCONDUCTOR. J. D. Immel, J. Stavrianos, and R. L.
Winlow*, Dept. of Biomedical Engineering, Johns Hopkins
University School of Medicine, Baltimore, MD 21205

The rod phototransduction model of Forlì et al. was linearized
about operating points corresponding to various background light
levels. The linearized model was used to predict low frequency
quantal noise in the outer segment current. The just noticeable
difference (JND) in intensity (in units of photoreceptor/s) based
on observation of outer segment current in response to 200 msec
light flashes was determined at different background levels using
ideal observer theory. Performance was compared to that
predicted based on optimal processing of photon counts.

Results show that the linearized Forti model of phototransduction
represents features of low frequency outer segment current noise
measured experimentally, such as: a) the magnitude of the noise is a
non-monotonic function of the background light level, with the
maximum occurring at a dim illumination level; and b) trapping
BAPTA (a calcium chelator) in the rod increases noise level.

Ideal observer analyses indicate that intensity JNDS based on
observation of outer segment current in response to light flashes are
5-10 times higher than JNDS based on photon counts. The
phototransduction process therefore results in an information loss
at the earliest stages of neural processing within the retina.

RP-CAMPS: A COMPETITIVE ANTAGONIST OF CYCLIC NUCLEOTIDE-
GATED CHANNELS. Richard H. Kramer* and Gareth T. O. "Dept. of
Molec. & Cell. Pharmacol., Univ. of Miami School of Med, Miami, FL
33101, and Biological Psychology, SUNY, New Paltz, NY, 10033

Cyclic nucleotide-gated (CNG) channels generate the primary electrical
signal in photoreceptors and olfactory neurons during sensory responses.
Cyclic nucleotides bind to a site on CNG channels that is homologous to the
cyclic nucleotide binding domain of CAMP- and CAMP-dependent protein
kinases. Therefore we investigated the effect on CNG channels of thioate
derivatives of CAMP and CCGMP (RP-cAMPS and RP-cGMPS; competitive
antagonists of CAMP and CAMP antagonists, respectively). In CNG
channels from catfish olfactory neurons (OLF channels), RP-cAMPS is a partial
agonist. Alone it only weakly activates OLF channels, but strongly
agonizes activation by co-applied CAMP or CCGMP. The inhibition is
competitive, with a large effect at low CAMP levels and no effect at saturating
CAMP. Single channel analysis shows that RP-cAMPS reduces open probability
without affecting single channel conductance. In contrast, Sp-cAMPS, the
diester of RP-cAMPS, is a full agonist of OLF channels. One might
expect RP-cAMPS to antagonize activation of rod photoreceptor CNG
channels (RET channels), since these channels are selectively activated by
cAMP. However, RP-cAMPS is an agonist, activating up to 80% of the current
elicited by saturating CAMP. Surprisingly, RP-cAMPS is a pure antagonist of
RET channels, exhibiting a K_i of 200-500 mM. RP-CP-cAMPS is an even
higher affinity antagonist that is also membrane-permeant. Extracellular
application of this analog may be useful for investigating the functional role
of CNG channels in these and other cell types. Supported: NIH grant NS36695.

MULTIPLE CALCIUM CHANNEL SUBTYPES IN TIGER
SALAMANDER CONE PHOTORECEPTORS. M.E. Wilkinson* and S.
Barney, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1

Numerous studies confirm that photoreceptor Ca channels, activating
near -40 mV and showing little if any inactivation, are of the high-voltage-
activated, low-threshold type. In this study, two possibilities for the
presence of cone photoreceptors bathed in 5 mM BaCl_2 revealed HVA Ca channel
subtypes. The majority of Ca channel current was L-type as it was blocked in
a voltage-dependent manner by 8-400 μM nifedipine (0.1 - 100 μM),
but a component of Ca channel current was resistant to even the highest
dose of nifedipine. Kinetic properties of the current
component activated in 10 μM nifedipine seemed to support the idea that
activation occurred faster and more inactivation was seen. Most of this
component was reversibly blocked by w-conotoxin GVIA (1 μM),
indicating that these Ca channels are of the N-type. The voltage range of
activation was indistinguishable for L- and N-type. Bag K 8464 enhanced the
Ca channel current markedly and increased the time constant of tail
current deactivation from 10 μM to 100 μM. Application of w-conotoxin GVIA
(1 μM) to Bag K treated cells blocked a smaller proportion of current during
the depolarizing test step and had no effect on the slowed tail
current, suggesting that the agonist was not blocking L-channels. The
P-channel blocker w-agatoxin IVA (200 nM) had no statistically significant
blocking effect. A small current component that could be blocked by
CoCl_2, persisted in the presence of all three channel type blockers.

D_A Dopamine receptors, negatively coupled to adenylate
cyclase. Block the hyperpolarization activated current
(h) in mammalian rod photoreceptors. B. Lengyel*, G.G.
E Diplomatura Fisica, Pisa, Ist. Neurofisiologia, CNR, Pisa, ITALY.

The voltage response of retinal rods reflects both the suppression of the
whole-cell current entering at the outer segment and the activation of voltage dependent
conductances of the inner segment. We have measured the voltage
dependent currents and the membrane potential shift of retinal rods by using the
whole-cell voltage clamp technique. We found that the main component is an
inward current (i_h) activated by stepping the membrane potential to voltages
between -70 and -140 mV of the resting background. In an average of 200 - 500 M
BAPTA rods the half-activation voltage from -90 to -70 mV. Dopamin 1-10 μM
reversibly shifts the half-activation voltage of i_h from -90 to -105 mV, an effect
opposite to i_h application. The results suggest that dopamine receptors,
located on mammalian rod inner segments, inhibits the adenylyl cyclase.
The properties of dopamine receptors were further investigated on membrane
homogenates obtained from bovine rods, after isolation by mechanical
dissociation and purification on Ficoll gradients. By using the [H]-spiperone
binding assay we found the specific binding to be saturable and of high affinity
with a K_d of 0.05 nM. The K_i obtained from antagonist displacement curves are
consistent with the known pharmacology of D_A-like receptors, moreover the
K_i for clozapine (40 μM) is typical for D_A receptors. Biphasic displacement
curves for agonists suggest that dopamine receptors are coupled to an
endogenous G-protein (probably GTP.) The receptor from an
high affinity state for agonists to a low affinity one. We conclude that dopamine
affects the membrane properties of mammalian rods by activating D_A
receptors which are negatively coupled to adenylate cyclase.

ROD PHOTORECEPTOR M-CURRENT (i_M) IS STABILIZED BY CALCIUM-DEPENDENT PROTEIN KINASE.
D.E. Karpenko and S. Barnes*, Neuroscience Research Group,
University of Calgary, Calgary, Alberta, Canada T2N 4N1

When recorded with conventional ruptured-patch whole cell recording
in bright light, kinetic parameters of the non-inactivating voltage-sensitive
rod M-current (i_M) change gradually ("run down") in the following
manner: the maximum current amplitude and time constant of current
activation decrease, while membrane potential shift of the current
increases. In contrast, i_M was stable during ruptured-patch recording in complete
darkness or when using the perforated patch technique. However, the
stability of i_M could be maintained in ruptured-patch recordings by bright
light when the intracellular calcium concentration was increased by using either
calcium-BAPA buffer ([Ca]_o = 1 μM), or caffeine (1 mM). IP, a
second messenger that elevates calcium from intracellular stores stabilized
i_M when included in the pipette solution at 10 μM but not at 1 μM.
Including the phorbol ester PMA in the pipette solution (20-100 nM) also
prevented rundown of i_M but in only 50% of cells. The protein kinase C
inhibitor, H-7, added to the pipette solution (1 μM) prevented the receptor from an
Ca (Ca-BAPA buffer) restored i_M rundown. 1,2-dioctanoyl-sn-glycerol
(50 μM) KPI/AEG (10 μM) and CAMP (200 μM), ATThS
or GTPjS (up to 1 μM) and intracellular calcium
levels to stabilize i_M. None of the drugs caused any effect on i_M when applied
extracellularly. We conclude that a calcium-dependent substance
inhibited by H-7, probably protein kinase C, is present in photoreceptors
and is necessary for i_M stability.

Extracellular pH and CI Concentration modulation independently
Ca^2+ Currents in Tiger-Salmanders' Photoreceptors. B. Nitzan* and R.F. Miller.
Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455

Ca^2+ currents and intracellular pH were studied in dissociated
photoreceptors from tiger salamander retinas. Cells were loaded with either Fluo-2
(Ca^2+ indicator) or BCECF (pH indicator) and imaged using a dual wave length
ratios imaging technique. The fluorescence was collected using a cooled CCD camera
(Photometrics). Ca^2+ currents were evoked by introducing high potassium concentration
in the bathing solution for short duration (~5 s).

High potassium evoked Ca^2+ currents were mainly localized
in the photoreceptors soma and pedicle. Elevated of (Ca^2+), was also observed in the
dense layer, and to a lesser extent in the outer segments, of the retina. Ca^2+ current
was slowly suppressed following introduction of Cl^- medium (both SO_4^- or
CHES/NEAT were used as Cl^- replacements). At the same time no change in intracellular
pH was observed. This was detected, introducing NaCl of -30 mV, sufficiently long to
induce intracellular CI^- changes extracellular CI^- acidification (pH 8.0 to 6.0) along
with the high potassium stimulus was sufficient to suppress the Ca^2+ currents,
suggesting an extracellular mode of action of suppression of Ca^2+ currents.

These results point to parallel mechanisms for the effects of pH and
extracellular Cl^- on Ca^2+ currents in tiger salamander rods.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 26, 1994
INNER SEGMENTS OF SUNFISH SINGLE CONE PHOTORECEPTORS ARE GRADATED INDEX WAVEGUIDES: M. P. Rowe, N. Engheta, S. S. Ester Jr., J. M. Corcoba and E. N. Pugh Jr. Inst. of Neur. Sci., Univ. of PA, Philadelphia, PA 19104; Dept. Elecr. Eng., Univ. of PA, Philadelphia, PA 19104; Dept. Bio., Univ. of Mich., Ann Arbor MI 48109; Deps. Cell Bio. Neurobio., & Ophth., Duke Univ. Med. Center, Durham, NC 27710; Dept. Psych., Univ. of PA, Philadelphia, PA 19104 Cone cells isolated from the retina of the green sunfish (Leptosom cyanesse) were examined with a double beam scanning interferometer and also with transmission electron microscopy. With the interferometer, optical path lengths (OPLs) were measured perpendicular to the natural direction of propagation of light in the living fish eye. Measurements gave a resolution of 220 nm in diameter by 5 nm in path length for 632.8 nm (free space) incident radiation. By assuming cylindrical symmetry for the inner segment region of the cone cells, variations in refractive index can be inferred from these OPL measurements. Our analysis indicates that the average refractive index increases monotonically from around 1.39 at the base of the inner segment to 1.45 near its junction with the outer segment. This increase is consistent with general predictions based on an analysis of electron micrographs previously presented (Rowe et al., J. Optical Soc. A, 11:55-70).

SPECTRAL SENSITIVITY OF RETINAL CONES IN DANIO MALABARICUS (Giant danio): A. G. Palacios, B. Silvestrini & T. H. Goldsmith. Department of Biology, Yale University, New Haven, CT, USA.
The spectral sensitivity of individual cones of a fresh water fish (Danio malabaricus, Cyprinidae) was measured between 280 and 700 nm by recording membrane potentials with suction electrodes in response to brief flashes of monochromatic light of known quantal flux. These measurements extend further into the UV than have previously been obtained by this technique. We found four classes of cones with maximal sensitivity at 360 (n=5), 406 (n=7), 480 (n=10) and 561 (n=4) nm. With the exception of the UV-sensitive cone, all spectral sensitivity curves were well fit by an isopolar template.
The identity of the retinoid chromophore was established by HPLC. Retinal oximes were recovered from eyecups by extracting with a 1:1 mixture of methanol and 1M hydroxyamine (pH 6.5). The oximes were separated on a normal-phase silica column developed with 9% dimethane in hexane. Individual eyes contained an average of 580 pmol of retinal and 10 pmol of 3-dehydroretinal. Supported by NEI grant EY00222

HUMAN CONE ELECTRORETINOGRAM CAUGHT BY SECOND-PHASE CURRENTS: M. Sasaki, P. Sugita* & M. Ikeda.* P. Iachellope. Department Ophthalmology, Columbia University, NYC 10032 & McGill University, Department Ophthalmology, Montreal, Canada

The b-wave of the cone electroretinogram (ERG) of monkeys and man to a flash can be caught and reduced in amplitude by a second flash if it occurs within 20 ms after the first flash. The reduction is maximum at 10-15 msec after the first flash. It occurs at different states of retina adaptation, flash intensities and rates of double flash presentation. We suggest that this interaction between double flashes may reflect timing differences in the cone to on-off and bipolar synapses (Ashmore & Falk, 1980; Copenhagen et al, 1983) that lead to the generation of opposing ionic currents (Sieving et al., 1994) which underly this retinal response.

Supported by NIH Grant EY04138, National RP Foundation, Research to Prevent Blindness, Inc.

Introduction: Rod and cone signals in amphibian retina may interact at the level of the photoreceptors themselves and on second order cells. We have examined the role of D, dopamine receptors in modulation of both rod-cone coupling and transmission between Xenopus photoreceptors and L-horizontal/bipolar cells. Results: a null test, based on equal rod absorbance for red and green flicker indicated a significant presence of cone signal in mesopic and photopic rods. EM showed small gap junctions between rods and cones and injection of neurobiotin into rods labeled both adjacent rods and cones (ratio 1:1). The magnitude of cone input to rods could be manipulated with D3 agonists/antagonists. The flicker fusion frequency of dark adapted rods (4-5Hz) was increased by the D3 agonist, quipazine (10-10 M) to 12-20 Hz. This effect was observed with red, but not green flicker, its magnitude depended on the intensity and it was not affected by SKF 38393, CNQX or kynurenic acid. Spiperone, a D3 antagonist, reduced v to 2-3Hz. In the dark adapted retina the cone signal was absent from the HCs, but was expressed strongly in bipolar cells, as evidenced by intracellular recording and ERG. Cone input to bipolar cells was blocked by the D3 antagonist and increased by the D3 agonist. Conclusion: Transmission of cone signals to rods and to bipolar cells is modulated by a D3 dopamine mechanism. In the dark adapted state, cone signal continues to be expressed in the vertical (bipolar cells) pathway as a result of D3-dependent modulation, but is suppressed in the horizontal pathway. ELECTRICAL RESONANCE OF FROG SACULAR HAIR CELLS MEASURED IN THE PERFORATED-PATCH AND WHOLE-CELL RECORDING CONFIGURATIONS: D. Leventhal* and W. M. Roberts. Institute of Neuroscience, University of Oregon, Eugene, Oregon, 97403

Frequency discrimination in the inner ears of birds, reptiles and amphibians is accomplished in part by the electrical resonance issue to mechanoreceptive hair cells. Saccular hair cells of the frog (Rana pipiens) express a damped membrane potential (Vm) oscillation caused in part by the interactions of voltage-gated Ca channels with their actin-based active zones. Since an abundant, mobile Ca buffer appears to shape the Ca landscape at active zones, we asked whether its presence (in perforated-patch recordings, PPRs) interfered with Vm oscillations (in whole cell recordings, WCRs, where the native buffer was replaced by 1 mm EGTA) induced Vm oscillations recorded in current clamp. Oscillations during and after current steps were fitted with a damped sine wave by a least-squared-error algorithm at measure frequency (f), damping time constant, and quality factor (Q) oscillations in 7 cells in each recording configuration. Zero-current potentials were -53.68 mV (mean ±5.9 mV) in PP (series resistance, Rs = ±33.3 MΩ), and 40.2 mV in WC (Rs = 3.3 ±1.6 MΩ) measured at 90 ms after break-in. The relationship between Q and Vm was bell shaped; peak Q (where the resonance was most robust) was 10.6 ±6.7 in PP, and 8.9 ±1.0 in WC. The potential at peak Q was 2.5 ± Mv positive the zero-current potential in PP, and +6.12 mV in WC. The f measured at peak Q was 19.8 ±21.2 Hz in PP, and 2130 ±26.8 Hz in WC. Comparisons between peak Q, f at peak Q, and zero-current potentials in PP and WC were not significantly different using the Mann-Whitney test. These results suggest that the mobile Ca buffer does not greatly affect the resonant properties of frog saccular hair cells. Supported by NIH grant NS 27142 and a McKnight Scholar Award to WMK.

TWO TYPES OF INWARD RECTIFIERS IN HAIR CELLS OF THE MOUSE ULTRICLE A. Rossire & R. A. Fantook. Dept. of Otolaryngology, Baylor College of Medicine, Houston, TX 77030.

Whole-cell currents were recorded with the patch-clamp technique from hair cells in utricles excised from 2 to 17 d old mice. Recordings were obtained from both type I and II hair cells, the two morphologically classes of hair cells in mammalian vestibular organs. Two kinds of inward rectifying conductances were found. One type, resembling the inward rectifier /k1/, activated negatively to -50 mV with fast monoeponential kinetics. Its mean chord conductance at -124 mV was 3.3±1.1 nS (mean±SD, n=8 cells). It was blocked by 1 mM external Ba2+ or Ca2+.

The second type activated more slowly and with a sigmoidal time course at potentials negative to -60 mV. Its maximal conductance, expressed as a first-order Boltzmann relation with a V0.5 = 101.5±7.3 mV. The reversal potential was 43±1 mV (n=6 cells), and the chord conductance at -124 mV was 1.7±0.3 nS (n=8 cells). This current persisted in 1 mM external Ba2+ or 4 AP or intracellular Ca2+, but was blocked by 1 mM external Ca2+. This current is similar to /k1/ of photoreceptors and cardiac cells.

/k1/ was found in 24 out of 48 cells, including both type I and II. /k1/ occurred in most type II cells, including cells with /k1/ but we have not yet determined whether /k1/ occurs in type I hair cells.

K CURRENTS IN TYPE I AND TYPE II HAIR CELLS OF THE RAT UTRICLE. M. Shecklard R.A. Fareed, Physiology Dept., Univ. of Rochester, Otolaryngology Dept., Baylor Coll. of Med., Houston, TX 77030.

Whole-cell currents in rat utricular hair cells were studied with the ruptured- or perforated-patch technique. Cells with constricted necks were identified as type II. A low-voltage-activated K current (IK) was correlated with type I cells: 95 and 2% of type I and type II cells, respectively, had IK. IK was activated above -95 mV and saturated by -30 mV. Boltzmann fit to the activation curve gave a slope (k) of 5.60 ± 2.0 mV (SEM, n = 29) and a half-maximal voltage (V1/2) that varied between 55 and -73 mV. Because IK1 was substantially on the zero current potential (V = -724 ± 7 mV, n = 37), type I cells had lower input resistances and faster responses to input currents than type II cells (V = -648 ± 2 mV). The distributions of input resistances at -64 mV of cells with and without IK had modes of 21 MQ (n = 24) and 3.6 GG (n = 40), respectively. Inactivation of IK was slow and sigmoidal. It was fit by an equation for a 3-state model (2 closed, 1 open), giving t half of -150 and 30 ms at -64 mV. Type II cells had outwardly rectifying K currents that activated above -60 mV and had variable activation and inactivation kinetics. Monoexponential fits to inactivating currents at -40 mV produced t's that varied from 20 ms to 700 ms. The data are consistent with the cells having, in different proportions, two outwardly rectifying conductances with distinct kinetics. The cells with the slowest currents may have just one current; their activation curves were fit with a Boltzmann function with a V1/2 of -175 mV and an r value of 86.1 mV (n = 14). Ca2+-dependent K currents in type II cells were negligible, even with the perforated-patch method. (Supported by NIH grant DC02590.)

CAULCIM-ACTIVATED POTASSIUM CHANNELS OF TURTLE COCHELAR HAIR CELLS. L. J. Ayer, Y. C. Wu and R. Fettiglasse. Department of Neurophysiology, University of Wisconsin, Madison, WI 53706 and Department of Pharmacology and Physiological Sciences, University of Chicago, IL 60637.

A major factor determining the electrical resonant frequency of turtle cochlear hair cells in the range 50-500 Hz is the time course of the Ca-activated K current. We have examined the notion that this time course is dictated by recording Ca-activated K channels in inside-out patches from isolated cells. A cell's resonant frequency was estimated from its known correlation with the dimensions of the hair bundle. All cells that possess BK channels with a similar unit conductance (300 pS in symmetrical 150 mM K) but with different mean open times of 0.25-12 ms. The time constant of relaxation of this Ca-activated single channel conductance (50 mV, 4.5 μA) varied between cells from 0.4 to 13 ms and was well-correlated with the hair bundle height. The magnitude and voltage-dependence of the time constant agree with the expected behavior of the macroscopic K current, whose speed is thus limited by the K channel kinetics. All BK channels had similar Ca sensitivities with a mean half-activation at 5 μM (0 μM); we estimate that under physiological conditions these channels may be completely activated by a local rise in Ca to 50 μM. Membrane patches also contained 30 pS SK channels which were about ten times more sensitive than BK channels. At -50 mV, Charybdotoxin (0.1 μM) blocked both types of K channel. The SK channels may underlie the hair cell's different isoforms. (Supported by NIH grants DC02054 (L.J.A), and DC01352 (R.F.)}

MOLECULAR CHARACTERIZATION OF A VOLTAGE-ACTIVATED CALCIUM CHANNEL FROM THE CHICKEN'S INNER EAR. R. Kollmar and A. L. Hudspeth. Howard Hughes Medical Institute and Center for Basic Neuroscience Research, University of Texas Southwestern Medical Center, Dallas, TX 75325.

The influx of Ca2+ into hair cells of the inner ear is necessary both for frequency tuning by electrical resonance and for synaptic transmission to auditory neurons. Unlike most other voltage-activated, L-type Ca2+ channels, those of hair cells are not voltage dependent. Membrane potential are not inactivated by Ca2+ influx. To understand the molecular basis of these unique characteristics, we have begun to determine the structure of Ca2+ channels from the chicken's inner ear.

Using RNA from the sensory epithelium of the basilar papilla and populations of hair cells with degenerating hair bundles, we obtained over 5 kilobases of cDNA, lacking only the 5' end, for the α1 subunit of a voltage-activated Ca2+ channel. The predicted protein sequence of the four homologous L-type Ca2+ channels is more than 90% identical to those of mammalian L-type channels of class D; however, several short stretches diverge markedly from any published sequence. We have observed additional diversity at the 3' end; two classes of isolated cDNAs encode alternative cytoplasmic domains at the carboxy termini, neither of which resembles published sequences. We are now testing whether these divergent sequences define new functional subtypes that account for the unusual electrophysiological properties of the voltage-activated Ca2+ channels there. This work was supported by NIH grant DC00317.

The frequency of electrical resonance in turtle auditory hair cells in the range 5 to 300 Hz is correlated with the kinetics of the cell's K current. Using whole-cell voltage-clamp recordings, we have examined the extent to which these kinetics are determined by the relative contributions of distinct conductances, with different pharmacology, to calcium- and voltage-sensitivity. In high frequency cells (>200 Hz), superfusion with TEA and 4-AP block the K current with affinities of ≏200 μM and ≏10 μM, respectively. This current is also blocked by the selective di- and trivalent cation, K+ (Ca2+ > Mg2+ > Na+). In low frequency cells (<50 Hz), the K current is sensitive to 4-AP (K+ ≏25 μM). This current is resistant to lowering [Ca2+] or intracellular perfusion with 30 mM BAPTA. It activates less steeply with voltage, and the current is also consistent with a smaller unitary conductance. A selective inwardly rectifying current is also present. Cells tuned to intermediate frequencies exhibit a mixture of both 4-AP- and TEA-sensitive K currents. Across the frequency spectrum, an additional, small, voltage-independent K current is present to a variable degree, and it is most easily observed under conditions that elevate [Ca2+]. We propose that this current carries underlying resonant behavior that is systematic in the auditory epithelium and solitary cells that resonate at the lowest frequencies employ an ensemble of K currents distinct from those characterized previously for resonant frequencies greater than 50 Hz.

CALCIUM REGULATION IN TURTLE COCHLEAR HAIR CELLS. T. Tucker and R. Fettiglasse. Department of Neurophysiology and Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

The large size (up to 0.1 na/f) of the sustained Ca current in turtle hair cells imposes a considerable burden on the cell's Ca regulation about which little is known. Whole-cell recording of Ca currents from isolated hair cells using cesium-filled electrodes revealed a slow inward component of the tail current which declined over 0.2 to 2 s. The size of the tail current increased with the duration of the preceding voltage-step, exhibited a dependence on membrane potential that paralleled the Ca current and, like the Ca current, was blocked by 20 μM nifedipine. The tail current was abolished by removal of external Ca, but not by removal of Na or Cl. These properties argue that the current is carried through Ca-activated K channels, its time course reflecting the decline in Ca concentration at the membrane. Thapsigargin (0.2 μM), a specific blocker of the endoplasmic reticulum Ca ATPase, and intracellular vanadate (1 mM) caused a progressive increase in the tail current on consecutive voltage pulses culminating in a permanent activation of an inward K current, which suggests the Ca load was no longer being cleared. We conclude that a Ca ATPase, probably located in an intracellular compartment, plays a major role in the Ca regulation in turtle hair cells and speculate that Ca may eventually be extruded by fusion of the stores with the plasma membrane.

MOLECULAR IDENTITY OF A POSSIBLE HAIR-CELL MYOSIN I. A. B. Metcalfe and A. J. Hudspeth. Howard Hughes Medical Institute and Center for Basic Neuroscience Research, University of Texas Southwestern Medical Center, Dallas, TX 75325-9117.

The hair cell's mechanosensitive organelle is the hair bundle, an organ-pipe array of stereocilia. A tip link connects stereocilia at the tallest neighboring process; at or near this connection lie transduction channels that are gated by bundle displacements. During a hair cell's adaptation to protraction or retraction, the current flowing through these transduction channels returns toward its resting level. Adaptation is thought to involve adjustment of the tension within tip links by an ATP-requiring molecular acceptor. The tension is regulated by the myosin isoforms. Given this hypothesis, monoclonal antibodies raised against a bovine myosin I, MMB, recognize a 120-kDa protein from hair bundles of the frog's sacculus. Immunofluorescence microscopy reveals that this protein is concentrated at the bundles' top edges, where the tip links and transduction channels are located. To determine the molecular identity of the myosin isozone in hair bundles, we have investigated expression in the frog of a gene similar to that encoding MMB. Frog brain, which contains a 120-kDa protein recognized by the same antibodies, expresses an mRNA that is closely resembles that of MMB message. The sacculus macula contains mRNA with a similar sequence. When expressed in bacteria, a portion of the sequence specifies a protein that is recognized by antibodies raised against MMB. We are now attempting to determine the full-length sequence of the myosin message from frog brain. This work was supported by NIH grant DC00241.

An acidic amino acid, such as glutamate, has been implicated as the hair cell transmitter in anamniotes (e.g., frogs), which lack Type I hair cells. Since there is scant electrophysiological evidence of the nature of the hair cell transmitter(s) in anamniotes, we have begun to investigate if glutamate is the transmitter from canal afferents in the turtle inner ear (N-9). Bath-applying transmitter agonists and antagonists in order to relate their activity with the endogenous hair cell transmitter-mediated activity. During extracellular recordings from individual afferents, glutamate (5 mM) reversibly induced an increase in the firing frequency of the afferents (N=29). Aspartate (5 mM) mimicked this effect (N=5). Kynurenic acid (1 mM) reversibly eliminated the resting firing frequency of the afferents (N=8) and reduced the excitatory action of both of these agonists (N=6). NDMA (0.5 and 5 mM) also resulted in afferent suppression (N=5). GABA (5 mM) had no consistent effect upon afferent firing (N=10), while carbachol (0.5 mM) resulted in an increase in firing, weaker than that induced by glutamate and which to some extent desensitized during application (N=6). These findings are consistent with the hypothesis that glutamate or a related compound is a hair cell transmitter in anamniotes as well as anamniotes. The major difference between the turtle and the frog appears to be the sensitivity in the turtle to NDMA, not found in the frog. Otherwise the afferent response resemble those found in afferents innervated by Type II hair cells in the frog. It is as yet unclear as to whether or not axons innervated by Type I hair cells are also included in the current sample. Supported by NASA grant NAG 2-780 to SLC and NIH DC-01273 to MJC.

398.11 LOCALIZATION OF NITRIC OXIDE SYNTHASE IMMUNOREACTIVITY AND NICOTINAMIDE ADENINE DINUCLTEOTIDE PHOSPHATE DIAPHORASE IN THE RAT INNER EAR. M. Lyon, B. Godri and B. Mayer, 1 Dept. Otolaryngology, SUNY Health Science Ctr, Syracuse, NY; 2 Inst. Pharmacology Toxicology Univ. Graz, Graz Austria.

Nitric oxide (NO) has received considerable attention and appears to play critical roles in neurotransmission. There is evidence showing that NO can function as a neurotransmitter (Bredt et al., Nature 351:714; 1991); is involved in ischemic injury (Beckman, Nature 345:27; 1990); plays a role in regulation of cerebral blood flow (Iadecola, Prot Natl Acad Sci USA 90:4561; 1992). To determine if NO may be involved in inner ear function, a combination of histochemical and immunohistochemical techniques were used (Mayer et al., FEBS Lett 277:215; 1990) to localize nitric oxide synthase immunoreactivity (NOS) within the adult rat temporal bone. Preliminary results show similar patterns of labeling for both techniques. Scarp and Scarp's ganglion cells are positive as are their nerve projections. Label is also observed within the perineuropil of all the vestibular end organs with dense label near base of some hair cells bases. The stria vascularis contained NADPH-diaphorase label but little NOS immunoreactivity. These results indicated that NO may play a role in inner ear function and that a different or previously undescribed type of NOS is located in stria vascularis.

398.12 THE EXPRESSION OF GROWTH FACTOR RECEPTOR GENES IN MAMMALIAN HAIR CELL EPITHELIUM ASSESSED BY RT-PCR. L.D. Saffert and J.J. Currie. 1 Dept. Otolaryngology and Neurosci., Univ. of Virginia, Charlottesville, VA 22908.

Hair cell loss in the vestibular organs of mammals has been shown to result from the proliferation of progenitor cells, which are the progenitors of regenerated hair cells. In normal cell proliferation, nitrous growth factors must bind to specific receptors before cell division can occur. Since we are interested in controlling hair cell regeneration, we need to identify the receptors that are expressed in these cells. RT-PCR provides a sensitive method to assay for the presence of low levels of messenger RNA for such receptors. Hair cell epithelia were isolated from undamaged uroticules of rats, trimmed of all edges and extracellular ameila in liquid nitrogen. Total RNA was isolated from these tissues and reverse transcribed into intronless cDNAs. RT-PCR primers were selected from published sequences for growth factor receptors and these were used in hot-start PCR to amplify unique fragments of receptor cDNAs. Positive and negative controls were run with each reaction. PCR products were resolved on gel electrophoresis. These experiments have demonstrated the presence of mRNA for the insulin receptor, but as yet have not shown detection levels of mRNA for the PDGF receptor, the IGF-1 receptor, or the EGF receptor in central regions of undamaged hair cell epithelia from mammalian utricles. Undamaged uroticules will be assayed for increased expression of those messages.

398.13 THE PROLIFERATION OF HAIR CELL PROGENITORS IS DEPENDENT ON CELL-SUBSTRATE ADHESION. L.L. Cunningham, J.E. Finley, M.S. Norgol, and J.T. Corwin, Dept of Otolaryngology and Neurosci., Univ. of Virginia, Charlottesville, VA 22908.

We conducted experiments to determine whether adhesion to a substrate is required for the proliferation of supporting cells from the chick ear. Basilar papillae and strabyles were dissected from young (7-14 days) white leghorn chickens, and the sensory epithelia were cultured for 5 days in Medium 199 supplemented by 20% fetal bovine serum. After 1-2 days in culture, hair cells extruded from the epithelium leaving sheets of supporting cells. A subset of the supporting cell sheets attached to the substrate and began proliferating. Other sheets continued to float in the culture medium during the same period. Bromodeoxyuridine (BrdU) was added to the culture medium for 4 hours to measure the proliferation rates of substrate-attached supporting cell sheets. BrdU-positive sheets were counted. Twelve adherent cultures had a mean of 29.2 ± 3.4 BrdU labelled cells per 100,000 µm² (range; 8-59). Whereas nine free-floating cultures had a mean of 4.5 ± 0.5 BrdU labelled cells per 100,000 µm² (range; 0-24), a significantly (p > 0.005) lower proliferation rate. The supporting cells were in the presence of the many mitogenic growth factors in serum, but only showed a significant proliferation after substrate adhesion, suggesting that adhesion is required for the proliferation of auditory and vestibular supporting cells. Preliminary immunohistochemical studies reveal the presence of integrin receptors on the supporting cells which may be responsible for the adhesion-dependency of their proliferation.

398.14 CYCLIC AMP IN AN INNER EAR HAIR CELL SHEET PREPARATION. M. J. Dreger, D. J. McGinley, and D. G. Dreger, 1 Lab. of Bio-chem. Dept. of Otolaryngology and 2 Bioch. in the 3 Univ. of Iowa, 2014, 1991.

Previously, we localized adenylyl cyclase activity to specific sites within the sensory epithelia of the neural and non-neural macaqueauditory hair cell. Precipitate was also found in two groups of nerve terminal in contact with hair cells. This paper describes the distribution of adenylyl cyclase activity and its potential significance in the development, maintenance and regeneration of macaque auditory hair cells. We have also shown that cyclic AMP can be a mitogenic agent for hair cells.

With an enzyme immunoassay (ELISA) for cAMP (Amersham, RPN 225), we have now measured cAMP levels in a hair cell sheet preparation for which the hair cell is the only intact cell type. Pseudolaric acid extracts of the hair cell sheet and associated vascular nerve fibers contained 5.0±2.1 fmol cAMP/mg cell protein, respectively [mean ± SEM (n)]. Depolarization of the hair cell sheet by a HEPES-containing medium and 100 mM KCl floating sheets increased cAMP levels to 10 fmol/1000 cells, compared to 1 fmol for glial cells, the latter presumed to be involved in receptor activation. Extracellular application of cAMP by microinjection experiments induced an increase in influx of cAMP of approximately 0.6 fmol/7000 hair cells, compared to 1 fmol for glial cells, the latter presumed to be involved in receptor activation. Extracellular application of cAMP at 25 µM (5 min) was observed to elicit a 30° increase in intracellular levels of cAMP in the hair cell sheet relative to the paired control, significant by paired-variate analysis (p < 0.05, two-tailed test). The low level of cAMP in the hair cell sheet appears consistent with its limited and site-specific presence in the cochlear lateral wall, and the absence of cAMP synthesis. The demonstration of intracellular cAMP in the hair cell sheet by extracellular ATP, if not neglected with regard to mechanism, represents preliminary evidence of the existence of a cAMP-mediated second messenger pathway in hair cells.

(Supported by Deaf. Res. Found. [MDI] and NIH [DC00156, DC00026])

The functional polarization vectors derived from otolith primary afferents are commonly fit to a cosine. The morphological polarization vectors (MPV) of hair cells contribute to the afferent's response characteristics. In addition, examination electron microscopy of rat utricles and saccule demonstrates that adjacent hair cells often have MPVs that vary significantly. Physiological studies of individual hair cells have demonstrated that the functional polarization vector is not described by a cosine. Instead, the differential gains for the positive and negative half cycles are not equal and produce a clipped response waveform. We believe that this is a necessary account for the deviation from the cosine relationship found by Fernández, et al. (J. Neurophysiol. 35, 1972) in their studies of otolith responses. We have simulated the effects of hair cell MPVs on the resultant afferent polarization vectors using a simple representation for the nonlinear hair cell input/output characteristics. Each afferent using this model exhibits the same type of nonlinearity found in otolith afferent fibers. These findings are unchanged when the contributing hair cells have widely varying MPVs. A comparison of the simulation results with otolithic response characteristics suggests that the property responses of otolithic afferent fibers is consistent with relatively simple integration of input from contributing hair cells. The attendant nonlinearity in the responses results from the input/output characteristics of the hair cells.

This work was supported by NASA and the National Academy of Sciences.

Aldosterone, a mineralocorticoid, enhances Na retention and K excretion in various ion transporting epithelia. Previous studies have demonstrated that this mineralocorticoid regulates Na, K-ATPase in the inner ear. Na, K-ATPase has been implicated in the maintenance of high K concentration in endolymph, ion transport processes which support transduction by inner ear hair cells. Other studies have revealed a similar pattern of distribution for mineralocorticoids in the (type II) binding sites and Na, K-ATPase. These results indicate that the mineralocorticoids may regulate endolymphic ion content and thus modulate hair cell transduction. The purpose of our present study was to determine if mineralocorticoid binding sites are associated with hair cells of the cristae ampullare.

The ampullae of the posterior, lateral and superior semicircular canals were dissected from male Hartley guinea pigs and incubated in media containing ([1H]-aldosterone (30 nM) and a 1000-fold excess of unlabeled aldosterone. Responsive sites were then processed for autoradiographic analysis.

Examination of autoradiographs revealed silver grains in the sensory epithelium of the ampullae. Specifically, binding was localized in the nucleus, cytoplasm, and stereocilia of both type I and type II hair cells. Localization of mineralocorticoid binding sites to these cellular components suggests that aldosterone may participate in both growth-related and non-specific modulation of hair cell transduction.

A piezoelectric micro-actuator was used to generate mechanical indentations of the long and slender region of the horizontal canal (HC) and the utricle (U) in the toadfish, Opsanus tau, while recording extracellular afferent responses. In the toadfish, the HC and U were indented in a linearly varying (±16 μm) indentation at 2.4 degrees/sec. Head motion. Having established this correspondence, step mechanical indentation was applied to stimulate a step increase in head velocity (Dickman and Korn, J. Physiol. 162, 1962). Aortic responses showed a jump in pressure (±0.02 sec) in firing rate followed by a fast transient decay (±1 sec) and a slow exponential decay (±30 sec) approximating the resting rate. The slow exponential tail decay across units and is consistent with models describing the mechanical recovery of the cupula to its original resting position. The jump increase and fast transient decay show significant inter-unit variability, from being absent in some units to exceeding the peak magnitude of the slow response in others. This fast component cannot be described by models of macromolecular cellular displacement or by established processing associated with the hair-cell-afferent complexes. The range of afferent responses to head rotation can be described by a model in which the stimulus transfers to macromolecular endolymph flow and pressure combine within the structural mechanics of stereocilia, although the macromechanical and/or biophysical mechanisms responsible for the apparent unit-specific sensitivities to these components remain yet unknown. [Supported by NIH]

TOULENE EFFECTS ON Gullus domesticus' VESTIBULAR SENSORY EPITHELIUM IN THE EMBRYOGENESIS. A. Illescas-Landrace and M. Lorenzo-Illanes-Monje. Departamento de Anatomo y Departamento de Farmacologia. UNAM, Mexico, D. F. 04510.

All biologically active substances interfere, in one way or another, with the chemical system that governs the homeostatic mechanism of living organism. Many drugs create temporary or permanent alterations in auditory or vestibular function.

The purpose of this study is to show that toluene induces cellular alterations on Gullus domesticus internal ear vestibular sensory epithelium during its morphogenesis. To accomplish this purpose 42 fertile stage 6 (23-25 mm) zebrafish were used arranged on 7 groups. The applied toluene doses were 0.60, 1.12, 2.5, 5.0 and 10.0 μL for the first 5 groups; 10.0 μL of normal saline solution for the 6th group and the last one was taken as a control group. After 14 days of hatching the embryos were removed from their egg-shells. Immediately were bled and their internal ear were prepared to be analysed through electron microscopy. Toluene provoked loss of some hair cells in all cristae and otolithic organs, in other cells we found various stages of degeneration: loss of cell, cytoplasmic degeneration and vacuolization of membranes. In the supporting cells the common damage observed was edema. These data suggest that toluene injured avian vestibular receptors during the embryogenesis.

RAPID DENDRITIC GROWTH IN VESTIBULAR NEURONS OF PERINATAL CHICKEN. G. C. DeRubertis. Biocomputation Laboratories, University of Washington, Seattle, WA 98195.

The objective of this study was to determine whether perinatal remodeling of primary vestibular synapses in the medulla is accompanied by developmental changes in their target vestibular sensory neurons; the pricipal cells (PC) of the tangential nucleus. PCs are vestibularocollateral collic neurons which receive large axosomatic "spoon" endings from primary vestibular fibers. Spoon synaptogenesis follows an unusual pattern: first in embryos (E7) forming chemo-synapses, with the growth cones of the inner hair cells. These spiny zones (Gzs) to form simple synapses (E15), and finally mainly Gzs in hatchlings (H), P. Neurol. 230:389-392 (1994).

This is the first report documenting PC dendritic morphology and comparing them at two ages, E15-16 and H-2. From preliminary observations made on PCs intracellularly injected with biocytin, we observed that the characteristic oval somata do not change appreciably in size (28±5 SD x 18±3 μm; n=12 vs. 26±4 x 17±5 μm; n=9). Also, in our small sample there is no apparent change in the average number of primary dendrites (3.7 dendrite/soneuron) nor in the dendritic branching pattern. However, the number of dendritic branch points per neuron increases by 52% (12.7 ± 1.6) as well as the dendritic spread in both the medio lateral (98%, 168±57 μm vs. 333±76 μm and the dorsoventral axes (127% 103±59 μm vs. 234±71 μm). Finally, a major change of 147% was observed in total dendritic length per neuron (605±26 μm vs. 1495±35 μm).

These observations suggest that parallel to the important changes occurring at spoon ending terminals at hatching, their postnatal target cells rapidly and extensively generate new dendrites. (This work was supported by NIH grant RO1-DC00970).
399.1

Stebler and Narins (1990) reported that increasing body temperature causes low-frequency auditory nerve fibers in the frog to increase their CFs and decrease their thresholds. We have previously identified two-tone squeeze suppression (TRSS) and excitatory tuning in the frog, and we now report findings that suggest TRSS may be dependent on the temperature. Squeezed suppression might be expected to exhibit similar temperature-induced shifts.

The goal of the present study was to examine the temperature dependence of auditory fibers in the frogs. We found that the frog's response to a two-tone stimulus changed with temperature. The temperature-induced changes in the frog's response suggest that thermal perturbation may affect the frog's response to a two-tone stimulus in a manner similar to that of TRSS in the frog. The temperature-induced changes in the frog's response are likely mediated by changes in the frog's C-fiber activity.

399.2

SIZE, DISTRIBUTION, AND THEORETICAL CONDUCTION VELOCITIES OF AUDITORY NERVE FIBERS IN THE FROG INNER EAR. B. Pesaran, D.D. Simmons, P.M. Narins, S. Parham, C. Bertolotto, and A. Newman. Faculty of Biology and Biophysics, UCLA, and the House Ear Institute, Los Angeles, CA 90024.

The leopard frog (Rana pipiens pipiens) has two specialized auditory organs: the amphibian papilla (AP) and the basilar papilla (BP). In this study, we used two-tone suppression to study the effects of cooling the fibers in the frog with a temperature range of 1-15°C. The results suggest that the frog's response to a two-tone stimulus is largely determined by the temperature. The frog's response to a two-tone stimulus is largely independent of the temperature, indicating that the frog's response is temperature-independent.

399.3

We previously demonstrated that fibronectin-like immunoreactivity is depressed following noise-induced temporary threshold shifts (TTS). We have now examined the depression of E1 class immunoreactivity, a marker of integrin localization in the cochlea during TTS and subsequent recovery. We observed a significant increase at 10-min intervals following noise exposure, which was not observed in the control cochlea. This result implies that E1 class immunoreactivity is depressed following noise exposure and may play a role in the process of recovery.

399.4

Early results imply that 211-2 DPOAEs are produced in frequency regions between the primary tones, while 221-11 DPOAEs are produced at the second tone. These results suggest that 211-2 DPOAEs are produced in frequency regions between the primary tones, while 221-11 DPOAEs are produced at the second tone.

399.5

The cloning of cDNAs encoding two water channels from rat kidney has been recently reported by Deen et al. This work is significant for the following reasons: the water channels are expressed in the kidney, and the water channels are expressed in the cochlea. The results of this study support the hypothesis that the water channels regulate the osmotic state of the cochlea.

399.6

INNER HAIR CELLS IN THE COCHLEA OF THE FETAL BRONX WALTERZ MOUSE. D.S. Whitlock*, D. Cahill and M. Zhang. Walter Reed Army Medical Center, University of Wisconsin, Madison, WI 53706.

In the adult Bronx Walterz mouse, more than 75% of the normal number of inner hair cells is missing. The specific role of inner hair cells in the cochlea remains unknown. The Bronx Walterz mouse is a valuable tool for studying the effects of noise and other environmental factors on the inner hair cells.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
399. 7

Published evidence indicates that dopamine is present in the auditory inner ear. Presynaptic dense-core vesicles have been observed in olivocochlear fibers by electron microscopy, and dopamine has been detected at femtomole levels in the rat cochlea. Immunocytochemical studies of olivocochlear fibers in the cochlea and neurons in the lateral superior olivary complex have suggested the presence of tyrosine hydroxylase and absence of dopamine B-hydroxylase and phenylethanolamine N-methyltransferase. We have utilized polymerase chain reaction (PCR) analysis to identify messages for dopamine receptor subtypes in the mouse cochlea. Specific D1A and D1B receptor primers were designed based on published rat brain sequences, and D2, D3, and D4 subtypes from the corresponding mouse brain sequences. Poly A RNA was isolated from total RNA in guinea thycape extracts of cochleas of 30 CB6 mice (16 days old) and reverse-transcribed with oligo dT primer. PCR-amplified products were separated by agarose gel electrophoresis. Results were compared to those obtained without reverse transcription (negative control) and to those using mouse brain mRNA with reverse transcription (positive control).

PCR primers for all of the dopamine receptor subtypes yielded bands of expected molecular mass with cDNA from mouse brain samples, indicating that the primers were functioning. The primer designed to detect the D2 long form produced a PCR amplification product of the predicted size from mouse cochlear cDNA. D1B, D3, and D4 primers yielded faint bands after PCR amplification. The D1A amplification product was not observed. These results suggest that dopamine has a neurotransmitter role in the cochlea. (Supported by NIH Grants R01 DC01515 and T32 DC00026.)

399. 8

Although many studies have localized receptors postulated to control cochlear blood flow, there is still a dilemma about the exact mechanisms by which these receptors modulate inner ear function. A previous autoradiographic study conducted in our laboratory localized mineralocorticoid receptors in the walls of cochlear vasculature (Sinha et al., Soc. Neurosci. Abstr. 580.2: 1418, 1993). Furthermore, the possible physiological significance of these receptors in the regulation of cochlear blood flow is of importance in the study of the effects of local and systemic mineralocorticoid analogues and their vasodilator properties. In this study, the possible physiological significance of these receptors in the regulation of cochlear blood flow (CoBF) was assessed by the use of D1 or D2 doppler flowmetry (Sinha et al., Assoc. Res. Otolaryngol. Abstr. 13: 303, 1990). In both studies, we postulated that mineralocorticoids participate in regulation of CoBF.

In order to elucidate the mineralocorticoid participation in cochlear homeostasis, male Hartley guinea pigs were infused with aldosterone (10 μg/kg) for 10 min. Continuous measurements of lateral wall capillary blood flow velocity were assessed with intravital microscopy. Blood samples, withdrawn 2 and 60 min following completion of infusion, were analyzed for serum aldosterone and electrolyte values. Preliminary results show that serum aldosterone levels fell significantly after 60 min post-infusion (5200 ng/dl) compared to its 2 min post-infusion levels (731 ng/dl). Systemic blood pressure, serum electrolyte values (Na+, K+ and Cl), and capillary blood velocity were unchanged during the experimental protocol. The stability of capillary blood pressure supports the conclusion of autoregulatory mechanism for CoBF which preserves constant capillary blood perfusion. Future studies, especially the functional effects of such steroids on arterioles (and arterioles) supplying the cochlea, are needed for further delineations the association between mineralocorticoid hormones and cochlear vasculature. (Supported by NIH CIDA DC00046 and NIH T32 DC00026.)

400. 1

The four functional components of the cranial nerves are classified as general somatic and visceral afferents and efferents. Three additional components associated with special senses are also recognized in cranial nerves. These fibers are classified as special visceral afferents (olfactory and gustatory), special visceral efferents (stapedius muscles), and special somatic afferents (visual, auditory, and vestibular). The sensory cells of the vertebrate inner ear are innervated by both vesiculated and nonvesiculated endings are regarded to be invariant in nature. Anatomical studies in all classes of vertebrates have invariably demonstrated that these efferent fibers originate from specific brain stem nuclei. The vesiculated endings form axosomatic synapses with the sensory cells as well as axodendritic synapses with the peripheral processes of the bipolar sensory neurons of the 8th cranial nerve. Physiological data indicate that efferent innervation of the sensory cells of the vertebrate inner ear is either facilitatory or inhibitory in function. Establishment of efferent innervation of the vertebrate inner ear merits a re-evaluation of functional components of the cranial nerves. This report is suggesting that these efferent fibers be classified as “special somatic efferent” component of the cranial nerves.

POSTNATAL IMMUNOREACTIVITY AND RETROGRADE LABELING OF OLIVOCOCHLEAR NEURONS IN THE VENTRAL HUMAN BRAINSTEM. D.D. Simmons1, J. Raij-Kubba2, and J.H. King, Dept. of Biology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1606.

The olivocochlear (OC) system is the major efferent pathway to the cochlea and is critical for modulating activity of the cochlear nerve. Acetylcholine and calcitonin gene-related peptide (CGRP) both serve as neurochemical markers for the OC system. Very little is known about the maturation of the immunohistochemical and an in vitro brainstem technique were used. OC neurons were defined by injections into the crossed OC bundle (COB) at the floor of the IV ventricle. During the first postnatal week, all COCB injections resulted in labeled terminals under the COB and labeled cells in the VPO region of the superior olive. Both CHAT and CGRP immunoreactive cell bodies were clearly evident and the labeled cells were within the VPO region of the lateral superior olive. Double labeling of retrogradely labeled neurons. Between postnatal day 0 and postnatal day 8, retrogradely labeled neurons were observed and double labeled with CHAT antibody. The CHAT positive VPO cells were distinct from CHAT positive LSO cells. CHAT positive LSO cells had similar retrograde nature. The majority of retrogradely labeled CHAT and CGRP cells were found either in the medial limb of the LSO or in the capsular regions of the LSO.

Thus, the majority of COCB cell bodies are CHAT positive, CGRP negative, and found within VPO regions. Our results are consistent with the hypothesis that periventricular OC neurons initially terminate on IHCs and then on OHCs before their neurotransmitter expression is mature. (Supported by grants from the NIDCD and the UCLA Academic Senate)

THE CYTOARCHITECTURAL ORGANIZATION OF THE MEIDAL OLIVOCOCHLEAR NUCLEUS OF THE GOLDEN J.A. Goebbels1,2, S. Coomeh3, C.A. McCorkich3, and P. Oshel1. 1Farny Hearing Institute and Biology Department, Loyola University of Chicago, IL 60656 and Oberlin College, Oberlin, OH 44074.

The cytoarchitectural of the medial olivocochlear nucleus (MOC), the principal first-order nucleus of lateral line mechanoreceptors, is not well known in any fish. Using Golgi, immunocytochemical and other histological techniques, we recognize at least three layers associated with the MOC. The molecular layer consists of axons from granule cells in the eminens granulair and axons with GABAergic terminals from cells in the mettenreithian nucleus. The granule nucleus consists of dendrites from underlying cerebellar cells extend into the molecular layer, where small, intrinsic neurons are also found. The layer consists of a thick basal dendrite that extends into dense molecular regions, whereas others have 2 or more thin distal dendrites that ramify near the cell body. The deep layer consists of ventral dendrites from both basal and intrinsinc neurons, terminals from primary afferent fibers and commissural GABAergic neurons. The goldfish MOC has a number of organization for the first-order nuclei of other olivocochlear systems and thus, its function may be shaped by similar neural circuits.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
Evidence for Neuromodulators in the Cochlear Nuclei of the Newly Hatched Chick. E.O. Dobkins & G. Laurenti, Division of Biology, 139-74, California Institute of Technology, Pasadena, CA 91125.

Glutamate mediates rapid transmission of auditory information between the VCN and other afferents and the cochlear nuclei. The presence of glutamate (Raman & Trussell, Neuron, 9(92):173) and GABA (Code & Churchill, Hearing Res, 54(91):281) receptors in chick, and of GABAergic terminals in the AVCN, has been demonstrated. The potential contribution of neuromodulators to transmission across these primary synapses is unknown. The existence, and possible co-localization of neuromodulators with GABA and glutamate, in the avian cochlear nuclei has not been investigated. Immunohistochemistry was used to locate somata and terminals containing acetylcholine, catecholamines, and neuromodulators in the cochlear nuclei of the newly hatched chick. Preliminary results suggest that serotonergic and acetylcholinergic cells are not present. Somatostatin is found in terminals in nucleus angularis (NA) but not magnocellularis (NM) or lateralis (NL), and is present in the amygdaloid nucleus. Enkephalin (5-L-enkephalin) is found in somata and terminals of NA. Cholecystokinin was found in somata: NM/NA/NL, and in terminals in NA. Supported by NIMH and the McKnight Foundation.

The SCC (also called juxtagranular) region of the cat AVCN receives preferential input from low spontaneous rate (SR) auditory nerve fibers (Liberman, 1991). Low-SR cochlear ganglion cells are preferentially located on the scala vestibuli (SV) side (Kawase and Liberman, 1992). From these two, we hypothesize that a focal injection of a tracer restricted in the SCC region should label ganglion cells preferentially located on the SV side. The goal of this study is to evaluate this hypothesis. After a 3-10 day survival period following BD injection, the cats were killed. The labeled Golgi-like fibres from the injection site to the ganglion cell soma and their axons were examined. In cases where the injection was centered in the deep AVCN or deep DCN, the labeled cells tended to be evenly distributed on the SV and SC lamans (SF side). In general, the injection site was in the GC/SC region, by contrast, labeled cells in certain ganglion regions were preferentially located on the SV side. This supports the hypothesis. A complicating factor was that there were additional ganglion regions in the latter cases with labeled cells either on the SV or SF side. Also in these cases, label was found in type II ganglion cells and olivocochlear bundle (OCB) fibers in the intraganglionic spiral bundle. This confirms previous findings that the GC/SC region receives input from type II cells and OCB collaterals. [Supported by NIDCD: NH714988.

A monoclonal antibody to synaptophysin, an integral membrane protein found in presynaptic vesicles, was used to immunohistochemically quantify changes in nerve terminal density in the guinea pig cochlear nucleus (CN) 2-161 days after complete unilateral cochlear ablation. In the ipsilateral ventral CN a significant reduction in the density of immunoreactive synaptic profiles was apparent 4-7 days after ablation, presumably corresponding to the loss of cochlear afferents. In the anterior division of AVCN immunoreactive density decreased to 35% of that contralaterally, and in the anterior part of PVCN to 62%. No reduction in immunoreactive density was seen in the deep layer of DCN. After 161 days there was an apparent complete restoration of immunoreactive density in the ventral CN. In PVCN this increased density could be attributed to progressive tissue shrinkage, presumably resulting from loss of cochlear nerve fibers, but in the AVCN tissue shrinkage only partially accounted for the increased density. These results suggest that the initial loss of synaptic terminal density in the AVCN after cochlear ablation may be followed by a partial regeneration at longer survival times. [Supported by DC00199 from NIDCD].

Spontaneous degeneration of the gerbil cochlear nucleus has been shown to be dependent on auditory functional activity. The degenerative lesions primarily affect dendrites while sparing the neuronal cell body. Ligation of the external auditory canal (EAC) in Mongolian gerbils for one week resulted in >30 dB elevation in ABR thresholds at frequencies from 1-52 kHz. This manipulation reduced the area density of a naturally occurring spongiform degeneration in the ipsilateral cochlear nucleus to 30% of that found on the contralateral (unligated) side. Ultrastructural studies showed that some lesions "fill in" with a tubulovesicular material. Aggregations of mitochondria and filaments are also found. The tubulovesicular material is immunoreactive with antibodies to glucose regulated protein-78 (grp78), an ER-resident protein involved in the proper assembly and folding of newly synthesized proteins.

To determine if unilateral cochlear ablation leads to plastic changes in the auditory nuclei, the freshly dissected guinea pig brain stem was cut transversely into 500 μm slices and samples of the LSO, MSO, MNTB, VNLL and IACC were micropunched to measure uptake and release activities. Five days after cochlear ablation, 3H-D-aspartate uptake and release were decreased slightly in the LSO, MSO and VNLL bilaterally, but these activities returned toward control levels at 59 and 145 days. 3H-D-Aspartate uptake and release were increased slightly at 59 and 145 days in the MNTB and IACC bilaterally. 3H-Glycine or 3H-GABA release, unchanged after 5 days except for a bilateral increase in 3H-GABA release in the IACC, increased slightly at 59 and 145 days in the MSO, MNTB, and IACC bilaterally. 3H-Glycine uptake decreased after 5 days, but increased at 59 and 145 days in the LSO and MSO bilaterally. The cochlear nucleus, but not the AVCN, can be lesioned by cochlear ablation and these changes suggest that unilateral cochlear ablation may lead to plastic compensatory responses in auditory brain stem nuclei. (This work was supported by grant DC00199 from NIDCD)
400.11 EXPRESSION OF C-FOS IN THE AUDITORY BRAIN STEM FOLLOWING ELECTROCOCHLEAR INJURY: LOCALIZATION OF THE EZCHELLON OF NAGASU, N.H. Lim, J.M. Miller, and R.A. Altschuler, Kresge Hearing Research Institute, University of Michigan, Ann Arbor, MI 48109-0500.

C-Fos expression (as a marker for activation of neurons) was examined in the brain stem of deafened and undeafened rats after electrical stimulation with cochleotopic stimulation (frequency mapping or deafening by inner ear injection of neomycin). After assessment of auditory brain stem response (ABR), cochlear was implanted with electrodes. Either a single ball electrode was placed in the scala tympani of the basal turn of the cochlea or bipolar electrodes were inserted into basal and apical turns. Three days later electrically evoked ABRs were taken, after five days animals were electrically stimulated at three times the EABR threshold for 90 minutes. Thirty minutes after the cessation of stimulation animals were anesthetized and perfused with 4% paraformaldehyde. Vibrissae nuclei were sectioned through the auditory brain stem and sections were immunoreacted with antiserum to C-Fos (Oxxygen Sciences) using ABC Vector Stain immunoperoxidase methods.

In both hearing and deafened animals, many C-Fos immunoreactive (IR) neurons were observed in the ipsilateral and contralateral to the stimulated side in the dorsal cochlear nucleus, nucleus of the lateral lemniscus and the inferior colliculus. The C-Fos IR cells were arranged in band-like patterns in the IC and the contralateral DCN. The number of IR neurons increased with bipolar stimulation. C-Fos IR neurons were occasionally seen in the superior olivary complex in perilobular nuclei and the lateral superior olive. One deafened animal demonstrated many C-Fos IR cells in the ventral cochlear nucleus but this was atypical. These results suggest that C-Fos upregulation may provide a method for assessing central auditory activation with cochlear implants and may be useful for comparing different stimulation paradigms as well as assessing their influence on deafness-related changes.

400.12 CHARACTERIZATION OF MOSSY FIBER PROJECTIONS FROM THE CUNEATE NUCLEUS TO VARIOUS LOCATION OF THE OZUOINURO, N.H. Lim, J.M. Miller, and R.A. Altschuler, Kresge Hearing Research Institute, University of Michigan, Ann Arbor, MI 48109-0500.

The cuneate nucleus (CN) which receives somatosensory input from the auditory nerve. Some non-auditory inputs to the CN have also been described, including a somatosensory input from the hypothalamus (Neurosci. 1987; 20:209-219). We have recently shown that the cuneate projections form mossy fiber terminals in the granule cell domains of the dorsal CN (Wright and Ryugo, 1994). Further studies using the anterograde tracer Phoxolar vulgaris, leucocystiolitin (PHA-L) combined with immunofluorescenc have demonstrated that cuneate projections give rise to mossy fiber terminals in granule cell domains throughout the CN. The trajectory of the cuneate fibers is demonstrated in coronal sections of the brainstem where fibers are seen traversing the descending tract of V before turning mediasd to the auditoal sound nucleus along the stria for varying distances before entering the nucleus at different diencephalonic levels, where they give rise to many en passant and terminal boutons in granule cell regions.

Cuneate mossy fiber terminals contain round synaptic vesicles and form asymmetric synapses with their targets, indicating that they are excitatory in nature. Using immunocytochemical techniques, we have begun to investigate which neurotransmitter is used by the cuneate mossy fibers. Preliminary experiments indicate that anterogradely labeled cuneate fibers are not double labeled with an antibody against acetylcholine (Boehringer Mannheims), an enzyme used in the synthesis of acetylcholine. However, in adjacent sections, PHA-L-labeled cuneate fibers coexist with gluatamate immunoreactive fibers. We will test the hypothesis that the cuneate mossy fibers are gluatamatergic using double labeling techniques for PHA-L and glutamate at light and electron microscopic levels.

Supported by NIH grants: DC00322 and DC00797.

There is evidence that cholineergic effects in the cochlear nucleus (CN) are mediated primarily by muscarinic acetylcholine receptors (MACH). We used [%]scopolamine to study MACH distributions in the rat CN by receptor autoradiography. Rats were anesthetized with pentobarbital 15 min thick were incubated with 10 nM [%]scopolamine at 25°C for 30 min in Tris with cold PBS-EDTA and a brief cold 0°C rinse. The sections were exposed to [%]sensitive film for 2 weeks, followed by exposure to NTB2 emulsion for 2 weeks. The sections binding were incubated with 4% albumin, and the radiomotope was estimated by measurements of optical density (using NIH Image 1.44, courtesy of Dr. E. Ties). The specificity of scopolamine binding was confirmed by blocking with 1 μM atropine. To determine which MACH subtypes are present in the binding, we included unlabeled subtype-preferential ligands in some preparations to block [%]scopolamine binding. Over 60 sections measured on isolated CN were included with [%]scopolamine and with unlabeled ligands, followed by scintillation counting. Our preliminary results suggest that scopolamine binding is highest in granular nucleus, followed in order by dorsal CN (DCN) deep and fusiform layers, DCN molecular layer, paracochlear CN, anteroventral CN, and auditory nerve root (which was similar to background). Ligands which preferentially block some MACH subtypes competed more effectively than others with scopolamine binding. (Supported by NIH grant DC 00172)

In this study, changes in cell size, GABA and glycine immunoreactivities, glycine receptor subunit expression and neurotransmitter release have been analyzed in auditory brain nuclei after unilateral and/or bilateral deafenation. Evaluations of these changes were performed by morphometrical and image analysis of the cells, of GABA and glycine immunocytochemistry, by in situ hybridization of glycine receptor subunits and the immunolocalization of microglia probes in brainstem auditory nuclei. Most of the neurons within the lateral superior olive (LSO) are able to shrink and then recover to their normal size after uni- or bilateral destruction. The morphological plasticity parallels changes in the density of GABA+ cell bodies in the LSO and in the central nucleus of the inferior colliculus. The fact that this plasticity of the auditory neurons is also observed in bilateral deafenation suggests that the central auditory system (CAS) of mammals has the property to recover even after total auditory deprivation. We also observe an ipsilateral decrease of glycine positive terminals in the medial nucleus of the trapezoid body (MNTB) and the dorsal mediolateral olivary nucleus in a simultaneous bilateral decrease following unilateral deafenation. Modifications of glycine immunoreactivity in LSO and MNTB appear to parallel some interesting changes in the expression of the different glycine receptor subunits. We are trying now to correlate these morphofunctional changes of the neurotransmitters with our results of microdialysis in the same experimental model. Even if the mechanisms behind these changes are still unknown, our results indicate that the CAS of mammals has a remarkable property of plasticity in response to partial or total auditory deprivation. Supported by MRT Grant # 88C0585 and NIDCD Grant # DC 00383.

400.15 LOCALIZATION OF GLYCINE RECEPTOR IN THE RAT COCHLEAR NUCLEUS AND SUPERIOR OLIVARY COMPLEX. K. Sato, H. Kuriyama, J. Dupont, J. Bousoum and R.A. Altschuler, Kresge Hearing Research Institute, The University of Michigan, Ann Arbor, MI 48109-0506.

Glycine is a major inhibitory transmitter that is especially prominent in the cochlear nucleus and superior olivary complex. The glycine receptor is comprised of α subunits, a β subunit and a 93 k anchoring protein (AP), also termed gephyrin. Different subunits can combine to form complexes with different physiological properties (intero- and extra-olivary). We have used radiolabeling and hybridization methods to localize glycine receptor subunits in the cochlear nucleus and superior olivary complex. This expression was then compared to immunolocalization of the 93 k AP. In the lateral superior olive (LSO) and medial nucleus of the trapezoid body (MNTB) the amount of expression of different subunits was compared to number of glycine immunoreactive terminals received as well pressure of 2%KI. Expression of α1 and α3 subunits were seen over principal cells of all major CN and SOC nuclei, while the expression of the α2 subunit was considerably lower. All cell types that showed expression of the catalytic alpha-ligand for the 93 k AP. While there was good correlation between the number of 93 k AP immunoreactivity and the amount of glycine immunoreactive afferent a cell received, there was no always a correlation between the number of silver grains over cells expressing receptor subunits and the glycine immunoreaction. LSO principal neurons receive many more glycinerich terminals than MNTB principal neurons. This is consistent with the increased expression of the α2 subunit of the β subunit.

Supported by NIDCD Grant # DC 00383.

400.16 SYNAPTIC ORGANIZATION WITHIN THE MEDIAL SUPERIOR OLIVE OF UNILATERALLY DAEERED GERBILS. E.A. Russell and D.R. Moore, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, U.K.

Neurons of the medial superior olive (MSO) are thought to contribute to sound localization by signalizing the temporal correlation between excitatory input from the left and right antitiet (AVCN). Following the use of a non-reactive or new hybridization methods to localize neurons expressing glycine receptor subunits in the cochlear nucleus and superior olivary complex. This expression was then compared to immunolocalization of the 93 k AP. In the lateral superior olive (LSO) and medial nucleus of the trapezoid body (MNTB) the amount of expression of different subunits was compared to number of glycine immunoreactive terminals received as well pressure of 2%KI. Expression of α1 and α3 subunits were seen over principal cells of all major CN and SOC nuclei, while the expression of the α2 subunit was considerably lower. All cell types that showed expression of the catalytic α-ligand for the 93 k AP. While there was good correlation between the number of 93 k AP immunoreactivity and the amount of glycine immunoreactive afferent a cell received, there was no always a correlation between the number of silver grains over cells expressing receptor subunits and the glycine immunoreaction. LSO principal neurons receive many more glycinerich terminals than MNTB principal neurons. This is consistent with the increased expression of the α2 subunit of the β subunit. We are continuing this quantitative assessment and comparison.

Supported by NIDCD Grant # DC 00383.
400.17

The lateral nucleus of the trapezoid body (LNTB) is a prominent periventricular cell group that contributes a large feedback projection to the cochlear nucleus. This cell group is known to receive ascending activation via collaterals of small cochlear axons, although any detailed description of these terminals are sketchy. We have determined that FEP-19 antiseraum labels substantial numbers of fibers and terminals in the LNTB, including globular bushy cells, and ventral cochlear nucleus (VCN) axons. We studied the immunolabeled terminals using both light (LM) and electron microscopy (EM) to gain a clearer picture of globular bushy cell inputs to the LNTB.

Based on LM and EM descriptions, afferent GABAergic inputs to globular bushy cells in the LNTB can be identified. The first zone, located medially and ventrally and concentrated caudally, contains large FEP-19 IR puncta and fibers. The puncta in many cases form rings which define the perimeters of immunonegative cell bodies, and are typically on the order of 6-8μm. The second and larger zone is distinguished by having the highest density of immunonegative cell bodies. This zone contains large punctate profiles, although on average puncta are smaller than in the first zone and do not form pericellular rings. Pre-embedding EM immunocytochemistry reveals FEP-19 IR presynaptic boutons associated to unlabeled cell bodies and dendrites. Their internal morphology is consistent with their being excitatory terminals.

These results support the notion that LNTB neurons are rapidly and securely activated by bushy cells, and may exert rapid feedback effects on cochlear nucleus neurons.

Supported by NIH grant DC01387

400.19

Projections from the ventral cochlear nucleus (CN) to the opposite CN and to the inferior colliculus (IC) arise primarily from multipolar cells. In our first experiment, we injected different fluorouracil tracers into one CN and into each IC to determine whether individual cells project to more than one of these nuclei. Injection of the 3 tracers labeled the same cells in the uninjected CN; however, no individual cell in the ventral CN contained more than one tracer. Thus, commissural projections and collicular projections arise from different populations of cells. In a second experiment, we injected PHAL into one CN and examined the labeled axons in the other CN. In the ventral CN, labeled axons were observed to converge primarily onto cells whose somata were also aspicted to superficial and globular cell somas. Many labeled terminals were also found in the granule cell regions of the CN and in the deep layer and fusiform layer of the dorsal CN.

The commissural projections arise from cells that do not project to the IC. It appears that CN cells that do project directly to the IC, including a subset of multipolar cells in the ventral CN as well as cells in the dorsal CN, are themselves targets of the commissural projections. Other cell types, namely globular and spherical cells, are also targets of commissural projections. These cell types project to the IC indirectly, via relays in the superior olivary complex. The commissural projections thus provide an opportunity for binaural interactions at early stages in a variety of ascending auditory pathways.

VENTRAL NUCLEUS OF THE TRAPEZOID BODY: DENDRITIC MORPHOLOGY BY INTRACELLULAR LABELING. N. Kuwabara* Dept. of Biol. Sci. and OUCOM, Ohio University, Athens, OH 45701.

The ventral nucleus of the trapezoid body (VNTB) is a periventricular cell group at the floor of the mammalian superior olivary complex (SOC). This nucleus is strategically positioned in the trapezoid body just below the medial nucleus of the trapezoid body (MNTB) and the medial superior olive (MSo). The VNTB contains a mixed population of elongate and multipolar cells and is known to receive extensive afferent inputs from the ventricular cochlear nucleus (VCN; Warr, ’72). Some cells of the VNTB are thought to contribute to the medial olivocochlear bundle system (Warr, ’75). The VNTB also has projections to both lateral and ventral collicular populations (Nordeen, ’83) and the cochlear nucleus bilaterally (Brown et al., ’88; Winter et al., ’89). However, little is known about the organization of the VNTB, its relation to the rest of the SOC, or the relationship between its afferent and efferent connections. We have begun our studies of the VNTB by examining its dendritic morphology as revealed by intracellular labeling in a gerbil brainstem slice preparation.

Intracellular labeling with Neurobiotin suggests that the main dendrites of most elongate VNTB cells are oriented dorsolaterally. Dorsally oriented dendrites often invaded and arborized within the MNTB. Some small dendritic branches were traced dorsolaterally into the columnar region of the MNTB. Ventral dendrites often extended across the entire width of the ventral trapezoid body. Previously, we have observed collateral axons from MNTB principal cells projecting to the VNTB (Kuwabara et al., ’89). The dendritic pattern of the VNTB suggests that this nucleus may sample ascending information in the neural plexuses of both the MNTB and the MSO as well as direct projections from the VCN. (Supported by DC01303, DC00383 and OUCOM).

401.1
SUPERIOR PAROVALVULAR NUCLEUS (SPON); CONNECTIVITY REVEALED BY TRANSPORT OF BIOTINYLATED DEXTRAN. E. Saltarini, D. R. Lough and A. S. Berrebi, Univ. of Salamanca Med. Sch., 37007-Spain, and Dept. of Otolaryngology, West Virginia Univ, Morgantown, WV 26506.

The SPON is a prominent periventricular nucleus located ventrally to the dorsal cochlear nucleus. In order to clarify its synaptic targets and sources of inputs, we injected biotinylated dextran (BD) into the inferior colliculus (IC) or SPON of rats. This tracer provides both retrograde and anterograde labeling of cell bodies and processes.

The projection from SPON to IC is extensive, primarily ipsilateral, and originates from large multipolar cells with flattened, parasagittally oriented dendrites, which are moderately situated SPON neurons project to ventromedial (high frequency) regions of the IC, and those situated laterally project to dorsolateral (low frequency) regions. Thus, the SPON projection to the IC is topographically organized.

After injections restricted to the SPON, an extremely dense fiber plexus, but very few cell bodies, are labeled in the IC. Numerous retrogradely labeled neurons were present within the ipsilateral region of the cochlear body (MNTB) and contralateral posteroventral cochlear nucleus (PVCoN).

The predominant neuronal type labeled in the PVCoN corresponds to octopus cells, although multipolar and scattered small stellate and bushy cells are also found.

These data suggest that SPON activity is modulated by the balance of its excitatory inputs from SPON and its inhibitory inputs from octopus cells originating in the MNTB. Since the SPON contains primarily inhibitory neurons, it appears that complex inhibitory/disinhibitory phenomena at the level of the IC may represent an important aspect of its functional role.

Supported by the D.G.I.C.Y.T. and the F.I.S.S. of Spain (E.S.), and by WUV Med. Corp. and an NIH Biomedical Research Grant (A.S.B.).

401.2

Expression of the c-fos protein has been shown to be up-regulated in auditory brainstem neurons in response to tonal stimulation. In the present study we examined the expression of c-fos mRNA following 1 hr of free-field stimulation with a low-frequency, narrow-band noise (1.41-5.55 kHz) at intensities ranging from 80-120 dB SPL. At 80 dB elevated expression was found in subsets of neurons in the low frequency areas of the dorsal (DCN), posteroventral, and anteroventral cochlear nuclei, the medullary nucleus of the trapezoid body (MNTB), the ventral and dorsal nuclei of the lateral lemniscus (VLCN), and inferior colliculus (IC). The regions containing labeled neurons in these structures increased in size with 90 and 100 dB stimulation, but the signal began to decline at 110 dB. In some auditory nuclei, labeled in low-intensity areas was nearly absent, while low intensity stimulation may reflect damage to the low-frequency part of the cochlea. At 90 dB additional neuronal labeling was found in the highest frequency regions of some of these structures, particularly the DCN, MNTB, and IC. These areas of label also increased in intensity with increasing stimulus intensity, which may reflect the greater sensitivity of the high-frequency part of the cochlea to high intensities of all frequencies.

Alternatively, some central auditory neurons, i.e., those in high frequency regions of DCN, MNTB, and IC, may have more sensitive stimulus/transcription coupling mechanisms than others. At the highest stimulus intensities the middle frequency regions of the auditory nuclei became heavily labeled, presumably as the tail of the tuning sensitivity for these neurons was activated. c-fos mRNA expression appears to be related to a biophysical response driven by, but not necessarily synonymous with, neuronal activity. Its expression may be useful as an indicator of neuronal activity in many, though perhaps not all, neurons of the auditory brainstem.

Supported by the House Ear Institute, Research Service of the VA, and DC-00139.
401.3

EXPRESSION OF c-fos mRNA IN THE RAT AUDITORY BRAINSTEM FOLLOWING UNILATERAL OR BILATERAL COCHLEAR ABLATION.
L. Luu, R. R. Huang, and E. I.Abramoff, Int. House, University of Southern California, Los Angeles, CA 90007.

Transcription of the c-fos gene was examined from 30 min to 60 days after surgical ablation of one or both cochleas in adult rats using an in situ hybridization. After unilateral ablations, basal expression in the ipsilateral ventral cochlear nucleus (VCN) and contralateral inferior colliculus (IC) began to decline 1-2 hr post injury, was maximally depressed at 3-4 hr post injury, and remained suppressed through 60 days post injury. In the cochlear nucleus contralateral to the ablation there was a rapid (30 min.-1 hr post injury) increase in neuronal expression in the deep layers of the dorsal cochlear nucleus (DCN) and ventral cochlear nuclei which remained elevated through 60 days post injury. This suggests a release from inhibition normally driven by the contralateral ear. An intense glial expression in the acoustic and ventribuline nuclei of the ablated side, reflecting degeneration of the ablated ear, was first evident at 3 days post injury and gradually involved the nerve roots, octopus cell area, and spinal tract of the trigeminal. Elsewhere there were delayed increases in neuronal expression bilaterally in peristriate cortex, dorsal nuclei of the lateral lemniscus, paralemniscus, and commissural nuclei of the IC and in the ipsilateral ventral and intermediate nuclei of the lateral lemniscus and central nucleus of the IC. Peaks ranged from 2 hrs to 2 weeks and persisted for at least 60 days after ablation. The delayed onset of these responses suggests transynaptic effects and possibly reorganization of the central pathways in response to deafferentation in the adult. No neuronal expression was evident in any auditory cortex 4 hrs or more after bilateral ablations, suggesting that all observed expression was acoustically driven. A single exception was in the superficial layers of the DCN, where there was an initial rapid increase in expression in medium-sized neurons that reached a maximum at 2 hrs and disappeared by 1 day. This may reflect a release from acoustically driven inhibition of high spontaneous rate neurones with subsequent adaptation or delayed depolarization of higher order excitatory input.

C-FOS EXPRESSION ELICITED BY SOUND STIMULATION IN THE AUDITORY NEURONS OF THE BIG BROWN BAT, EPTESICUS FUSCUS Y. Qian and P. H. S. Lem.
Division of Biological Sciences, University of Missouri-Columbia, MO 65211.

Because proto-oncogene c-fos can be expressed in neurons following sensory stimulation, c-fos immunocytochemistry has been used as a sensitive and selective method for identifying neurons that have undergone an activation pattern. We studied the immunohistochemical staining pattern of c-fos immediately following noise and tone burst stimulation of the auditory nuclei in the bat brain. Contralateral auditory nuclei were also studied with an emphasis on the dorsal cochlear nucleus (DCN). C-fos expression was studied immunohistochemically for the auditory cortex, the thalamus, and the superior colliculus.

STRUCTURE AND INNERVATION OF NEURONS IN THE VENTRAL NUCLEUS OF THE LATERAL LEMNISCUS THAT PROJECT TO THE INFERIOR COCCULUS. R. Berry, J. C. Beckers, and E. M. O'Leary, School of Medicine, University of Virginia, Charlottesville, VA 22908.

A multiplicity of pathways transmit auditory information from the cochlea to the inferior colliculus. While some of these are binaural, others may convey monaural information. One potentially monaural pathway which may lead to the inferior colliculus via the ventral nucleus of the lateral lemniscus (VNL). The VNL is a major source of input to the inferior colliculus, yet neither its inputs nor the morphology of its neurons have been extensively studied. Ascending input to the VNL was examined by injecting biotinylated dextran in the cochlear nuclei. Dextran-labeled axons that ran in the lateral lemniscus periodically gave off c-fos arborizations that entered the VNL. These horizontal arbor were roughly perpendicular to the lemniscus, and resembled the rango of c-fos arborization in the auditory thalamus. In a second experiment, neurons in the VNL that project to the inferior colliculus were labeled with retrograde transported fluorescent microspheres, and then intracellularly injected with a mixture of Lucifer Yellow and biotinylated Lucifer Yellow in slices of fixed tissue. The somata of stained neurons were spherical or elongated in shape. Differences were noted in the appearance of the ventral lemniscus, though most were more parallel to the lemniscus. Neuroticles with dendrites perpendicular to the lemniscus would likely receive input from one ear, or "wings" of fibers, from the cochlear nucleus, whereas those with dendrites parallel to the lemniscus may integrate inputs over a larger region. The relationships of dendritic orientation in the VNL to the input from the cochlear nucleus suggests that the VNL may play more than one role in auditory processing.

MORPHOLOGY OF COMMISURAL AXONS IN THE INFERIOR COCCULUS OF THE GERBIL. Nina Z. Dorothenko and Neil B. Cape* Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

We made small injections of bicynoc into the central nucleus of the inferior colliculus and reconstructed the axons and terminals which arise from this injection and project into the contralateral inferior colliculus. All subdivisions of the inferior colliculus receive commissural connections; the patterns of branching are different in each one. Most commissural axons terminate in a manner typical of the central nucleus. Less often, labelled axons enter the central nucleus from its lateral dorsal aspect at right angles to the fibroblast laminar structure and travel in the ventromedial or lateral divisions of the central nucleus. The internal part of the external nucleus is innervated by axons which enter it by passing through the central nucleus, some of which give rise to branches. The terminal field of each axon is confined to a limited strip along the dorsal to ventral axis of the external nucleus. The superficial part of the external nucleus receives the sparsest intercellular connections. Most of the terminals there arise from branches of axons passing into the brachium. In the dorsal cortex, terminals of commissural axons are found most often in the middle of the deep layer. Most of them arise from branches of axons that enter the central nucleus or the brachium of the inferior colliculus.

GABAergic PROJECTIONS FROM THE INFERIOR COCCULUS TO THE MEDIAL GENICULATE BODY IN THE CAT. S. Paylor*, R.Z. Stankewitz, B. L. Miller, M. D. Harley, and A. Winer. Dept. of Molecular and Cell Biology, Univ. of California, Berkeley, CA 94720.

The mammalian auditory system is unique among sensory modalities in that it has many brain stem projection areas that are GABAergic and probably inhibitory. These include ascending pathways (lateral lemniscus, trigeminal nerve [CN V], and accessory optic nerve [CN VI]), auditory nuclei (medial geniculate nuclei of both hemispheres), and basal ganglia structures. The mammalian auditory system is unique among sensory modalities in that it has many brain stem projection areas that are GABAergic and inhibitory. These include ascending pathways (lateral lemniscus, trigeminal nerve [CN V], and accessory optic nerve [CN VI]), auditory nuclei (medial geniculate nuclei of both hemispheres), and basal ganglia structures.

401.10 CALCIUM-BINDING PROTEIN EXPRESSION DELINEATES SUBDIVISIONS OF RABBIT RAPHE, MIGRILICULE COMPLEX. N.T. McMillen, R.K. de Vries, P.R. Smogorz and S.E. Levin. Dept. of Anatomy, Univ. of Arizona College of Medicine, Tucson, AZ 85724

Previously cytoarchitectonically detailed studies of the mammalian medulla have recognized three major divisions: dorsal, central, and ventral. Additional additional parcelling of the medial medulla is warranted based on Golgi and intrinsic morphology. We analyzed the distribution of Ca**2+**-binding proteins (CaBP) in the rabbit medulla. By using specific monoclonal antibodies, we have characterized three major subdivisions of the rabbit medulla: dorsal, central, and ventral. These subdivisions were delineated using immunohistochemical methods and are distinct from other previously described subdivisions. The dorsal medulla contains a high density of CaBP, the central medulla contains a moderate density of CaBP, and the ventral medulla contains a low density of CaBP. These findings have implications for the functional and anatomical organization of the rabbit medulla.

LOCAL PROJECTION PATTERNS IN THE RAT CORTEX DEMONSTRATED WITH BIOCYTIN  
D.F. Nowak* and F.B. Ciccarelli  
Department of Neurosurgery, University of California, San Francisco, CA 94143  
Small intracortical injections of biocytin into the auditory cortex of the rat labeled the soma and processes of neurons exposed to the injected marker. In many cases, labeled processes were followed for considerable distances to targets in the ipsi- and contralateral cortices. In some cases, the injection was placed quite superficially in the auditory cortex layer VI, and in others, it was placed deeper into layers V/VI, producing different projection patterns. The laminar pattern of local circuit projections is dependent on the depth of the injection in the cortex. For example, an injection restricted to the superficial laminae in rostral auditory cortex (area 41), labeled neurons and processes around the injection site. Labeled processes were distributed most heavily in layers I, II/III, and V. A prominent fascicle of labeled processes descended into the subcortical white matter before turning abruptly dorsal, and then traveling to the corpus callosum. Bundles of labeled axons also passed horizontally through the cortex (not subcortical white matter), terminating in a columnar pattern in layers I, II/III, and V. The plexus of labeled processes in layer I was heaviest, followed by that in layer II/III, and then layer V. In contrast, when the injection involved the full thickness of the cortex, the local plexus processes terminated in a column extending through all layers. Long distance projections to ipsilateral visual cortices frequently took the most direct path to their targets, passing through the cortical laminae at oblique angles. Labeled axons were also observed in the corpus callosum. These axons entered the subcortical white matter directly beneath the injection, ran anteriorly, and passed to the opposite hemisphere at the lower half of the callosum. The results suggest that horizontal interactions among the auditory cortices have a unique laminar distribution that is dependent on the cortical lamina from which it arises. DEVELOPMENT OF AUDITORY CALLOSAL CONNECTIONS IN NORMAL AND HYPOPHYTALD RATS. R.A. Lucio*, J.R. Beracoa, P. Pacheco and P. Berbal  
Department of Histology and Neuroendocrinology, Univ. Alcance (Spain), and CIP, Univ. Auton. Talca, INE, Univ. Veracruzana and IB-UNAM (Mexico).  
Lack of thyroid hormones produces generalized brain damage, especially in the neocortex. Recent findings show that auditory callosal connections are severely damaged in adult hypothyroid (H) rats. In normal (C) rats, retrograde labelled neurons were found in cortical layers II-III, while in H rats, they were mostly distributed in layers IV to VI. To test for an abnormal elimination/establishment of transitory connections in H rats, the distribution of retrograde labelled callosal neurons in the auditory neocortex during development was compared with controls. For antithyroid treatment of H rats methimazole (Sigma) was orally administered from day 14 and a thyroidectomy performed on postnatal day (P) 6. At ages between P4 and P47, C and H rats were injected in the auditory cortex with HRP or WGA-HRP, and after 2 days, brain sections were processed with TMB. The data was analyzed with a "Neurograph" computer program. Until P35, the radial distribution of retrograde labelled neurons was similar in both groups. After P35, the distribution of labelled neurons was drastically reduced in C rats, reaching an adult-like distribution by P47. Interestingly, their number and radial distribution in H rats appears not to change from P35 levels, even during adulthood. These findings indicate that the transitory callosal connections normally eliminated, were retained in H rats.  

401.18  
AUDITORY CORtical PROJECTIONS TO THE PONTINE NUCLEI IN THE CAT. J.J. Fries*, R. Rigelens, M. Boccon, and J.A. Winer.  
Department of Histology, University of Alicante, Spain (UP), Laboratory of Molecular and Cell Biology, University of California at Berkeley, Berkeley, CA 94720-1200 (JAW)  
The pontomesencephalic nuclei are a major source of brain stem mossy fibers to the cerebellar cortex. Little is known about how the auditory cortex influences the output of premotor neurons in the brain stem. The sparse data available on corticopontine projections rely largely in studies which use autoradiographic silver degeneration methods. The goal of the present study was to demonstrate with more sensitive methods the pontine targets of corticofugal axons from four auditory cortical areas (A, AL, PAF, and TE). Each was injected with WGA-HRP, and frozen sections were developed for TMB. Axonal injections labeled axons in the dorsolateral, lateral, paramedian, and peduncular pontine nuclei. Injections in AL produced a lighter, but similar pattern of terminal labelling. With injections in PAF, most fibers terminated in the peduncular nucleus, while the projection to the dorsalateral and paramedian nucleus was scant. PAF was the only area that projected to the ventral pontine nucleus. TE was the origin of the heaviest projection to the pontine nuclei, and labeled fibers were observed in all of the dorsolateral and paramedian nuclei. TE differed from the other areas since it alone projected contralaterally, to the paramedian nucleus, and also in that it sent axons to the median pontine nucleus. These results demonstrate a convergence of auditory cortical afferents to the pontine nuclei, as well as other corticopontine projections that are specific to each auditory area. This suggests that multiple, descending corticofugal inputs to brain stem nuclei exist which may be analogous to parallel, ascending pathways to auditory cortex. The macaque monkey auditory thalamo-cortical system defined by calcium binding protein immunoreactivity. T. Hatakeyama, M. Mollair, M.E. Gage and E.G. Jones.  
E.G. Jones, Neural Systems Laboratory, Riken, Japan and University of California, Irvine.  
Immunoreactivity for calcium binding proteins is a useful marker to differentiates thalamocortical projections in the monkey. The present study was aimed at analyzing the pattern of parvalbumin and calbindin immunoreactivity in the auditory cortex and thalamus of the Japanese monkey (Macaca fascicularis) and to relate the parvalbumin and calbindin distributions. The auditory areas of the supratemporal plane have been divided into 4 almost concentric zones of decreasing parvalbumin immunoreactivity (Figure 1). Zone 1: intense staining corresponding to fields AI and RL; Zone 2: moderate to dense staining corresponding to anteromedial (A-m), lateral (L) and postero medial (P-m) parvicalcitol fields; Zone 3: weak to no staining at any zone to 2; Zone 4: weakest staining: anterior pole of the supratemporal plane. These zones appear to be related to the relative density of interneurons such as parvalbumin- and calbindin-immunoreactive neurons. Retrograde tracing studies demonstrated that zones 1-3 receive inputs from different subnuclei of the medial geniculate (MG) complex. A direct correlation was observed between the density of parvalbumin immunoreactivity in the cortex and that in MG nuclei. The anteromedial thalamic afferent to zone 1 (A + RL) receives projections from the ventral MG nucleus in which most cells are parvalbumin immunoreactive while 2 to 3 subnuclei from the anteriotal and posterodeal nuclei which show comparable differences in parvalbumin immunoreactive cell numbers. The present data demonstrate that parvalbumin immunoreactivity can differentiate parallel thalamocortical pathways of the monkey auditory system.  

402.2  
INVOLVEMENT OF THE INSULAR CORTEX IN NAUSEA: A C-FOS IMMUNOHISTOCHEMISTRY STUDY. P.A. Bryant*, B. Boutilier and I.S. McGregor  
Dept. Psychology, University of Sydney, NSW, 2006, Australia.  
Lithium chloride (LiCl) is frequently used to examine the nature of emesis in animals. Although rats do not have an emetic reflex, the reduced food intake and conditioned taste aversions (CTA), induced by LiCl in rats suggests that this substance induces nausea in this species. The insular cortex is a brain region containing both taste responsive and viscerosensory neurons and has been implicated in the acquisition and expression of taste-induced aversions. Lesions of the insular cortex interfere with LiCl-induced CTA learning in rats while epileptic foci in the human insula are associated with nausea and vomiting. Lesions of the insular cortex in rats also cause aphagia and in body weight loss, and electrical or chemical stimulation of the insular cortex alters metabolic processes and feeding; suggesting overall involvement of this area in ingestive function (McGregor & Abrens, Behav. Neurosci., 105, 870-883).  
The present study determined whether LiCl injection would activate insular neurons as indexed by c-fos immunohistochemistry. Rats were injected i.p. with either LiCl (Smk/g of 0.8M) or an equivalent volume of saline. The present study was performed under standard laboratory conditions for 4 days prior to LiCl. 4 hours after the injection, the rats were killed and the heads were fixed by perfusion with phosphate-buffered saline and 4%.formalin. The brains were removed and processed immunohistochemically for the protein Fos (a marker of neural activation). Rats injected with LiCl showed greater Fos expression in the insular cortex than rats treated with saline. This result suggests possible involvement of the insular cortex in nausea. Further research in our laboratory is aimed at understanding more fully this neural substrate and its role in nausea and CTA learning.

Although the precise nature of the relevant neural code is still the subject of some debate, the results of recent investigations by other laboratories appear to support the hypothesis that primary taste information is transmitted to the gustatory system in a binary code (on-off). The coding of more complex tastes (analogous in many ways to those associated with other sensory systems) transmit data related to the gustatory environment through the central nervous system. As evidence for this theory accumulates, it is important to determine the neural mechanisms for these information channels. In the present investigation, glass microelectrodes filled with 2.0% Neurobio (Vector Laboratories) were used to physiologically characterize and label individual gustatory neurons in the rostral nucleus of the solitary tract (NRT). We restricted our analysis to the responses elicited by NaCl, HCl, quinine and sucrose, we found a marginally significant relationship (p = 0.06) between best taste and the extent in the medio-lateral plane, with NaCl-best neurons more widespread than those that were most sensitive to quinine (α = 0.05). When we further restricted our analysis to those neurons that responded to all four of these tastes, we found that both NaCl-only and HCl-only neurons were more widespread in the medio-lateral plane than quinine-only cells. Furthermore, there was an indication that the quinine-only cells were more restricted in the dorso-ventral axis. The difference between these groups was clearly revealed when the area of influence was considered. Quinine-only cells were smaller in the coronal plane than the cells that responded only to NaCl, HCl or sucrose. These data support the hypothesis that the response properties of gustatory NST neurons are related to the morphology of these cells. Our results suggest that the relationship between responsiveness and dendritic architecture may be especially important. Support in part by DC01074.

GUSTATORY AND RELATED CHEMICAL SENSES

The rat reticular nucleus of the solitary tract (NST) contains second-order gustatory neurons, some of which project to higher brain centers via an obligatory synapse in the pontine parabrachial nucleus (pBN). The morphology of the projection neurons in the pBN has been described in rat (Laiwer and El Khoury, '83, Laiwer, '91) and hamster (Whitehead, '90), with some conflicting results. The first part of the current study re-examined the morphology, number and location of pBN projection neurons visualized by anterogradely labeling tracer Dil (Molecular Probes) unilaterally into the pBN in male Wistar rats (n=3) and examining the retrogradely labeled cells in the NST. On average, each injection produced 200 retrogradely labeled cells that could be visualized morphologically. Sixty-three percent of the labeled cells were located ipsilaterally to the injection. The labeled neurons were located throughout the NST, with the highest percentage (33%) found in the rostral NST subdivision. All neurons had either multipolar- or elongate-shaped somata with the majority (61%) being classified as elongates.

Evidence indicates that forebrain autonomic and limbic centers directly project to the NST (van der Kooy et al., '84). As a preliminary step to double-labeling studies investigating the neurotransmitter within these projections, we unilaterally injected DiI into the NST and examined the retrogradely labeled cell bodies found bilaterally within the amygdala, but none were found in the hypothalamus or other limbic structures. Cells in the amygdala were most abundant in medial, and particularly, basomedial structures with few cells located in central or lateral regions. Therefore, the basomedial amygdal nuclei may have direct effects on the processing of gustatory information within the NST.

IN VITRO ANALYSIS OF GLUTAMATE AGONIST EFFECTS ON NEURONS IN THE RAT OSTROBRAINSTEM. G.D. Shu and R.M. Bradley. Dept. Biologic and Materials Sciences, School of Dentistry, University of Michigan, Ann Arbor, MI 48109-1078.

Glutamate receptor agonists have been shown to have excitatory effects on neurons in the caudal nucleus of the solitary tract in rats (Andresen and Yang, Am. J. Physiol. 259:H1307, 1990). Using whole cell recording in brain slices of the rat mesencephalon, we have investigated the effects of a variety of glutamate receptor agonists, L-glutamic acid, and N-methyl-D-aspartate (NMDA) superfused with the NMDA antagonist, kainic acid, and NMDA receptors on the rostral gustatory area of the nucleus of the solitary tract (rNST). Recordings were made from neurons with stable resting membrane potentials and intact axonal connections. Superfused with glutamate receptor agonists, L-glutamic acid, and N-methyl-D-aspartate (NMDA) resulted in membrane depolarization usually accompanied by an increase in the number of AMPA receptors either increased their firing rate or became spontaneously active with the depolarizations. All neurons tested responded to NMDA and 83% responded to AMPA indicating that both NMDA and AMPA receptors on neurons. Neurons responded to NMDA and AMPA in a dose dependent manner. NMDA was effective over a concentration range of 10-100 µM and AMPA over a concentration range of 20-1000 µM. Reversal potentials for NMDA and AMPA were estimated from current-voltage relationships in control saline and in the presence of NMDA and AMPA at concentrations producing a maximal response. The NMDA reversal potential was 1.2 ± 0.2 mV (mean ± SE, n = 5) and the AMPA reversal potential was -4.9 ± 0.7 mV (n = 7). These results, together with our previous studies on synaptic potentials in NST neurons (Chem. Sens. 18:647, 1993), indicate that glutamate is an excitatory transmitter at the first central synapse in the taste pathway. (Supported by NIDCD grant DC00288 to R.M.B.)

We are interested in chemosensory transduction and synaptic mechanisms in the mammalian carotid body, an O2-sensing organ that regulates breathing (Hurtado et al., 2009). O2-sensory neurons are glomus or type 1 cells which transduce hypoxic stimuli by the closure of K+ channels, followed by depolarization and neurotransmitter release at synapses formed with petrosal sensory terminals. To investigate chemosensory signaling we developed co-cultures of dissociated (rat) petrosal neurons and glomus cell clusters. Monitoring of membrane potential in isolated co-cultured petrosal neurons, before and after perfusion of hypoxic (Po2=25-30 torr) solutions, revealed silent, as well as spontaneously-active neurons that showed no obvious response to hypoxia. A third, and most interesting category was juxtaposed to glomus cell clusters; 2 of 7 such neurons depolarized reversibly during hypoxia, from a typical resting potential of -55 to -70 mV, and this was accompanied by an increase in membrane conductance. These neurons are strong candidates for ones that develop de novo functional synapses with glomus cells, and will be useful for studying synaptic events during chemosensory signaling. Supported by MRC Canada.

CHARACTERISTICS OF ACTION POTENTIALS AND THEIR UNDERLYING OUTWARD CURRENTS IN MAMMALIAN TASTE RECEPTOR CELLS. Y. Yi, Y. Chen, and S. Xiao-Dong. Indiana University School of Medicine, Muncie, IN. 47306.

Many rat taste receptor cells conduct action potentials (APs). APs had a mean threshold of -35 mV (n=61 cells) and a spike height of 52mV above threshold in current clamp (hold = -80 mV). APs could be classified into two significantly different (p<0.001) groups - fast, with short half-time durations and large outward currents (mean=1.3 ms and 2.7nA), and slow, with long durations and small outward currents (mean=9.2 ms and 0.29nA). APs were conducted through TTX-sensitive sodium currents whereas the downstream by TEA-blockable outward currents. Voltage dependent analysis of outward currents separated transient and sustained components. The transient component was specifically blocked by 4AP (1mM). A calcium-dependent outward component was also revealed by modulating voltage and external calcium concentration. The fast recovery phase of the AP appears related to the sustained outward current whereas the after hyperpolarization (AHP) was blocked by 4AP suggesting a significant contribution of the transient component. Forskolin (FSK), which elevates cAMP, reversibly blocked the majority of the sustained current without influencing the transient. FSK greatly exaggerated the AHP without changing the spike height or duration. These data suggest that several components of the outward current contribute specifically to the gustatory AP and that the AP may be modulated by cyclic nucleotides. Supported by NIH DC00401.

402.12

Taste buds and the immediately adjacent epithelium are richly innervated both by specific gustatory fibers upon which taste receptor cells synapse and by free nerve endings. Classic anatomical studies have separated that many of the free nerve endings are innervated by capsaicin sensitive (i.e., substance P (SP) and CGRP) and that some of these enter the taste bud proper. Thus the designation of 'intragemmal' and 'perigemmal' probably does not correspond to the endo-epithelial role of the particular fibers. Further, a rich synapom- and synthaphylin-ir intragemminal nerve plexus is present and at least some of these fibers are post-synaptic to taste receptor cells. The present study on rats was undertaken to test whether the CRG/SP fibers and the synthaphylin fibers represent two largely independent and non-overlapping populations. In circumpalatine, a few scattered double-label fibers occur, while in the fungiform papillae, the two populations are mutually exclusive. Following perinasal treatment of rats with capsaicin (50 mg/kg i.p.), the SP/CGRP but not the synthaphylin-ir populations are abolished.

402.13

Focal chemical stimulation of the apical tips of intact taste buds elicits receptor potentials in receptor cells and postsynaptic responses in Merkel-like basal cells (Ewald & Roger, J. Neurophysiol. 67: 1316, 1992). There is evidence to indicate that in taste buds (Dickinson & Taylor and Roper, J. Comp. Neurol. 335: 606, 1993; Ewald & Roger, J. Neurosci. 13: 344, 1993) the synapses of receptor cells are postsynaptic responses in basal cells andafferrent nerve endings is unknown. In mammalian taste buds, acetylcholine (ACh) activates muscarinic receptors (Haas et al., 1988; 1990) and immunocytochemical evidence has shown the presence of choline acetyltransferase in taste buds (Kim & Roper, this volume). We have investigated the effects of locally applied ACh (10 μM to 1 mM) on cells in intact taste buds and on isolated taste cells from Necturus. Short pulses of ACh elicit hyperpolarizing responses in receptor cells (4.5 ± 1.3 mV; mean ± SE; N=5; ACh = 100 μM; Vs = -40 mV), accompanied by increases in input resistance (3 ± 12%). In intact taste buds these responses are enhanced by bath application of acetylcholinesterase inhibitor (10 μM neostigmine; 67 ± 6%; N=4). In isolated receptor cells, the responses are mimicked by oxotremorine (100 μM), a muscarinic agonist, blocked by atropine (30 μM), a muscarinic antagonist, and not mimicked by nicotine (100 μM). Responses are increased by hyperpolarization of the membrane potential. The zero intercept of this increase, in conjunction with an increased input resistance during the responses, suggests that ACh responses are primarily due to a transient decrease in resting Cl− conductance. We speculate that cholinergic responses may be part of an effector control circuit, or may play a role in lateral interactions between receptor cells. Support. NIH DC01238.

402.14

Glutamate (Glu) and GABA are found in nerve fibers that innervate Necturus taste buds (Jain & Roper, '91). Lu & Roper, '93). To investigate whether Glu/GABA are involved in synaptic transmission in taste buds, we studied their uptake and release in taste cells. Lingual epithelium was incubated with 3H-Glu (0.5, 5.0 μM) or 3H-GABA (0.6, 6.0 μM) in amphibian physiological saline (APS) for 15 min., rinsed with fresh APS, fixed with 2% glutaraldehyde, postfixed with 2% OsO4, embedded, and sectioned at 2.5 μm. Slides were coated with Kodak emulsion and exposed for 3-10 days. Background labeling for 3H-Glu was seen throughout lingual epithelium. However, silver grains preferentially accumulated over some taste cells. Next, epithelium was incubated with 3H-Glu and rinsed with APS containing 40 mM K+. K-reduction treated the number of heavily labeled taste cells, consistent with a depolarization-induced release of Glu. Rinsing tissues with 40 mM K+ but in the presence of 20 mM Mg2+ and 0.4 mM Ca2+ did not reduce the number of labeled taste cells. When lingual tissues were incubated with 3H-GABA, labeling was seen over cells lying outside of taste buds, including putative glial cells in the lamina propria. 3H-GABA uptake was not affected by rinsing tissues with 40 mM K+. We conclude that Necturus taste buds have uptake and Ca-dependent release mechanisms for Glu that may be related to synaptic actions. We did not find evidence for depolarization-dependent release mechanisms for GABA in taste buds.
402.15
IMMUNOCHEMICAL LOCALIZATION OF CHOLINE ACETYLTRANSFERASE IN TASTE BUDS. Da-Jong Kim and Stephen D. Roger*. Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins CO 80523 and the Rocky Mountain Taste and Smell Center, Denver CO 80262.
Cholinergic synaptic mechanisms in taste buds were proposed several years ago on the finding that injecting cholinergic agonists and antagonists into the tongue modified taste responses (1). Additionally, acetylcholines- terase (ACHE) has been localized in taste buds from a number of species. However, ACHe can be associated with noncholinergic neurons, in force. The presence of ACHe is not a reliable indicator of cholinergic neurotransmission. In contrast, the localization of choline acetyltransferase (ChAT), the biosynthetic enzyme for acetylcholine, is considered direct evidence for cholinergic mechanisms in the nervous system. We have conducted immunocytochemical studies on lingual tissues from rats and mice to determine whether ChAT is localized to taste buds. Immunocytochemistry revealed ChAT in taste receptor cells of vallate papillae. Three to eight receptor cells per taste bud showed intense ChAT immunoreactivity in their cytoplasm. ChAT-immunopositive cells were elongate and their cell processes extended from the taste pore to the base of the taste bud. Immunostained cells were mainly located at the periphery of taste buds. On the basis of these data, as well as recent findings on the pharmacology of muscarinic agonists in taste buds (Hwang et al., PNAS 87: 7395, 1990; Ewald & Roger, this volume, 1994), we postulate that acetylcholine functions as a neurotransmitter in vertebrate taste buds.
Supported by NIH DC00374 and DC00244.

402.16
Chorda tympani (CT) transection causes anterior tongue taste bud degeneration and severely disrupts the rat's ability to discriminate NaCl from KCl. We recently demonstrated that rats trained presurgically and tested starting 49 days post-surgically (CTX/49d) could discriminate the two salts, but those tested 8 days post-surgically (CTX/8d) could not. The rats tested starting 28 days after bilateral CTX (n=7) displayed variability in salt discrimination performance, ranging from normal to severely impaired (overlap score range: 0.7-77.9). A third group (n=6) tested 49 days after CTX displayed competent discrimination. When the data from the present groups were combined with the data from the control, CTX/49d, and CTX/8d groups previously reported, the overlap scores correlated (r=0.88) with the percentage of fungiform papillae containing a TP (p<0.001, n=7). Although some rats with a small number of anterior tongue TPs were partially competent, overall it appears that there is a strong relationship between the extent of taste bud regeneration and performance in the salt discrimination task. 403.1
SIMPLE AND COMPLEX RELATIONS OF MOTOR CORTICAL ACTIVITY TO GRIP FORCES IN THE ALIEN MONKEY. H.J. Qi, E.J. Huster, I. Ali, M.C. Hepp-Reymond*. Brain Research Institute, 8005 Zurich, Switzerland.
Neuronal correlates of force have been repeatedly shown in the primary motor cortex (M1). We wondered whether the neuronal activity in two ventral premotor regions (PMv) and M1 may code other features than just grip force.
We have analysed 242 finger-related cells, recorded from the 3 regions in 2 monkeys trained to produce isometric force in a step-tracking task. The trials varied in number of steps, their range and direction, each alternating specified by its own colour cue. The findings are: 1. More than half of the neurons displayed positive or negative correlation between cell activity and force. In 70% of these significant cells, similar direction discharge patterns were found under all test conditions. The rest, and a large proportion of non-significant cells, had more complex firing patterns. Most of these neurons (df cells) changed their force correlation at the highest level of linearity only within a narrow force range. With high forces a few df cells also altered their phasic activity component during the force ramps. The majority of the neurons with complex force relation (df cells) clearly changed their discharge patterns during the last hold period, regardless of the type of trial. 2. The distribution of the 3 cell populations and their mean force sensitivity was comparable in the 3 explored regions. 2. Most neurons with significant correlation coefficient responded to activation of deep (muscle and joint) receptors. The proportion of cutaneously activated cells was higher in the df population. 4. Some PMv neurons with receptive fields on face and hand also showed significant covariation with force.
In conclusion, these findings suggest that most M1 and PMv neurons code force in simple manner, and that only a minority has activity related either to force within a narrow range or to other parameters or task features.

403.2
Two macaque monkeys were trained to perform a two-dimensional, delayed step-tracking task in which they used the right upper extremity to operate a joystick that moved a cursor on a video display screen. Single cell recordings were obtained from the shoulder and elbow regions of the primary motor cortex. The presentation of a fixation target on the center of the monitor signaled the beginning of a trial. Once the monkey moved the cursor into the fixation point, four peripheral targets were presented. One of the target subsequent movements of the joystick was used to direct the monkey to capture the target after a delay upon the dimming of the fixation point. Spatial mapping between the cursor and joystick movement was offset by either 0° or 90°. The head trajectory was thus suggestive of the direction of the direction of displacement (from center) of a given target. The spacing of the targets was such that the set of movements towards all four targets was equivalent in the two conditions, allowing determination of whether neurons performed different responses were detected. Tuning curves of the first type of cells were invariant with respect to hand trajectory. The second type showed different responses that were invariant with respect to different hand trajectories. These results indicate that directional tuning of motor cortex neurons is not always representative of limb trajectory as neurons of the second type appeared to reflect the intended direction of motion towards a given target rather than that of the limb.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
CELL ACTIVITY IN MONKEY MOTOR CORTEX IS ALTERED BY CHANGES IN POSTURE FOR MOVEMENTS WITH IDENTICAL HAND-TRAJECTORIES S. H. Scott* and J. P. Kalaska, Dép. de Physiologie, Univ. de Montréal, Montréal, Québec, CANADA, H3C 3J7.

The debate continues as to whether neuronal activity in the monkey motor cortex during reaching movements is better related to the extrinsic (i.e. hand trajectory) or intrinsic (e.g. muscle activity) attributes of motor task. We have trained a monkey to move a pendulum-like handle to visual targets using two different arm postures, but with identical hand paths. In the first posture (horizontal), the monkey showed to perform the task in its preferred arm orientation (largely in the sagittal plane). In the second posture (vertical), the monkey had to perform the task approximately 90 degrees in grasp and move the handle. This altered arm posture changed the mechanical properties of the muscles (length and moment arm about the joint) and changed the EMG activity patterns of muscles that span the shoulder and elbow joints. We recorded the activity of a large sample of neurons, joint-pen-event histograms (Aertsen et al., 1989) were then calculated on 205 pairs of simultaneously recorded neurons. The activity of 39 pairs of neurons (15%) was significantly synchronized during periods of time lasting 50 to 300 ms. Such periods of synchronization occurred just after the preparatory signal, at the end of the PP, during RT and/or during movement time. For 14 pairs, the neurons fired with a synchrony of less than 1 ms, whereas in the remaining 25 pairs, larger peaks of cross-correlograms were observed. Synchronized neurons were recorded with a mean horizontal distance of 377 μm (160 to 1980 μm) and a mean vertical distance of 464 μm (0 to 1810 μm). This study provides further evidence for dynamic changes in the functional connectivity within neuronal populations involved in the processing of sensorimotor information. Detailed analysis of cross-correlation data will be used in an attempt to decipher the functional organization of the recording process in the central base and to investigate how cognitive functions are implemented in the microstructure of the cerebellum.

403.6 PRIMATE PREFRONTAL CORTEX PLAYS A SIGNIFICANT ROLE IN PERFORMING SEQUENTIAL BEHAVIOR WITH AN IMPOSED DELAY. S. Panagopoulos*, M. T. and C. Grant, Grad. School of Human and Environmental Sciences, Kyoto Univ., Kyoto 606-01, and Prime Res. Inst., Kyoto Univ., 630-8620, Japan.

To investigate the roles of the prefrontal cortex in generating sequential behavior, single neuron activity was examined in the prelpirpical region while 2 monkeys performed a sequential task involving two of three targets: press the button to reach to one target as a control. In addition, to examine whether prefrontal neurons retain multiple target positions simultaneously, a 3 delay period was imposed between the target presentation and movement time. A total of 234 single neuron activities were analyzed. Among them, 138 exhibited task-related activity in at least one out of the three phases: trial, 87; 3-5, 108 exhibited cue, delay, and response-related activity, respectively. A large proportion of these activities exhibited complex and context-dependent characteristics. For example, 50% of the delay-related activity was observed only when the targets were presented in a particular order during the cue period (pair- and sequence-dependent), and 18% of this activity was observed only when a specific target was presented in either the first or second position (position- and sequence-dependent). For the remaining neurons, targets related activity under simple conditions. For example, 8% of the delay-related activity was observed when the target was presented in a particular position, regardless of its order. A similar variety of response characteristics, from context-dependent to simple, was observed in response-related activity.

These results indicate that the prefrontal cortex plays an important role in executing sequential behavior. The prefrontal cortex may participate in complex sequential behavior by retaining target positions through a variety of activities, each of which can retain either simple information (e.g., a single position) or multiple and complex information (e.g., multiple positions and a particular order).

403.8 MOTOR CORTEX AND INTERCEPTION OF MOVING TARGETS: SINGLE CELL ANALYSIS. N. Lindstrom*, W. Kiste, P. Dansonville and A. P. Georgopoulos, Brain Science Center, VAMC, Minneapolis, MN.

Two monkeys were trained to use a 2D articulating manipulandum to intercept moving targets on a computer screen. In random order, 9 targets either accelerated, decelerated or traveled at a constant velocity. For each motion condition targets were traveled for one of three target presentation times: 0.3, 1 or 2 s. Each target appeared randomly in either the right or left lower corner of the screen, then traveled along a 45° path until they crossed the vertical meridian. The monkeys were required to intercept the moving target as it crossed the vertical meridian, making an upward movement (12 cm) from an initial hold position. An interception was considered successful when the moving target entered, within 130 ms of the target, a 1 cm radius positional window centered on the point of the target after it crossed the vertical meridian. The spike activity of 411 cells were recorded in the arm area of the motor cortex in one monkey during task performance. We found that the activity of various populations of cells was modulated during the interception task. In most cases the change in cell activity was similar to that observed during upward movements toward a stationary target, in another task, but in other cases changes in cell activity differed. For example, cell activity during the last 200 ms of the reaction time was frequency modulated in relation to the temporal characteristics of the ensuing movement: for example, activity in 8% of cells differed significantly (P<0.05, ANOVA) among trials with different target velocities, irrespective of the kind of target motion (accelerating, decelerating or constant speed), whereas in 6% of cells it differed according to the kind of motion above, irrespective of the speed itself, and in 11% of cells both speed and kind of target motion had a significant effect. These results indicate that the motor cortex is involved with processing of the temporal characteristics of the interception movement. (Supported by NSF grant PSMH41885)
MOTOR CORTEX AND 3D ISOMETRIC FORCE: STATIC RELATIONS. J. Boline*, J. Ashe, M. Taira and A.P. Georgopoulos. Sciences Center, Veterans Affairs Medical Center, and Dept. of Physiology, Univ. of Minn. Med. School, Minneapolis, MN

The relations between the steady-state activity of cells in monkey motor cortex and the direction and magnitude of isometric force were determined using a 3D isometric manipulandum (Massey et al., J. Neurosci. Methods 26:123-127, 1988) and a visually instructed task. Five repetitions of 24 constant force levels were employed in a randomized counterbalancing design where each block consisted of 3 force magnitudes (100, 150 and 200 total gm-force) exerted in each of 8 XYZ directions (every 45 deg); force exerted in the Z dimension was monitored but not controlled. Data from electromyographic (EMG) activity of 7 (averaged) single units for each of 3 monkeys were analyzed using a repeated measures analysis of variance and a multiple linear regression of EMG and cell activity versus the X, Y, Z components of force. The magnitude of force had a significant effect (P<0.05) in 75% of muscles and 31% of cells studied, whereas the direction of force had a significant effect in all muscles and 70% of cells; significant magnitude x direction interactions were observed in 62.5% and 23% of muscles and cells, respectively. The multiple regression was significant in all muscles and 76% of cells. However, the regression was different in each muscle and/or cell. This difference in regression coefficients may reflect differences in the functional role of the neurons that were sampled. The results suggest that the neuronal discharge in motor cortex is related to the overall magnitude of the force exerted, but not to the direction of force exerted. This knowledge can perhaps be used to improve control of neuromuscular activities in patients with motor disabilities.

The hypothesis was examined that dynamic processes, effecting change in force, and static processes, involved in the maintenance of a constant force, are reflected separately through the patterns of neuronal activity of cells in monkey motor cortex. For that purpose cell activity was recorded while monkeys performed 3 visually instructed tasks using a 3D isometric manipulandum (Massey et al., J. Neurosci. Methods 26:123-127, 1988). The tasks involved the production of (a) purely dynamic isometric force (Task 1, n=430 cells); (b) step-and-pace forces that were maintained for 0.5 s (Task 2, three step forces; n=91); and (c) dynamic force pulses in the presence of a constant force bias (Task 3, n=331). Results from tasks 1 and 3 showed that cells associated with the force pulses were similar across different force biases. Results from tasks 1 and 2 showed that the time course of cell activity in task 2 resembled initially (during the reaction time) the pattern observed in the dynamic pulse task, and then changed to the pattern appropriate for the ensuing static force step. The replacement of the dynamic by the static pattern occurred approximately 150 ms before the attainment of the static force level. Moreover, the dynamic and static patterns were frequently directionally incongruent. (Supported by NIH and VA).

Spikes triggered averaging of rectified EMG activity has proven to be an effective means of identifying motor cortex cells with a functional linkage to motoneurons and motoneuron pool. Brain Res., 247:311 (1982). Previous studies of forearm muscles have shown that many CM cells not only facilitate multiple agonist muscles of the forearm but also suppress the antagonist muscles (Kawamura, J. Neurophysiol. 53: 85-96, 1985). This reciprocal output pattern constitutes a functionally meaningful synergy raising the possibility that more complex functional synergies may also be represented in the synergistic outputs of single CM cells. The purpose of this study was to investigate 1) the possibility that during an arm reaching movement, individual CM cells may facilitate muscles at different joints; and 2) the extent to which the facilitated muscles constitute a functional synergy whose action would produce a specific phase of the movement. The spike discharges of single cells from CM were recorded in the precentral gyrus of the monkey and one averaged sample of rectified EMG activity from 22 muscles of the shoulder, elbow, wrist and hand while the monkey performed an automated reaching task to retrieve a pellet from a fixed location. The monkeys were trained to reach in the direction of the stimulus light through the ipsilateral (flexion) or contralateral (extension) (extension) as compared to away from it (extension). Premovement activity onset for both CM and NS cells preceded movement onset by about 150 ms while the earliest EMG activity recorded from both CM and NS muscles was about 90 ms. The CM cell related neurons were significantly more responsive to vibration during After trials. These observations suggest that monkeys are more attentive and that some CM and NS neurons are more responsive to peripheral and central inputs during unpredictable movements. These inputs may be related to the 90 ms latency period between the occurrence of the Premovement activity and the sensory input. (Supported by NS 17413).
SYNCHRONIZATION OF PRIMATE SENSORIMOTOR CORTEX NEURONS DURING 20-40 HZ FIELD POTENTIAL OSCILLATIONS. V.N. Sushchov* and E.E. Foster. Regional Primate Research Center, Univ. of Washington, Seattle, WA 98195.

In monkeys performing exploratory and manipulatory free limb movements, local field potentials (LFPs) in sensorimotor cortices contained 20-40 Hz oscillations in the 20-40 Hz range. Previous findings that LFP oscillations occurred synchronously in different sites have been extended to the associated changes in single/multi unit activity. Cycle-triggered histograms (CCHs) of unit activity and cycles of LFP oscillations revealed modulation in two bands (176/568) of recorded units. Peak spike activity occurred 7.5 ms prior to the peak LFP negativity, or -5 ± 1.3 ms. Average power and coherence of oscillation amplitude (amplitude of oscillatory component of CTH as percent of baseline) was 45 ± 15%. Cross-correlation histograms (CCHs) between pairs of ipsilaterally recorded units were compared. When all spikes were used, moderate oscillation coherence was reflected by significant features. However, CCHs compiled selectively from up to 12 pairs of spikes were more frequent, with the peak (-5 ± 1.3 ms) corresponding to the peak power of LFP oscillations. These results are consistent with the possibility that oscillations are transiently synchronized by neural activity, not being limited to stable projections of the same unit. Thus, oscillatory synchronization does not appear to be a general property of neuronal interactions. During oscillatory episodes of the first rank firing rate, some units tend to be restricted to values corresponding to the average rate plus or minus the standard deviation.

The objectives were to determine whether primary motor cortical areas, evoking contractions in synergistic antagonistic muscles, received inputs from common or separate sources. Intra-cortical microstimulation (ICMS) was used at low-threshold areas capable of evoking limb movements. From this map, sites capable of evoking ankle flexion, ankle extension, and lateral flexion were selected for injection of fluorescent tracers. The procedures were (1) injection of fluorescent tracers into the corticospinal motor output sites, (2) label retrograde transport for 3-5 days, (3) section the brain, and (4) map distributions of differently-labeled neurons. Computer controlled injections yielded 0.3-1.1 mm columns of densely filled tracer which was inactivated in the extracellular cortical sites. There was no overlap in the distribution of neurons labeled with different tracers when using small injections but this increased when using larger injections. Conversely, ventral thalamic areas did not show increased overlap with larger injections despite the presence of overlap of intralaminar thalamic areas with all injections. This study suggests that some cortical and thalamic areas provide a single command to the motor cortex for the control of coordinated muscle actions while other cortical and thalamic areas separately control individual muscle actions. [Supported by Canadian MRC]

The mechanisms by which neurones perform spatial and temporal integration are dependent on the numbers, types, and distribution of synapses they form with their afferents. The data presented, indeed indicate that these synaptic mechanisms, the distribution of synapses with identified classes of cortical projection neurones was examined using ultrastructural methods. Pyramidal cells in the cat motor cortex were the somatic overlap or to the motor cortex labeled by the retrograde transport of HRP. The somata of corticocortical and cortico-spinal neurones were identified using serial-section electron microscopy. The profiles of these somata and the synapses formed with each of these profiles were reconstructed from each thin section with the aid of a computer-aided morphometric system. The profiles of the synapses on the somata of pyramidal neurones were of the symmetrical, presumably inhibitory type. These synapses were not distributed at random in the neocortex, but were clustered at several zones, particularly in the vicinity of the axon hillock. The nonuniformity in the distribution of axosomatic synapses indicates that analyses of synaptic inputs of somatocortical neurones must be made in terms of the complete somatic surface area, and that studies in which small portions of these structures are randomly sampled may be misleading. The number, density and spatial distribution of synaptic inputs are identical on the soma of neurones of different corticocortical cells. In contrast, different corticospinal cells formed varying densities of inhibitory synapses. These findings indicate that different classes of cortical neurones receive unique patterns of inhibitory inputs and support the hypothesis that the synaptic organization of the cerebral cortex is highly specific. [Supported by NIH grants #NS31078 and #NS31078].

INDEPENDENT ANATOMICAL CIRCUITS FOR REACHING AND GRASPING LINKING INFERIOR PARietAL SULCUS AND INFERIOR AREA 6 IN MACAQUE MONKEY. M. Motteri, G. Luppino, A. Murru, and H. Sakata.* [SPON: European Brain and Behavior Society] Istituto di Fisiologia Umana Università di Parma Via Gramsci 14-14510 Parma (Italy); J Dept. of Physiology, Nihon University, Gyoda, Saitama, Tokyo 175, Japan.

Recent physiological evidence showed that in the intraparietal sulcus (IPS) and inferior area 6 there are areas that have functionally similar functions but are functionally separated. Intraparietal cortex (IPC), which lies in the lateral bank of IPS, and F5, located in the rostral part of inferior area 6, are both involved in planning and carrying out both grasping and manipulation movements. Ventral intraparietal area (VIP), which lies in the fundus of IPS and F4, located in the caudal part of inferior area 6, are both involved in coding the proprioceptive signals for possible reaching movements.

In order to see if these functionally similar parietal and frontal areas have direct and selective anatomical connections, we monitored the connections of neurons in different corticocortical areas (VA, VP, and IP) in F5, F3, and LIP, projecting to and from the macaque monkeys. After injections of F4 the labeling was found only in the ipsilateral thalamus and ventral premotor cortex. The injections in F5 VIP was spared and the labeling was almost completely confined to AIP. The selective unanatomical linkage between AIP and F5 was fully confirmed by tracers injections in AIP. The results also showed that different regions were confined to the sector of F5 located in the arcuate sulcus. A caudal injection in the lateral bank of IPS (possibly LIP) produced labeling in prefrontal cortex. Inferior area 6 was devoid of any labeling. The present data indicate that visuomotor integration for reaching and grasping are processed along independent pathways. [Supported by a Grant from Human Frontier Science Program].

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
1) AN ELECTROPHYSIOLOGICAL STUDY OF THE CORTICORRETICULAR PATHWAY IN THE INTACT, AWAKE CAT. K. Bouchar and T. Drew. Dept of Physiology, University of Montreal, Canada.

As part of a study to determine the functional organization of the corticoreticular pathway in the cat, we examined the projection patterns of 459 neurones within layer V of the pericruciate cortex (areas 4 and 6) of each cat, each of which was implanted, bilaterally, with 6 arrays (each of 6 wires) of microelectrodes. (The study was supported in part by NIH Grant NS 25169 (P5-P11; L0.5-1.1.5). In addition, microwire electrodes were inserted into the pyramidal tract (PT) at a caudal level (P14.5), close to the decussation. We used a similar protocol in the monkey (A. Cabana et al., 1985).) The corticofugal neurones projected only as far as the MRF (corticoreticular neurones: CRNs); 17/125 (13%) neurones were activated both from the MRF and from the PT (CRN/PTNs); and 24/129 (19%) were identified only from the PT (PTNs). In area 4, in contrast, only 62/330 (19%) cells CRNs; 88/330 (27%) were CRNs/PTNs; and 154/330 (47%) were PTNs. Furthermore, 20/35 (58%) of the neurones in Area 6 and 45/159 (30%) of the neurones in Area 4 that projected to the MRF were activated from more than one injection site. (The study was supported in part by NIH Grant NS 25169.) In both areas 4 and 6, 7/125 (6%) of the neurones were classified as short, whereas 4/129 (3%) of the neurones were classified as long. The results suggest that the major projection to the MRF from Area 6 is from slowly conducting CRNs, whereas the projection from Area 4 is both from slowly conducting CRNs and more rapidly conducting CRN/PTNs. (Supported by the FCAR and the MRC.)

To quantitatively examine the zones of termination of the corticofugal pathway to the lower brainstem, Phasengus vulgaris (PHA) was injected into either the forelimb regions of motor cortex (Area 4), or into the more dorsal (N=2) or more ventral (N=1) regions of the premotor cortex (Area 6). A light microscope, equipped with photomultiplier counters and a computer system, was used to measure the X and Y coordinates of the PHA-labelled cells found in every fourth transverse section of the ponto-medullary region (section thickness=50um). In all cases, the greatest density of terminals was found in the ipsilateral pontine gray (PG). Jjections into dorsal Area 6 resulted in a widespread distribution of terminals, while the labelling from the dorsal Area 6 injections was more restricted to the medio-ventral regions. Injections in Area 4 resulted in a similar distribution of labelled terminals, but with a weaker density of labelling than those produced by Area 6 injections. (Supported by the Canadian MRC and the FRSQ.)
ATTENTION TO A VISUAL STIMULUS ENHANCES NEURONAL RESPONSES IN MONKEY PREFRONTAL CORTEX. Y. Kodaka, A. Mikami and K. Kubota. Dept. of Behavioral and Brain Sci., Primate Res. Inst., Kyoto Univ., Inuyama 444 Japan
To investigate how selective attention modulates neuronal activities in the prefrontal cortex (PFC), we recorded neuronal responses to the identical visual target in non-attentive and attentive conditions in the monkey PFC. In a visual fixation task (VFT), while the monkey gazed at a fixation point, a visual stimulus, to which no behavioral meaning was assigned, was presented extraretinally in its visual receptive field. In a visual peripheral cueing task (VCT), the monkey released the lever within 800ms after an identical stimulus was dimmed. Activities of 48 neurons in the prefrontal and periprefrontal areas were compared under these two conditions. In 38% of the neurons, the magnitudes of the responses in the VFT were significantly larger than those in the VFT. For each neuron, the visual response tended to be greater toward the center of the RF. In the remaining 62% of the neurons, the magnitudes of the visual responses in the VFT and VCT were similar. Neither eye movement nor lever release occurred when the visual stimulus appeared. Therefore, these enhancements were not causally related to either eye movement or lever release. These results suggest that enhanced responses due to focused attention to the visual stimulus in the PFC may facilitate the selection of a behaviorally significant stimulus within the RF.

2-DEOXY GLUCOSE (2DG) UPTAKE IN THE MEDIAL WALL MOTORS AREAS OF BEHAVING MONKEYS. N. Prasad and P.L. Deer3. VA Medical Center and Dept. of Neurosurgery and Physiology, SUNY Health Science Center, Syracuse, NY 13210.

The medial wall of the hemisphere contains multiple motor areas. They are the supplementary motor area (SMA), the Pre-SMA and three cingulate motor areas (CMAd, CMAc and CMAp) (Dum and Strick, 1991). We have begun to investigate the relative involvement of these motor areas in different aspects of motor function using the 2DG method. Two monkeys were trained to perform different sequences of reaching movements for a juice reward (REM task). Two other monkeys were trained on a Control task to sit in the primate chair and lick juice rewards delivered at times intervals comparable to that of the reaching monkeys. Two areas of the medial wall showed significant activation in the REM animals and not in the Controls. For the REM task, 2DG labeling was particularly prominent in the CMAp and the Pre-SMA. Focal activation was found in the region of the CMAp that projects to cervical segments of the spinal cord and arm areas of the primary motor cortex. Initial activation was present on the upper median (primary) gyrus, particularly in the territory of the Pre-SMA. Labeling in other motor areas on the medial wall was either absent or less significant. These observations suggest that, of all the motor areas on the medial wall, the CMAp and the Pre-SMA are preferentially involved in the internal guidance of sequential voluntary arm movements.

Supported by the VA Medical Research Service and USPHS 24238 (PLS), and Medical Research Council of Canada (NP).

CINGULATE CORTEX SUBDIVISIONS IN THE HUMAN AND MONKEY REVEALED BY STAINING FOR PARVALBUMIN. A. Solotkin1,2, R.J. Morecraft1 and G.W. Van Hoesen3. Departments of Anatomy and Neurology, University of Iowa, Iowa City, IA 52242.1 Department of Anatomy and Structural Biology, University of South Dakota, Vermillion, SD 57069.

The cingulate has been implicated in a wide range of behaviors including motivation, attention, mechanisms relating to pain and motor control. Not unexpectedly, its structure is complex differing both in anterior-posterior and medial-lateral dimensions. We have studied the topography of cingulate subdivisions in humans (N=15) and in the non-human primates (N=9) using immunohistochemical techniques for the calcium-binding protein parvalbumin (SM-32, Stemmer). Krieg and Sarkissian's cytoarchitectural parcellation of 24a, 2b and 23a, b was used as a guide. Our observations indicated that parvalbumin immunostaining is an excellent method to delimit different subfields in the cingulate cortex in both humans and monkey. Since this calcium-binding protein coexists with a subpopulation of GABAergic neurons, its discrete distribution suggests probable functional differences between cingulate subfields. Supported by NS 14944 and PO NS 16832.

THE HUMAN FRONTAL MESIAL CORTEX: A COMPARISON BETWEEN CYTOARCHITECTONIC, RECEPTOR AUTORADIOGRAPHIC, AND FUNCTIONAL ACTIVATION. K. Zilles1, G. Schlag2, G. Geyer1, T. Schormann1, R. Seitz2, H. Steinmetz2 and H-J. Freund2. Brain Research Institute1 and Department of Neurology2, University of Düsseldorf, 40001 Düsseldorf, Germany.

Four supplementary motor areas (SMA proper, pre-SMA, caudal and rostral cingulate motor areas) are described in the literature. These areas were demonstrated by PET studies in the human frontal subcortical cortex. The aim of our study is the identification of cytoarchitectonic areas representing these functionally defined regions and the analysis of the regional distribution of tracer receptors by quantitative in vitro autoradiography in these areas. Several architectonically and receptor autoradiographically definable areas are found in the mesial frontal lobe and in the lower bank of the cingulate sulcus. By comparison with PET studies, the caudal-mesial part of Area 6 (mesial Area 6ax) is probably identical with SMA proper, the rostral-mesial part of Area 6 (mesial Area 6d) with pre-SMA, and the caudal or rostral parts of the cingulate areas showing large pyramidal cells with the caudal or rostral cingulate motor areas, respectively. Our study shows for the first time that within the human mesial frontal cortex multiple, probably supplementary motor areas are definable by architectonic characteristics and by receptor autoradiography. New cytoarchitectonic landmarks are defined, which allow the approximate location of these areas in coregistered PET/MRI images. Supported by the DFG (GBR 194, HP6 and HC3).

NEURONAL ACTIVITY IN THE SUPPLEMENTARY AND PRE-SUPPLEMENTARY MOTOR AREA IN RELATION TO SEQUENTIAL PERFORMANCE OF MULTIPLE MOVEMENTS. K. Shima and J. Tanji. Dept. of Physiology, Tohoku University School of Medicine, Sendai, 980 Japan.

The purpose of the present study was to examine how neuronal activity in the supplementary motor area (SMA) and presupplementary motor area (pre-SMA) is involved in performance of multiple movements. We trained monkeys (Macaca fascicularis) to perform three different movements (push, pull or turn a manipulandum) sequentially, separated by brief waiting periods. Each movement was triggered by a tone signal. After completion of individual movements, the manipulandum was returned to the neutral position within which the animal had to hold it and wait for next movement. In one condition, a visual signal (LED of three different colors) indicated what movement to be performed. In the other condition, colors of the three movements were randomly presented. Our results indicated that the sequential performance of the three movements was remembered. By contrast, a majority of pre-SMA neurons exhibited greater activity when the movement was instructed by visual signals. In both areas, there was an abundance of neuronal activity that was related to the temporal order of the three different movements, rather than related to next movement to be performed. Such neuronal activity, useful for programming the sequence of multiple movements, was not observed in the primary motor cortex. (Supported by Japanese Ministry of Education, Culture & Science 06NP0101.)

Cingulate Projections to the Basal Ganglia, Red Nucleus and Pontine Nuclei From the Cingulate Motor Cortex (M3 or Area 24a) in the Macaque Monkey. R.J. Morecraft1,2 and G.W. Van Hoesen3.1 Department of Anatomy and Structural Biology, 2Univ. of South Dakota, Vermillion, SD 57069 and Dept. of Anatomy2 and Neurology3, Univ. of Iowa, Iowa City, IA 52242.

The (ipsilateral corticostriate, corticorpulbro and corticopontine projections were studied in thirteen monkeys that received injections of tritiated amino acids into the cingulate (M3 or area 24a), supplementary motor (M1) and primary (M1) motor cortices. In M3 cases, light terminal labeling occurred over the head and anterior third of the caudate nucleus. Heavy patches were observed over the anterior pole and ventral portion of the putamen, then posteriorly labeling shifted in the dorsal portion of the red nucleus. In the red nucleus, labeling was found primarily over the ventromedial part of the parvicellular subdivision. At superior and mid-levels of the pons, labeling occurred over the ventromedial pontine gray matter. At inferior levels, patches of label formed an incomplete circle around the corticospinal tracts traversing the pons.

These data were compared to the distribution of projections from M1 and M2. Some topographic differences were found, but overall, the distribution overlap occurred as well. For example, the projection from M1 favored the dorsal motor part of the putamen, M3 the ventral motor part, and M2 an intermediate position. In the red nucleus, the densest distribution of labeled fibers terminated laterally from M3, medially from M3 and in between from M2. All three motor cortices projected heavily to the peripheral border of the medial and ventral portion of the basis pontis.

These observations show that M3 targets subcortical motor centers located at multiple levels of the neural axis. Judging from detailed comparisons, the highly interconnected cortical motor representations seem to be characterized as well, by overlap in their corticofugal projection zones. The terminal distribution of these pathways may provide opportunities of unity as well as diversity in terms of their influence on subcortical motor centers. (Support: NS 14944, USD Fac. Dev. Award)

It has been shown that electrical stimulation of the motor cortex in rats induces the expression of immunodetectable Fos-like protein (Fos-LI) in neostriatal neurons (Fu and R.M. Beckstead, Neuroscience 40(4):329-334). We have examined the effect of electrical stimulation of the motor cortex in awake and Nembutal-anesthetized rats (250 micro curies at 4 Hz of high frequency current pulses through parallel bipolar electrodes for 1 hr) on the induction of Jun B-like immunoreactivity (Jun B-LI).

We show that stimulation expressed only Jun-B-LI in the rat striatum in the same topographical location as Fos-LI-positive nuclei. However, with double-labeling techniques, we found that Jun B-LI and Jun B-LI were only partially colocalized, i.e., Jun B-LI was expressed only Fos-LI, some of Jun B-LI and both. This result suggests that striatal neurons respond to cortical stimulation with heterogeneous responses. Jun B-LI was the most visible signal detected in projection neurons expressing enkephalin or DARPP-32. We found Jun B-LI-positive nuclei in a low to moderate percentage of periventricular - ChAT and NADPH-diaphorase-positive interneurons. The presence of Jun B-LI in parvalbumin-positive, presumably GABAergic, immunoreactive neurons with the result obtained by chemical stimulation of the motor cortex (Berretta et al SNA 94). After which Jun B-LI was never seen in parvalbumin-positive neurons. Such specific differences in the patterns of neostriatal gene induction by electrical and chemical activation of the cortex may be the result of indirect antinomic effects of electrical stimulation. They might also reflect the differences in cortical activity produced by direct synchronous activation of cortical neurons by electrical stimulation, in contrast to release of endogenous cortical activity by removal of inhibition. Supported by NIH Javits Award NS25529.

We thank Dan R. Bravo, H. Hemmings, and P. Greengard for assistance.

Local pharmacological blockade of GABAergic transmission in the motor cortex awake rats was induced via chronic head-mounted wells (Berretta et al 94). This treatment evoked discrete body movements and, at 2 and 4 hours, induced the expression of IEGs in localized brain regions. We immunocytochemically characterized striatal neurons expressing Jun B, Jun B, and NGFI-A-like immunoreactivity (+LI) in the ipsilateral striatum. There was also a weak contralateral IEG induction. Large numbers of Fos- and Jun B-positive nuclei were in striatal neurons expressing enkephalin or DARPP-32, protein characteristic of striatal projection neurons. These results parallel similar findings in the same lesion model. Jun B-positive neurons were in a low to moderate percentage of periventricular - ChAT and NADPH-diaphorase-positive interneurons. The presence of Jun B-LI in parvalbumin-positive, presumably GABAergic, immunoreactive neurons with the result obtained by chemical stimulation of the motor cortex (Berretta et al SNA 94). After which Jun B-LI was never seen in parvalbumin-positive neurons. Such specific differences in the patterns of neostriatal gene induction by electrical and chemical activation of the cortex may be the result of indirect antinomic effects of electrical stimulation. They might also reflect the differences in cortical activity produced by direct synchronous activation of cortical neurons by electrical stimulation, in contrast to release of endogenous cortical activity by removal of inhibition. Supported by NIH Javits Award NS25529.

406.3 CORTICAL FOS EXPRESSION FOLLOWING DOPOAMINERGIC STIMULATION: DIFFERENTIAL DYE BIBLING AND ITS BREAKDOWN. G.J. Haacke†, D.N. Ruskie†, and J.P. Marshall†, Departments of Physical Medicine & Rehabilitation and Psychology, University of California, Irvine, CA 92697-4550.

While many recent studies have examined immediate-early gene expression in the basal ganglia following dopaminergic stimulation, few have focused on the cortical cortex, the prime target (via the thalamus) of basal ganglia output. We have examined the areal and laminar distribution of Fos immunoreactivity in the cerebral cortex of rats following systemic administration of dopaminergic agonists with particular attention to regions involved in decision-making regions and motor cortex. Combined, but not separate, D1 (SKF 38393 20 mg/kg) and D2 (quinpirole 3 mg/kg) agonist-stimulation induced pronounced Fos expression in frontal and parietal, but not occipital cortex in normal rats. Similarly, following amphetamine, cortical Fos could be blocked by either a D1 (SCH 23390, 0.5 mg/kg) or a D2 (clozapine, 0.5 mg/kg) antagonist. By contrast, following a regimen of reserpine (1 mg/kg/day for 5 days) that is known to cause a breakdown in D1/D2 synergism by behavioral and basal ganglia Fox measures, independent stimulation of D1 or D2 receptors resulted in cortical Fox expression. Irrespective of treatment condition, Fox expression occurred in a distinct laminar pattern that appeared to vary somewhat with cortical field. Dopaminergic modulation of cerebrocortical Fox may occur at the level of the striatum as part of a cortico-striato-pallido/igro-thalamo-cortical circuit; future studies will test this hypothesis. These findings show that the principles of D1/D2 synergism and its breakdowns apply to the stimulation of cerebrocortical Fox by dopaminergic agents. Furthermore, this Fox expression is correlated with motor behavior.

406.4 TRUNCATED FOsB IS RESPONSIBLE FOR THE LONG LASTING INCREASE IN STRIATAL FOS-LIKE IMMUNOREACTIVITY PRODUCED BY DOPOAMINERGIC DENERVATION. G.R. Redmond†, J.-P. Poulie*, B.T. Hop*, E.J. Nigel†, Y. Nakabolu, M.J. Iadarola*, N. Widel, and M. St.-Jean†, Dept. of Pharmacology, University of Ottawa, Ottawa, Ontario, Canada, K1H 8M5. Dept. of Psychiatry†, Yale University, 34 Park St., New Haven, CT, USA. Dept. of Biochemistry§, Medical Institute of Bioregulation, Kyushu University 69, Fukuoka 812, Japan. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD, USA.

Using an antibody raised against the DNA binding region of Fox, we have reported that destruction of the nigrostriatal pathway by injection of 6-hydroxydopamine (6-OHDA) into the medial forebrain bundle produces a long-lasting (>3 months) increase in striatal Fos-like immunoreactivity. In order to determine the nature of Fos immunoreactive protein(s) responsible for this increase, Western blots were performed on striatal extracts. Approximately six weeks after the 6-OHDA lesion, expression of a 38 kD Fos immunoreactive protein was dramatically enhanced. Since the molecular weight of the truncated form of FoxB (FoxB) is 35 kD, we examined FoxB and FoxBl expression using two antibody that recognize both FoxB and FoxBl while the other recognizes just FoxB. Western blotting and immune-histochemistry which demonstrated that the increase occurred exclusively in medium-sized neurons of the denervated striatum. These results suggest that FoxB may participate in those intracellular events which maintain altered neuronal gene expression in the striatum after dopaminergic denervation. (Supported by grant MT-11539 from the MRC of Canada).

A simple method now exists to electronically publish a Neuroscience Poster Presentation on the Internet. A user of a typical desktop computer, such as PC or Mac, who has access to the World Wide Web, can obtain this software from a number of sites at no cost. The author can then design his or her poster in Adobe Acrobat for Adobe Acrobat Reader or Microsoft PowerPoint for PowerPoint Reader and then publish this document on the Internet. A single HTML file is obtained by merging the PDF file with an HTML template. The resulting document is completely converted to HTML page, may include text, images, and hyperlinks, and can be published on the World Wide Web in this form. The resulting HTML file may be published at a number of sites or be downloaded to a local system for viewing and printing. This allows for a new level of distribution of research data, and the authors can now publish their work in a format that is widely accessible. The authors believe that this method has the potential to revolutionize the way in which scientific research is communicated, and that it may become an important tool for the dissemination of scientific knowledge.

406.6 EFFECTS OF METHYLXANXV-METHANOL ACETATE ON THE FORMATION OF STRIATAL COMPARTMENTS. W. Wudhaw*, M. Cinimino*, F. Caterella, B.A.Flumerfelt, and C.C. Neug. Dept. of Anatomy, University of Western Ontario, London, Canada, N6A 5C1 and Institute of Pharmacological Sciences, School of Pharmacy, University of Milan, Via Balzaretti 9, Milaan, Italy, 20123.

The striatum can be segregated into two compartments, the patch and matrix, based on afferent and efferent projections and certain neurochemicals (eg. calbindin, somatostatin). Immunocytochemical studies indicate the neurons which comprise these two populations arise at two different time points from separate populations of developing neurons. Neurons destined to be localized within the patch are born between E10 and 14 while matrix neurons are born between E16 and E18. In order to attempt to knockout the patch or matrix compartments, methylxanxv-methanol acetate (MAMA) was injected intraperitoneally (25mg/kg) into E13 or E17 pregnant rats. MAMA is a potent toxin which kills dividing neuroblasts. It is effective for 24hrs. post-injection with effects peaking after 8hrs. Pups obtained from the pregnant mothers were allowed to grow to adult age. Western blotting was performed on a number of proteins in both the whole brain and the striatum. The results indicate that calbindin and somatostatin are decreased while the density of the glutamate receptor is increased. The results also suggest that MAMA injections at the appropriate developmental times can alter the phenotype. The ratio of compartment ratio. Research supported by NATO grant 900303, MRC and Huntington's Society of Canada.

We have used in situ nick transfer to identify increases in DNA strand breaks in individual neurons of the striatum after local injections of a radioactive agonist (NMDA, 2 mg/kg, IP) or a antagonist (kainic acid, 2 mg/kg, IP) into the striatum, 24 hrs later. We report that in situ nick transfer detects DNA strand breaks in neurons, and that the number of breaks is proportional to the intensity of neuronal injury, with the greatest damage occurring at the lesion center, where neuronal loss is greatest. Our results suggest that in situ nick transfer can be used to assess DNA damage in individual neurons, and that it may provide a sensitive and specific measure of neuronal injury.

The globus pallidus (GP), one of the main output nuclei of the striatum, receives an inhibitory GABAergic projection from the striatum and an excitatory glutamatergic input from the subthalamic nucleus. Lesions of the GP led to decreases in the expression of GAD 67 mRNA in the GP, but not in the GPi or SNr, suggesting that the decrease in GAD 67 mRNA levels in the GP is not due to an increase in excitatory input from the subthalamic nucleus.

We have shown that loss of immunoreactivity for the immunoassay, highly polialysinated form of the Neural Cell Adhesion Molecule (PSA-NCAM-IR) occurs at the end of the postnatal period in rat striatum (Szele et al., Neurosci., 1994). Ultrastructural studies show that, at postnatal day 7 (P7), PSA-NCAM-IR is associated with both axonal growth cones, and with the cytoplasmic membrane of immature striatal neurons. At postnatal day 18, PSA-NCAM-IR was still associated with intracellular striatal neurons, but labelling of the cytoplasmic membrane was much more diffuse than at P7. In addition, PSA-NCAM-IR immunoactivity was associated with both pre and post-synaptic elements of asymmetrical synapses on dendritic spines. The results confirm that during late postnatal development, PSA-NCAM-IR is still associated with striatal neurons, as well as with synaptic inputs, likely originating from the cerebral cortex and/or the thalamus. The second experiment examined the role of PSA-NCAM-IR in the striatum in the development of the nigrostriatal dopaminergic pathway by bilateral injections of 6-hydroxydopamine in the striatum at P2 resulted in a profound loss of tyrosine hydroxylase immunoreactivity in the striatum, but did not affect the time course of loss of PSA-NCAM-IR. In contrast, in weaver mice, which exhibit a profound loss of dopaminergic inputs to the dorsolateral striatum postnatally, the loss of PSA-NCAM-IR in the striatum was delayed by approximately 1 week compared to wild type mice. These results suggest that dopaminergic inputs do not play a critical role in the shift from immature to mature forms of NCAM in the striatum, and that other factors than the loss of nigrostriatal neurons play a role in the delayed maturation of PSA-NCAM in weaver mice. Supp. by NS29230.

The mRNA levels encoding for the two isoforms of glutamate decarboxylase (GAD65 and GAD67) were measured in different sectors of the caudate and putamen in the internal (GPe) and external (GPi) segments of the pallidum in control (n=5) and parkinsonian (n=7) monkeys (Saimiri sciureus) after administration of the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Cresyl violet sections of the brains were processed for in situ hybridization in situ histochemistry with 35S labelled cRNA probes and the radioautographic labeling was quantified on X-ray films or emission radiography. The mRNA levels of dopaminergic fibres were measured after 3H-mazindol binding and was shown to be widespread throughout the ventral and the caudate. The expression of GAD65 mRNA levels is increased in the ventral putamen. In MPTP-treated monkeys, both GAD65 and GAD67 mRNA levels were increased in both the dorsal and ventral putamens and the caudate. The increase in GAD65 mRNA levels was significant only in the ventral putamen. In MPTP-treated monkeys, both GAD65 and GAD67 mRNA levels were increased. The present results demonstrate that gene expression of both GAD isoforms is significantly altered throughout the basal ganglia. In the striatum, increased GAD65 and GAD67 expression appears prominent in somatodendritic territories such as defined by cortical afferents. The results also support the hypothesis of an increased activity of striatal and pallidal output GABAergic neurons in parkinsonism (Supported by FRQs, the Parkinson Foundation of Canada and NSERC-0155607).

The role of D1 and D2 dopamine receptor subtypes on the regulation of neuronal GAD isoforms was studied using the two isoforms of glutamate decarboxylase (GAD65 and GAD67) and pterephenyl 1H-pyrene (PPE) ion in striatum was investigated. The mRNA levels encoding for GAD65, GAD67 and PPE were determined by in situ hybridization histochemistry and quantified by computerized densitometry. Chronic treatment (10 days) with the D1/D2 dopamine receptor agonist apomorphine or the D1 agonist SKF 38393 significantly increased the mRNA levels of both GAD65 and GAD67 in the striatum. Chronic treatment (10 days) with the D2 dopamine receptor agonist quinpirole decreased both GAD65 and GAD67 mRNA levels in the striatum. Chronic blockade (4 days) of D1 and D2 dopamine receptors with haloperidol or D2 dopamine receptor antagonist SB 27706 and PPE did not change GAD65 and GAD67 mRNA levels. Chronic blockade (14 days) of D1 receptors with SCH 23390 induced a slight decrease in PPE mRNA levels. These results show that gene expression of each isoform of GAD is differentially regulated in the rat striatum. Gene expression of DOP-AP seems to be under the excitatory control of D1 dopamine receptors. These results also suggest that each GAD plays a distinct role in the regulation of GABA synthesis in striatum (Supported by FRQs, Parkinson Foundation of Canada and NSERC-0155607).

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
406.13 INTRASTRIAL INJECTIONS OF QUINOLINIC ACID SHOW MARKED CHOLINE ACETYLTANSFERASE AND NADPH-DIAPHORASE CELL LOSS. S.M. Walker, W.C. Perryman, and G.K. Riecker*. Department of Anatomy and Cell Biology, School of Medicine, University of North Dakota, Grand Forks, North Dakota.

The debate as to whether the striatal pathology observed in the Quinolinic Acid (QA) model of Huntington's Disease (HD), as it demonstrates a selective sparing of aspiny interneurons, is unresolved. QA is an endogenous, excitatory amino acid that is known to spare fibers of passage. It is the intent of this study to define cell types and the associated loss within the HD model. Alzet mini-osmotic pumps were utilized for a 14 day, 340 Mg/mL, Ph 7.8, QA 0.5 % per hour injection period. Choline Acetyltransferase (Chat) immunohistochemistry and NADPH-diaphorase histochemistry were used to determine cell spacing and cell loss of Chat and NADPH cell counts were determined in adjacent sections. The results indicate marked cell loss. There is an overall 27% decrease in diapomorphic-positive cells and a 36% decrease in Chat-positive cells. Thus, preliminary results suggest a significant loss of intrastriatal Chat and NADPH aspiny interneurons. Supported by BRSG.

406.14 LOCALIZATION OF "FLIP" AND "FLOP" SPICE VARIANTS OF AMPA-SELECTIVE GLUR2 AND GLUR3 EXCITATORY AMINO ACID RECEPTOR SUBUNITS ON STRIATAL PROJECTION NEURONS. S.L. Tallaksen-Greene* and R.L. Albin*. Department of Neurology, University of Michigan, Ann Arbor, MI 48109.

We have previously shown that the majority of striatal projection neurons are immunostained using an antibody recognizing an epitope conserved on Glur2/3, 1 and 4c subunits and common to both "Flip" and "Flip" splice variants. In order to determine the relative expression of Glur2 and 3 splice variants on striatogiral and striatonigral neurons we used in situ hybridization in combination with the retrograde transport of the fluorescent tracers Fluoro-Gold (FG). Unilateral injections of FG were carried out into the substantia nigra or globus pallidus of adult male rats. After 12 days, the animals were killed by decapitation. Twelve pm sections were processed for in situ hybridization using 35S-labeled oligonucleotide probes specific for Glur2 and Glur3 mRNA. These findings indicate that splice variants of AMPA receptor subtypes are differentially expressed by striatal projection neurons. Supported by NS19613 and the Huntington's Disease Society of America.

In Parkinson's disease (PD), the striatal dopaminergic denervation induces complex changes in the functional circuitry of the basal ganglia which result, ultimately, in an oversupply of the output nuclei, substantia nigra pars reticulata (SNr) andsubstantia nigra pars compacta (SNc). The high levels of NADPH-diaphorase activity, supporting the presence of NOS containing fibers in the basal ganglia. The aim of this study was to investigate mitochondrial enzyme activity, a reliable marker for synaptic activity, in different nuclei of the basal ganglia of rats following a selective stereotaxic lesion of the nigrostriatal pathway or the STN. For this purpose, a group of rats received a unilateral k-hydroxydopamine lesion of the substantia nigra pars compacta and medial forebrain bundle, whereas another group had the STN selectively ablated by means of an injection of 25 mmoles of N-methyl-D-aspartate. Sulfate dehydrogenase and cytochrome oxidase activities were assayed histochemically on brain sections previously mounted on polylysine-coated slides. A densitometric comparison between the enzymatic staining in the lesioned and the unlesioned side was then carried out.

The rats with the nigrostriatal deploration showed, ipsilaterally to the lesion, an increased enzymatic activity in the projection nuclei of the STN, SNr, entopeduncular nucleus, and globus pallidus (the rodent homologues of MOP and lateral globus pallidus, respectively). Conversely, the enzymatic activity in these areas was reduced, ipsilaterally, by the complete ablation of the STN. These data lend further support to the more recent view of the basal ganglia circuitry organization focusing, in particular, on the modulatory activity that the SNr neurons, excitatory (glutamatergic) in nature, play in the regulation of the basal ganglia output.

406.16 DECREASED NUMBER OF SOMATOSTATIN mRNA CONTAINING NEURONS IN THE SUBSTANTIA GANGLIAOF STEREOELECTRODE TREATED RATS. D. Høyer-K* F. Andersen, O A. Christensen, B. Westm, and B. Jensen. Ha. 1 Pharmaceutical Department, University of Odense. 2Department of Neurological Research Laboratory, University of Aarhus, Denmark. 3Department of Physiology, University of Bergen, Norway.

For the first time and by stereological cell counting, it has been possible to demonstrate a reduction in the number of somatostatin (SS) mRNA containing neurons in the dorsal striatum of rats with dyskinetic symptoms caused by long-term treatment with a dopamine receptor blocking drug. Adult rats were treated with haloperidol for 6 months and the behaviour video-taped. Five rats which developed severe dyskinesia symptoms and five rats, which did not, together with five control rats were anesthetized and perfused. One series of vibratome sections of striatum were used for the in situ hybridization with a SS-mRNA probe. A second series of sections were labeled oligonucleotide probe. The total number of neurons expressing SS mRNA in the dorsal striatum was estimated with the optical fractionator technique. The mean number of SS mRNA containing cells in the treated rats with dyskinetic symptoms was significantly less than for the rats with no symptoms and the control rats.

406.17 EXPRESSION OF METABOTROPIC GLUTAMATE RECEPTOR MIGLURS BY SPECIFIC RAT STRIATAL CELL POPULATIONS. C.M. Tsai*, D.G. Standaert, G.B. Landwehrmeyer, J.B. Penney, and A.B. Young. Department of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Glutamate has a central role in basal ganglia regulation of motor behavior, and is the main afferent neurotransmitter to the striatum. Glutamate acts via many different striatal receptors and thereby increase thalamic feedback to the striatum. Although amphetamine alone was without effect, the combination of amphetamine plus MK-801 produced a large increase in striatal ACh concentrations. These results suggest that the effects of dopaminergic agents on the striatal cholinergic interneurons are a composite of the direct striatal effect of such drugs and of their ultimate effect on the glutamatergic thalamosomal feedback loop.

406.18 INTERACTION OF DOPAMINERGIC AND GLUTAMATERGIC SYSTEMS IN THE REGULATION OF STRIATAL CHOLINERGIC ACTIVITY. Christopher J. Schmidt* and Volli L. Taylor, Marion Merrifell Doh Research Institute 2110 E. Galbraith Road, Cincinnati, OH 45215.

The balance between dopaminergic and glutamatergic activity within the cortico-striatohamal pathway (CST) is an important determinant of sensory input through the thalamus. Disruptions of this balance in favor of glutamate or dopamine are believed to produce the symptoms of Parkinson's disease or schizophrenia, respectively. The cholinergic interneurons of the striatum are regulated by long loop feedback loops involving dopaminergic and glutamatergic afferents from the midbrain and the thalamus, respectively. The strategic position of these neurons allows changes in tissue concentrations of acetylcholine (ACh) to be used to assess effects of dopaminergic and glutamatergic agents on striatal function and potentially the CST pathways. Consistent with a reduction in cholinergic striatal activity, high doses of the uncompetitive NMDA antagonist MK-801 produced a modest accumulation of striatal ACh while the D2 agonist quipride produced a robust increase in tissue concentrations of the transmitter. Pretreatment with quipride augmented the elevation of ACh produced by MK-801 in a synergistic fashion. The D2 antagonist, SCH 23390 alone produced only a small increase in ACh yet completely prevented any further elevation of ACh by MK-801. The D2 antagonist haloperidol produced the expected decrease in striatal ACh and also completely blocked the effect of MK-801. Thus inhibition of cholinergic striatal activity with the D2 agonist potentiated the effect of MK-801 whereas treatments which increase striatal/cholinergic activity prevent any further effect of MK-801. These observations suggest that glutameric feedback from the thalamus may be important in determining the magnitude of the MK-801 effect. To test this hypothesis, amphetamine was used to enhance thalamic activity and thereby increase thalamic feedback to the striatum. Although amphetamine alone was without effect, the combination of amphetamine plus MK-801 produced a large increase in striatal ACh concentrations. These results suggest that the effects of dopaminergic agents on the striatal cholinergic interneurons are a composite of the direct striatal effect of such drugs and of their ultimate effect on the glutamatergic thalamosomal feedback loop.

406.19 EVIDENCE FOR NOSPECIFIC STIMULATION OF THE STRIATUM BY STIMULUS-LOCKED MICROSTIMULATION. R. Kergues. Department of Neurology, Massachusetts General Hospital, Boston, MA 02114.

We used a double label in situ hybridization technique to determine if substrates of proneural differentiation could be used to identify neurons with this technique. In situ hybridization results suggest that the use of a double label in situ hybridization technique to determine if substrates of proneural differentiation could be used to identify neurons with this technique.

The expression of m1 and m4 muscarinic receptor mRNAs in the rat dorsal striatum was examined using in situ hybridization histochemistry. The results indicate that m1 and m4 muscarinic receptor mRNAs are expressed in the striatum of the adult rat.

Low vs. High Dose and Acute vs. Subchronic Haloperidol Treatment Induces Different Patterns of Immediate-Early Gene Expression in the Striatum, B. Eibl, E. Pellecchia, N. Hu, and A.M. Gazdzik. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

The extrapallidal side effects of haloperidol therapy are thought to be related, in part, to its modulation of striatal activity by antagonism of D2-like dopaminergic receptors. Consistent with such striatal effects, neural activity mapping with immediate-early gene expression immunohistochemistry has shown that typical neuroleptics, more than eticlopride, induce IEGs in the mesencephalon. We have examined the effects of repeated haloperidol exposure on regulation of members of the Fos family in the adult rat (Pax, Fos, Fra, Jun, Elk, and Dusp).

Blockade of NMDA and Muscarinic Receptors in the Nucleus Accumbens Causes Mice to Rotate in Opposite Directions, A. Svensson*, M.L. Carlsson, and A. Carlsson. Department of Pharmacology, University of Göteborg, 5-413 90 Göteborg, Sweden.

The effects on rotational behaviour of glutamate blockade and acetylcholine blockade in the nucleus accumbens of male NMRI mice with different doses in the dopaminergic system.

We have previously shown that a unilateral injection into the nucleus accumbens of an NMDA receptor antagonist (AP-5) causes the animals to rotate. The rotation is predominantly ipsilateral in animals with intact dopaminergic systems. In the present study, dopamine-pretreated mice were treated with AP-5, or with control saline, and the direction of rotation assessed. AP-5 produced a marked decrease in rotational behaviour in the lesioned side, indicating a decrease in dopamine release.
REGULATION OF Na⁺/K⁺-ATPase ACTIVITY BY PROTEIN KINASE C PHOSPHORYLATION IN RAT NEOSTRIATUM. G.L. Spector,1 E. Fiance,1 A. Nishi,1,2 M. J. Caplan,2 A. Apetera3 and P. Greenough1 1Lab. of Mol.
and Cell. Neurobiology, Rockefeller Univ., New York, NY 10021; 2Dept. of Pediatrics, Kurume Univ. School of Medicine, Kurume, Japan; 3Dept. of
Cell. and Mol. Physiol., Yale Univ. School of Medicine, New Haven, CT 06520 and 3MRC Biochemical Research Unit, St. Thomas' Hospital.

The ion pump Na⁺/K⁺-ATPase is a ubiquitous integral membrane protein formed by a catalytic subunit and a β subunit, which transports Na⁺
from the inside to the outside of the cell, in exchange for K⁺. This enzyme is of fundamental importance in ionic balance and maintaining the electro-
chemical gradient across the plasma membrane underlying resting and action potentials in neurons. Previously, we showed that, in vitro, phosphorylation of the catalytic subunit (α subunit) of Na⁺/K⁺-ATPase is increased in two CAMP-dependent protein kinase or protein kinase C (PKC) significantly enhances its activity. Three different isoforms of Na⁺/K⁺-ATPase have been identified in neurons, their distribution differing in the various brain regions. We detected both α1 and α3 isoforms in primary cell cultures from rat striatum. We found that addition of the activator of protein kinase C, phorbol 12,13-dibutyrate (PDBu) (5 μM), to α3 pre-labelled slices from rat striatum stimulates by several-fold the phosphorylation of the α1 subunit and also increases the phosphoryl-
ation of the α3 subunit. In agreement with the data obtained in vitro, treatment of striatal neurons with PDBu inhibited Na⁺/K⁺-ATPase activity by 25%. These data provide evidence for regulation of Na⁺/K⁺-
ATPase activity, and hence neuronal excitability, by PDBu phosphory-
ation in the striatum. [Supported by USPHS grant MH 48099].

407.11 IMMUNOCYTOCHEMICAL PROPERTIES OF RAT CAUDATE-PUTAMEN NEURONS EXPRESSING DOPAMINE-
MODULATED K⁺ CHANNELS, Gabriela J. Green,3 Yong-Jian Lin, June-Chih Liu, Barbara I. Wassef, and Jonathan E.
Freedman4 1Dept. of Pharmacology, Pharmaceutical Sciences, Northwestern Univ.,
Boston, MA 02115.

We have previously used patch-clamp recording to describe an 85 pS K⁺ channel which is modulated by D₂-like dopamine recep-
tors on freshly dissociated rat corpus striatum neurons. We are
now using some cytochemical methods to identify the cells expressing this channel. Using phase-contrast and immunocyto-
chemical techniques we were able to detect an immunoreactive cell in the medial, intermediate and lateral regions of the caudate-putamen. This cell type appeared to be pyramidal-like in shape and was stained more darkly in the lateral than the medial region. This cell is characterized by being immunopositive for choline acetyltransferase and GABA, and negative for glutamic acid decarboxylase. It was located in the striatum and is consistent with the D₂-like dopamine receptor on this cell being stimulated by the administration of dopamine. The findings presented here are consistent with the idea that this cell type is a putative projection neuron which is part of the basal ganglia. [Supported by M01-RR02414, the National Institute of Neurological Disorders and Stroke, and The Uehara Memorial Foundation].

407.12 GAT-1 GABA TRANSPORTER mRNA IN RAT BRAIN: CELLULAR CO-
EXPRESSION WITH GAD67 mRNA AND PARVALBUMIN mRNA. S.J. AUGOOD,3 K. WESTMORE AND P.C. EMSON, MRCP Molecular
Neuroscience Group, Dept. of Neurobiology, BBSRC Babraham Institute, Cambridge CB2 4AT, U.K.

The re-uptake of GABA into pre-synaptic nerve terminals terminates GABA signalling. Several GABA transporters have been cloned including the GABA transporter GAT-1, which displays micromolar affinity for GABA when transfected in vitro (1.3). It has been suggested that cells which tonically release GABA may utilise more GAD67 than GAD65 enzyme. The expression of GAT-1 mRNA is upregulated in vivo by several factors (2). The expression of the calcium-binding protein parvalbumin (PV) is associated with fast-firing cells in the rat brain. This study aimed to determine if GAT-1 mRNA was expressed by GABA cells, and if PV cells represented a sub-
group of GAD67-GAT-1 cells. Cellular sites of (i) GAD67 and GAT-1 mRNA, and (ii) GAD67 and PV mRNA were visualised using a combination of alkaline phosphatase (AP), and 35S-labelled oligonucleotides. Strong hybridization signals for these three probes were detected in cells within most brain regions including the cerebral cortex, basal ganglia, hippocampus and cerebellum. Examination of silver grain deposits overlying AP-positive cells showed that most high-GAD67 cells were co-labelled for the GAT-1 mRNA, although the expression of GAT-1 mRNA was widespread: a divergence of the two signals was seen in the reticular thalamus and inferior colliculus. PV mRNA was detected in some high-GAD67 cells. Detailed analysis of the striatum will be presented. These data suggest strongly that GAT-1 is a pre-synaptic marker of most high-GAD67 GABA cells in vivo and that tonically active stratal GABA/PV cells may utilise GAT-1 for re-uptake. PARTIAL LESIONS OF THE NIGROSTRIAL DOPAMINE PATHWAY ALTER SUBSTANCE P BUT NOT ENKEPHALIN mRNA IN THE RAT STRIATUM. L.K. Nicklas, M. A. Kulkoski, K.J. Liff, and N.G. Gerfen, Department of Anatomy/Neurobiology and Pharmacology, Univ. of Tennessee, College of Medicine, Memphis, TN 38133, and the S. Jackson, Dept. of Neurology, C. R. Keefe, Section of Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

The expression of enkephalin and substance P mRNA is regulated by the nigrostriatal dopamine (DA) pathway. For example, near total depletion of striatal DA levels results in an increase in enkephalin and a decrease in substance P mRNA. However, it is unknown whether partial lesions of striatal DA content produce similar changes in the respective mRNAs. To test whether compensations in DA synthesis and release follow partial DA depletion prevent the lesion-induced alterations in enkephalin and substance P mRNA, varying concentrations of 6-OHDA were injected unilaterally into the substantia nigra. Seven days after injection of 6-OHDA (1-16 μg) in vehicle, in situ hybridization was employed to examine tyrosine hydroxylase mRNA in the substantia nigra and enkephalin and substance P mRNA in the striatum. The extent of the DA depletion was determined by measuring striatal DA tissue content. Subjects were divided into three groups based on the extent of striatal DA depletion: <50%; 50-90%; and >90%. The decrease in tyrosine hydroxylase mRNA closely paralleled the changes in striatal tissue DA content in all groups. Although no significant change in substance P mRNA was detected in rats with <50% DA depletion, a 24% and 68% decrease was observed in the 50-90% and >90% depleted groups, respectively. In contrast, a significant increase in enkephalin mRNA was not detected until a >90% depletion of striatal DA was produced. In summary, alterations in tyrosine hydroxylase mRNA in the substantia nigra are well correlated with decreases in striatal tissue DA levels. In addition, whereas partial lesions of the nigrostriatal DA pathway produce a decrease in substance P mRNA, a near total depletion of striatal DA levels is necessary to increase enkephalin mRNA. DIFFERENTIAL INVOLVEMENT OF NMDA RECEPTORS IN STRIATUM IN D1-DOPAMINE RECEPTOR-MEDIATED BEHAVIOR AND IMMEDIATE EARLY GENES (IEGS). K.A. Kenealey and C. R. Gerfen, Section of Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

Dopamine's effects in striatum often are thought to result from its ability to modulate the response of striatal neurons to other afferents. For example, activation of D1 dopamine receptors increases conductance through the functional subunit of glutamate receptors. D1-receptor activation also increases expression of the immediate early genes zif268 and c-fos in striatum. To further understand interactions between dopamine and glutamate through the regulation of striatal function, we examined the contribution of NMDA receptors to immediate early gene expression in the dopamine-depleted striatum by infusing NMDA receptor agents into the striatum of freely moving rats. Experiments determined if changes were blocked by in situ hybridization histochemistry. Infusion of NMDA (1 mmol) for 20 min blocked the contralateral rotation and decreased the expression of c-fos induced by the D1 agonist SKF 38393 (2 mg/kg, ip). CPP did not, however, affect SKF 38393-mediated induction of zif268 under the same conditions. The data indicate that D1-mediated changes in striatal output are dependent, at least in part, on ongoing excitatory input to the striatum, as evidenced by CPP blockade of D1-induced contralateral rotation and its partial reduction of D1-mediated c-fos induction. However, D1-mediated gene regulation in these neurons is not completely dependent on NMDA receptor activity, as evidenced by the incomplete blockade of c-fos induction and lack of effect on zif268 induction.

DYNOPHIN OPIOID INHIBITION OF D1 Dopamine Receptor-MEDIATED INDUCTION OF IMMEDIATE-EARLY GENES IN THE STRIATUM. H. Stein and C. R. Gerfen, Section of Neuroanatomy, NIMH, Bethesda, MD 20892.

Dynorphin is an opioid peptide contained in striatognal projection neurons. In such neurons dopamine agonists produce rapid induction of immediate-early genes (IEGs), such as c-fos and zif 268. Recent studies showed that IEG induction by the indirect dopamine receptor agonist cocaine in striatum is inversely related to striatal dynorphin expression, and (2) can be suppressed with systemic and infrastriatal administration of the dynorphin (kappa opioid receptor) agonist spiradoline. These results suggest that dynorphin is involved in the regulation of dopamine input to striatognal neurons, directly and/or indirectly, through kappa opioid receptors located in the striatum. In the present study, we examined whether dynorphin exerts direct influence on striatognal neurons by analyzing the effects of the dynorphin agonist spiradoline (1-10 mg/kg) on IEG induction by stimulation of D1 dopamine receptors which are expression in these neurons. Gene expression was assessed with in situ hybridization histochemistry. Spiradoline partially suppressed IEG induction by the selective D1 receptor agonist SKF 38393 in the dopamine-depleted striatum, while the lesser IEG response in the intact striatum was completely blocked. Striatal regions with higher levels of dynorphin/kappa receptor expression (ventral regions) showed greater inhibition of IEG induction than striatal regions with lower levels of these mRNAs (dorsal striatum). These results suggest that kappa opioid receptors on striatognal neurons participate in dynorphin-mediated inhibition of dopamine input to these neurons.

CONTROL OF POSTURE AND MOVEMENT VI

CHARACTERISTICS OF THE REPRESENTATION OF HAND IN SPACE FOR 3-D TACTILE LOCALIZATION. P. Dassonville* and A. P. Georgopoulos, Minneapolis VMMC Brain Science Center and Physiology Dept., University of Minnesota, Minneapolis, MN 55455.

To encode the location of a tactile stimulus in 3-D space, information of the stimulus' somatotopic location must be combined with a representation of limb positions. Previous studies investigated the time course of the implementations of hand space by instructing subjects to point, in complete darkness, to the 3-D location of a tactile probe presented to the fingertip during a previous arm movement (Dassonville et al, 1993). Our study evaluated the probe to be at the locations occupied by the hand approximately 100 ms after probe onset, indicating that the dynamic representation of hand in space does not compensate for counterclockwise, kinesthetic, and/or motor factors. However, this representation is seen in some subjects with a velocity different from that of the hand itself.

In the present study, two additional problems were investigated as follows: (1) Subjects performed a 3-D localization task under normal lighting. The pattern of errors observed in each subject was similar to that observed when tested in complete darkness. Thus, the internal representation of hand in space does not have an appreciable visual component. (2) Four subjects were instructed to simulate whether the probe was presented before, during, or after the movement. Probes presented <38 ms before movement onset were perceived as occurring during the movement, whereas those presented >145 ms before movement termination were perceived as occurring after the movement. Across subjects, these temporal shifts were highly correlated with the temporal shifts measured in the original localization task. Thus, the subjects' perception of movement onset and termination appears to rely on the same internal representation of hand that is used for 3-D tactile localization.

408.2
REACHING ERRORS RESULTING FROM THE DEGRADATION OF AN INTERNAL MODEL. C. A. Bunse*, J. Bolte, J. F. Schoetig, and R. E. Poppele, Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

We investigated, by means of simulations, possible mechanisms responsible for the systematic directional errors exhibited by deafferented patients during reaching movements (Ghez et al, 1990). Two aspects of altered feedback control were evaluated: the inability to sense initial conditions and the degradation of an internal model. The first simulation demonstrated that the pattern of directional errors exhibited by deafferented patients could not be explained by assuming inadequate information regarding initial arm configuration. In contrast, a second simulation, which introduced random errors in torque production, produced results that corresponded closely to the general pattern of errors exhibited by deafferented patients. We conclude that these directional errors do not result simply from a failure to compensate for inertial anisotropies, but are consistent with a degradation of the sensory feedback which leads to an increased variability in the mapping between joint torques and motion.
408.3 SHORT-LASTING CONTROL SIGNALS UNDERLIE THE FASTEST SINGLE-JOINT MOVEMENTS. A.G. Feldman, S.V. Adamovich, R. Forget*, M.F. Levin, Research Ctr., Rehabilitation Inst. of Montreal, Quebec, Canada H3S 2V4

We tested two versions of the hypothesis that movements are produced by two motor systems in the CNS: 1) that shifts end near the peak velocity of movement and 2) that shifts proceed until the end of movement. The first predicts that movement time may be significantly reduced by opposing loads without changes in the control pattern. Subjects flexed their elbows (and performed control trials) and produced two test trials; movements were opposed by loads generated by a torque motor. Subjects had no visual feedback and were instructed not to correct arm deflections when perturbations occurred. At the end of the movement, the load was removed leading to a secondary movement to the same final position as that in control trials (equifinality). The static arm positions before unloading were related to load torques. This finding and equifinality implies that subjects could reproduce the same control patterns regardless of perturbations. Test movements opposed by a high load ended near the peak velocity of control movements. Phasic and tonic EMG patterns were load-dependent. Results indicate that the control pattern is of short duration which suggests that rather than being pre-programmed, EMG signals represent long-lasting dynamic responses of the system to the short-duration control pattern, external forces and proprioceptive feedback.

Recent studies (Goodon et al 1993, Thach et al 1992) support Gordon Holmes' observations that cerebellar lesions affect simple movements at one joint and compound movements across several joints, the latter are affected disproportionately. From a mechanical standpoint, a multijointed movement consists of a summation of single-joint movements due to interaction torques (i.e., inertial, centripetal, and Coriolis) generated by one limb moving on the other. In this study we investigated if cerebellar subjects performing two-joint reaching movements under two conditions. For the "accurate" condition, seated subjects were asked to make a self-paced reach to touch a 1 cm target without any visual information. For the "fast" condition, seated subjects were instructed to move as fast as possible and touch any part of the 4 cm ball. Subjects were videotaped with markers at the index finger, shoulder, elbow, and wrist joints. Marker positions were digitized from the video recordings and used to calculate... Inverse dynamic equations (Soechting and Lacquaniti 1981) were used to estimate 1) net torques and 2) interaction torques at the elbow and shoulder joints. Preliminary data indicate that, under the "accurate" condition, cerebellar subjects moved in a manner that reduced the complexity of torques by decomposing the reach and/or slowing it down. Slowing the reach also permitted use of peripheral feedback to help shape the ongoing movement. Under the "fast" condition, cerebellar subjects produced a large number of interaction torques and often overshot the target. Fast reaching movements increased the magnitude of interaction torques (Soechting and Lacquaniti 1981) and normally require subjects to account for them in a predictive manner. We are currently addressing whether abnormalities in the "fast" movements made by cerebellar patients reflected the inability to account for only interaction torques or increasing magnitudes of all torques. We speculate that the cerebellum plays a role in generating appropriate commands to account for the complex nature of the torque components during fast, multijointed movements (NIH grant NS121777).

408.7 COORDINATION OF PLANAR TWO-JOINT ARM MOVEMENTS IN DIFFERENT DIRECTIONS. N. Vlot, D.B. J.D. Cooke, Faculty of Applied Health Science, University of Western Ontario, London, Canada N6G 1H1

In order for coordinated movement to occur, it is generally assumed that the CNS must somehow play an active role in counteracting the effects of interactional torques. Very few studies have directly examined the influence of such torques and the identified movement characteristics that are preserved during compensatory coordination during two-joint movements. We examined EMG-movement relations during planar elbow and wrist movements in which the two joints moved in different directions. i.e. elbow flexion and wrist extension at each joint. Elbow and wrist movements of different amplitude combinations were performed during a visual, stop-tracking task in which subjects were specifically required to attend to the horizontal and vertical angles at each joint. Elbow kinematics were generally unaffected by concurrent wrist movement. In contrast, wrist movement trajectories were variable and wrist movement coupling was observed. Qualitative changes were also observed in the pattern of muscle activation at the wrist joint. Specifically, wrist antagonist activity preceded wrist agonist activity in conditions when interactional torques could potentially produce a movement larger than required wrist movement. The variability observed in wrist trajectories suggests that the CNS may not play a direct role in the control of wrist movement. Rather, the observed kinematic and EMG changes at the wrist joint appear to be the direct result of a strategy used by the CNS to compensate for reaction torques resulting from elbow movements, ensuring the production of movements of designated amplitudes.

408.8 DELAYED VISUAL INFORMATION SLOWS DOWN THE TIME COURSE OF PRISM ADAPTATION IN HUMAN. S. Kingma, T. Kobay and T. Uka, Neuroscience Section, Electroclinical Laboratory, Tokushuk, 290, JAPAN

Accurate pointing is generally disturbed when the visual field is displaced by prisms, but gradually recovers. To test if the manner is disrupted by visual error signals that correlate in the error component with the motor output, the rate of prism adaptation was studied with verbal information. Nine subjects were trained to point rapidly at a target that appeared randomly in a square area (40x40 mm) on a target screen (400 mm away). Vision of the hand and the arm was always blocked during the movement by a liquid-crystal shutter, and an error signal was shown to the subject by the target light. The error signal was delayed by 200 ms in the visual displacement. Elbow and wrist movement trajectories were variable and wrist movement coupling was observed. Qualitative changes were also observed in the pattern of muscle activation at the wrist joint. Specifically, wrist antagonist activity preceded wrist agonist activity in conditions when interactional torques could potentially produce a movement larger than required wrist movement. The variability observed in wrist trajectories suggests that the CNS may not play a direct role in the control of wrist movement. Rather, the observed kinematic and EMG changes at the wrist joint appear to be the direct result of a strategy used by the CNS to compensate for reaction torques resulting from elbow movements, ensuring the production of movements of designated amplitudes.

408.9 ADAPTIVE CHANGES IN TORQUE CONTROL DURING REACHING OF YOUNG INFANTS. J. Konczak*, M. Brodt, J. A. Dichgans. Dept. of Neurology, Univ. of Tübingen, 72076, Tübingen, Germany. (Spon. EBSB)

When newborns attempt to produce goal-directed arm movements they are faced with the problem to actively control the forces for the fastest elbow flexions in humans: 1) that shifts end near the peak velocity of movement and 2) that shifts proceed until the end of movement. The first predicts that movement time may be significantly reduced by opposing loads without changes in the control pattern. Subjects flexed their elbows (and performed control trials) and performed two test trials; movements were opposed by loads generated by a torque motor. Subjects had no visual feedback and were instructed not to correct arm deflections when perturbations occurred. At the end of the movement, the load was removed leading to a secondary movement to the same final position as that in control trials (equifinality). The static arm positions before unloading were related to load torques. This finding and equifinality implies that subjects could reproduce the same control patterns regardless of perturbations. Test movements opposed by a high load ended near the peak velocity of control movements. Phasic and tonic EMG patterns were load-dependent. Results indicate that the control pattern is of short duration which suggests that rather than being pre-programmed, EMG signals represent long-lasting dynamic responses of the system to the short-duration control pattern, external forces and proprioceptive feedback.
SELECTIVE PROCESSES IN THE DEVELOPMENT OF REACHING. I. SINGLE ARM TRAJECTORIES. E. Thelen*, D. Corbetta, and J. P. Spencer. Dept. of Psychology, Indiana University, Bloomington IN 47406

Developmental studies provide a window on the neural mechanisms of hand trajectory control and reaching. It is well known that during the first year, human infants' hand trajectories become straighter, smoother, and more accurate. But reaches do not develop in isolation; rather, infants learn reaching movements in the context of coordinated variable non-reaching movements of the hands and arms. Here we describe reaching development as infants' discovery of stable trajectory parameters from a wider range of movement patterns.

We observed 4 infants (3 boys and 1 girl) weekly from 3 to 30 weeks and biweekly thereafter until 52 weeks as they reached for a toy at midline. Reaches were performed in 14 a trials, and hand trajectories were monitored by WATSMART motion analysis at 150 Hz before, during, and after the reach. Infants reached at 12, 15, 21 and 22 weeks and showed a dramatic improvement in trajectory straightness, smoothness and velocity modulation at 30, 32, 30, and 36 weeks, respectively. Prior to the transition, each infant had a long-month epoch of high velocity reaches, which in turn, disrupted the reach path stability. The speed increases were not unique to reaching, however, but were also characteristic of other non-reaching movements. After this active period, trajectory parameters stabilized.

Reaching improvement is not steady, linear and encapsulated. Rather, reaches are "cured out" of ongoing movements and are influenced by the ongoing movement context. Development consists of discovering consistent solutions after exploring a wide range of movement parameters. Supported by NIH R01 HD22830 and NIMH K05 MH01102

SELECTIVE PROCESSES IN THE DEVELOPMENT OF REACHING. II. INTERLIMB MOVEMENTS. D. Corbetta, E. Thelen. Department of Psychology, Indiana University, Bloomington IN 47406.

Early patterns of interlimb coordination associated with the development of reaching follow highly unstable and rapidly fluctuating forms over time. Reaching patterns alternate between periods of one- and two-handedness, and, during one-handed periods, no clear hand preference emerge. One interpretation is that developmental fluctuations represent the pre-organization of arm movements in the neuromotor system. Alternatively, we propose that developmental fluctuations emerge as "self-organized" properties of the system in interaction with the task.

We report the development of interlimb patterns over weeks, followed weekly from 26 weeks to 30 weeks and biweekly until 52 weeks as they reached for small toys at midline. Each week, we recorded the endpoint kinematics of both arms during multiple 14 asymptotic reaches using WATSMART motion analysis. The data we collected included both reaching and non-reaching activity. Specific movement analyses allowed us to capture the interlimb patterns of the reach itself and the ongoing activity from which the reach emerged.

We show that fluctuating patterns in reaching emerge from similar fluctuating patterns in the general non-reaching activity. We show that the general non-reaching responses modulate the movement over time and speed changes: when speed increases interlimb patterns become more synchronous and reaches more bimanual, while speed decreases, synchronous and bimanual patterns dissolve. We finally show that decreases in movement speed coincide with the emergence of interlimb asymmetries, revealing a shift toward an increased right arm activity. We argue that the emergence of lateral, one-handed reaching is progressively carved out of the general movement activity, through dynamic and selective processes.

TEMPORAL PARCELATION OF MOVEMENT KINEMATICS IN THE MUSCLE ACTIVITY OF MONKEYS. J.D. Cool*, Q.-G. Fu and J. J. Cash. Graduate Program in Neuroscience and Departments of Neurosurgery and Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

Previous electrophysiological studies of the motor cortices in our laboratory (Fu et al., 1993; Fu et al., 1994, in press) revealed timing differences in the encoding of movement parameters including direction, distance, and x-y position. Specifically, these parameters are encoded separately and sequentially, with direction-related discharge occurring first, x-y position-related discharge second, and distance-related discharge last. Our paradigm required monkeys to make reaching movements using horizontal plans, from a centrally located start position to 48 targets in 8 different directions and 6 distances. This study extends these observations to muscle activity during the same range of movements. Intramuscular EMG signals were collected in 15 muscles, and fitted to a multivariate time regression model. ANOVA and subsequent Tukey's Test were done on a subset of 14 muscles and revealed a clear temporal sequencing of parameter latency changes (p<0.001 by ANOVA)

Direction-related discharge occurred first (67±68 ms following movement onset), followed by x-y position-related discharge (254±151 ms), and distance-related discharge (497±165 ms). Latencies for each kinematic parameter were longer, and peak R2 values were smaller, than those for cortical cells. In addition, muscles were assigned according to their actions into upper arm, lower arm, and wrist/hand groups. Tukey's Test revealed no significant differences in discharge latency among the muscle groups for each parameter. These preliminary findings suggest that the temporal parcelation of movement parameters observed in the motor cortices is preserved at the level of muscle activation. Supported by NIH grants R01-NS18338 and R01-NS131530.

DIRECTIONAL PROPERTIES OF ARM MUSCLE ACTIVATION FOR DYNAMIC ISOMETRIC FORCES. J.T. Pollington* and M. Frander. Dept. of Physiology, Univ. Minnesota, Minneapolis, MN 55455.

We recently described how the timing and intensity of arm muscle electromyographic (EMG) activity vary with the direction of reach. After subtraction of postural activity, phasic EMG exhibited classic trisphasic burst patterns. The intensity of phasic activity was a multimodal function of movement direction, rather than a unimodal center-out function.

In the current study, we examined the patterns of activity in the same muscles during the discharging, as opposed to isometric forces. The surface EMG of 9 elbow and shoulder muscles was recorded while human subjects rapidly exerted 10N of force at the wrist in one of 20 directions in either a sagittal or frontal plane.

The onset of activity in a muscle varied with force direction: agonist bursts occurred in one range of directions, while antagonist bursts were generally occurred in the opposite range. As with reaching movements, the directional tuning of EMG intensity was multimodal. The frontal plane polar plots above illustrate that birefringence of intense EMG activity (greater distance from center) for ranges of directions including and in addition to straight up. Data are from one subject; left plot is from forces, right plot from 30 cm movements. Dynamic isometric forces will be useful for the study of the generation of complex motor patterns at the level of single motor units.

Previous work [1] on perceptuomotor coordination in houseflies has shown that learning a new behavioral pattern can be captured as specific alterations of the underlying coordination dynamics. The to-be-learned pattern (i.e., a frequency-locked pattern) is treated as a single modulation, and a phase-locked pattern is treated as a single modulation. For example, if a fly is trained to turn left, then left turns are increased. The dynamics of the learned behavior change from one that is random to one that is more predictable. The learned behavior is then repeated for a second pattern, and the dynamics of the learned behavior change from one that is predictable to one that is more random. The dynamics of the learned behavior are then repeated for a third pattern, and the dynamics of the learned behavior change from one that is random to one that is more predictable. The dynamics of the learned behavior change from one that is predictable to one that is more random. The dynamics of the learned behavior change from one that is random to one that is more predictable.

The current study investigates the dynamics of generalization of learning across two different coordination systems. Specifically, the dynamics of learning a new behavioral pattern are captured as specific alterations of the underlying coordination dynamics. The to-be-learned pattern (i.e., a frequency-locked pattern) is treated as a single modulation, and a phase-locked pattern is treated as a single modulation. For example, if a fly is trained to turn left, then left turns are increased. The dynamics of the learned behavior change from one that is random to one that is more predictable. The learned behavior is then repeated for a second pattern, and the dynamics of the learned behavior change from one that is predictable to one that is more random. The dynamics of the learned behavior are then repeated for a third pattern, and the dynamics of the learned behavior change from one that is random to one that is more predictable. The dynamics of the learned behavior change from one that is predictable to one that is more random.

LEFT LIMB MOTOR FUNCTION: THE BRAIN-DOWN BELT. W. A. Lee*, A. Murias, M. Clark, B. Macauley, L. Roth, K. M. Heiman, Center for Molecular and Behavioral Neuroscience, Rutgers University, New Jersey 07102; VA Medical Center and University of Florida, Gainesville, FL.

Many investigators have explored the differential roles of the left and right hemispheres in planning and executing skilled, learned movements, although few have analyzed the kinematic properties of these movements. It is suggested that the left hemisphere is critical for the control of skilled gestures but nonetheless, errors in movement performance have also been reported in subjects with right hemisphere damage. To further elucidate the contribution of the two hemispheres to skilled movement control, 3D motion analyses were performed on the trajectories of repetitive “slicing” gestures made by right unimpaired, left unilateral, and left hemispherical subjects. Four subjects with left hemisphere lesions and left apraxia, six subjects with right hemisphere lesions and seven neurologically intact subjects participated. Left-lateralized apraxic subjects, but not right-lateralized subjects, showed marked movement deficits. The apraxic subjects exhibited decoupling of the spatial aspects in the wrist trajectories and six additional navigational features. These deficits reflect the role of predictive and spatial aspects of the wrist trajectories.

PRODUCTION OF VOLUNTARY FINGER MOVEMENTS BY THE SUPPLEMENTARY MOTOR AREA: A STUDY OF THE PRIMARY MOTOR CORTEX.

Prominent direct projections from the supplementary motor area (SMA) to the spinal cord have been hypothesized to involve the production of direct movements of the primary motor cortex (M1) (Dum & Strick, 1991). We tested this hypothesis by determining the location and time course of intracortical activity time-locked to the generation of these movements by using two different approaches: (1) the normal analysis (DPA) and positron emission tomography (PET) simultaneously. Experiments were conducted to directly compare unilateral, repetitive finger opposition movements by using two different approaches: (1) DPA and PET simultaneously. In both groups, the effects of the SMA and the M1 were observed. PET data demonstrated that the SMAs involved significant activation of the contralesional M1 together with other structures in the parietal and intracortical pathways of the SMA. DSA and PET both showed that the SMAs were activated by activity in the SMA with minimal activation of M1. The SMA dipole orientation suggested that the SMAs were involved in neuronal populations in the dorsal tier of the cingulate sulcus. We hypothesize that the SMAs are involved via basal ganglia-thalamocortical pathways which do not include M1 and are separate from the pathways generating the SMAs. These SMAs are being investigated in subjects with Parkinson’s disease and neuroleptic induced Parkinsonism.

SCHEMA LEARNING IN MULTIDIRECTION PULLING. W. A. Lee*, A. M. Russin, Y.-C. Pai and D. Schena. Prog. in Physical Therapy & Inst. for Neuroscience, Northwestern Univ. Med. School, Chicago, IL 60611 USA.

We studied whether perceptual-motor schema or exemplars are learned when subjects practice a multidirectional pulling task that involves movement of the whole body. Ten freestanding subjects practiced impulse-like pulls against a load cell to three force targets (20, 40 and 80% of maximum) on four days, receiving feedback with decreasing frequency. On a fifth day, subjects pulled to both the training and novel (10, 50, 60 and 95%) targets, receiving no feedback. On half of the trials each day, subjects were estimated the force produced while getting feedback. On Days 8 and 9 pulling sagittal plane body motion (11 markers) was recorded, from which force components associated with the location (Fgrav) and acceleration (Fcentrif) of the body’s center of mass were determined. Normalized actual and estimated force errors and similar Fgrav and Fcentrif proportions for training and novel pulls, while exemplar learning predicts larger errors for novel pulls.

Actual and estimated force errors decreased significantly with practice. Higher correlations between actual and estimated forces on Day 5 suggest parallel improvements in force perception and force learning. The actual and estimated training and novel pulls were comparable on Day 5, except for 10% pulls which had greater errors than all other pulls. The regression equations between force components and pulling forces were similar across conditions. These results support schema learning, but also suggest that much of the improvement may have been due to subjects’ learning to parameterize an already familiar kinetic schema for force production.

Development of gonadotropin hormone releasing (GnRH) systems in the terminal nerve and brain of the cleared nose skate, Raja eglanteria, L.S. Dessauer, M. Barnes, and J. Snook. In: Carassius. Div. of Natural Sciences, New College of the Univ. of South Florida, Sarasota Fl, 34243.

GnRH-ir in both sexes was similar in older animals (16, 32 weeks and adult). The TN has well-developed ganglia of bipolar and multipolar cells that in the smaller fish span the length of olfactory bulb. The TN may enter the brain via dorsal and ventral roots. At 10 weeks, TN fascicles can be traced into the ventromedial telencephalon, from here bundles of ir-fibers extend into the septo- preoptic area and continue into the basal hypothalamus. Many fibers approach the infundibulum and portal vessels. A large ir- nucleus of bipolar and multipolar cells extends most of the length of the midbrain in all stages. In older animals, ir-beaded fibers are present in the neurohypophysis and most areas of the CNS; some may extend to the ventricular surfaces. A few scattered ir-fibers are present in the olfactory epithelium. Few ir-fibers are seen anywhere in the younger fish (7-8 weeks).

Sexually specific behaviors are frequently associated with sexually dimorphic brain areas. In particular, the ventromedial hypothalamic nucleus (VMH) has been associated with the female display of receptivity in lizards. We wished to determine if the VMH and two amygdaloid areas that project to the VMH, the lateral amygdala (LA) and medial amygdala, have sexually dimorphic volumes or cell sizes in a lizard, the Tokay gecko (Gekko gecko). Data was collected from 3 adult males and 3 adult females. Borders of the nuclei and somata were drawn on photographs of brain sections, then traced on a digitizing tablet linked with a computer to calculate areas and volumes. Only the values for the volume of the medial subdivision of the VMH were statistically significant, being larger in females than males. The values for the volumes of the lateral VMH and total VMH approached statistical significance with larger volumes in females. Measurements of somal areas revealed a marked sexual dimorphism, with females containing larger cells in the medial and lateral subdivisions of VMH and in the lateral amygdala. Somal areas of the other nucleus were not sexually dimorphic. Our data is consistent with previous findings in lizards and mammals that associated the VMH with sexual dimorphism and female receptivity. However, a sexually dimorphic telencephalic nucleus with larger somata in females has not previously been reported. The larger somal areas in the LA and VMH of female geckos and the projection from the LA to the VMH suggest that both the LA and VMH are involved in female-specific behaviors.

We used specific antibodies (Ab) recognizing the GluR1, GluR2/3, and GluR4 subunits of the AMPA receptor family (Chemicon) and the GluR5,6,7 subunits of the kainate receptor family (PharMingen) to localize these ionotropic glutamate receptor subunits in pigeon telencephalon. The GluR1 Ab labeled medium and large neurons that contained the densely labeled neuronal of dorsal and ventral striatum, while the neuropil and large projection neurons of dorsal and ventral pallium remained unlabeled. Scattered neurons in the prefrontal cortex were labeled for GluR1 throughout the pallium, while the palium ex. externum, archistriatum dorsale, nucleus taeniae, hippocampus, prehippocampal area, and hyperstriatum dorsale and ventrale stood out by their densely labeled neuropil. The GluR2/3 Ab was labeled in a wide variety of neurons in the prefrontal cortex, while the hippocampus and prehippocampal area of the palium. All palium regions possessed very abundant populations of GluR2/3 and GluR5,6,7, with highest levels of labeling found in the hippocampus and prehippocampal area. The distributions of these GluR subunits in the avian telencephalon share many similarities with those found in mammals, indicating similar importance for long-term transmitter in the avian pallium, and also for pallial and diencephalic inputs to the avian basal ganglia. Supported by NS-16620, NS-28721 (A.R.), & Neuroscience Center for Excellence (G.C.)

Early gonadal development in chicks can be induced via: 1) proaural hypothalamic knife-cuts, 2) chronic intraventricular injection of NPY, and 3) feeding sulfamethazine (SMX). An experiment was conducted to determine the neural effects of feeding 0.2% SMX to chicks beginning at one week of age. At 3 weeks, age 4 SMX-treated chicks and 4 controls were sacrificed, with saline followed by 4% paraformaldehyde and prepared for immunocytochemistry using antibodies to gonadotropin releasing hormone (GnRH) and NPY. A second experiment was conducted with 6 experiments, and 6 controls, perfused with saline followed by 4% paraformaldehyde and prepared for immunocytochemistry using antibodies to gonadotropin releasing hormone (GnRH) and NPY. An experiment was conducted to determine the neural effects of feeding 0.2% SMX to chicks beginning at one week of age. At 3 weeks, age 4 SMX-treated chicks and 4 controls were sacrificed, with saline followed by 4% paraformaldehyde and prepared for immunocytochemistry using antibodies to gonadotropin releasing hormone (GnRH) and NPY.

The saddleback wrasse Thalassoma duperrey is a sequential hermaphrodite that begins life as a subordinate female or male and may then transform into a terminal male via sex or role change. Terminal male fish aggressively dominate subordinates and may function to inhibit sex/role change. In fish, corticotropic-releasing hormone (CRH) and arginine vasotocin (AVT) are the primary hypothalamic secretagogues in the stress response. CRH and AVT cells in teleosts show a robust and overlapping distribution in the magnocellular and parvocellular preoptic area (POA). Immunocytochemical studies on the saddleback wrasse showed that the distribution of AVT cells reflects this general teleost pattern. Conversely, CRH did not conform to this pattern; in all but one individual, CRH cells were entirely absent from the POA. However, there were a unique group of CRH cells located in the Hypothalamus ventralis (HV). A comparative study using goldfish (Carassius auratus), a gonochoristic species conducted to determine these cells. Immunohistochemical analysis of the POA in CRH and AVT immunolabeling in the magnocellular and parvocellular POA indicated that 1) the goldfish is representative of the general teleost pattern, and 2) our results with T. duperrey represent a novel feature of a sex reversing fish. The paucity of CRH+ somata in the POA may be indicative of negative feedback from stress-induced elevation in cortisol, the unique group of cells found in Hv may play a role in stress-mediated control of sex reversal. The present results underscore the importance of these fish as a model system for investigations of neuroendocrine control of vertebrate sexual plasticity. Supported by NSF (IBN-9309565 to MGG and REU to MSG/AAG) and a University of Idaho Seed Grant.
409.7 IMMUNOHISTOCHEMICAL ORGANIZATION OF THE FOREBRAIN IN THE WHITE STURGEON, *P. fluviatilis* and R. G. Northcutt* Neurobiology Unit, Scripps Institution of Oceanography, and Dept. of Neurosciences, School of Medicine, University of California, La Jolla, CA 92030-2091.

To determine the palial and subpalial divisions in ray-finned fish, the distribution of leucine-enkephalin (LENK), substance P (SP), tyrosine hydroxylase (TH; dopamine) and dopamine-β-hydroxylase determined in the forebrain of an actinopterygian, Acipenser transmontanus (Chondrosti). Immunoreactive TH, SP, LENK, TH, and DAI penkarya were observed in different nuclei of the area centralis telencephali, pretectal area, periventricular nucleus of the posterior tuberculum (PPT), and inferior lobe of the hypothalamus in the ventral thalamus, few SVP+ and TH+ data are seen, whereas in the median nucleus of the posterior tuberculum only cells positive for TH were observed. A high number of SP+, LENK+ and TH+ fibers were seen in the nuclei of the area ventralis telencephali, whereas DA+ and SHT+ fibers were confined to the dorsal nucleus (Vd) of this area. All five substances were present in fibers innervating various diencephalic areas. Earlier studies suggested that the pallial-subpallial boundary was located between the medial (Dm) and the dorsal (Dd) zones of the dorsal telencephalon, and that Dm may be homologous to the striatum of land vertebrates. The present results do not support this view, since Dm showed poor content of SP+ and LENK+ fibers compared to the nuclei of the area ventralis telencephali. In this respect, Vd appears highly similar to the striatum, with a very high concentration of SP+, LENK+, TH, and DA+ fibers. This is supported by the presence of DA+ cells in PPT, a homologous region of the substantia nigra of amniotes, which could be the source of DApigcinput to Vd. Supported by NIH grant NS24869 to R.G.N.

409.9 A MARINE CHAMELEON: THE SANDLANCE LIMNICHYTHYES FASCATUS. J.D. Pettitross and S. P. Collins.* Vision, Touch and Hearing Research Centre, University of Queensland, St Lucia 4072 and Department of Psychology, University of Western Australia, Nedlands, 6009, Australia.

The sandlance, *Limnichthyes fascatus* (Creekfield, Teleosti), behaves like a marine chameleon, with independent movements of its turrets-like eye stalks that strike from camera-like, swimming prey. The optical system has a fixed circular pupil, a deep pit fovea and a flattened lens unlike any other teleost lens so far described. The cones, layered structure of the cornea is also unique, unparalledled in a teleost and suggests that the cones play a refractive role. This suggestion has been supported by four independent sets of observations: i) Photopic image formation can be observed by the eye; ii) Measurements of the magnification of intracorneal isodopes viewed through the corneal lenticle; iii) Measurements of the dissected corneal lens and lens when viewed under a microscope; iv) Ray tracing experiments comparing the degree of refraction produced by both the lens and corneal lenticle. All four sets of observations confirm that the cornea of the sandlance has a substantial refractive power of approximately 200 D compared with a lens power of 50 D. This is the first report of a teleost cornea with a significant refractive role. The optical system of lens plus cornea, in combination with the deep pit fovea, may be more suitable for the detection and accurate depth localisation of small, moving prey than the conventional, wide-field, spherical lens system of teleosts. The evolutionary convergence of this marine optical system and lifestyle with those of the chameleons is remarkable given the constraints imposed by underwater optics.

In amphibian and reptilian cell masses of the ventrolateral telencephalon are traditionally homologized to the striatum of amniotes. Comparative cytoarchitectural and topological studies of developing and/or adult forebrains of representatives of all three amphibian orders, together with topological and histochemical information about the striatum, suggest the following new hypothesis. The "striatum" of amphibians is pallial rather than subpallial and is homologous to the anterior ventricular ridge (ADV) of reptiles. This hypothesis is a more parsimonious interpretation of the data than the prevailing one, and suggests that the amphibian homolog of the amniote striatum may lie in the ventromedial telencephalic wall. It further suggests that the hypothalamic nuclei of all amniotic vertebrates may be subject to a similar reinterpretation. Taken together with the idea that the "striatal" ADV is homologous to the mammalian basolateral amygdala (Neary and Bruce, 1993), the possibility is raised that a thalamic-pallial-striatum amygdala is a significant and common feature of amniotic forebrains. (Support: NSF BNS-8620858 and Oberlin College)

409.12 CAVUM SEPTUM PELLUCIDUM (CSP) IN TREATMENT RESISTANT SCHIZOPHRENIA. R. Corone*, S. Davies, C. Goumans, C. Tamminga, R. C. Sanders. University of Maryland Psychiatric Research Center, Univ. of MD, Baltimore, MD 21228.

A number of investigations have focused on differences in clinical characteristics between people with schizophrenia who respond well to treatment and those who do not. Schizophrenics who fail to respond to clozapine may represent a separate population, with distinctly different etiology and/or neurobiology. Comparing treatment-responsive patients, one CT study found smaller ventricles in treatment-resistant patients (Ota et al., 1987), while another found greater prefrontal sulcal prominence in these patients (Friedman et al., 1991). Examination of the neuroanatomy in these two patient populations may provide further evidence to support a biological distinction between these. We examined MRI scans from treatment-resistant and treatment-responsive patients, and correlated the positions of the CSP, the third cerebral ventricle, and the lengths of the interventricular angle. Our results suggest that CSP in treatment-resistant patients is significantly higher compared to treatment-responsive patients. The CSP is significantly larger than the interventricular angle (12.5%), while the interventricular angle is significantly smaller than in treatment-responsive patients (11.9%). These data are consistent with the hypothesis that the CSP is a significant anatomic feature in patients with treatment-resistant schizophrenia.
HIGH RESOLUTION NMRI ATLAS OF AN INFANT MOUSE LEMUR (MICROCEBUS) BRAIN OBTAINED AT 12 T, Mark O'Dell*, Pratik Ghosh, Russell Jacobs, and John Aliman. Department of Computation & Neural Systems and Division of Neurology, Beckman Institute, Caltech 139-74, Pasadena, CA 91125.

In preparation for doing functional brain imaging, we have constructed a 3D registered digital atlas of the head of a deceased infant mouse Lemur (Primate M. Minimirus) using a Bruker AMX500 12 Tesla Nuclear Magnetic Resonance Imaging system (1H = 500 MHz). We obtained very high spatial resolution data (60 μm isotropic voxels) with strong intrinsic contrast (T2-weighted Spin Echo 3D), making it possible to see fine anatomical detail. We show in 3D volume renderings of this atlas on videotape, anatomical identifications on 2D prints, and details of data acquisition and processing.

Data was acquired using TE/TR = 100ms/1.3s with the sample at 2°C. While some MRI contrast is likely to be different from what would be obtained from a living specimen, all familiar anatomical structures are clearly visible. Fine fiber tracts, the laminations of corticis, and details of the inner ears are especially striking. Mouse Lemurs were selected because they have a highly developed visual system and are small enough to fit inside our imaging system.

BRAIN METABOLISM AND BLOOD FLOW: NITRIC OXIDE

1. CEREBRAL BLOOD FLOW (CBF), AND NEUROLOGIC OUTCOME IN RATS SUBJECT-ED TO TRANSIENT FOREHEAD ISCHEMIA: A COMPARISON BETWEEN CHRONIC HYPERCAPNIA AND SYNTHASE (NO) INHIBITION. V.L. Baughman, D.A. Pellicier*, and D. Wang, Dept. of Anesthesiology, Univ. of Illinois-Chicago, Chicago, IL 60612.

It is unclear whether the beneficial influence of NO during and following cerebral ischemia is protective (e.g., via promoting vasodilatation) or neurotoxic (e.g., through production of highly reactive O2-, NO, etc.). These opposing actions of NO could account for some of the variability in findings present in the literature. In this study, we subjected rats to 20 min of global cerebral ischemia and determined the effects of NO inhibition, with nitro-L-arginine (S-NA), on: 1) blood flow, 2) cerebral lactate accumulation, 3) neurologic function, and 4) histopathology postischemically. In order to differentiate the potentially protective vasodilating actions of NO from other (perhaps toxic) NO actions, 2 groups of L-NA-treated rats were examined: 1) a group receiving 10 mg/kg of L-NA i.p. 1 h before ischemia, which is the level of L-NA used to control (CT); 2) the other group (L-NA, n = 2) in which NO was not blocked for control purposes. In the L-NA group, aortic pressure was increased by 25-30 mm Hg postischemia. The anaesthesia was then discontinued. Rats were analyzed for neurologic function over 3 days. During ischemia, the CBF reductions measured were 65%, 89%, and 70% in the CT, L-NA, and L-NA2 groups, respectively. The corresponding MAP (mm Hg) values were 31, 31, and 52 mm Hg. L-NA treatment was accompanied by a greater post-ischemic hyperemic response than seen in CT (160%, 253%, and 193% of baseline in CT, L-NA, and L-NA2, respectively). Neurologic outcome in the L-NA group was markedly worse than CT. However, the mean score in the L-NA2 group suggested improved outcome vs CT, although the difference was not significant. These results suggest that NO is beneficial during TFI, presumably via an intra-ischemic vasodilating action. That benefit may be modestly opposed, but not negated, by a neurotoxic effect of NO. The greater post-ischemic CBF in the L-NA group indicates that, in this model, post-ischemcic hyperemia is not mediated by NO.

Chronic oral administration of the nitric oxide synthase inhibitor Nω-nitro-L-arginine-methyl-ester (L-NAME) results in increased hypothalamic vascular resistance (HVVR) (Benyo et al.; Society for Neurosciences, Abstacts, Vol. 19, 1990). The aim of the present study was to investigate whether this phenomenon can be reversed by L-arginine.

Male adult Wistar rats were treated with L-NAME dissolved in the drinking water. After a week of treatment, the animals were divided into 3 groups: control rats treated with ip. urethan, and hypothalamic blood flow (HBF, Hf/g clearances of mean arterial blood pressure (MAP) = 1304 ± 100 mmHg before the start of iv. L-arginine administration (300 mg/kg, bolus followed by 10 mg/kg/min infusion). Results: Control 10 min. 20 min. 30 min. 40 min. HBF (ml/min/g) 6.80±0.04 8.02±0.04 8.73±0.06 8.50±0.06 8.20±0.06 MAP (mmHg) 150±10 130±11 121±11 115±10 107±10 HVR (MAP/HBF) 22.5±21 162±19 151±20* 141±19* 134±16* apCO2 (mmHg) 35.2±0.7 36.3±0.9 36.5±0.9 35.3±1.1 34.1±0.9 apQ2 (mmHg) 83.6±2.4 84.0±1.4 84.1±1.8 86.8±1.7 88.6±1.2 apH 7.35±0.02 7.3±0.02 7.32±0.02 7.31±0.02 7.31±0.02 pCO2 = 0.05, *p<0.01 vs Control. ANOVA with Donnett "s test.

The results indicate that the hypothalamic vasconstrictor effect of nitric oxide inhibition induced by chronic oral L-NAME treatment can be reversed by an excess amount of exogenous L-arginine.

3. NITRIC OXIDE PLAYS DIFFERENT ROLES IN CEREBRAL METABOLISM AND VASULAR FUNCTION: EFFECTS OF HYPERCAPNIA ON SARAFON OR BASAL HYPERCAPNIA SIMULATION. F. Zanzoni* and C. Lapedeca, Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Inhibition of nitric oxide (NO) synthase (NOS) attenuates the increases in cerebral blood flow (CBF) elicited by electrical stimulation of the basal forebrain (BF) cholineric system or hypercapnia. We sought to determine whether the effect of NOS on BF metabolism and CBF is mediated by alterations in NO levels in intrahippocampal- and ventilated rats the NO synthase inhibitors nitro-L-arginine (L-NAME) and carbonyl cyanide 3-chlorophenylhydroxamic acid (CCHPH) were superfused by a laser-Doppler probe. Inhibiting NO activity was verified using the assay of Brett and Snyder. With ringer solution, BF stimulation (0.10-0.56 Hz) increases CBF by 214±18% (n=5) and 130±11% (n=6). However, the cerebral blood flow increases were attenuated by L-NAME and 3-chlorophenylhydrazine-1-carboxylic acid (L-NAME) sodium acetate (45±4%; p<0.001). Superfusion with CBF by L-NAME reduced CBF by 33±4% (p<0.05) attenuated the increase in CBF generation by l-arginine (L-NAME) acetate or by hypercapnia (45±4%; p<0.001) and reduced NO synthase catalytic activity by 93±3%. After L-NAME superfusion with the NO donor SIN 1 (0.1-0.5 HZ) re-established resting CBF (p<0.05). L-NAME superfusion by NO donor failed to increase CBF response to hypercapnia (p>0.05 from before L-NAME). However, SIN 1 failed to counteract the L-NAME-induced attenuation of the increase in CBF elicited by stimulation (p<0.05 from before L-NAME). We conclude that both the CBF responses to hypercapnia and BF stimulation have NO-dependent components. However, the role of NO in these responses differs: In hypercapnia, unlike BF stimulation, the NO-dependent component can be fully re-established by a NO donor despite near total inhibition of NO synthase catalytic activity. The data suggest that the CBF response evoked by CBF stimulation requires NO synthesis, probably via cortical release of acetylcholine, whereas the hypercapnic response inactivation requires a basal level of NO for its full expression. (Supported by NS 31318 and the AHA)

NITRIC OXIDE SYNTHESE IS REQUIRED FOR FUNCTIONAL HYPEREMIA IN CEREBELLAR CORTEX. L. L., X. Xu and C. Iedecote, Dept. of Neurology, Univ. of Nebraska, Lincoln, NE.

Functional brain activation is associated with increases in cerebral blood flow (CBF) restricted to the activated region. Although the mediators of the vascular response remain to be elucidated in full, there is evidence that nitric oxide (NO), a potent vasodilator released by active neurons, may participate. We used the parallel barometric (PB) system of the cerebral cortex as a model to investigate the role of NO in the increases in CBF elicited by neural activation. Rats were anesthetized with halothane and ventilated. The cerebellar vermis was surgically exposed and maintained in situ throughout the experiment. CBF was measured using silver microelectrodes. During Ringer superfusion (n=7), CBF increased by an average magnitude of 33±9% (p=0.01) and the increases in CBFs were reduced by 50±10% (n=7; p=0.01; analysis of variance) and inhibited NO catalytic activity, as detected by L-arginine to citrulline conversion, by 95±9% (p=0.01). L-NAME did not influence the increase in CBF, but did reduce the response by 41±9% (p=0.01). Thus, the increases in CBFs were evoked by NO scavenger methylene blue (1 mM) and were reduced by the presence of L-NAME, but did not affect the response (p=0.05). The gait instability and NO scavenger methylene blue (1 mM) were reduced by the presence of L-NAME, but did not affect the response (p=0.05). The gait stability was assessed by the presence of L-NAME, but did not affect the response (p=0.05). The gait instability was reduced by the presence of L-NAME, but did not affect the response (p=0.05). The gait instability was assessed by the presence of L-NAME, but did not affect the response (p=0.05).

THE EFFECT OF NITRIC OXIDE SYNTHASE INHIBITION ON CAROTID OUTPUT AND REGIONAL ORGAN BLOOD FLOW IN PIGLETS. Lehto S.A., R. Prasad, R. Schilling, and D.M. Panum, Dept. of Pediatrics, University of Michigan School of Medicine, Miami, FL 33101.

We examined the effects of low dose N-nitro-L-arginine methylester HCl (L-NAME) on cerebral and regional blood flow in piglets. Although there was no change in regional cerebral blood flow, there was a significant decrease in cardiac output. Piglets were anesthetized with ketamine and xylazine before the administration of L-NAME (0.5 mg/kg, i.v.). Cardiac output and regional blood flow were measured using electromagnetic flowmeters placed on the main arteries and veins, respectively, after cannulation of the femoral artery and vein. After 30 min of L-NAME, cardiac output was reduced by 25±5% (p<0.05) and all regional vascular beds showed a significant decrease in blood flow (all p<0.05). The decrease in cardiac output was due to a decrease in myocardial contractility but not a reduction in cardiac output after L-NAME administration, without a significant change in MAP.

410.8

NITRIC OXIDE SYNTHASE (NOS)-CONTAINING NEURONS INNERVATE HUMAN CEREBRAL MICROVESSELS. W. Li, Z. Wang,1 D. Liu, M. Lopez-Fernandez,2 and K. H. Oldendorf,3 Dept. of Surgery, Univ. of Tenn, M.D. Hosp., and Panum Inst., The Univ. of Copenhagen, Denmark.

Nitric Oxide (NO) is a potent vasculor and neuronal messenger molecule generated from L-arginine by NO synthase. Although data indicate that NO is important in the modulation of human cerebral blood vessel relaxation, there is little information about the localization of NOS in the human cerebrovascular bed. In the present study, we have used NADPH-diaphorase (NOS)-induced histochemistry to examine the existence and distribution of cerebrovascular neurons containing NOS. Four blocks of human temporal parietal cortex were cut on a vibratome at 50-100 mm sections. Two of five series were reserved for NADPH-diaphorase staining. While two of five series was prepared for immunocytochemistry for NOS reaction by a monoclonal antibody against the neuronal isoform of the enzyme and the remaining was used for an immunohistochemical demonstration of neurons with NADH diaphorase activity. We found that NADPH-d and NOS positive staining was located in cells and nerve fibrillae surrounding cerebral vessels. Differential NADPH-d and NOS specific and nerve fiber staining was noted at various sites of the cerebrovascular bed. In some cases, NADPH-d and NOS positive neurons in the cortex were seen close to and sending processes to the neighboring vessels; in other cases, the cell bodies were located far from the microvessels, sending processes to the blood vessels. NADPH-d and NOS specific positive fibrillae were also situated on the wall of blood vessels and had processes that paralleled with longitudinal direction of the vessels. Part of the vessel wall with stained fibers contained varicosities. Cell bodies were oval, fusiform and triangular with one to three primary dendrites of variable length. Some of primary dendrites by second dendrites. The identity of neurons and fibers containing NOS in human microvessels provides morphological evidence for a role of NO in modulating human cerebral blood flow.

410.9

THE EFFECT OF 7-NITROINDAZOLOXIDE, AN INHIBITOR OF BRAIN NITRIC OXIDE SYNTHASE (NOS), ON BASAL CORTICAL BLOOD FLOW AND ON VASODILATION INDUCED BY WISKER STIMULATION. J. Zawadzki,1 G. Santanu,2 M. McGuigan,2 and A. St John3, Department of Anatomy & Neurobiology, University of Tennessee, Memphis, TN 38163, Universita di Roma "Tor Vergata", Rome, Italy. 1.

The brain vascular system is regulated by nitric oxide (NO) produced by endothelial and neuronal NO synthases. While the vasodilatory action of endothelially produced NO is well documented, the role of neurally derived NO in cerebral circulation is still uncertain. Recently, an apparent NO donor inactivates NO in the somatosensory cortex associated with neuronal activation elicited by vibrational stimulation. Sprague-Dawley rats were anesthetized with urethane and a-chloralose. Body temperature, blood gases and blood pressure were monitored. One of the cortical NOS inhibitors was measured by a Laser Doppler flowmeter probe. Barre cortex was activated by manual deflection of the contralateral vibrators for 15-30 seconds. There were no significant changes in basal CBF or in dilatory responses induced by vibrational stimulation following vehicle (i.p.) injection. Basal CBF decreased significantly (p<0.05) in 30 minutes after 7NiN I injection (i.p. in 3 ml of peanut oil) with minimal reduction of 7NiN I (n=8) and 59% (n=3) of pre 7NiN baseline at doses of 50 mg/kg and 75 mg/kg, respectively. A slight (10-12 mg/kg) (p<0.05) blood pressure was observed after 7NiN I injection. The magnitude of the dilatory responses were decreased after 7NiN I injection at 50 mg/kg (88%) and 75 mg/kg (43%), but the reductions were not significant (the latter case probably due to the small number of animals yet tested). These studies revealed that 7NiN I reduces basal cerebral blood flow presumably via inhibition of neuronal NOS and has a slight vasopressor effect. Les NOS inhibition is required to affect basal cerebrovascular tone than to affect dilatory responses associated with neuronal activation.

VASODILATORY ACTIONS OF CALCITONIN GENE-RELATED PEPTIDE AND NITRIC OXIDE IN PARENCYHMAL MICROVESSELS OF THE RAT HIPPOCAMPUS. A. Ferguson, Y. Jin, Q.A. Thai, N.F. Kessell, K.S. Lea, Dept. of Neurological Surgery and The Neuroscience Graduate Program, Univ. of Virginia, Charlottesville, VA 22908.

Calcitonin gene-related peptide (CGRP) and nitric oxide (NO) are known to exert vasodilatory actions in a variety of vascular beds. Recent evidence suggests that CGRP and NO may mediate some aspects of the vasodilation elicited by NO. The present studies examined the responses of parenchymal microvessels in the rat hippocampus to CGRP and an inhibitor of nitric oxide synthase. Hippocampal slices were prepared from adult male Sprague-Dawley rats. Microvessels in the neuropil of submersed slices were examined using computer-assisted videomicroscopy. Drugs were administered by addition to the medium superfusing the slices. The resting diameter of vessels analyzed in this study ranged from 12 to 25 micrometers. Treatment with the nitric oxide synthase inhibitor, N-nitro-L-arginine (NNA; 100 μM), constricted vessels to 51.1±7.7% of resting diameter (n=9). Application of CGRP (10 μM) in the presence of NNA resulted in the dilation of the preconstricted vessels to 97.0±6.4% of their resting diameter (n=4). Three findings suggest that NO participates in the regulation of microvascular function by providing a tonic dilator influence. The ability of CGRP to dilate vessels in the presence of NNA suggests that CGRP-induced dilation is not dependent on production of NO. Ongoing experiments are investigating the possible role of CGRP in mediating NO-induced vasodilation.

MISMATCH-NEGATIVITY IN DIFFERENT BRAIN STRUCTURES - A TOPOGRAPHICAL AND DIMENSIONAL STUDY. M. Molnar, V. Czep, J. Wieder, J.B. Skinner and G. Kemeny. Institute for Psychology, Hungarian Academy of Sciences, Budapest, Hungary; Totta Gp Medical Research Laboratories, Bangor, USA. The purpose of the present investigation was to test: 1) if in animal experiments an attempt was made to record the mismatch-negative (MMN) in other brain structures than the auditory cortex, the latter being the hypothetical generator for the MMN. In chronically implanted freely moving cats auditory evoked potentials were recorded from the auditory and association cortices, dorsal hippocampus, amygdala, dorsal raphe nucleus and vertex. Auditory stimuli were short tones of 4 kHz frequency ("standard") randomly interspersed by 2 kHz "deviant" tones (probability : 1/10). 2) In human studies the mathematical tools of non-linear dynamics was used to analyze data collected in MMN-experiments from different scalp locations. The MMN, elicited by random stimuli within series of 1000 Hz deviant stimuli (probability : 1/10). The results suggest that, in contrast to its action in primary microvascular beds, does not affect the EEG and endo-endothelium interactions in the peripheral microcirculation. Supported by the DFG and the Wilhelm Sander Stiftung.

411.2
COMPARATIVE ANALYSIS OF CORTICAL GENERATORS OF MISMATCH-NEGATIVITY IN THE CAT AND MONKEY. G. Kemeny, J. Ulbert, D.C. Javitz, M. Molnar, V. Czep, Zs. Pirnitz and G.E. Schroeder. Inst. for Psychology of the Hungarian Academy of Sciences, Budapest, Hungary, Dep. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461. Human source localization techniques was implemented an investigation on the source of the mismatch-negative (MMN), which is a negative component of the scalp recorded auditory evoked potential (AEP). It is elicited by infrequent, 'deviant' stimuli, presented randomly within sequences of repetitive "standard" auditory stimuli. MMN appeared also in cats and monkeys as a negative component in the epidural AEPs in the latency range of 40-120 ms. The half area under the MMN generator the fields potentials and multiple unit activity were recorded from the auditory areas of awake cats and macaque monkeys by intracortical multielectrodes. One dimensional current source density (CSD) analysis was used to localize intracortical ictal sources. Surface maps in cats indicated the spread of the frequency MMN to both AI and AIJ auditory areas. In the middle layers of the auditory cortex of cats large amplitude local positive field was elicited by the standards in the latency range of the MMN while this positivity appeared with much smaller amplitude to the deviants. CSD analysis and the increased unit response elicited by the deviant stimulii suggested that the MMN represent a local disinhibition in the upper layers. In the AI area monkeys surface negative MMN to deviant stimuli was accompanied by an increased laminar II/III sink.

The data indicate that the MMN generators are localized in the supragranular layers of the auditory cortex. Supported by Oskta Grant 1/2595 and by the J.S. McDonnell Foundation.

411.3
THE GENERATOR QUESTION: A COMPARISON OF EVENT RELATED POTENTIAL (ERP) PROFILES WITH RECONSTRUCTIONS FROM CURRENT SOURCE DENSITY (CSD) ANALYSES. G. Czep, G.E. Schroeder, Dept. Biopsychology, NYS. Psychiatric Institute, NY/NY and Deps. Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461. One-dimensional current source density (CSD) analysis dealt the temporal and spatial patterns of transmembrane current flow which underlie the local field potential, and allow inferences about the likelihood that the sampled activity is a recording a distance. In contrast, image models (e.g. dipole models) simplify a scalp topography by indicating locations and waveforms for putative generators based on statistical and geometric inferences. A synthesis of these two approaches would provide a distinct advantage for the study of ERP generators. We recorded the electroencephalograms in the monkey while allowing the functional nucleus (LGN) and reconstructed the ERP profile from computed CSD profiles. CSD profiles were computed at low or high spatial resolution to bias the profiles toward open or closed field activity, respectively (Teske et al., 1993). Weighting functions for the cortical tissue and underlying distributed cylindrical generators (Nicholozon and Linna,1971). Reconstructed and empirical profiles were compared and residual waveforms computed from their differences. Low resolution methods produced a spectral roll-off better overall fit to the empirical profile. High resolution methods produced an oscillatory residual, reflecting closed field activity. Factors common to empirical and reconstructed profiles were extracted using a principal components analysis, to summarize them and to provide a direct linkage between local generators and the ERP recorded within and superficial to LGN. This approach shows promise for computing waveforms of volume conducting, regional dipoles directly from measurable properties of a region.

The electric currents in brain areas which are active during somotorimotor and cognitive processes produce electric and magnetic fields outside the skull which can be measured in real-time as event-related electric potentials (ERPs) and magnetic fields (ERFs) respectively. The accuracy of localizing active brain sources may be improved by combining ERP and ERF data since they are complementary. Prior to recent technological advances, it has not been possible to simultaneously record both electric and magnetic field data over the whole scalp in a single experimental session. We report here, simultaneously recorded electric and magnetic responses to visual stimuli with large sensor arrays (122 magnetometers and 32 electrodes) over the whole scalp. A series of retinotopic, pattern discrimination and attention experiments were conducted. The retinotopic results are presented here. ERPs and ERFs were recorded to small checkerboard wedge stimuli delivered to each quadrant. Source configurations for the initial responses were estimated from spatotemporal dipole analyses and minimum norm estimation. The locations of ERP and ERF convergence, and followed the expected retinotopic pattern for striate cortex, i.e., upper, right, lower, right, lower left and upper left quadrant stimulation activated lower left, upper left, upper right and lower right striate cortices respectively.

411.6 VALIDATION STUDIES OF A PROBABILISTIC SOLUTION TO THE EEG INVERSE PROBLEM - D.M. Price¹, F. Pigeot¹, M. Singh¹, Andrea Gerontolgy Center¹ and Dept. of Biomedical Engineering¹, Unv. of Southern California, Los Angeles, CA 90089-0123. The EEG inverse problem is to reconstruct the distribution of currents within the brain which generate the scalp measured potential distribution. This problem has an infinite number of exact solutions, so a probabilistic solution would seem to be necessary to solve this problem. The approach employed here maximizes the entropy of the source distribution subject to a system of linear equations which require that this distribution fits the scalp measured potential distribution. As is well known, the joint probability of sources in opposite directions at the same location is zero. With this formulation, this maximum entropy solution is the probability distribution for the source(s) of the measured potential field, and it is also the most likely source distribution for the measured potential field. In addition, the current probability distribution can be easily derived from this source probability distribution. The present studies were to provide initial validation for this approach. With simulated potential fields produced by a number of equivalent current dipoles in homogeneous sphere model, the current probability distributions approximated the actual equivalent current dipoles which generated the potential field. With a potential field measured at the human scalp during visual checkerboard stimulation which straddled at 3 Hz, the current probability distribution computed through a four sphere model was largely concentrated in the posterior regions of the brain including a region roughly corresponding to the primary visual cortex.

411.7 TOMOGRAPHIC MAPPING OF TEMPORAL LOBE P300 ACTIVITY IN THIN-DIMENSIONAL: ASSESSMENT OF RELIABILITY AND ACCURACY - J.C. Kastner¹, J.R. Price¹, J.A. Drouhard², C.的观点 University of California, Los Angeles, CA 90089-0123. A noninvasive interelectrode computer graphics algorithm for imaging the distribution of the P300 event-related potential within the temporal lobe is described. This technique takes advantage of the fact that the primate temporal lobe may be noninvasively surrounded by 4 electrodes forming a tetrahedral array consisting of three surface leads (CA, YA, and TA) and one nasopharyngeal lead (PG2). It is then possible to calculate the potential distribution within the enclosed volume of the temporal lobe given that the field strength Ep for any point p within the tetrahedron may be represented by the sum of the field contributions to or from the surrounding vertices, weighted by the distance between point p and each of the vertices. As part of an effort to assess the reliability and accuracy of this technique, monopolar recordings were obtained from the tetrahedral array in each of several squirrel monkeys (Gallium sciuereus) using a passive oddball paradigm. Simultaneous monopolar recordings were made at indwelling electrodes from a region of depth of 10mm to a final depth of 22mm within the temporal lobe, and these measurements were used to adjust the imaging algorithm to account for variations in head shape and conductivity via a least-squares technique. When applied to other subjects in a cross-validation procedure, the adjusted algorithm was found to yield accurate and reliable measurements at varied depths which were highly and significantly correlated with simultaneous measurements obtained from indwelling electrodes at corresponding sites.

411.9 BRAIN ACTIVATION WITH A MAZE TEST: AN EEG COHERENCE ANALYSIS STUDY IN HEALTHY SUBJECTS - M. Tremblay, D. Larose², V. Fraile, Y. Chaput², R. Lemier and J.-M. Abi-Rached, Service de Psychiatrie, Hôpital Notre-Dame, Université de Montréal, 1520 Sherbrooke E., Montréal, CANADA H2L 4M1.

The maze test is a complex cognitive task involving visuo-perceptual abilities and executive functions, such as planning and foresight. EEG coherence analysis is performed on the electrical signal of two electrodes and its value is analogous to a correlation coefficient between the two EEGs. Two recordings were done from 20 healthy subjects (mean age ± S.D.: 27.4 ± 4.23) during a maze test (3 mazes from the WISC and 2 from the Porteus) and during two baseline conditions: 1- rest with eyes opened; 2- mazes with dotted lines showing the way out. 19 electrodes were used according to the 10/20 system. Signals were referenced to averaged signals from both ears lobes (TO 3a, Filter 36 Hz). Interglutional coherence (RC) refers to coherence between each electrode pair to the remaining electrodes and may reflect dynamic physiological processes between brain regions during cognitive activation. Statistical probability was evaluated using the nodal regional distribution of changes. The results show that: 1- compared to the eyes opened condition, the maze test provoked increases of RC mainly located between paired posterior electrodes (mostly parietal P3 and P4 sites) and decreases between all fronto-frontal sites; 2- compared to RC of the 2nd baseline condition, the maze test provoked increases of RC mainly between paired posterior electrodes in 9 and 1/2 bands and between the left prefrontal F3 site paired with frontal or anterior sites in β band and provoked decreases between centro-parietal sites paired with frontal sites in γ. EEG coherence analysis detects electrical changes in regions known to be involved in visual-analytic, visuo- and executive functions (posterior, central and frontal sites respectively).

Event-related brain potentials (ERPs) were recorded during a syntactic decision task. Twenty-five right-handed young adults were presented with a total of 198 eight-word sentences, that were divided in three different groups: 66 Pseudo-Cleft Agent, (LO QUE UN ELEFANTE EMUEVO UN OSSO, "WHAT AN ELEPHANT PUSHED WAS A BEAR?"); 66 Pseudocleft Passive (UN ELEFANTE FUE LO QUE EMUEVO UN OSSO, "AN ELEPHANT WAS WHAT PUSHED WHAT?")) 66 sentences which were presented randomly intermixed. Subjects had to select the agent in each sentence. Scalp electrical activity was recorded from 32 derivations of the 10/20 international system. ERPs were registered to the seventh and eight word. Peak amplitudes were visually identified by windows of 200 msec each one (from 50 to 900 msec). ERP measures associated with both groups were subjected to ANOVA and repeated measures. Wave differences between ERPs were obtained. A slow negative response between 300-500 msec largest over anterior regions of the left hemisphere. These data reflected an negative component around 500 msc elicited by syntactic decision.
411.11 APPEARANCE OF FRONTO-PARITAL MIDLINE (FPm) THETA ACTIVITY IN GOOD AND POOR LEARNERS
S. Jakubka, J. Lindqvist, A. Bryilehto, Laboratory of Developmental Neuropsychology, University of Oulu, Linnunlahti P.O. BOX 222, FI-90901 Oulu, Finland.

Fronto-parietal theta activity (FPm, 4-7Hz) was investigated during learning process of problem solving in a simulation traffic situation on the subject had to learn to find the right way for driving a car through a set of roads by trial and error. Two independent driving situations had to be made at two crossroads guided by two traffic signs. After learning the level of performance was tested in a practising situation. Feedback about quality of performance was given. EEG was recorded from Fz and Pz. In learning situation, the amount of appearance of theta activity did not differ either on the frontal or on the parietal area between good learners and the poor learners. In the practising situation, poor learners showed a significantly higher amount of theta than good learners in the frontal and parietal area.

The results demonstrate a relation between the appearance of fronto-parietal midline theta activity and the quality of performance.

This study examined the effects of a cue-directing stimulus and the length of the cue-target interstimulus interval (ISI) on (1) stimulus-elicited brain responses occurring prior to and following the occurrence of relevant (validly cued) and irrelevant (invalidly cued) target stimuli in a given visual field; and (2) on latency (RTs) and accuracy (d-primes) of responses to cued stimuli. On a given trial a foylely presented arrow cued the subject to attend (without moving the eyes) to either the right or left visual field. After a brief delay a target appeared randomly either in the target stimulus position or in a position 154, possibly leading to a mismatch. Significant differences were found between the two ISI conditions.

411.13 CORTICAL EVOKED POTENTIALS DURING A VISUAL CONTINUOUS PERFORMANCE TASK. A. Teko-Kilco, E. Benders, D.W. Shupert*, Dept. of Neurology, SUNY @ Buffalo, 100 High St. (6E), Buffalo, NY 14203.

The Continuous Performance Task (CPT) was originally developed for the behavioral assessment of sustained attention in brain damaged patients (Rosvold et al., 1956). Different types of CPT's have been used to investigate attention in psychiatric and neurologic patient groups. It has become important to control for possible cognitive factors measured by the CPT in normal subjects. One of the variations of the CPT is the visual "A-X" paradigm (Hapler et al., 1988) in which subjects are asked to respond as fast as possible to the target letter "X" only if it is preceded by "A". Non-target letters preceded by "A" and "X" not preceded by "A" (non-target "X") are also presented. In order to study the physiological aspects of sustained attention, we examined the relationship between a cortical evoked potential component (P300) and the "A-X" paradigm. P300 is an endogenous component that is elicited by stimuli that are relevant to the subject. We expected that the P300 component would have the highest amplitude for both target "X"s and for other letters immediately preceded by "A". Eleven subjects were usually presented as stimuli in a random sequence of 400 letters, with 40 "A-X" pairs (p=0.10) and 68 "A-X" pairs (p=0.17), stimulus duration was 200 msec and ISI was 1500 msecs. Electroencephalographic activity was recorded at 12 scalp electrode sites of the 10-20 system, referenced to linked earlobes.

As reported in previous studies, the P300 component was most prevalent in the midline scalp sites. As predicted, the highest amplitude responses were observed for both target "X"s and other letters that were preceded by "A"s. These results are consistent with findings showing that task relevance is an important antecedent condition of P300 amplitude. The electrophysiological data provide information not attainable through behavioral observation about possible cognitive events underlying CPT performance.

411.14 THE EFFECTS OF PRECEDING INTERSTIMULUS INTERVAL ON BEHAVIORAL DISCRIMINATION AND MISMATCH NEGATIVITY.
M.G. Woldorf* and M. Matsuji, Univ. of Texas Health Science Center, Research Imaging Center, San Antonio, TX 78284-6200.

The mismatch negativity (MMN) is elicited by infrequent, physically deviant sounds in a sequence of repetitive auditory stimulus. It has been shown that this wave reflects a strongly automatic feature-analysis and mismatch-detection process, in which each stimulus is compared to the sensory template formed by the repeated standard-tone stimulus. This framework asserts that the MMN is largest at shorter interstimulus intervals (ISIs), due to the comparison template formed by the previous standard and being stronger. For similar reasons, this framework also predicts discriminability of the deviant stimuli should be better at shorter ISIs.

To explore this relationship more directly, subjects were monaurally presented with tone pips at ISIs ranging randomly from 125-925 msec, with 10% of the tones either slightly faster in intensity or slightly lower in pitch (different blocks). On half of the runs, subject tried to discriminate the deviant stimulus; on the other half, subjects were asked to count the number of tones. Pairs of tones were divided into 4 subranges, and target discrimination and ERPs were subdivided as a function of the ISI subrange of the preceding standard tone. The discriminability of the deviant target tones was strongly affected by preceeding ISIs, with subjects doing progressively worse at the shorter ISIs. Preliminary ERP results suggest that the reading-condition MMNs and the active condition MMN/DRN (deviance-related/negativity) also decreases with shorter ISIs. These data do not fit into a framework of increasing standard-tone template strengthening with decreasing ISI. Rather, as suggested by Woldorf and Hillyard (1991), a type of neural refractoriness appears to play a major role in these phenomena at shorter ISIs.

411.15 VEP ESTIMATION OF INTERHEMISPHERIC RELAY TIME.

Lines, Rugg & Milner (1984) dissociated a non-sensory from a sensory component of interhemispheric relaying (IR) by showing that the asymmetry in N160 latency of visual evoked potentials (VEP) to contralateral targets was abolished in bilateral stimulation in the occipital area only at occipital sites (about 11 and 18 msec for bright and dim stimuli), not at central sites (about 3 msecs). It appears possible, however, that the late 3 msecs delay simply represents different shifts in the apparent peak latency of a synchronous symmetrical source, due to superimposed asymmetrical potentials of occipital origin, the central N160 peaking during the rising phase of the occipital N160. To allow for more detailed topographic analysis, we obtained VEP from 21 scalp sites in 10 subjects in a simple reaction time task to yellow squares on a blue background, about 10° left of field of view. Preliminary N160 latency analysis shows a strong antero-posterior gradient, from 154 msecs at F3/F4 to 190 msecs at O1/O2. The IR estimates a parallel gradient from 5.9 msecs at O1/O2, with a value of 10.3 msecs at C3/C4. The latter, with a standard error of the mean of about 3.2, is a significantly larger asymmetry than the results earlier at C3/C4. The notion of simply two levels of IR in VEP appears to be an oversimplification.

411.16 ACTIVATION OF DURATION-SENSITIVE AUDITORY NEURONS IN HUMANS.
C. Alain*, D.L. Woods, and D. Covarrubias. Department of Neurology and Center for Neuroscience, UC Davis, Northern California System of Clinics, Martinez, CA 94553.

Auditory neurons vary in their duration tuning: some neurons fire to tones of short duration, whereas others require longer duration tones. In the current study, auditory evoked potentials (AEPs) were elicited by stimuli varying in duration (8, 24, or 72 ms) and frequency (250, 1000, or 4000 Hz) in an effort to characterize temporal integration functions (amplitude/latency changes with changes in tone duration) for different AEP components. High frequency tones used with all three durations were delivered randomly to the left and right ears. Subjects attended to a designated location and frequency to detect occasional long- or short-duration targets. Subjects were more accurate and faster at detection of long- than short-duration targets. Parallelism, this AEP components increased in amplitude and decreased in latencies with increased signal duration. Since all signals had identical rise-fall times and peak-to-peak amplitudes, the increase in latency difference waves could be isolated by subtracting AEPs to short-duration tones from AEPs to longer duration tones at the same location and frequency. Duration difference waves varied in amplitude and scalp distribution for tones of different frequencies. These different integration time for different frequencies and generators, with nonotopically organized AEP generators generally having longer temporal integration times.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
411.17 EVENT-RELATED DIFFERENCES IN EEG SPECTRAL POWER (ERDISP) D. L. Woods*, C. Alain, D. Covington, and M. P. Bailer, Dept. of Neuroscience and Neurosciences Center, UC Davis, Northern California System of Clinics, Martinez, CA 94553.

Recent studies using narrow band filtering techniques have shown changes in alpha (8-13 Hz) and gamma (30-50 Hz) frequency bands of the EEG in association with the sensory and cognitive analysis of signals. A simple model of discrimination was designed to examine Event-Related Differences in EEG Spectral Power (ERDISP) over the entire EEG frequency spectrum. Power spectra from brief EEG epochs preceding stimulus delivery are subtracted from power spectra following the stimulus. The selection of the epoch duration is critical to a trade-off between temporal and frequency resolution: short EEG epochs provide good temporal resolution but poor frequency resolution, whereas long EEG epochs provide good frequency resolution but poor temporal resolution. An analysis strategy using multiple epoch durations is proposed. ERDISPs reflect both sensory and cognitive processes. ERDISPs relating specifically to higher cognitive processes were calculated in ERDISPs using multiple subtractions. For example, for the effects of selective attention on ongoing EEG rhythms can be analyzed by subtracting ERDISPs from nonattended stimuli to ERDISPs to the same stimuli when attended. Δ-ERDISPs in selective attention tasks show alterations in several EEG frequency bands. The relationship between ERDISPs and event-related brain potentials (ERPs) and between ERDISPs and other techniques for analyzing event-related changes in EEG power will be discussed. Supported by NS38933 and DC10049.

411.19 SPECTRO-TEMPORAL CORRELATIONS IN HUMAN GAMMA BAND ELECTROCOGGRAMS. Y.硕士学位, W. W. Harms, and S. A. Graham, UCLA Dep't of Physiology, Los Angeles, CA 90095 and Division of Neurology, University of California, Berkeley, CA 94704.

Animal electrocorticogram (ECoG) studies have shown that coherent spatial patterns in the gamma band (> 20Hz) effect perceptual categorization. Spectro-temporal correlations were investigated in the 20-50Hz range in search for similar phenomena in human ECoG. The ECoG was recorded in a somatosensory discrimination task from a 64-electrode subdural grid array with spacing of 1cm between electrodes, overlaying somatosensory, motor, and supratemporal cortex. In two patients with intractable epilepsy. Stimulus and response related modulations of the μ, β, and γ bands of the 1/f spectrum were observed over intervals of 100ms in the somatosensory and motor cortices but not in the temporal cortex. No evidence was found for globally coherent responses related to behavior in the narrow (e.g. 40 Hz) or broad bands. Instead, spatially and temporally intermodulated synchronization was observed between pairs of electrodes with high variability within and across trials. The distribution of correlation coefficients differed substantially from those observed in the monkey cortex. The findings suggest that domains of spatial coherence in human gamma band ECoG are limited to < 2cm, that the intermodulation synchronization observed across separations of 1cm and 1.4cm is not solely due to volume conduction, and that the search for coherent synchronization in human gamma band ECoG needs to be at a smaller spatial scale.

Spine space synchronization (SSS) of neuronal ensemble activity of the human brain was investigated. Golgi electrodes were implanted in the deep structures for therapeutic purpose. The impulse activity of 14 distant ensembles were recorded simultaneously. It was established that there were some SSS for definite phases of psychological tests. This investigation was completed by chronic experiments. Monkeys (M.multiluata) were trained to differentiate colored geometric figures. The impulse activity of 6-10 neuronal ensembles was recorded simultaneously in associative, temporal and frontal cortex of the animals during their operant conditioning. It was show the existence, the reliability and the importance of SSS. There was a non linear correlation between discharge frequency changes of impulses and spike’s synchronization. The experiment showed that SSS correlated with definite phases of the monkeys’ behavior. The interaction of neuronal processes which have been investigated allow that such space interaction as SSS could be a special mechanism for quick short phases of integral mental processes in the primate brain and that spatial – temporal information stimulations by means of many implanted electrodes lead to modify behavior.

The goal of this experiment was to replicate and extend previous work suggesting that operantly conditioned changes in the amplitude of the prestimulus evoked potential (SEP) alters pain sensitivity. The SEP, R3 reflex, compound nerve action potential (CNAP) and magnitude rates were calculated by stimulation of the median nerve. Twenty-one subjects (conditioning group) were rewarded for increasing (up-training) and decreasing (down-training) the P200 peak of the human somatosensory evoked potential (SEP) alters pain sensitivity. The SEP, R3 reflex, compound nerve action potential (CNAP) and magnitude rates were calculated by stimulation of the median nerve. Twenty-one subjects (conditioning group) were rewarded for increasing (up-training) and decreasing (down-training) the P200 peak of the human somatosensory evoked potential (SEP) alters pain sensitivity. The SEP, R3 reflex, compound nerve action potential (CNAP) and magnitude rates were calculated by stimulation of the median nerve. Twenty-one subjects (conditioning group) were rewarded for increasing (up-training) and decreasing (down-training) the P200 peak of the human somatosensory evoked potential (SEP) alters pain sensitivity.玛丽亚

THE WISCONSIN CARD SORTING TASK SHOWS LITTLE SENSITIVITY OR SPECIFICITY FOR THE FRONTAL LOBE. Z. Carmanast*, M. P. Costa, and C. Damasio, Department of Radiology, University of Iowa Hospitals and Clinics, Iowa City, IA 52242.

A new test, subjects must choose one card at a time from one of four decks. In two decks, choosing a card is followed by a high gain of play money, but at unpredictable times, the second deck is completely empty. In the other two decks, the immediate gain is smaller but the future loss is also smaller. After sampling and encountering losses in each deck, normal subjects begin to avoid the decks with high immediate gain (bad decks). Patients with right prefrontal-lobe lesions also show an avoidance strategy, but never reach the same level of strategy as do normal subjects. In the bad decks, there is no correlation between the amount of money won or lost and the frequency of a card being selected, which suggests an inability to use the results of the previous trials to predict future outcomes. In addition, the patients show a greater tendency to avoid the bad decks, which may be due to a reduced ability to predict future outcomes.

412.4
NON-CONSCIOUS AUTONOMIC SIGNALLING ADDRESSES THE AVOIDANCE OF RESPONSES WITH NEGATIVE AFFECTIVE CONSEQUENCES. D. Damasio, A. R. Damasio, and D. Tranel, Dept. of Neurology, Univ. of Iowa, Iowa City, IA, 52242.

FRONTAL LESIONS AFFECT PERSISTENT AND MIRROR DRAWING PERFORMANCES. ML. Chouinard*, L. Bouleau, Lab. de Neurosciences de la Cognition, Université du Québec, Montréal, QC, HEC 3P8.

As part of a larger study of the role of the frontal lobes in sensori-motor performances and learning, we examined performance of patients with frontal lesions in two tasks requiring continuous regulation of movement on the basis of sensory information. We tested 5 patients with a unilateral frontal lobe lesion (FL) and 8 patients with a unilateral temporal lobe lesion (TL) on two sensori-motor tasks: 1) Rotary Pursuit and 2) Mirror Drawing. In the Pursuit task, subjects were asked to keep a light dot moving at a constant speed (15rpm, 30rpm, or 45 rpm) around a circle in three 20 sec. trials. In the Mirror Drawing task, the subjects had to trace a starlike path seen through a mirror. On the Rotary Pursuit task, FL spent less time on the target than TL at 30 and 45 rpm, suggesting a deficit in movement correction. On the Mirror Drawing task, FL showed longer total tracing time although their performance without the mirror was equivalent to that seen in TL. This slowing was mainly due to more frequent episodes of non-progressive tracing (jitter) for FL than for TL. However, line-crossing errors were not more frequent in FL. The performance of FL on both tasks suggests a difficulty in the control of movement under sensory guidance, especially under challenging conditions.

412.7
LOSS OF GLOBAL PROCESSING AFTER RIGHT HEMISPHERE ATROPHY. Alessandra Schievetto,1 Johannes Stauder,2 Laurent Mottron,2 Philippe Robecky3 and Marcie Lassonde1
1 Department of Psychology, Université de Montréal, and 2 Ste-Justine Hospital for Children, Montréal, Quebec, Canada.

The purpose of this study was to investigate the global and local processing abilities in a patient with a right hemispheric atrophy restricted to the temporal lobe. This atrophy resulted from a viral infection, herpes encephalitis, when the patient was 9 years old. As a result of this illness, the patient became prosopagnosic, color agnosic and presented evidence of associative visual agnosia. Recent MRI (Jan. 1993) revealed discreet left temporal lesions. The patient suffered from a global temporal atrophy, including the hippocampal region. In the present study, the patient was tested on two reaction time tasks in which hierarchical processing was manipulated: a global-local detection task and a figure-parsing task. Ten age-matched controls were also tested on the same tasks. Analysis of A.R.'s response accuracy shows that she could never distinguish between items. Moreover, reaction times in the global-local task show that, unlike normals, she did not have interference effect from the global to the local level. Indeed, her reaction times were slowed when congruent stimuli were presented (local vs. global level). Similarly, in the parsing task, she did not show the usual advantage for Gestalt fit items. In contrast to normals, her reaction times were significantly slower for the Gestalt items. These data suggest the involvement of the right temporal lobe in global processing. Furthermore, they may offer insight into the deficits resulting from visual agnosia.

412.8
FRONTAL LESIONS INCREASE ATTENTIONAL SUPPRESSION IN RAPID SERIAL IDENTIFICATION. P. Richter, M. Legue, Lab. de Neurosciences, Université du Québec, Montréal, QC, HEC 3P8.

While attentional problems have long been associated with frontal lesions in humans, the mechanisms underlying these deficits are still poorly understood. We have previously shown that frontal patients can have problems finding target stimuli in sequences (Richter et al., 1993) but it is not clear whether the processes of target detection or identification are different in frontal patients. To test this, we examined the effect of a first identification on a subsequent one in six patients with frontal lesions and six normals. Subjects were asked to name the two white letters embedded in rapid sequences of 15-24 black letters presented centrally on a video monitor at rates of 6 or 8/sec. After 20 practice trials, 60 sequences were presented in which the first target letter (T1) appeared randomly at times 9 through 15 and in which the second target letter (T2) appeared randomly at positions 1, 3, 5, or 7 following T1. Both frontals and normals showed near perfect identification of T1. In the case of T2, normals showed near perfect performance at all positions while frontals showed a poorer identification at positions T2 at T1+1 and T1+3 (50% correct), but not at T1+5 and T1+7 at a rate of 8 letters/sec. Frontals did not show this deficit at the slower presentation rate. These results indicate that the deficit in frontal patients may be due to pronounced or longer lasting interference on subsequent processing in frontals than normals.
413.9

We previously reported that localization of sound sources in hemispherectomized patients was less accurate than that of the controls in the homolateral hemisphere, and we hypothesized that this was due to a lesion in the midbrain. Moreover, their performances obtained with fixed sources were generally more precise than those obtained with moving sources (Neuropsychologia, 1994 in press). In order to precisely evaluate the effects of the hemispherectomy on free-field sound localization performances, the present study examined response accuracy to auditory targets in one patient, shortly before and 6 months after a functional right hemisecotomy was performed. We also evaluated the performances of three matched controls. Listeners reported sound positions by pointing with their dominant hand to the apparent sound location in an anechoic chamber. Two conditions were tested: (i) localization of a fixed-sound source and (ii) localization of the beginning and the end of a simulated moving stimulus. Prior to the operation, the patient was performing almost as well as the controls when fixed sources were used, but was significantly worse when moving sources were used. After the operation, the patient’s responses to fixed sources were less accurate than those of the controls in all positions tested in the hemifield contralateral to the removed hemisphere. Unexpectedly, the patient was now able to perform the moving task. These results are discussed in terms of the effects attributable to the surgery per se and they suggest the existence of a differential involvement of cortical and subcortical structures in the processing of stationary and moving sounds (supported by FCAR and CRNG).

413.11

VISUOSpatial ATTENTION SHIFT IN CEREBELLAR DISORDER. S. Yamaguchi1, H. Tsuchiya and S. Kobayashi, Third Div. of Internal Medicine, Shimane Med. Univ., Izumo, 693 Japan.

Cerebellar patients are known to be suggested to be involved in attentional shift mechanism. The present study investigated contributions of cerebellum on visuospatial attentional ability in a trial-by-trial cueing task involving covert orientation of visual attention. Event-related poten-
tials (ERPs) and reaction times (RTs) were measured in patients with cerebellar degenerative disorders and age-matched controls. The cerebellar group had slower RTs to both valid and invalid targets. The effects of cue validity on RTs were larger for the cerebellar group in both the central and peripheral cue experiments, suggesting efficiency of the attention shift process in the cerebellar group. ERP data over the cue-target interval (i.e. 800msec) in the central cue experiment demonstrated comparable effects of voluntary attention shift in both groups, the effects which were reflected in negative potential shifts at contralateral parietal and temporal sites in the early stage and central and frontal sites in the late stage. Peripheral cues also generated comparable effects of the early automatic and late voluntary attentional shift on ERPs in the cerebellar and control groups. The only difference in ERPs was CNV amplitudes, which were significantly diminished in the cerebellar group. These results suggest a preserved ability of visuospatial attention shift in cerebellar disorder.

413.12

Recent research in the field of intelligence has witnessed a resurgence in the search for brain correlates of intelligence. The current study examines two such explanations: brain volume and nerve conduction velocity. This study is composed of two phases. In Phase I, 40 healthy adult female subjects (ages 20 to 30 years) underwent magnetic resonance imaging (MRI) and nerve conduction velocity (NCV) procedures. It was found that brain volume was significantly correlated with IQ (r=.395, p<.05), but that NCV measures (taken along the median nerve and ulnar nerve) were not correlated (r=.12 and r=.02, both n.s.). A reanalysis of this and past NCV findings indicated a possible sex difference with NCV differing to be equal in males but not in females. Finally, it was found that brain volume and NCV were not correlated (r=.10 to .19, all n.s.). Phase II of this study, which is currently under way (36 subjects collected to date, with new subjects being obtained at the rate of about 3 per week), expands the study with a sample of healthy adult male siblings. Beyond a simple replication, Phase II uses MRI procedures that allow for advanced multi-exponential calculations of white matter relaxation times in addition to the brain volume, and therefore additionally in addition to peripheral, NCV. The use of siblings allows for assessment of within as well as between family effects, and so can illuminate the type of genetic and/or environmental factors at work in obtained correlations.

414.12

CENTRAL AUDITORY PROCESSING IN A FAMILY WITH 'DYSSARThIA'. D. M. Daly, Box 210685, Dallas, TX 75211-0685.

'Dyssarthria' includes various disorders involving control of movements in speaking. Using sets of computer synthesized sounds we examined auditory processing in a 6 yr. old boy referred with a diagnosis of 'functional dysarthria' and seven other members from three generations of his family. All had appropriate audiometric thresholds for age. One sibling, mother, and maternal grandmother reported similar problems: their speech is difficult for unaffected individuals to understand, yet they understand each other with less difficulty; they have difficulty drawing circles, turning a screwdriver/nothing hair curlers, or pedaling a bicycle; they are athletically challenged; they also have difficulty 'carrying a tune'. Two generations have received school based speech therapy; all three generations reported that speech improved spontaneously at 10-11 yr. All performed at or above grade level on core subjects. Unaffected individuals are free of these problems.

On sets of time varying synthesized sounds, neither proband, mother nor maternal grandmother distinguished B/D. Mother and maternal grandmother reported GV as vocable and yet with clear transition 20-30 msec less than controls. The affected sibling also differed significantly from controls. On sets of frequency varying sounds (BDG) mother and sons were less aberrant. Paternal grandmother, father, paternal grandfather and uncles were unaffected. There were no apparent transitions. Concurrent testing of affected and unaffected members confirmed marked perceptual differences; LRCS measures of divergence from individual and control composites substantiated these findings. Distribution in the pedigree is compatible with autosomal dominant expression.

412.15 A VERBAL ABSTRACTION DEFICIT IN MULTIPLE SCLEROSIS. W. W. Rebusck*, K. A. Harris, G. E. Bianco, R. H. Paul and E. L. Wilkins. Dept. Psychiatry & Behavioral Sciences, University of Oklahoma Health Sciences Center, P.O. Box 28901, Oklahoma City, OK 73190.

Impairments on nonverbal tests of abstraction by patients with multiple sclerosis (MS) have been reported frequently, but findings on verbal abstraction tasks are mixed. To examine the status of verbal reasoning in comparison to nonverbal reasoning in MS we administered the Shipley Institute of Living Scale (SILS), the Visual and Card Sorting Test (VCST), and a shortened version of the Free Sorting part of the California Card Sorting Test (CCST) to 100 MS patients and 32 age- and education-equated control subjects. The MS group achieved lower scores on the VCST, lower correct sorts on the CCST, and lower scores on the Abstraction scale from the SILS than did control subjects. Patients also scored lower on the Vocabulary Scale from the SILS, but because they also attained lower Conceptual Quotients, their poorer performance on the verbal abstraction cannot be attributed solely to lower verbal ability. Persuasive responding by patients was clearly elevated on the VCST, marginally increased on the CCST, and did not occur on the SILS, suggesting that difficulties in generating and identifying concepts are the major reasons MS patients often have difficulty on tests of problem solving or abstract reasoning.

412.19 DOES IMPAIRMENT OF WORKING MEMORY PRECEDE DEVELOPMENT OF DEMENTIA IN EARLY ALZHEIMER'S DISEASE? S. Martha, H. Chenow*, H. Bergman, N. Phu, Bloomfield Center for Studies in Aging, Lady Davis Institute, Jewish General Hospital, Montreal, Quebec, Canada.

Working memory (the store capable of holding information in memory while another cognitive task is performed) is impaired in subjects with dementia of the Alzheimer type (DAT) compared with elderly control subjects. We wished to examine whether a deficit in memory impairment may be demonstrable in elderly subjects not yet meeting criteria for dementia but having Age Associated Cognitive Decline (AACD).

Working memory was assessed with the Brown/Peterson task on 15 DAT, 17 AACD, and 12 elderly control subjects. On this task, consonant trigrams (three letters presented at once) were recalled over intervals of 3s, 5s, 10s and 20s. During the interval the subject is either allowed to rehearse the material with no distraction or is disrupted with subsidiary tasks (articulatory or digit rehearsal).

The results indicated that the average percentage of trigrams recalled by the three groups differed significantly (F = 9.20, P = .001). DAT subjects showed a moderate decline after 5s (35%) and 10s (42%) delay intervals, and the AACD subjects showed a mild decline at both the 5s (83%) and 10s (77%) interval. Elderly subjects showed a very slight decline at both conditions.

The percentage of trigrams recalled with digit reversal distraction after 5s indicated that the control subjects never showed greater than a 20% decline from baseline performance. 4/17 of the AACD subjects, and 10/15 of the DAT subjects demonstrated a decline below this performance level. These results demonstrate that working memory is not only impaired in DAT, but also in AACD subjects.

It is known that up to 2/3 of AACD patients eventually go on to dementia. Since working memory impairment can be demonstrated in a percentage of the AACD subjects it is possible that this might be a cognitive marker for future development of dementia.

412.20 IMPAIRED AUTONOMIC RESPONSES TO EMOTIONALLY SIGNIFICANT STIMULI IN ALZHEIMER'S DISEASE. C. C. Chu*, D. Tran, A. R. Damasio. Dept. of Neurology, Univ. Iowa, Coll. Med., Iowa City, IA 52242

Pathological changes in Alzheimer's disease (AD) selectively involve layer V neurons in Brodmann's area 25, posterior orbitofrontal cortex, and anterior insula, which project directly to subcortical autonomic centers. Disruption of these cortico-autonomic projections would be expected to compromise autonomic responses. We hypothesized that autonomic responses elicited by emotionally significant pictures would be impaired in AD patients. Color slides with high (target) or low (control) emotional significance were shown for 6-8 s while each stimulus was presented. Three to five target and control stimuli were presented in randomized order. The P300 components to the target and novel stimuli. Topographical maps of activity to the novel stimuli show a pattern of frontal activation in children not seen in adults. Results are compared to previous work with infant subjects and are discussed in terms of differences in attentional capacity, as well as the role of hippocampal and frontal lobe development in mediating the novelty response.

412.16 DISORDERS OF PROSODY IN PARKINSON'S DISEASE. H. Cohen*, Laboratory of Cognitive Neuroscience, Université du Québec, P8 8888, Station A, Montreal, QC, Canada H3C 3P8

Disturbances of intonational patterns of speech are some of the most common signs in Parkinson's disease (PD). If deficits in movement planning are responsible for this deterioration, we should then observe greater impairment in PD as the speech production tasks become more difficult. In this study we attempted to determine whether PD patients are more impaired, relative to controls, in the production of simple vowel syllables in increasingly more complex intonation contexts. Twenty non-demented PD patients (mean age = 68.6) and 15 controls matched for age and education (all subjects ≤ 75 yr) and no other neurologic or psychiatric disorder were asked to produce the vowels (a, e, i, o, u) in four intonation conditions: stable contexts (low and high intonation) and two unidirectional change contexts (ascending and descending intonation) for a period of five seconds. Subjects were recorded individually in a soundproofed room and speech was then digitized to extract indices of fundamental frequency (F0). ANOVAS were conducted on F0 measures, for each intonation condition, to determine the extent of group differences. Except for the low stable intonation condition, analyses revealed main effects of Group, suggesting a significantly more restricted F0 range in PD patients when producing vowels in stable high, as well as in ascending and descending intonation conditions (p < .001). The results suggest that the subcortical structures affected in idiopathic movement disorders are also involved in disorders of prosody. These structures are implicated in deficits in planning and sequential execution of movement and cognitive acts.

413.3 FACILITATION OF AMPA RECEPTOR ACTIVATION INCREASES CLASSICAL FEAR CONDITIONING IN RATS. M. Rogan*, U. Stubli, J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003.

Rogan and LeDoux have previously shown that AMPA receptor agonists facilitate fear conditioning.

The authors examined the effects of ETOH pretreatment on classical conditioning and found that it selectively impairs the acquisition of contextual conditioning.

The study investigated the role of perirhinal cortex lesions in disrupting classical fear conditioning.

413.6 MEDIAL ORBITAL CORTEX LESIONS INCREASE RESISTANCE TO EXTINCTION BUT DO NOT AFFECT ACQUISITION OF FEAR CONDITIONING. M.A. Morgan* and J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003.

The authors found that lesions of the medial orbital cortex increase resistance to extinction but do not affect acquisition of fear conditioning.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
SEPTAL LESIONS POTENTIATE FREEZING BEHAVIOR TO CONTEXTUAL BUT NOT TO PHASIC CONDITIONED STIMULI.

P.D. Sparks* and J.C. LeDoux. Department of Psychology and Center for Neural Science, New York University, NY 10003.

Damage to the hippocampal formation interferes with the conditioning of fear responses to contextual but not phasic conditioned stimuli. Given the anatomical similarities and functional relationship between the hippocampus and the septum, we examined the effects of septal lesions on the conditioning of fear reactions to phasic and contextual stimuli. In the first experiment, rats with electrolytic lesions (n=9) or sham operations (n=6) were examined. Thirty days after surgery, blocks of two conditioning trials consisting of a tone (10kHz, 75 dB, 20 sec) paired with a foot shock (500 msec, 0.5 mA) were presented on two consecutive days. Tone alone trials were presented each day thereafter until extinction criterion was met. The amount of freezing elicited by the context but not by the tone was greater in the septal lesioned animals than in controls. The lesions involved the lateral and dorsoventral hippocampus.

Evidence from these experiments suggests that the hippocampal septal connections are necessary for the expression of contextual fear conditioning.

HIPPOCAMPAL LESIONS BLOCK LATENT INHIBITION BUT NOT NEGATIVE TRANSFER BY A NON-NMDA RECEPTOR MEDIATED PROCESS. S. J. Young*, S. Maren and M. S. Fanselow, Dept. of Psychol., Univ. of Cal., Los Angeles, CA 90024-1563.

Latent inhibition describes a Pavlovian learning deficit caused by preexposure to the conditional stimulus (CS). Negative transfer is also a learning deficit but is caused by prior pairing of the CS with a weak unconditional stimulus (US). The two phenomena have traditionally been considered the result of a similar CS processing deficit. Evidence that both negative transfer and latent inhibition are context specific support this speculation. Latent inhibition is reversed by hippocampal lesions but the hippocampus does not block negative transfer. We have examined Experiment 1 examines the possibility that transfer is hippocampus dependent while latent inhibition is reversed by hippocampal lesions but the hippocampus does not block negative transfer. These results provide evidence that latent inhibition and negative transfer are different. The second set of experiments examined the role of NMDA receptors in latent inhibition. Application of a competitive NMDA receptor antagonist (APV, 5 µg/μl) had no impact on hippocampal and context dependent latent inhibition. These results are surprising because NMDA receptor mediated processes in the hippocampus are important for learning to recognize contextual cues. Supported by NIH 1F31MH10380-01 (SLV) and NSF BNS 9008820 (MSF).

SEX DIFFERENCES IN HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) AND PAVLOVIAN FEAR CONDITIONING IN RATS. M. S. Fanselow*, S. Maren and B. DeOca, Department of Psychology, University of California, Los Angeles, CA 90024-1563.

An emerging body of evidence indicates that the hippocampus is required for some forms of classical conditioning, particularly Pavlovian fear conditioning to contextual stimuli (CSs). Lesions placed in the fornix, dorsal hippocampus, or entorhinal cortex produce marked impairments in contextual fear conditioning. Recently, there has been a focus on what aspects of experience are critical for the acquisition and expression of contextual fear conditioning. In the current study, we examined the effects of hippocampal lesions on the acquisition and expression of contextual fear conditioning. We found that hippocampal lesions impaired the acquisition of contextual fear conditioning but had no effect on its expression. These findings support the idea that the hippocampus is necessary for the acquisition of contextual fear conditioning but not for its expression.

Supported by NSF grant BNS-9008820 to MSF.

C-FOS mRNA EXPRESSION FOLLOWING FOOTSTOCK STRESS AND CONTEXTUAL FEAR CONDITIONING. J. B. Rosen 1, M. S. Fanselow 2, S. L. Young 3 and S. Maren 1. 1Biological Psychiatry Br., NIMH, Bethesda, MD 20892, 2Psychol. Dept., Univ. of Cal, Los Angeles, CA 90024-1563.

Rats display conditional freezing behavior to contextual cues associated with footstock. Although the amygdala plays a prominent role in the expression of fear, little is known about its function in fear conditioning. We examined the role of the amygdala in fear conditioning by determining the effect of amygdaloid lesions on the expression of contextual fear conditioning. We found that lesions of the amygdala produced a complete and selective block of contextual fear conditioning.

Supported by NIMH 1F31MH10380-01 and NIMH grant MH-39786 to MSF.

DIFFERENTIAL EFFECTS OF VENTRAL AND DORSAL PERIAQUEDUCTAL GRAY (PAG) LESIONS ON DEFENSIVE RESPONSES OF RATS TO CATS, SHOCK AND TASTE AVERTION. B. DeOca, J. P. DeCola, J. L. Treadway and M. S. Fanselow. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

Anatomical structures within the midbrain have been implicated in fear-related and defensive behavior. The present experiments examined the effects of lesions of the midbrain that included damage to the ventral portions of the periaqueductal gray (PAG) on defensive freezing responses to rats of the presence of a cat. Lesions that spared the ventral PAG did not affect freezing to a cat even if they produced extensive damage to the dorsal PAG. These results support the idea that the PAG plays a role in defensive response to rats of the presence of a cat. Lesions that spared the ventral PAG did not affect freezing to a cat even if they produced extensive damage to the dorsal PAG. These results support the idea that the PAG plays a role in defensive response to rats of the presence of a cat.
LESIONS OF THE AMYGDALA BLOCK CONDITIONED EXCITATION BUT NOT CONDITIONED INHIBITION OF EAR NOISE-INDUCED PAIN-POTENTIATED STARTLE.

W.A. Falle,* A.M. Davis, Dept. of Psychiatry, Yale Univ. Med. Sch., 34 Park St., New Haven, CT 06508.

Although much is known about the neural systems responsible for the acquisition and expression of conditioned fear, little is known about the neural systems responsible for the inhibition of fear. We have recently described a behavioral procedure for producing conditioned inhibition of fear-potentiated startle effect. Following training in which a light is repeatedly paired with shock (i.e., shocks) and a light-noise compound stimulus (i.e., light + shock), the animals acquire the ability to inhibit fear-potentiated startle to the light in a noise–light summation test (Falle and Davis, 1993; Neuroscience. Aflr. vol. 19, p.172, 115.6).

Amygdala lesions have been shown to disrupt both phase and magnitude of the fear-potentiated startle (Falle and Davis, 1993). When rats were given 15 light–shock pairings on each of 2 days, followed by a light-alone test on the third day, the magnitude of the startle response was increased. The lesioned rats showed a larger increase in the startle response magnitude than did the sham-operated controls. This is consistent with the hypothesis that the amygdala is involved in the production of conditioned inhibition of startle. The results are consistent with the hypothesis that the amygdala is involved in the production of conditioned inhibition of startle.

These results indicate that lesions of the amygdala critical for initial performance of fear-potentiated startle are not critical for the expression of conditioned inhibition.

DIFFERENTIAL EFFECTS OF AMYGDALA LESIONS ON ANTINOCICEPTIVE AND CARDIOVASCULAR RESPONSES TO CONDITIONAL AND UNCONDITIONAL AUDITORY STRESSORS. F.J. Hellstrom, G.L. & S.T. Tershner, Dept. of Psychology, University of Wisconsin, Milwaukee, WI 53201

Exposing rats to a tone that has been paired with shock or to a novel loud noise will produce a set of fear-related defensive behaviors which includes a simultaneous increase in arterial blood pressure (ABP) and decrease in sensitivity to pain. In the present study we directly compared the expression of conditioned and unconditioned fear responses using these two dependent measures within small groups of rats (9) which were presented to one of two groups: conditioned (C) or unconditioned (U). The conditioned group was exposed to a series of paired (or unpaired) presentations of a tone CS (60sec, 72dB) and shock and then retrained with a tone CS to the classical actions of a response. During subsequent testing all rats were exposed to both the CS and white noise (60 sec, 95dB) while recording ABP and radiometric heat flick (TF) latencies. Both auditory stimuli produced significant inhibition of TF in sham-operated animals that had received paired training. As reported previously, amygdala lesions blocked both fear of the CS and white noise while TBs also produced large time-dependent elevations in ABP with the noise-evoked response being considerably larger. However, animals with BLA damage that blocked hyperalgesia showed normal or potentiated ABP responses to both stimuli. These results suggest that neural systems responsible for the expression of learned versus unlearned fear responses may not differ although the control of ABP and TF may be dissociable within the amygdala.

Our laboratory has proposed a fictitious acoustic startle circuit that consists of the auditory nerve, pontine cochlear nucleus (VCN), an area ventral to the ventral cochlear nucleus (VCN, also known as the cochlear nuclei) of neurons in the spinal cord (Davis et al., 1992). The dorsal nucleus of the ventral cochlear nucleus (VCN, also known as the cochlear nuclei) consists of neurons in the spinal cord that are involved in the acoustic startle circuit more precisely. For example, lesions of VLN in the original study included the cochlear nucleus was primarily the auditory relay nucleus for the central auditory system and the central auditory system, including the central auditory system and the cochlear nucleus. Therefore, the present study re-evaluated the role of the structures previously implicated in the primary acoustic startle circuit using lesions bilateral, cochlear and central auditory systems, and the central auditory system.

Small lesions of VLN in the present study were used to eliminate the startle reflex, whereas large lesions included the entire area ventral to VLN and an area lateral to the ventral cochlear nucleus. Lesions were found in the ventral cochlear nucleus and in the area lateral to the ventral cochlear nucleus. In rodents, the lesioned neurons were found in the cochlear nucleus, named cochlear root neurons (CRN), that receive input from the cochlea, and have very little cytoplasm that consists of collagenous fibers terminating contralaterally in the ventromedial PRC (Lopez et al., 1993). Therefore, it must have been suggested that RN may be involved in an auditory paradigm (Verstraete & Fransen, 1990) in the acoustic startle reflex. Kainate lesions of CRN reduced the acoustic startle reflex by 90%, which is significant to the fact that these animals still retained the startle response and intact excitatory potentials recorded from the VCN using an 80-97 Hz white noise pulse or 10 Hz tone bursts.

Although the role of the VCN is yet to be fully determined, we now think that the acoustic startle reflex is more complex than it had been generally thought, consisting of only three synapses onto 1) RN, 2) neurons in the ventromedial PRC, and 3) neurons in the brain stem and spinal cord.

In a variety of mammalian species, the startle response elicited by a strong stimulus (the pulse) is reduced when preceded by a weak stimulus (the prepulse) which itself does not elicit startle. The phenomenon of "prepulse inhibition" (PPI) is often viewed as the mechanism of "memory gating" to the imperative stimulus (the pulse). For all groups the instrumental interval was varied between 15 and 30 sec (mean = 15 sec).

One hundred and five min. after the completion of the 9th trial session, all rats were subjected to another 10-trials session of active testing (no prepulse) with the trial interval varied between 30 and 60 sec (mean = 60 sec). As expected, the Prepulse group injected with MK-801 showed less prepulse inhibition than did the saline group. Additionally, the Prepulse group showed less freezing than did the saline group, consistent with the suggestion of NMDA receptors in the acquisition of conditioned fear. Responding to startle alone trials was similar in both the startle alone and the prepulse (excluding prepulse trials) paradigms. MK-801 appeared to increase responding to startle alone trials irrespective of paradigm. It is concluded that MK-801 produces deficits in prepulse inhibition but also in conditioned fear sensitization. Supported by ACS and NH&MRC.

MK801 ATTENUATES BOTH STARTLE PREPULSE INHIBITION AND CONDITIONAL FEAR SENSITIZATION. J. Crumley, T. Hargreaves, G. Pausini, and M. Neumaier, School of Psychology, The University of New South Wales, Sydney, 2052, Australia.

The non-competitive NMDA receptor antagonist MK-801 (MK-801) is known to decrease prepulse inhibition in the auditory startle paradigm (Munzchoth and Geyer, Neuropsychopharmacology, 1989, 2:299-308). The present study replicates and extends these observations by measuring freezing (an index of fear sensitization) in the prepulse inhibition paradigm as well as in a startle alone paradigm. Rats were administered with either MK-801 (0.1 mg/kg s.c.) or saline and presented 20 min later with 97 startleeliciting (122-dB) white noise stimuli. For rats in the prepulse inhibition paradigm, 48 of the 97 startle stimuli were preceded (100 msec earlier) by a low intensity (80-dB) white noise stimulus (the prepulse). For all groups the trial interval was varied between 10 and 20 sec (mean = 15 sec).

One hundred and five min. after the completion of the 9th trial session, all rats were subjected to another 10-trials session of active testing (no prepulse) with the trial interval varied between 30 and 60 sec (mean = 60 sec). As expected, the Prepulse group injected with MK-801 showed less prepulse inhibition than did the saline group. Additionally, the Prepulse group showed less freezing than did the saline group, consistent with the suggestion of NMDA receptors in the acquisition of conditioned fear. Responding to startle alone trials was similar in both the startle alone and the prepulse (excluding prepulse trials) paradigms. MK-801 appeared to increase responding to startle alone trials irrespective of paradigm. It is concluded that MK-801 produces deficits in prepulse inhibition but also in conditioned fear sensitization.

EFFECTS OF ENTORHINAL CORTEX APOSIONS ON ODOR- AND CONTEXT-GUIDED FEAR CONDITIONING. T. Oros* and K.M. Schiller. Program in Biopsychology and Behavioral Neuroscience, Dept. of Psychology, Rutgers University, Newark, NJ 07102.

Previous work has demonstrated that hippocampal lesions abolish contextual fear conditioning but spare fear conditioning to a discrete tone CS (Phillips & LeDoux, J. Neurosci., 1992). The present study was conducted to determine the effects of damage to entorhinal cortex on contextual vs. odor fear conditioning using an odor as a CS. A group of male Sprague-Dawley rats received bilateral aspiration of the entorhinal cortex (n=12); a second group served as operated controls (SHAM, n=11). Ten days after surgery all subjects received 6 pairings of an odor (cis-3-Hexanol) and footshock (0.6mA, 2sec) in a distinctive operant chamber. On each of 6 trials the odor was presented for 30sec (delivered by means of a flow-dilution olfactometer and blown through the roof of the chamber) and the footshock overlapped with the final 2sec of odor delivery; the ISI was 4min. Twenty-four hours later each subject was placed in a novel operant chamber and measuring freezing behavior for 5min using a time-sampling method (5sec inter-sample interval). Conditioning to the odor was assessed by placing subjects into a context that was assessed by placing subjects into the operant chamber in which training took place and measuring freezing behavior for 5min using a time-sampling method (5sec inter-sample interval). Conditioning to the odor was assessed by placing subjects into a novel operant chamber and measuring freezing for 5min; the odor CS was presented during the second minute and remained in the chamber throughout the final 5min of sampling.

Histological verification of lesion placement has not yet been completed. However, preliminary analyses suggest that, using this paradigm, entorhinal cortex aspiration attenuates conditioning to both odor and the odor CS as indicated by significantly less freezing behavior for ENT subjects. This pattern of findings is consistent with the effects of hippocampal damage on contextual fear conditioning, but suggests that there may be a degree of sensory specificity in the role of the entorhinal cortex/hippocampal system in odor fear conditioning.

414.1

While the cerebellum is necessary and sufficient for the learning of the classical conditioning of the nictitating membrane in a delay paradigm, the hippocampus is required for the learning in a trace paradigm when at least 300 ms separate the onset of the CS from the US onset. However, the importance of the cerebellum in a trace paradigm is not well understood. While the interpositus nucleus is absolutely necessary for the performance of a previously learned trace conditioning task, its importance during the acquisition phase is not well understood. In an attempt to answer this question, we produced reversible inactivation of the cerebellum by muscimol infusion in the interpositus nucleus during the acquisition phase for a trace paradigm.

Male New Zealand white rabbits were implanted with a cannula in the interpositus ipsilateral from the stimulated eye. Rats were then trained on a trace paradigm (500 ms trace interval) and infused with muscimol before each training session. The rabbits were trained with muscimol infusion for 12 sessions after which they were infused with saline for the following sessions. The animals did not show any CRs during the first 12 training sessions and gradually developed CRs thereafter as would naive animals.

Numerous studies have demonstrated that during classical conditioning of the eyelid reflex, subjects learn to time the conditioned response (CR) so that the peak of the CR occurs at about the time the US is normally delivered. The present study was designed to investigate whether the red nucleus might play a role in accurate timing of the CR. Two groups of rabbits were implanted with cannulae aimed at the contralateral red nucleus (RN). Following recovery, all rabbits received 6 training sessions in which a tone CS (650 ms) was paired with a concomitantly airpuff US (100 ms) so that the interstimulus interval was 550 ms. All rabbits were then given 7 more training sessions in which the ISI was shifted to 200 ms. Prior to the first 3 of these 200 ms ISI sessions, one group was infused with muscimol into the RN while the other group received vehicle infusions into the RN. Consistent with previous studies, all rabbits learned to time the CR during the first 6 sessions so that the peak occurred at about 500 ms after US onset (as measured on CS alone test trials). When switched to the 200 ms ISI, the rabbits which were infused with saline (n=8) readily learned to time the CR so that after the first session, there was a significant reduction in peak CR latency and by the end of the third session, the mean peak latency was 250ms. In marked contrast, the rabbits infused with muscimol into the RN (n=6) performed no CRs during the 3 induction sessions with the 200 ms ISI (and none of the 3 induction sessions without muscimol) the mean peak CR latency did not differ from the peak latency obtained during the last session with a 550 ms ISI (session 6). During subsequent sessions, these rabbits learned to time the CR at the same rate as the saline infused controls. These data indicate that inactivation of the RN (which previous studies have shown to have no effect on the ability to acquire the CR with a 250 ms ISI) disrupts the animal's ability to properly time a previously learned CR. 414.2

Classical conditioning of discrete motor responses of the facial and neck musculature has been shown in rabbits implanted with stimulating electrodes in cerebellar cortex. Following threshold measurements for the elicitation of discrete motor responses, subthreshold stimulation was used as the CS and suprathreshold stimulation through the same electrode served as the US. In this paper we report on a discrimination conditioning following paired (but not randomly unpaired) CS-US trials, extinction following CS-alone trials, and reacquisition with savings, as well as a significant postretraining increase in the lateral cortical excitability. The results are consistent with the hypothesis that the cerebellar cortex plays an important role in the regulation of motor behavior. These findings indicate that the cerebellar cortex is involved in the regulation of motor behavior, in that the cerebellar cortex is involved in the regulation of motor behavior. These findings indicate that the cerebellar cortex is involved in the regulation of motor behavior, in that the cerebellar cortex is involved in the regulation of motor behavior. These findings indicate that the cerebellar cortex is involved in the regulation of motor behavior, in that the cerebellar cortex is involved in the regulation of motor behavior. These findings indicate that the cerebellar cortex is involved in the regulation of motor behavior, in that the cerebellar cortex is involved in the regulation of motor behavior.
414.6 MULTIPLE UNIT RECORDINGS FROM THE TRIGEMINAL COMPLEX.
EYEBLINK CONDITIONED UNIT RESPONSES DURING INTERPOSITOR OR RED NUCLEUS INACTIVATION VIA COOLING. Robert E. Clark, Elizabeth B. Gehl, and David G. Lavond. Departments of Psychology and Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

The trigeminal complex is of considerable interest to researchers of the conditioned eyelink response for primarily two reasons. (i) The conditioned response pathway involves the trigeminal system. (ii) Other research has suggested that the trigeminal complex may also participate in the generation of the behavioral conditioned response or even in the formation of the essential plasticity for the learned response.

Recordings were obtained from the trigeminal complex with the aid of a moveable electrode in rabbits classically conditioned with a tone-conditioned stimulus (CS) and an airpuff unconditioned stimulus (US). Units were examined over a block of 9 trials during normal training. These unit recordings were then examined over a block of 9 trials during reversible cooling lesions of either the interpositus or red nucleus.

Unit responses to the CS and US were frequently observed as were responses that modeled the learned behavioral response. The model responses were found in various regions of the trigeminal complex, but most prominently in the principal sensory nucleus and pars oralis of the spinal trigeminal. Cooling either the interpositus or red nucleus completely abolished the unit models but did not abolish the responses evoked by the CS or US. We conclude that the learning related activity in the trigeminal complex is driven by the interpositus via the red nucleus.

414.7 FUNCTIONAL LOCALIZATION AND NEUROANATOMICAL CONNECTIVITY OF NEURAL SUBSTRATES WITHIN THE ANTERIOR INTERPOSED NUCLEUS INVOLVED IN EXPRESSION OF THE NICTITATING MEMBRANE REFLEX.
S.A. Bartholomew, M.L. Webster, J.R. Bloom, V. Bracha-Barrow Neurological Institute, Phoenix, AZ 85013.

The purpose of the present study was to analyze the neuroanatomical and neurochemical connectivity of projections within the anterior interposed nucleus (AIN) which are critical for expression of the classically conditioned nictitating membrane reflex (NMR) in the rabbit. Animals were chronically implanted with a matrix of three guiding cannulae in the region of the AIN and then conditioned in the standard delay paradigm. A functional map of the AIN was reconstructed from the behavioral effects of systemic muscimol injection (20 mg in 50 nl) along the three injection tracks in trained animals. In each animal, the AIN subregion in which muscimol microinjections most effectively blocked the conditioned response performance was electrophoretically injected with antiserum (PHA-L) and retrograde (CTB) tracers.

The data indicate that besides the traditionally considered AIN connections with the red nucleus, the pontine nuclei, and the inferior olives, several other projections could also be relevant to AIN involvement in the NMR expression: 1) a direct afferent projection from the spinal trigeminal nucleus; 2) direct efferent connections to the mesencephalic periaqueductal and reticular accessory ocularis motor regions; and 3) an efferent projection to the pontine nuclei.

NIH Grants NS 30013 and NS 21958.

Stimulus-induced, perceptually related events are accessed in paired- and nocorres by recording the endogenously generated spatio-temporal patterns of the EEG. They take the form of amplitude modulation in spatial coordinates of a broadband spectrum, aperiodic carrier wave. This finding has been extended to characterize the evolution of such patterns across time and across sensory modalities. Arrays of 64 electrodes (8x8 at 0.79mm spacing) were fixed onto the epidural surface of either the prefrontal, visual, auditory, or somatosensory cortex of 12 rabbits classically conditioned to discriminate between pairs of stimuli (CS+ and CS-) not related to the cortical implant site. The 64-electrode tracings were decomposed by FFT, PCA, RMS, and spectral entropy analysis for 120ms/1/8second windows stepped at overlapping 20msSec intervals. Pattern differences were expressed as Euclidean distances in 64-space. Decomposition and successful classification of the EEG patterns indicated that sensory information is shared between all primary cortical sensory processing areas during lagged time periods after stimulus arrival. Long term EEG recordings have also shown that basaltic spatio-temporal patterns are inconstant and continually evolve at a constant rate corresponding to perceptual drift. A temporal frequency analysis of the EEG has demonstrated no relationship between periods where percept are formed and an increase or decrease in the power spectral density within narrow bands of the temporal spectra. We conclude that cortical function in perception is an endogenous process in which percepts are constructed, not filtered, by chaotic nonlinear dynamics. 414.11 THE ABSENCE OF INTERHESMERIC COMMUNICATION IN THE NORMAL RABBIT, BY J. Suele Russell, Anatomy, Texas A&M University, College Station, TX, 77843-1114.

The presence of the role of the cerebral cortex to inhibit interhemispheric communication in normal rabbits. Normal rabbits (N=40) were used for visual interocular transfer (U.O.T.) using a variety of visual tasks in a two choice situation. They were first trained monocularly to criterion. Following this they were trained with the other eye. No signs of IOT were seen in any animal. All animals had to be rescued from chance and showed no savings. This suggests that the normal intact rabbit functions as a "split brain" animal, i.e. the left hemisphere does not communicate with the right hemisphere.

To test this, a group of rabbits were monocularly trained on a pattern discrimination task. After reaching criterion the animals were hemidescorticized such that half of them had the hemisphere contralateral to the trained eye and the others had the ipsilateral hemisphere lesioned. The results showed that following retraining the intact hemisphere was again established in the normal rabbit. Perfect retention of learning was found following ipsilateral hemidecortication; whereas no retention was evident when the lesion was contralateral.

These findings suggest that the contralateral optical projections play an important role in collateral inhibition of the ipsilateral projections and thus prevent the formation of a bilateral memory record. The lack of such a record would also explain the absence of U.O.T. in the rabbit. Hemidecortication prior to learning was found to disrupt this inhibitory mechanism. Such hemidecorticated rabbits when trained monocularly showed a bilateral memory record and perfect IOT. These findings argue strongly that the rabbit has a cortical inhibitory control over the extent interhemispheric communication required during monocular viewings.

In rats, eyelink conditioning develops dramatically between postnatal day 17 (PND17) and PND24 (Stanton, Freeman, & Stammer, 1992). Retaring with mitomycin-C (67-655) has been found to disrupt cerebellar development (Alvarez, 1969; Comp. Neurol., 120, 269-294). The current study was designed to investigate the effects of mitomycin-C on cerebellar maturation as a result of disrupted eyelink conditioning in adult animals (Thompson, 1988, JNVS, 11, 152-155). These observations suggest that the ontogeny of eyelink conditioning depends upon the maturation of the cerebellum. In the present study, we experimentally manipulated cerebellar maturation by exposing neonatal rat pups to the antimitotic agent methylazoxymethanol (MMAM) during cerebellar cortical neurogenesis. Pups were then trained with eyelink conditioning procedures at different ages. In Experiment 1, pups were given saline or MMAM (0 mg/kg) on PND17 and 25 days again. The results showed that this treatment impaired eyelink conditioning at all ages tested without affecting unconditioned responding or delayed alternation in a T-maze. This study suggests that cerebellar maturation is critical for the ontogeny of eyelink conditioning.

Previous work in our laboratory (Stanton, Freeman, & Shelley, 1992, Revue. Neurosci., 106, 657-665) has determined that the classically conditioned eyelink response in the rat appears during postnatal Day 17 (PND17) and PND24. The current study sought to explore the possibility that conditioning acquisition does occur at PND17, but cannot be expressed until a later age. Animals were trained in a Pavlovian eyelink preparation utilizing a CS and a neutral shock US. Trials of two different frequencies, 2.8 and 5 kHz, were used because some of our recent findings have indicated that CS frequency can be an important variable in the ontogeny of conditioned eyelink responses. A "savings" design was used in which acquisition on PND20 was assessed as a function of prior training on PND17. Group P-P received 300 trials of paired training on PND17 and again on PND20. Performance of this group was compared with that of control groups that received no treatment (N-P) or unpaired training (U-P) on PND17, followed by paired training on PND20. Two control groups (U-U) received no treatment on PND17 and unpaired stimulus presentations on PND20. Response acquisition on PND20 was found to differ reliably as a function of the animals' experience on PND17. Group P-P showed accelerated acquisition of the conditioned eyelink response on PND20 relative to group U-P and N-P, indicating that some unspecified associative learning occurred during paired training on PND17. A surprising finding was that unpaired exposure with the 2.8 kHz tone had a facilitatory effect on PND20 acquisition, while unpaired exposures with the 5 kHz CS resulted in a significant retardation of day 20 acquisition. These findings suggest that maturation of fibers afferent to the cerebellum may play a role in the developmental appearance of eyeblink conditioning in the rat.

The rat eyelink reflex is an attractive model system for studying associative learning. The neural circuitry underlying the last component (R1) involves a three-synapse arc between the 5th sensory nerve and the organizing cellucl (A.o.) muscle, which is responsible for the eyelid closure. In the rabbit, the nictitating membrane response can be associatively modulated by an amygdala-dependent mechanism (Weisz et al., 1992). We were interested in knowing more about the relationship between the amygdala and the eyelink reflex in the rat, which is more convenient for in vitro cellular neurophysiology.

We note that stimulation of the amygdala facilitates the R1 component of the EMG recorded in the c.o. muscle. Twelve rats were implanted with a bipolar nerve cuff placed around the 5th nerve to elicct eyelink and a monopolar stimulating electrode targeted at the amygdala. Both nerve cuff (SNCS) and electrical brain stimulation (EBS; 100-400 μA, 0.2-0.8 ms) of the amygdala resulted in a single biphasic square wave pulse. All electrode placements were histologically verified. We found that amygdal stimulation facilitation R1 maximally when EBS and NCS were presented simultaneously, suggesting that the projection from the amygdala to the site of reflex modulation must be fairly direct.

We are presently using confocal microscopy to trace projections from the amygdala to the facial nucleus, using in vivo injections of anterograde fluorescent tracers into the amygdala and tetramethylrhodamine into the nictitating memble muscle to retrogradely identify motorneurons in the facial nucleus (Lothius and Brown, 1993).

The avian hippocampus is similar to the rat hippocampus in that it processes various types of spatial information. Avian hippocampal neurons can also be used for spatial memory tasks in a variety of species, including pigeons, parakeets, and crows. In particular, pigeons (Columbia livia) have been used extensively to study spatial memory due to their large size, ease of handling, and relatively simple social structure. Pigeons are able to learn and remember a variety of spatial tasks, including finding food in a novel environment, navigating through a maze, and even distinguishing between different types of visual stimuli.

Previous research has indicated that some species of birds, such as the black-capped chickadee (Parus atricapillus), are able to orient themselves using the sun as a compass. This orientation is thought to be important for food-finding behaviour, as chickadees often need to locate food resources in their environment. To study this behaviour, the researchers fed chickadees with black sunflower seeds, which chickadees are known to prefer. The birds were then exposed to a circular arena where they were given the choice of flying towards a real sun or a simulated sun, which was positioned at an angle of 45 degrees from the real sun. The results showed that the chickadees were able to orient themselves using the sun as a compass, suggesting that they use the sun as a cue for orientation.

Several recent studies have described sex differences in the size of the hippocampus that are correlated with ecological differences in the use of space. Male pigeons and female brood-parallel pigeons possess different spatial representations compared to non-parallel pigeons and male pigeons, respectively. This difference in the size of the hippocampus is correlated with changes in the use of space and the ecological differences described correlations could be advantageous. Black-capped chickadees (Parus atricapillus) store food and retrieve their stashed caches using spatial memory for cache sites. The present study examined sex differences in caching, cache retrieval, and accuracy for cache sites. The results indicated that the sex differences in caching were due to the size of the hippocampus. This result suggests that the size of the hippocampus is correlated with the use of spatial memory and the ecological differences described in the use of space and sex.

In the forebrain of domestic birds several brain regions are involved in early filial imprinting. While the immediate hyperstriatum ventrale (MHV) and the hyperstriatum accessorium (LPO) are not involved in visual imprinting, a system of interconnected forebrain areas such as the hyperstriatum ventrale externum (HVE), the hyperstriatum accessorium (LPO) and the caudal neostriatum (Ndc) is involved in auditory imprinting. Since a natural imprinting object combines visual and acoustic features, we postulate that in the imprinting region there must exist, in which the two sensory modalities are processed on a higher associative level. By using 2-deoxyglucose (2-DG) autoradiography, we could localize the activation patterns of acoustically or visually stimulated chicks with a high contrast against the background of the visual control. We conducted two different imprinting procedures: i) individual chicks were imprinted on rhythmic 400 Hz tone pulses without presenting visual stimuli, ii) individual chicks were imprinted on a rotating red flashing light without presenting auditory stimuli. During the 2-DG experiment imprinted chicks of both groups were exposed to either the visual or acoustic imprinting stimulus, respectively. A region in the dorso-caudal part of the neostriatum, which we term dorsocaudal neostriatum (Ndc), was strongly labelled in the acoustically as well as in the visually imprinted chicks. In order to rule out that the activation of emotional stress during the 2-DG experiment, we investigated the activation patterns in naive, unimprinted chicks, which were exposed. Other brain areas in the region of the Ndc were activated, which was consistent with the idea that the Ndc is a key structure in the learning of imprinting.

414.21  Dopamine in Learning Relevant Forebrain Areas of the Domestic Chick: A Combined Immunohistochemical/Tracing Study M. Metzger, H.J. Böcher* and K. Braun. Federal Institute for Neurobiology, Braunschweig, 39118 Magdeburg & Dept. of Biology, University of Bielefeld, FRG.

As demonstrated by 2-deoxyglucose autoradiography, acoustically imprinted domestic chicks develop an increased metabolic activity of several telencephalic areas, including the medio-dorsal neostriatum/hyperstriatum ventrale (MNV), the lateral parolfactory (LPO) and the dorsal neostriatum caudale (Ndc). Since there is no evidence for dopaminergic input to these areas, it is likely that the dopaminergic activity is mediated by a different neurotransmitter. To study the effects of dopamine DA stimulation, we have used an antibody to DA (dopamine), which labels all dopaminergic neurons in the brain. We then incubated the brains with dopamine and examined the distribution of the antibody. The results indicated that dopamine stimulation had no effect on the distribution of the antibody, suggesting that dopamine DA stimulation has no significant effect on the distribution of the antibody.

415.1 ACCURACY OF SPATIAL NAVIGATION: THE ROLE OF PLATFORM AND TANK SIZE. C.F. Maciewicz* and R.M. Bauer. College of Pharmacy, Tobacco & Health, State University of New York College of Medicine, University of Kentucky, Lexington, KY 40504.

The Morris water maze task has great popularity for assessing both the cognitive processes and spatial ability of animals; it involves the most time-consuming task of spatial learning. However, little systematic attention has been given to the role of several major parameters (e.g., tank and/or platform size) which may provide very different "instructions" to the animal. Adult Sprague-Dawley rats were trained for 90 days of age under one of three conditions: a small (3cm²), medium (10cm²), or large (14cm²) escape platform in a standard 1.2m diameter tank. All animals (n=18) received 9, 8, and 4 training trials on three consecutive days followed immediately by a probe test trial on the third day. After a 10-hour interval, the animals received 4 additional training trials followed by a second probe test trial (the previous extraneous context). Platform size differed during acquisition—the most rapid decrease in latency was associated with the largest platform. All groups demonstrated a significant spatial bias during the test trial. In marked contrast to the training data, the lateral crossing measure, the zone on as index of spatial accuracy, was enhanced inversely with platform size. Additional experiments demonstrated the generality of this relationship between spatial accuracy and relative platform size (1:60 - 1:450) was invariant to tank size (Uffen, 1:20). All groups performed significantly worse than naive animals when tested in an equivalent platform. The results of these studies were interpreted as follows: since rats are able to overcome a sensory-motor deficit, they are able to learn spatial cues which are not available in the environment. However, the ability to learn spatial cues is influenced by the size of the platform, with larger platforms facilitating learning. This finding suggests that the Morris water maze task may be a useful tool for assessing spatial learning and memory in rats. Additional experiments are needed to determine the extent to which these findings are generalizable to other species of animals.

415.2 HIPPOCAMPAL LESIONS IMPAIR NEGATIVE PATTERNING, BUT NOT CONDITIONAL LEARNING, USING CONTEXTUAL CUES. D.M. Skinner* and D. van der Kooij. Dept. of Anatomy and Cell Biology, University of Toronto, Toronto, Ontario, M5S 1A8.

While performance on tasks employing spatial and contextual cues depends on the integrity of the hippocampus, we have previously shown that acquisition of conditional discriminations is not impaired by hippocampal lesions. Animals were trained on a conditional discrimination task that employed task aversiveness. Half of the animals were placed in a novel context (a distinct test box) prior to a flavor-LiCl pairing. On alternate days animals were exposed to another distinct context prior to the flavor-LiCl pairing. Aspirin lesions of the hippocampus acquired the task (learning to drink on safe context trials), but at a slightly slower rate than sham controls. We now report that the acquisition of hippocampal lesion of the hippocampus severely impair acquisition of a negative patterning task that employed the same cues. In a negative patterning task each of two cues is followed by an unconditioned stimulus when presented singly, but the unconditioned stimulus is withheld when both cues are presented together. We used a novel 0.1% saccharin solution and a distinct context as cues. Each of these cues alone signaled an injection of LiCl, but when presented together signaled the absence of LiCl. Both lesioned and sham animals acquired the conditional component of the task, consuming more saccharin in the rats novel context than in the home cage. However, the addition of context-LiCl trials impaired the performances of both groups. With further training, the lesion sham animals acquired the negative patterning task.

Contextual cues are important in determining performance in behavioral "interference" paradigms, such as extinction, in which the CS is associated with different outcomes in successive phases of the experiment. After extinction, contexts control performance by retrieving the current relation between the stimuli. This research examined the role of the hippocampus in mediating the effects of context and extinction in a shuttle box pairing in rats. Half the animals from each group were given CS alone trials in Context A (Cont A, Form A), half in Context B (Cont B, Form B). Testing was conducted in Context A. None of the groups differed with respect to pre-CS baseline responding, rates of conditioning, or extinction. Rats with fornix lesions (Form A) showed increased spontaneous recovery when compared to controls, but no attenuation of renewal. Suppression ratios (SEM) on the first test trial were: Control A = 044 (Cont B = 08 03), Form A = 41 (04), Form B = 16 04. In reinstatement, the animals responding to an extinguished CS recovered when the animal is given unsignaled presentations in the context of extinction. Animals were reassigned such that half received reinstating US presentations in the same context, half in a context different from extinction. Animals with fornix lesions (Form A) showed extinction in the extinction context did not show reinstated conditioned responding to the extinguished CS, whereas the comparable control group did (Cont A). Suppression ratios (SEM) on the first test trial were: Control Same = 16 06, Control Diff = 44 04 (Form Same = 37 03, Form Diff = 44 05). Results suggest that the hippocampal system plays a role in some, but not all, effects of context after extinction.

415.4 EVALUATION OF TIME OF DAY AS A CONDITIONAL CUE FOR RATS. A. Koerner*, R. J. Sutherland, G. M. Martin, B. J. McDonald, & S. Avery. Dept. of Psychology, University of New Mexico, Albuquerque, NM 87131.

We evaluate representational theories of conditioning which ascribe an important role to when and where an event occurs. We describe 4 discrimination experiments which show that rats' sensitivity to time of day should not be given a special role in theories of learning. Our data indicate that we should distinguish between two types of where: The place of training and the contextual cues present during training.

All experiments involve conditional discrimination training based upon place or time of day. The rats were trained that X, not Y, was correct at Time 1 or Place 1, and that Y, not X, is correct at Time 2 or Place 2. Experiment 1 shows that rats can use time of day as a conditional cue after extensive training if they are required to distinguish between a black and white cue in a M-shaped and that hippocampal damage abolishes the discrimination. Experiment 2 shows that rats do not learn to use time of day as a conditional cue when they are required to distinguish between a left and right turn. Comparison of a control group and the rats showed a win-stay/lose-shift strategy. Experiment 3 shows that rats alter a single reversal readily spatial location as a conditional cue when they are required to distinguish between a black and a white cue in a Y-maze and that hippocampal damage abolishes the discrimination. Experiment 4 shows that rats do not learn to use time of day as a conditional cue when they are required to discriminate between a left and right turn. Experiment 4 eliminates spatially differential response requirements using operant chambers. Experiment 4 shows that rats are capable of using time of day and contextual cues (presence or absence of a clear plastic floor) as conditional cues after extensive training which does not involve changes in location of responding, when they are required to discriminate between a tone and light in an operant chamber. These results question the notion that time is a general salient dimension in discrimination learning.

415.5 A VISUAL CUE ENHANCED BY SOUND IMPROVES SPATIAL LEARNING AND DECREASES RESPONSES TO DISTRACTION IN ANIMALS WITH HIPPOCAMPAL DAMAGE. E. Hedba-Rauer*, T. Briones, and B. Therrien.

The University of Michigan, Ann Arbor, MI 48109.

Spatial disorientation is caused by damage to the hippocampal formation (HPC). We previously reported that a single visual cue improves spatial learning of animals with hippocampal damage but does not improve cognitive performance by a simple environmental distractor. This study used a visual cue enhanced by sound to determine the effects of a multi-modal stimulus (cue) on cue navigation in the presence of a visual cue with an auditory cue. Both trends with HPC damage and females with unilateral damage were not impaired. However, the animals trained with bilateral lesions remained impaired on all measures (p<.05). After four days of testing with the cue, a distractor was introduced. In the presence of the enhanced cue, males with unilateral damage were not distracted performing as well as controls on all test days. In contrast, all females with HPC damage and males with bilateral lesions were more distractible than controls (p<.05). However, all animals were housed in the presence of the enhanced cue as compared to animals exposed to a single visual cue. We conclude that a visual cue enhanced by sound markedly improves spatial learning of disoriented animals. Importantly it eliminates or reduces the disruptive effect of a simple environmental distractor in animals with HPC damage.

415.6 RATS WITH HIPPOCAMPAL DAMAGE LEARN SPATIAL RELATIONSHIPS WHICH THEY CANNOT USE TO GUIDE NAVIGATION. R. J. Sutherland, G. M. Martin, C. Edwards, & K. Williams, Deps. of Psychol., Univ. of New Mexico, Albuquerque, NM 87131 and Memorial Univ. of Newfoundland, St. John's, NFLD, A1B 3X9.

Many theories of hippocampal function hold that its activity represents a mechanism of relational information. Medial temporal lobe amnesics demonstrate effects of prior learning about an episode if tested in indirect memory tasks, but not in direct tests of memory. We examined rats using two tests of spatial relational memory in the same environment; one direct (place navigation) and one indirect (disambiguation of exploration). Twelve rats were trained in the Morris water task to locate a fixed, hidden platform. Half of the rats received microinjections of a neurotoxin solution of kainate+colchicine. All rats were allowed to explore a dry pool in a new room in daily 5-min sessions for 37 days. Four object stimuli were present in the pool in fixed locations. Two probe trials were conducted: 1) the pool and 4 objects were rotated 180° relative to the room and 2) two of the objects were removed and the pool was tested for place navigation in the new and the old room. The rats with HPC damage were profoundly impaired in the place navigation in the new and old rooms. In contrast, control rats and rats with damage detected the changes in spatial relationships in probe trials, as shown by reliable increases in exploration. Thus, learning the layout of an environment survives HPC damage, although this information is not used for accurate navigation.
415.1
HIPPOCAMPAL DAMAGE IN RATS CAUSES RETROGRADE AMNESIA FOR PLACE NAVIGATION BUT NOT FOR OBJECT DISCRIMINATIONS. R.S. Astur*, D.G. Mump, M.P. Weisend, and R.J. Sutherland. Depts. of Psych. and Physiology, Univ. of New Mexico, Albuquerque, NM 87131.

In order to examine the effects of partial and complete hippocampal lesions on object and place memories, 29 rats were trained on a different object discrimination task each week prior to surgery. To examine place memory, each rat was trained in the Morris water task in two different rooms, 14 and 7 weeks prior to surgery. Bilateral hippocampal lesions were made using multiple intrahippocampal microinjections of ibotenic acid. Ten rats received complete hippocampal lesions, 10 rats received partial hippocampal lesions, and 9 rats received sham lesions.

Retrograde effects were assessed by testing all rats on the five object discriminations and the two pool problems that they had learned previously. Anterograde effects were assessed by teaching rats two new object discriminations and one new pool problem. For the previously learned object discriminations, there were no significant differences between the groups in retaining the discriminations nor in their accuracy in the first five trials of testing. For the new object discriminations, there were no significant differences between the groups in learning either new object discrimination. For the previously learned pool problems, both HFC groups were impaired relative to controls in finding the platform and percent of time spent in the correct quadrant during probe trials. Only the complete HFC group did not learn the new pool problem. These data indicate that HFC is important for navigating to places, but not for object discriminations.

415.9
OBJECT DISCRIMINATION IN NORMAL AND HIPPOCAMPUS-DAMAGED RATS. D.G. Mump*, D. Pretz, R.S. Astur, R.L. Klein, R.J. Sutherland, and G.M. Martin. Depts. of Psych, University of New Mexico, Albuquerque, NM and Memorial University of St. John's, NF.

We examined whether rats can recognize objects independently of viewing perspective. Normal rats and rats with bilateral ibotenic acid lesions of the hippocampus (HFC) were trained to discriminate between three object pairs. Initially rats were trained with the objects in one orientation revealed that the original discriminations were retained (Mean errors to criterion, 4.6 & 5.1 for HFC and normals rats, respectively). Changing the orientation of the objects during training disrupted performance (Mean errors to criterion, 16 & 14 for HFC and normal rats, respectively). The objects were then coated with acrylic to increase the similarity of the objects' surface properties, including odor. Rats that were trained with the objects in the original orientation revealed that the acrylic did not affect performance (Mean errors to criterion, 2.1 & 3.5 for HFC and normal rats, respectively). The final test revealed that switching the orientations of the acrylic-coated objects interfered dramatically with acquisition of the discrimination (None of the rats reached criterion; Mean errors, 78 & 65 errors for HFC and normal rats, respectively). Further tests were carried out to assess the use of spatial information when the correct solution of an object depended upon its spatial location.

Object discrimination performance in our task depends upon object orientation. Moreover, it may be that rats solve object discriminations by distinguishing between object pairs on the basis of a single visual or surface property.

415.11

Fimbria-fornix lesions cause hyperactivity and learning difficulty in rats. During the course of other studies investigating memory deficit in fornix-lesioned rats we had occasion to observe pronounced stereotypic behaviour. Specifically a cannulated knife was used to produce selective lesion to the fornix in 12 Long Evans hooded rats; 9 animals undergoing sham operation served as controls. As expected the animals with fornical lesions demonstrated impaired acquisition, reversal, and working memory in the Morris water maze (p<0.01). However these animals also manifested maintained pretraining hyperactivity and stereotypic behavior. The stereotypic behavior may interfere with the testing of memory in this case, and since lesions to the FF disrupt cholinergic and gabaergic input to the hippocampus these results may also have some relevance to stereotypy in human disease states with similar deficits.

415.8
RETROGRADE AMNESIA FOR PLACE AND CUE INFORMATION AFTER HIPPOCAMPAL DAMAGE IN RATS. M.P. Weisend* & R.J. Sutherland, Depts of Physiology and Psychology, University of New Mexico, Albuquerque, NM 87131.

Retrograde amnesia after hippocampal damage may share the same specificity as anterograde amnesia (Weisend & Sutherland, 1993). We report here a replication and extension of our previous findings. Seventy-four Long-Evans hooded rats were trained in the same pool on two versions of the Morris water task: 1) fixed, hidden platform (place task) and 2) visible platform discrimination (cue task). Rats received 80 trials with the hidden platform and 160 trials with the visible platform discrimination. Hippocampal lesions were made using microinjections of kainic acid. Ten rats served as controls, and 41 rats were lesioned. The lesioned rats were divided into 2 groups based on whether or not they were tested for place and cue task amnesia. Ten rats in each group were lesioned within 2 weeks. Retention testing was performed during the recovery phase, when the rats were retested to the platform and platform position. The rats were retested for place and cue task amnesia, and the lesioned rats showed deficits only on the place task, which is consistent with previous findings. Interestingly, rats that showed deficits on the place task but not the cue task showed deficits in a visible platform discrimination task, which is consistent with previous findings. These results suggest that the hippocampus may be involved in spatial memory, but not in cue memory.

415.10

Fimbria-fornix (FF) lesions in animals are frequently used to model neurodegenerative and traumatic neuropsychitragies observed in humans, and have been used to evaluate the therapeutic efficacy of a variety of interventions, such as grafting or pharmacotherapy. However, the recovery in the absence of interventions (i.e., spontaneous recovery) has rarely been investigated.

The present study was designed to assess spontaneous recovery of spatial learning and navigation in the Morris water maze (MWM) following bilateral kafoxic acid (KA) lesions of the FF. Subjects were 32 male Long-Evans rats. They were pretrained (6 days) or left naive and were either injected with KA or sham lesions. Post-training assessment in the MWM consisted of 3 days of training with the platform in one location followed by 3 days with the platform in the opposite quadrant of the maze. FF cuts produced a marked deficit in navigating to the first platform location. Pretraining attenuated the deficit. Considerable recovery was exhibited over the period of testing for the control group and for the pretrained group. Recovery was again observed which probe tests indicated entailed the use of a spatial strategy.

These results show that considerable spontaneous recovery does occur following bilateral transection of the FF but that recovery of spatial navigation may occur without recovery of spatial learning. Furthermore, these results suggest that a distinction may exist between interventions that enhance or speed spontaneous recovery and those that provide alternative recovery mechanisms. (Supported by NSERC Canada)

415.12

In order to study the involvement of the different components of the hippocampal formation in learning, rats with selective ibotenic acid lesions of the hippocampus, aspiration lesions of the entorhinal/parahippocampal cortex (EC/PFC), and controls were trained in Exp. 1 on spatial and nonspatial versions of an 8-arm Morris maze, and in Exp. 2 on concurrent visual discrimination and spatial rewarded alternation tasks. Rats with hippocampal lesions were especially impaired on the spatial tasks and did not differ from controls on the nonspatial tasks. In contrast, EC/PFC rats were like controls on the spatial tasks but were impaired on the nonspatial tasks. This pattern of results (e.g., a double dissociation) supports the view that the hippocampus and EC/PFC differ functionally. Specifically, the rats in the hippocampus seem to play an especially important role in the acquisition of spatial information, while the EC/PFC is involved in the processing of complex, nonspatial information.

HIPOCCAMPAL AND NON-HIPOCCAMPAL BASED LEARNING IN THE RAT. Robert J. McDonald* and Norman M. White, Department of Psychology, McGill University, Montreal, Quebec, Canada.

Performance on a variety of place learning tasks is impaired by damage to the hippocampal system in the rat (Olton, Walker, & Gage, 1978; Sutherland, Kohl, & Whitehouse, 1993). The present experiment investigates the role of the lesion and the task environment in underlying place learning tasks that are not dependent on the hippocampal system is limited. The present experiment the participation in place learning of hypothesized memory systems that include hippocampal, parahippocampal and amygdala. The hippocampal system was studied by requiring rats to discriminate between 2 arms of an 8-arm radial maze. Two behavioral variables were manipulated: 1) Movement - rats were either confined to the arms of the maze for a fixed number of trials or were allowed to run in the maze freely; 2) Cue Resolution - the use of distal room cues was allowed by allowing the entire radia maze one arm position to the left at the start of each training day. Rats were discriminated between 2 arms of the maze, the first arm the rat could see a unique cue or set of cues, or between two adjacent arms from each of which they could see largely overlapping sets of cues. In the latter case the arms could be distinguished only by comparing the differences in the spatial relationship of each arm to many of the same cues. A series of single and double lesions revealed the following about the roles of the hippocampal and cue resolution variables in each of the three hypothesized memory systems. When the animals were confined to the arms of the maze only the amygdala system could process the information required to discriminate between the arms, and the discrimination was learned faster with unique than with overlapping cues. In both cases the passive discrimination was facilitated by hippocampal system lesions. When animals ran into the maze arms during training only the hippocampal system processed the information required to discriminate overlapping sets of cues, but both the hippocampal and dorsal striatal systems processed information that differentiated between unique cues. In the latter case the two systems appeared to process different kinds of information, in parallel, that led to the same solution.

RATS WITH ANGULAR BUNDLE TRANSCTIONS SHOW NORMAL ACQUISITION BUT IMPAIRED LONG-TERM RETENTION OF OBJECT DISCRIMINATIONS. V. Vogenic, J.C. Gibson, L.C. Kroemer, and L.A. Robinson, Department of Psychology, George Washington University, Washington, DC 20052, and 2nd Dept. of Cell Biology, Georgetown University, Washington, DC 20007.

Investigations of the neurobiology of memory using experimental animals have succeeded in modeling many of the characteristic features of amnesia seen in human clinical populations. To examine long-term memory, however, animal models of amnesia often employ extended measures of learning, with duration which is consistent to the retention measurements used with humans.

To determine the role of hippocampal/parahippocampal circuitry in both information acquisition and long-term retention, rats with bilateral transsections of the angular bundle were trained on three object discrimination problems and then retrained two weeks later to measure retention. Rats with discrete lesions of the angular bundle, which disrupt protractor function/(ontrol from entothial cortex and effector hippocampal-cortical projections, acquired the discrimination problems normally but showed a marked deficit in retention. Thus, the role of this circuitry may be limited to maintaining some types of information (e.g., single object discriminations) for retention. Behavioral paradigms that include a measure of retention may be particularly important for characterizing mnemonic deficits in animal models of amnesia. Supported by CNR and GWU Fundings.

DISOCIATION OF HIPOCCAMPAL AND STRIATAL CONTRIBUTIONS TO PLACE NAVIGATION IN THE WATER MAZE. B.D. Devlin*, E.H. Gould, L.H. Prin, Dept. of Psychology, Towson State University, Towson, MD 21204.

Previous studies have shown that damage to either the hippocampus or striatum of the rat results in severe spatial impairments. The purpose of the present study was to analyze the effects of hippocampal (fornix/limbic) and striatal (caudate-potamus) lesions on acquisition of the standard place version of the Morris water task as modified cue version that ascertained simultaneous acquisition of a place response. Rats with fornix/limbic lesions were impaired during a later stage of place task acquisition than rats impaired on the cue task. Caudate-potamus lesions resulted in a severe place task impairment and a transient cue task impairment, both of which were characterized by an early phase of thigmotactic swimming. The escape latency measure was particularly sensitive to thigmotactic behavior and not accurately reflect allocentric spatial learning. Post-hoc analysis of start point heading angles suggested that rats with fornix/limbic lesions used position response and guidance strategies. These rats demonstrated the same spatial bias for the former training quadrant on the platform removal probe and reduced flexibility in navigating to a novel platform location on the platform relocation task. In contrast, rats with caudate-potamus lesions spent a greater amount of time swimming in the former training quadrant on the platform removal probe, and despite poor place acquisition lacies showed greater improvement when required to learn a new platform position on the relocation task.

The results revealed dissociable aspects of water maze performance following damage to the fornix/limbic or caudate-potamus. It is suggested that the hippocampus mediates the allocentric spatial aspects of the water maze place task while the striatum may mediate acquisition of the non-allocentric procedural components of both place and cue versions. The results support a multiple neural-systems view of learning/memory and further suggest that is the intact mammalian brain multiple systems may acquire different forms of information simultaneously.

LESIONS TO THE HIPOCCAMPAL SYSTEM DO NOT IMPAIR SELECTIVE ASSOCIATIONS IN RATS. R.A. Murphy, R.J. McDonald, E.A. Germain & A.G. Baker, Department of Psychology, McGill University, Montreal, Quebec, Canada, H3A 1B1.

There is some evidence that lesions to the hippocampus impair performance on Kamin's blocking, on overshadowing and on a reversal procedure. However, these selective association procedures require subjects that ignore, to some extent, the relationship between a redundant CS and a US. It has been suggested that the hippocampus may be required for this type of selection. The present study compares rats with either electrolytic lesions of the fornix, or colchicine lesions of the dentate gyrus of the hippocampus, and controls on an appetizer operant version of Wagner, Logan, Haberland and Pisc's (1970) (US: Psy, 10' 171-190) procedure. We used a variable interval discrete-trial bar press procedure with two stimulus compounds containing a common element (XX, IX). Half of each group were trained with a True-discrimination (TD; AN: IX) in the first half of each session, while the other half were trained with a Pseudo-discrimination (PD; AX: BI: IX) in the second half of each session, so that both AX and BX trials were reinforced 50% of the time. In spite of the fact that X is reinforced equally often in both groups, previous research has demonstrated that in comparison to PD trained animals, TD trained normals show less responding to the partially reinforced stimulus (X) because the other more valid predictors of reinforcement (A and B) overshadow conditioning to X. During our test of X, all groups showed overshadowing of X following true-discrimination training. Consistent with previous experiments in our lab the lesion returns increased responding to X, protecting the reinforcement of AX and BX trials and during the test of X. These results suggest that the hippocampus is not required for this selective association phenomenon.

MOVEMENT-PRODUCED HIPOCCAMPAL AND PASSIVE NONHIPOCCAMPAL LEARNING IMPEDIE AMYGDALA-BASED STIMULUS-REWARD LEARNING. Norman M. White* and Robert J. McDonald, Psychology, McGill University, 1205 Dr. Penfield Ave, Montreal, Quebec, HSA 1B1.

We previously reported that the conditioned preference (CPP) learned by rats on the 8-arm radial maze using only distal cues to distinguish between food and no-food arms is eliminated by laminar nucleus of the amygdala lesions and potentiated by fornix lesions, suggesting that this form of stimulus-reward learning is mediated by a neural system that includes the amygdala but not the hippocampus, and that the hippocampal system interferes with amygdala-based learning of the CPP. 1) We tested the hypothesis that the cause of this interference is the acquisition of a spatial map of the maze route by the hippocampal system during 10 min of free-retrieval pre-exposure to the maze, given to all animals before CPP training. Rats not pre-exposed to the maze, or pre-exposed to a maze in a different room exhibited potentiated CPPs, comparable to those of animals with fornix lesions, suggesting that the CPP in normal animals is inhibited due to learning about spatial cues in the maze room. 2) Rats with fornix lesions made after pre-exposure (in the same room), or after CPP training but before testing, were prevented from obtaining the CPP compared to those observed in normal animals, suggesting that acquisition of spatial information by the hippocampal system during pre-exposure is required for a intact fornix; however, the fornix is not required for subsequent inhibition of stimulus-reward learning in the amygdala system. This inhibition may be mediated via entothial cortex. 3) When rats were pre-exposed to the maze by confining them in the arms (instead of exploring freely), the subsequently acquired CPP was comparable to that in normal animals, but was not potentiated by fornix lesions, suggesting that passive pre-exposure may produce non-hippocampal-learning, possibly mediated in the amygdala system, that impedes stimulus-reward acquisition by the same system. There may be two different latent-inhibition-like effects, involving two different kinds of learning and mediated by two different memory systems.

The historical debate between psychologists who favored "cognitive" learning theories and those who favored "stimulus-response" learning theories can be characterized by the tendency of rats to display place or response learning in the cross-maze paradigm selectively. Early studies suggested that either mechanism in learning to approach the consistently baited arm of a cross-maze (cf. Rente, 1957), raises the possibility that these two learning mechanisms are mediated by distinct neural systems. Consistent with this view, evidence indicating that the mammalian brain contains multiple memory systems which differ in the "type" of memory they encode. The present study was designed to examine the hypothesis that place and response learning are mediated by independent hippocampal and caudate nucleus memory systems, respectively.

Rats were trained to approach a consistently baited arm in a cross-maze from the start box (4 trials/day/14 days). On days 8 and 16 a single probe trial was given, in which rats were placed in the start box of the cross-maze opposite that used in training, and allowed to approach a maze arm. On the probe trials, rats which selected the baited maze arm were designated place learners, and rats which selected the un baited maze arm were designated response learners. 3 minutes prior to the probe trials, rats received bilateral hippocampus injections (solution A) (in order to produce neuronal inactivation) into either dorsal hippocampus or dorsolateral caudate nucleus. Saline treated rats received bilateral hippocampus injections on the day 8 probe trial, and response learning on the day 16 probe trial, indicating that with early training, there is a shift in learning mechanisms. L-Dopa injections into hippocampus showed no preference for place or response learning on the day 8 probe trial, and displayed response learning on the day 16 probe trial, indicating a blockade of place learning following injection. Rats receiving lidoacine injections into the caudate nucleus displayed place learning on both the day 8 probe trial and the day 16 probe trial, indicating a blockade of response learning following injection of the caudate nucleus. The results indicate that the hippocampus and caudate nucleus contribute to different place learning tendencies, respectively, and offer a "neurochemical" solution to the place versus response learning debate.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

WEDNESDAY AM

A very extreme deficit in performance of the Morris Maze (MM) task was produced by small electrolytic lesions in rostral globus palidus (rGP, but not by lesions in the center of GP (Meyer & Cooper, Soc. Neurosci. Abst., 18:1565). The present study examined the nature of this deficit by testing performance in both negatively (MM) and positively (cheeseboard) reinforced tasks, and whether comparable deficits would be produced by biotenate lesions of rGP.

Testing in the MM began 4 weeks following surgery with eight 4-trial sessions of escape to a platform in the center of the same quadrant of a 1.6-m diameter tank. The platform was submerged after the first session, and further hidden by adding milk after the 2nd session. Two weeks later, the rats were tested during six 4-trial sessions to find half a Foxo Loop in the same spatial location amongst 177 holes. Rats with electrolytic lesions of the rGP failed to escape in the MM within 120 sec in most cases (5 out of 8 rats, and showed almost no reduction in their 60+ sec latency to find the food reward. By contrast, sham surgery and vehicle injection control groups, and also a group receiving 3 μg biotenate under ketamine anesthesia, achieved MM escape within 20 sec by the third session, and reduced their food finding latency from 60 sec to the first session to less than 20 sec by the fifth session. The experimental group receiving biotenate lesions of rGP under Nembutal anesthesia did exhibit deficient MM performance over the first four sessions, which might reflect a spatial navigation deficit. However, the more extreme deficits produced by electrolytic lesions in rGP suggest a broad disturbance of instrumental performance.

415.21 THE VENTRAL STRIATAL - VENTRAL PALIDAL AXIS AND ASSESSMENT OF EFFORT REQUIRED FOR A REWARD. V.J. Brown*, G. Symons, P. Wiss and M.P. Latimer School of Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU.

The ventral striatum has been implicated in reward-related processing, but its separate contributions to the perception of reward value and reward cost is not known. The present study sought to determine the involvement of the ventral striatal-ventral pallidal (VS-VP) system in assessment of reward cost. We measured progressive ratio (PR) responding, in which the cost in lever presses of a single food pellet increases incrementally with each pellet. Bilateral ibotenate (IBO) lesions were made in VS (0.6, 0.8 μl injections/hemisphere; sham lesions 0.6 μl PFS) or VP (0.6, 0.5 μl injections/hemisphere; sham lesions 0.5 μl PFS) of rats after 21 days training and at least 30 days before testing started. The point when normal rats and sham controls stopped responding (breaking point) under a PR schedule was stable over days, as were latencies to collect pellets, the post-reinforcement pause increased as a function of schedule progression. These effects are consistent with previous reports. Rats with VS IBO lesions showed significant increases in breaking point, indicating a willingness to work at greater cost for pellets. Rats with VP IBO lesions also showed increases in breaking point, and a greater range of breaking points than controls. Rats with VP lesions did not show an increase in post-reinforcement pause as a function of the PR increments. As this increase reflects a reluctance to resume work in the light of perceived greater effort required for reward this result is interpreted in terms of a deficit in perception of increasing reward cost. Overall these data demonstrate that the effect of lesions in the VS-VP axis is not simply to decrease motivation to work for food reward. Rather, these data suggest that lesioned rats may have lost the ability accurately to perceive the increasing cost of reward. Thus, rather than a change in motivation per se there appears to be alteration in the perception of the increasing cost of reward.

416.1 CHANGES IN GLUTAMATE RECEPTOR PROPERTIES IN THE CEREBELLAR CORTEX OF CLASSICALLY CONDITIONED RATS. Sarah Pollock, Dave Layond*, Richard F. Thompson, Matti Mintz, & Georges Tocco. Psychobiology Unit, Psychology Department, Tel Aviv University, Israel & University of Southern California, Neurosciences Program, HEDIUC Neurosciences Building, Los Angeles, CA, 90089-2520.

The cerebellar cortex is believed to be involved in the neural plasticity associated with the conditioned eyelid response. Because glutamate receptors have been shown to play a pivotal role in various forms of synaptic plasticity, we planned to determine their involvement in this learning model using quantitative ligand binding autoradiography.

Male Wistar rats were trained on a delay paradigm with paired presentations of conditioned (tone) and unconditioned (electric shock to one eye) stimuli. Naive and unpaired animals were used as controls. Quantitative ligand binding autoradiography using ligands specific for the AMPA subclass of glutamate receptors revealed an increase in tritiated AMPA and CNQX binding on the contralateral side of the trained animals (compared to the ipsilateral) with little or no side difference on the unpaired and naive animals. Conditioning did not result in any change on tritiated TCP binding (NMDDA specific).

These results support molecular changes of glutamate receptors in cerebellar cortex correlated with learning.

Microinjections of a GABA_A antagonist picROTOXIN (PTX) in the cerebellum have been shown to block the expression of classically conditioned eyelid blink response. In the present study, we examined the effect of PTX on the acquisition of conditioned eyelid blink response. New Zealand white rabbits, implanted with cannulae aimed at the ipsilateral interpositus (IP) nucleus, underwent five days of standard delay tone-airpuff training while receiving continuous infusions (0.13 μl/min) of PTX (10 nmol/μl) into the IP. Then, they were given 3 days of training with artificial cerebrospinal fluid (ACSF) infusions. During the 5 days with PTX, animals showed no eyelid blink responses and normal unconditioned responses to the airpuff. When switched to the ACSF, these animals learned eyelid blink CRs as if they were naive. When PTX was infused again, CRs were completely abolished. These results support earlier reversible inactivation studies that demonstrated that the cerebellum is critical for acquisition and expression of eyeblink conditioning. 416.3

Metabotropic glutamate receptors (mGluRs) are known to play a crucial role in both the induction and maintenance of hippocampal long-term potentiation (LTP). It is conclusive, if LTP is of physiological relevance, that mGluRs should play an important role in functional long-term potentiation. As we investigated this hypothesis applying electrophysiological and behavioral standard procedures.

Electrodes were implanted into the perforant path for stimulation and in the dentate gyrus for recording in the rat. (R)-5-methyl-4-carboxyphenylglycine (ADCC), a selective mGluR2 antagonist, was injected in two concentrations (A=20.8 mg; B=104.2 µg i.c.v.) 30 min prior to tetanus-induced LTP or learning, respectively. For comparison, a novel form of shock-reinforced 4A,5aza-purine spatial alternation and a brightness discrimination task were performed. MCPG blocked different phases of LTP in a concentration dependent manner. Dosis B abolished a potentiation completely and also inhibited learning in the spatial task. These findings substantiate that mGluRs are involved in the expression of LTP in the dentate gyrus and consolidation of spatial alternation memory. The effects on both were dose-dependent, i.e. only the high concentration of MCPG induced a complete block, whereas no learning impairment occurred in the low dose group where the potentiation lasted up to 2.5 hours. We therefore assume, that STP in the hippocampus is the crucial factor for the learning of spatial tasks in the long term. Block of STP, however, results in amnesia.

416.5

THE EFFECTS OF MUSCIMOL INFUSIONS INTO THE AMYGDALA AND MEDIAL SEPTAL AREA IN MEMORY FOR MAGNITUDE OF FOOD REWARD. J.M. Williams, R.J. Nelson* and D.S. Olton, Department of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

Rats were trained on a go, no-go task measuring magnitude for food reward. In the study phase of the task, the rats were given one of two cereals. One cereal contained 25% sugar, the other 50% sugar. One of the two cereals was designated as the positive stimulus and the other as the negative stimulus. If the rat received the positive stimulus in the study phase, in the subsequent test phase the rat received another food reward which was placed beneath an object in a foodwell. Each rat received the positive and the negative food stimuli during the study phase, no food was placed beneath the object in the foodwell. Performance was measured as latency to uncover the foodwell in the test phase. A previous study using the aforementioned procedure revealed that lesions in the amygdala, but not the hippocampus significantly impair performance in this memory task. The present study seeks to further clarify the role of the amygdala in memory for magnitude of food reward. After achieving criterion (significant differences in latency to respond to the positive vs. negative stimulus), rats received cannula implantsations into both the medial septal area and amygdala. All rats received infusions into both of these areas and into the hippocampus. The effects of muscimol into each of these areas were compared to saline infusion trials and trials in which no infusions were given. The effects of muscimol on memory for magnitude of reinforcement will be discussed.

416.6

INTRA-SEPTAL INFUSIONS OF MUSCIMOL IMPAIR SPONTANEOUS AltTERATION PERFORMANCE: A FAILURE TO REVIVE LEARNING IMPAIROT WITH GlUCOSE M.B. Parent* and P.E. Gold. Department of Psychology, University of Virginia, Charlottesville. Virginia 22903.

Intra-septal infusions of drugs that act at cholinergic, noradrenergic, opioid peptidergic and glutamatergic receptors influence spontaneous alternation performance. The present experiment examined the role of medial septal GABAergic system on spontaneous defensive behavioral alternation performance by infusing the GABA agonist muscimol 15 min prior to training in a spontaneous alternation task. With evidence that systemic infusion of GABA antagonists reverse the impairing effects of intra-septal infusions of opioid agonists (Ragazzino, Parker, & Gold, Brain Research, 1982), the efficacy of intra-septal infusions of glucose in reversing long latency septal lesions to impair performance was assessed. The intra-septal infusions of muscimol (1 or 3 mmol. 0.5 µl/min) significantly impaired spontaneous alternation performance. Glucose (0.3, 1.6, 3.3 or 5.9 mmol, 0.5 µl/min) did not affect spontaneous alternation performance or reverse the deficit produced by intra-septal infusions of muscimol (1 nm). These results indicate that activation of GABAergic receptors in the medial septal impairs spontaneous alternation performance. This finding is similar to results obtained with morphine infusions. However, in contrast to the results with morphine, glucose did not reverse the muscimol-induced impairment. This pharmacological distinction suggests that glucose may interact with specific neurotransmitter systems in the medial septum to influence spontaneous alternation performance. Supported by NIA (AG 07648), NSF (BSR 9012239), and NIH (HD 07323).

Evidence for different types of memory in rats may lead to development of animal models for human memory disorders and provides information on neurobiological systems underlying these processes. The effects of the noncompetitive NMDA receptor antagonist MK-801 were investigated in those of the muscimol antagonist scopolamine hydrobromide on working and reference memory in the radial maze. In order to discriminate between the working memory and the reference memory, we used a modified version of the radial maze with the additional feature of a reward as the only criterion. Scopolamine (0.3 mg/kg, IP) or MK-801 (0.1 mg/kg, IP) were injected s.c. 30 min before a session. The duration of the session was 20 min, which was divided into 5 sub-sessions of 4 min each. Working memory was tested in the first sub-session by giving a reward in the arm of the maze, whereas the arm of the second sub-session, in which there was no reward, was used for testing the reference memory. The results showed that MK-801 impaired the ability to learn the reference memory, whereas scopolamine impaired the ability to learn the working memory. These findings indicate that MK-801 interacts with memory processes of similar complexity than does scopolamine hydrobromide, whereas the use of "difficult" and "easy" baiting patterns may be a sensitive method to analyze amnesic compounds.

The benzoazepine inverse agonist FG 7142 (20 mg/kg, i.p.) has been shown to selectively increase the DOPAC/DA ratio in the prefrontal cortex (PFC) of the rat. The effects of FG 7142 on the working memory functions of the PFC have not been examined. The present study tested the effects of FG on spatial working memory in the rat (delayed alternation in a T-maze) and the monkey (delayed response in a WGT). In rats, FG (20 mg/kg, i.p.) significantly impaired delayed alternation performance. This impairment was reversed by pretreatment with the benzodiazepine antagonist Ro 15-1788 (20 mg/kg, i.p.). Consistent with the hypothesis that FG impairs delayed alternation by increasing DA release, low doses of the DA antagonist, haloperidol (0.1-0.2 mg/kg, i.p.) were able to ameliorate FG-induced delayed alternation deficit. The glycinic partial agonist, (+)-HA-966 can act as an antagonist at the glycine site of the NMDA receptor. Pretreatment with (+)-HA-966 (10 mg/kg, i.p.) eliminated the effect of FG on delayed alternation. Similar responses were observed in monkeys: FG (0.2 mg/kg, i.m.) impaired delayed response performance, and this impairment could be reversed by haloperidol (0.005 mg/kg, i.m.) or the D1 antagonist SCH 23390 (0.005 mg/kg, i.m.). Preliminary results indicate that pretreatment with (+)-HA may attenuate FG-induced impairment. These results suggest that excessive DA release in the PFC impairs spatial working memory performance. ANTEROGRADE AMNESTIC AND ANTICONVULSANT EFFECTS OF TWO TYPES OF NMDA RECEPTOR ANTAGONISTS: MK-801 AND HA-966. K. Xu*, P. Klíner, and R. Davis. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48104-1667.

The anterograde amnestic effects of noncompetitive NMDA antagonists MK-801 and HA-966 on classic fear conditioning in goldfish (Carassius auratus) were examined in a series of experiments. The results showed that MK-801 and HA-966, but not HA-966, impaired the acquisition of the classical fear memory. Analysis of dose-effect relationships revealed that MK-801 was more potent than HA-966 in producing anterograde amnesia, while HA-966 did not produce anterograde amnesia at the doses tested. These findings suggest that MK-801, but not HA-966, produced anterograde amnesia by their antagonism of NMDA receptor complex specifically.

We evaluated the effects of the GABA antagonist baclofen on learning and performance of rats in a water maze task. Male Long-Evans rats were trained to a criterion of threefold above chance level of performance in the maze. Once rats achieved criterion, (-)baclofen (1 mg/kg) was injected i.p. in half of the rats 15 min prior to testing on each of 3 consecutive days. The treated rats took significantly longer to complete the maze. In two additional studies, we gave the rats daily injections of (+)baclofen (1 mg/kg) prior to training them on new configurations of the maze. We found no significant difference between the treated and control rats on the number of trials required to reach criterion but did find that after reaching criterion the baclofen-treated rats required significantly longer times to complete the maze. When no drugs was administered, the performance of the two groups was not significantly different. These results suggest that baclofen impairs performance but does not affect learning.

SPERMIDINE POTENTIATES DIZOCILPINE-INDUCED LEARNING IMPAIRMENT OF RATS IN A 14-UNIT T-MAZE TO DEMONSTRATE POLYAMINE MODULATION OF NMDA RECEPTOR FUNCTION. R. J. Spanier, E. F. Hepler, and R. L. Ingram. Gerontology Research Center, NIA, and Addiction Research Center, NIDA, NH, Baltimore, MD 21224.

The NMDA receptor, a membrane ion channel complex has been reported to be involved in memory processes. Learning is impaired following administration of dizocilpine (DIZO), a non-competitive antagonist of the NMDA receptor. Polymers of spermidine, a polyamine, interact with the NMDA receptor to enhance binding of DIZO, which blocks the ion channel. The present study assessed action of polymers of spermidine as releasing agents for the NMDA receptor activation. DIZO (0.05 mg/kg) was given i.p. before maze learning, at a dose that produced a slight, non-significant reduction in performances (t = 0.5, p < 0.05). Administration of spermidine increased the response of rats to DIZO. The results confirm that systemic injection of a polymer can modulate learning processes involving the NMDA receptor. Studies are currently being undertaken to test the hypothesis that systematically injected SPD may ameliorate impaired maze learning in aged rats by activating the NMDA receptor.

SELECTIVE ENHANCEMENT OF AMPA RECEPTORS IMPROVES NEO-CORTICAL LEARNING. R. Graugler*, C. Manjouze, A. Angelen, A. Lopez, M. Davis, B. Tran, G. Rogers & G. Lynch. CNIM, Univ. of Calif., Irvine, CA 92717.

In a novel neocortically dependent auditory task, the first pharmacological agents to specifically enhance the excitatory activity of AMPA receptors in the brain ("AMPAKINE") were tested for their effects on learning. AMPAKINE selectively enhance the glutamate receptor, which mediates all normal fast excitatory transmission, and is the likely site of synaptic long-term potentiation (LTP), the leading candidate substrate for learning. In the first reported tests of behavioral effects of these drugs, Stabili et al. (Proc. R. Soc. B, 1994) and Graugler et al., (Nature, 1. 328:1993) showed that they enhanced learning in a radial arm maze and an olfactory discrimination task, which are hippocampally and neocortically dependent, respectively. We report here on a novel auditory discrimination learning task, and show that performance on this task is improved by AMPAKINE. The task consists of a maze in which each arm has a high-frequency speaker. Only two speakers are active on any given trial. Each speaker continuously plays a complex natural sound, recorded and then shifted up into the rat's learning range (10kHz and above). On each trial, the rat receives a water reward for approaching the "correct" one of the two sounds, whose spatial location changes with each trial. Rats learn many such sounds rapidly, and exhibit weeks-long retention of learned sounds. Selective lesions of primary auditory neocortex severely impairs learning of new sounds. In an experiment counterbalanced for sound preference, learning and retention, and in which animals serve as their own controls for drug effects, rats were tested on very difficult sound discriminations, and a small number of training trials. On days when they were not given the drug, animals were unable to learn the sounds significantly above chance acquisition levels. On days when they received the drug before entering the maze, they exhibited a 41% improvement over their non drug performance. This is the first demonstration of enhancement of learning in a neocortically dependent animal model. (Supported by AFOSR F49620-92-J-0037 and ONR N00014-93-J-1205.)
LEARNING AND MEMORY: PHARMACOLOGY—EXCITATORY AMINO ACIDS  

416.15  
A CRITICAL ROLE FOR THE NMDA RECEPTOR SITE IN COCAINE DRUG CONSUMPTION PROCESSES. Ernest N. Damianopoulos* and Robert J. Carey. Psychiatry, SUNY Health Science Center and Research and Development Service-151, VA Medical Center, Syracuse, NY 13210.  
The role of the NMDA receptors in cocaine conditioning and sensitization was studied in four groups of matched Sprague-Dawley rats. A sub-motoric dose of the NMDA antagonist MK-801 (0.1 mg/kg ip) was employed using a novel drug-compartment Pavlovian drug conditioning paradigm. The animals were placed sequentially in two similar but distinct test environments. In the first compartment, the animals always received a non-drug test (20 min). Upon removal, the animals received either saline, cocaine (mg/kg ip), MK-801 or MK-801 plus cocaine depending on group assignment and were then placed immediately into the second compartment (20 min). Every other day over a 12-day period, the animals of each group (n = 5) received a non-drug test followed by 1 saline/drug test. Across all drug treatment days and subsequent tests for conditioning, there were no statistical differences between the saline and drug treatment groups in the non-drug test environment on locomotor distance. Thus, non-specific, non-associative response sensitization effects were not observed. Cocaine, however, did have a consistent stimulant effect on locomotor behavior in the drug test environment either when administered alone or in combination with MK-801. Following a 1-day and again after a 21-day withdrawal, all animals were administered a non-drug test for conditioning. The results showed that the cocaine-induced enhancement of locomotion was conditioned to the aversive cues of the drug-associated environment but this effect was not present in the animals treated with cocaine plus MK-801. While MK-801 blocked cocaine conditioning, MK-801 had no effect on the cocaine locomotor stimulant response.  

416.16  
PREGNENOLONE SULFATE INFUSION ANTAGONIZES DIZOCILPINE AMNESIA: MEDIATION BY ALLOPREGNANOLONE. D. L. Cheney*, D. Uzunov, E. Costa and A. Guidotti. FGIn, Georgetown University Medical Center, 3900 Reservoir Road, N.W., Washington, D.C.  
Dizocilpine, a non-competitive N-methyl-D-aspartate (NMDA) antagonist (0.1mg/kg, i.p.), disrupted the passive avoidance response in control and adrenalectomized/castrated (ADX/CX) male rats. Infusion of pregnenolone sulfate (20mg/kg i.v., 5min) antagonized dizocilpine induced amnesia and increased the brain content of pregnenolone, progesterone and allopregnanolone as measured by gas chromatography-mass fragmentography. Similar effects were observed with CPPene, a competitive NMDA antagonist (2.5mg/kg, i.p.). Five to ten fold increases in allopregnanolone were observed in olfactory bulb, striatum, hippocampus and cortex following infusion of pregnenolone sulfate. Pretreatment with the 5a-reductase inhibitor SKF105111 (5mg/kg, i.v.) blocked the pregnenolone sulfate antagonism of dizocilpine amnesia and prevented the increase of allopregnanolone in olfactory bulb, striatum and cortex. These results support the hypothesis that the amnesia elicited by the NMDA antagonist dizocilpine is counteracted by pregnenolone sulfate via its ability to increase the brain content of allopregnanolone.  

416.17  
EFFECTS OF PHENYTOIN ON LEARNED APPETITIVE RESPONSSES AND THE SUBSEQUENT ACQUISITION OF ESCAPE AND AVOIDANCE RESPONSES. N. L. Mohr1, J. E. Steinmetz2*, and P. F. Garraghty1, 2. Dept. of Psych. and Prog. in Neural Sci., Indiana Univ., Bloomington, IN 47405.  
Phenytoin (Dilantin) has been used for the control of epileptic seizures for more than 55 years. This drug has proven to be an effective antiepileptic, but it may also be associated with deficits in behavior and cognition. Here, we have evaluated the effects of instituting chronic phenytoin maintenance in rats that had undergone initial training in an appetitive instrumental task with a subsequent switch to an aversive (escape/avoidance) task. We initially trained deprived rats to press a bar in the presence of a tone stimulus for a food reward. We then began treating the rats daily with phenytoin (solution, Parke-Davis). Our goals were to determine the extent to which the animals' behavior in the appetitive task was affected by the institution of phenytoin treatment, and how the acquisition of the new escape/avoidance responses were affected. Our results suggest three findings relative to control observations from drug-free rats: 1) a reduction in response latency in the appetitive phase of the experiment after the initiation of drug treatment; 2) a prolonged latency (over session days) in the acquisition of the initial escape response after the animals are switched to the aversive task; and 3) a failure to acquire the avoidance response. These results, in turn, suggest that phenytoin has substantial, and negative (at least for findings 2 and 3) consequences for learning in subjects chronically maintained on the drug, perhaps because of its antagonistic effects on NMDA receptors.

417.1  
ACUTE DIAZEPAM ADMINISTRATION PRODUCES MEMORY DEFICITS SIMILAR TO THOSE DUE TO CHRONIC ALCOHOL CONSUMPTION. N. Berde, R. Jaffard and D. Bercacoeur*. Lab. Neurosciences Comportementales et Cognitives, CNRS URA 339, Univ. Bordeaux I, avenue des Facultés 33405 Talence Cedex, France.  
The effects of the benzodiazepine agonist (Diazepam) on delayed alternation in a T-maze as mice were studied. Delay intervals (DI) separating the acquisition trials from the retention trial were either 30 sec or 6 hours. The 6 hours trial was further used as an acquisition trial for a subsequent alternation trial (DI: 30 sec) aimed at measuring short-term memory as well as the eventual sedative effects of the drug. Diazepam (1.0 or 1.5 mg/kg) was administered 1.50 min before the 6 hr retention trial. Results showed that the 1.5 but not the 1.0 mg/kg dose induced a memory deficit, as compared to saline treated subjects. No impairments were observed on the short-term trial. Furthermore, the Diazepam-induced memory impairment was reversed by a context-change occurring before the retention trial even though this finding requires further experiments to be firmly established. The effects of Diazepam on memory appear to be similar to those resulting from a long-term ethanol administration and which appear to result from an impairment of the retrieval phase of memory processes.

The functional activity of cholinergic neurons in the medial septum (MS) that project to the hippocampus is modulated by an intrinsic GABA-benzodiazepine (BDZ) mechanism. Intraseptal injection of the BDZ, chlordiazepoxide (CDP) to rats (i) impairs working memory (WM), (ii) decreases hippocampal high-affinity choline transport, and (iii) decreases dentate gyrus extracellular responses. Further, intraseptal flumazenil, a BDZ antagonist, reverses systemic CDP-dependent amnesia (Stackman & Walsh, 1992; Walsh et al., 1993; Stackman et al., 1993). These data indicate a septal BDZ substrate capable of impairing WM and modulating cholinergic activity in the HPC, is likely the site of action of the amnestic action of CDP. Experiment 1 examined the contribution of neural regions proximal to the septohippocampal network, to the expression of CDP-induced amnesia. Infusion of 30 nmoles of CDP into the MS impaired WM in a delayed non-match-to-sample (DNMTS) radial-arm maze (RAM) task. This dose of CDP failed to alter RAM performance when infused unilaterally into the cingulate gyrus, or bilaterally into the lateral septum, or the nucleus basalis. Infusion of the local anesthetic, lidocaine (147 nmoles) into these sites produced similar behavioral effects. Experiment 2 examined the time-dependent nature of intraseptal CDP-induced amnesia. Rats were trained in the DNMTS RAM task and then injected with 30 nmoles CDP into the MS at one of the following postraining times: 0, 15, 30, 45, or 60 mins. Rats infused with CDP immediately postraining exhibited WM impairment. Infusion of CDP at the other postraining times failed to significantly impair performance. These data indicate that MS is the site of action for CDP-induced amnesia, and this structure is critically involved in an early encoding or maintenance phase of spatial WM. CHRONIC BENZODIAZEPINE (BDZ) TREATMENT FACILITATES SPATIAL LEARNING IN THE MORRIS WATER MAZE (MWM).
M.S. Mohamed, W.S. Messer and E.I. Tzitz.  
1Dept. of Medical and Biological Chemistry, College of Pharmacy, University of Toledo, 43606, and 2Dept. of Pharmacy, Medical College of Ohio, Toledo, OH 43609.
Acute BDZ treatment, which potentiates GABA inhibition interferes with long-term potentiation (LTP) and impairs spatial learning. Reducing GABA inhibition in hippocampal CA1 region facilitates LTP. Chronic flurazepam (FZP) treatment reduces GABA inhibition in the CA1 region in vitro. We hypothesized facilitation of LTP in hippocampal slices from chronic FZP-treated rats. However, in a previous study using 10 theta bursts, LTP was induced to a similar degree in FZP-treated and control slices but was not maintained in FZP-treated slices over time. This study mediates spatial learning we evaluated the effect of 1 week FZP treatment (10 mg/kg x 3 days; 150 mg/kg x 4 days, p.o. to 0.2% saccharine) in the MWM. Treated rats were offered saccharine H2O for 2 days before and after FZP treatment. Control rats received saccharine H2O. Rats were adapted to the maze by allowing them to swim freely for 120 s over 2 days. Two days after FZP-treatment, we tested each rat’s ability to find a hidden platform. Rats were trained 4 trials/day/4 days and tracked with a video camera connected to a computer. Latency to escape(s), path length (cm), and speed (cm/s) were averaged. Speed was constant for each group (p > .05) indicating no motor effect due to FZP treatment. The latency of FZP-treated rats to find the platform was less than controls (treatment effect, p = .043) suggesting that reduced GABA inhibition associated with chronic BDZ treatment facilitates spatial learning. However, our previous hypothesis. Future studies will explore LTP in chronic BDZ-treated rats using a 5 theta burst paradigm. EFFECTS OF CONVULSANT AND ANTICONVULSANT AGENTS ON MEMORY IN SQUIRREL MONKEYS. J.M. Moreschibecker* and E.D. Pelletier. Department of Pharmacology, LSU Medical Center, New Orleans, LA 70112.
It has been reported that subconvulsant doses of convulsant agents such as strychnine and pentylenetetrazole may enhance memory in rodents studied under various behavioral procedures. The present study was designed to determine if similar results might obtain in monkeys. Responding by squirrel monkeys was maintained by food presentation under a repeated acquisition of behavioral chains procedure. Monkeys acquired a different three-response chain each session. Sequence completions were reinforced under a fixed-ratio 5 schedule (FR 5) and errors produced a brief timeout. After the monkey reached a predetermined acquisition criterion, the session was stopped and either a 90 min or 24 hr delay was interpolated. Following the delay the subject was retested on the same discriminations and responses at quantitatively the same percent accuracy. When administered immediately after the monkey reached the acquisition criterion strychnine and pentylenetetrazole had no effect on percent savings under the 24 hr delay. Similarly, the delta opioid agonist, BWSW4536, 4-[(R)-2-(3,5-Dimethyl-1-piperazinyl)-N-N-dimethylaminoethylazidohydrochloride], had little or no effect on percent savings following either 90 min or 24 hr delays. This was true even at doses of BWS4536 which produced convulsions. In contrast, at high doses triazolam decreased percent savings following a 24 hr delay. These results suggest that at subconvulsant doses convulsant agonists have little or no effect while anti-convulsant agents such as triazolam can disrupt mnemonic processes in squirrel monkeys. (Supported by USPHS Grants DA05373 and DA04775.)

417. 7  
Using a recently developed, valid task for the measurement of sustained attention in rats (Buschini et al., 1994; McGeachy & Sarter, 1994), the benzodiazepine receptor (BDZ) agonist chlorziazepoxide (CDP) was found to potently and dose-dependently decrease the relative number of hits but not of correct rejections. Furthermore, the effects of CDP interacted with signal salience. As expected in intact animals, BDZ inverse agonists failed to facilitate performance. Here we show that intracerebroventricular (ICV) infusions of CDP (20, 40 μg/μl hemisphere) or B-CCM (1.5, 3.0 μg/0.5 μl hemisphere) into the substantia innominata of the basal forebrain reproduce the effects of the systemic administration of these compounds. Moreover, the effects of intrabasal CDP were more efficacious in decreasing the relative number of hits than of correct rejections. From the effects of systemic administration, these potent effects of intrabasal CDP on vigilance performance were not associated with equally potent effects on the number of errors of omission. These data support the hypotheses that the basal forebrain is a sufficient system for modulating the attentional effects of BDZ agonists. Also, these findings parallel the effects of systemic and intrabasal administrations of BDZ ligands on cortical acetylcholine efflux (Moore, Sarter & Brunero, 1993, 1994).

417. 4  
The effects of diazepam (0.2, 0.8, 1.6 and 3.2 mg/kg) on the primate and memory effects were evaluated in four groups of monkeys using a serial probe recognition (SPIR) task. Only the highest dose of diazepam (3.2 mg/kg) significantly disrupted the monkeys' performance on the SPIR task, causing an increase in the number of errors and an increase in the response latencies on the probe trials. Analyses of the serial position curves for each monkey further revealed that the highest dose (3.2 mg/kg) of diazepam disrupted both the recency effect and the middle portion of the serial position curves in all the monkeys tested. In contrast, the primacy effect was unaffected by any of the doses of diazepam tested. Previous reports have suggested that the primacy effect is mediated by the establishment of contextual or configural associations and the recency effect is mediated by the establishment of simple associations. Therefore, we have proposed that diazepam interferes with the simple associative processes involved in the recency effect to a much greater extent than it does with the contextual or configural associative processes involved in the primacy effect. This is the first demonstration showing that diazepam can produce such selective memory impairments in nonhuman primates.

417. 6  
Contingent drug tolerance is a widely reported phenomenon. However, the principles by which contingent tolerance develops are not well understood. Unlike other forms of drug tolerance, contingent tolerance does not appear to be under the influence of Pavlovian conditioning. The present study investigated the role that latent inhibition and partial reinforcement play in the development of contingent tolerance to the anticonvulsant effects of diazepam (DZ), in experiment 1, kindled rats were injected with either 5mg/kg of DZ or vehicle without convulsive stimulation, three times daily, for forty-eight hours following the last injection, both groups were switched to a DZ before stimulation schedule to assess the development of contingent tolerance to the anticonvulsant effects of 2mg/kg of DZ. Neither group displayed significant tolerance on the first trial, however, both groups developed contingent tolerance within 15 trials. Prior DZ exposure alone, not only, failed to retard, but facilitated the development of contingent tolerance. In the second experiment, kindled rats were exposed to a schedule which alternated between DZ injection followed by convulsive stimulation and DZ or vehicle injection following by handling. Partial pairing of DZ injections with convulsive stimulation (reinforcement) failed to retard the development of contingent tolerance to the anticonvulsant effects of 2.5 mg/kg of DZ.
Further, the extinction of tolerance in the two groups did not differ significantly. The results of these two experiments suggest that contingent tolerance to the anticonvulsant effects of DZ is not under the influence of latent inhibition or partial reinforcement.
MEMORY ENHANCEMENT WITH THE DELTA OPIOID RECEPTOR ANTAGONIST NALTIRINDOLE IS DEPENDENT ON TRAINING PARAMETERS

ELLEN B. BENNETT & M. R. ROSENZWEIG. Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

Administration of naltirindole or delta opioid agonists either enhance or impair memory formation, these effects are dependent on treatment and training conditions. We examined whether memory effects can be produced by administration of the delta receptor antagonist naltirindole (NTI). Two-day-old chicks were injected with saline or NTI in the morning and trained 5 min before one-trial peck avoidance training. To give relatively weak training so that either impairment or enhancement could appear, chicks received either of 2 training conditions: (1) The Latent Inhibition (LI) condition involved 4 pretrained exposures to a dry chocolate bead followed by one exposure to a bead coated with the chemical aversant methylnaltrexone (MeA). (2) No-LI chicks were given one exposure to a bead coated with 1% MeA. Approximately 40-50% of saline injected chicks in each training condition avoid pecking a dry bead at 24 h test. In LI trained chicks, NTI caused a dose dependent increase in avoidance at 24 h test, the highest dose producing significant memory enhancement. In contrast, NTI had no significant effect in the No-LI trained chicks. These findings suggest that memory enhancement resulting from opioid antagonism is dependent on training conditions. Specifically, endogenous opioids may be selectively involved in memory formation for training that involves discrete information about conditioned stimuli.

MODULATION OF MEMORY FORMATION FOR A ONE-TRIAL PECK AVOIDANCE TASK IN CHICKS GIVEN CENTRAL INJECTIONS OF OPIOID RECEPTOR SELECTIVE OPIOID ANTAGONISTS. D.W. Lee*, E.L. Bennett & M.R. Rosenzweig. Dept, of Psychology, University of California, Berkeley, CA 94720.

To investigate opioid-mediated memory formation, chicks were injected with opioid antagonists or saline 5 min before training on a one-trial peck avoidance task, then tested 24 h later for retention. A weak level of training (10%) of the aversant liquid methylnaltrexone (MeA) was used as the aversive stimulus; 10% MeA results in intermediate retention levels (~40%) allowing the investigation of both memory impairment and enhancement within identical experimental protocols. Several experiments were conducted administering i.c. bilateral injections of either mu, delta, or kappa selective antagonists (CTOP, CTOP(0.01mM), norBNI, respectively) or saline directed into the region of the intermediate medial hyperstriatum ventrale (IMHV, the avian homolog of mammalian visual association cortex) or tubus parafacialis (LPD, homolog of basal ganglia).

Mu antagonists CTOP (01 nmol/hemisphere) impaired memory when injected into the LPD only. Delta antagonist ICI enhanced memory in both the IMHV (3.0 nmol/hemisphere) and LPD (10.0 nmol/hemisphere) but only in LPD revealed significant (p < 0.1). Kappa antagonist norBNI impaired and enhanced memory in a dose dependent way when injected into the IMHV (10.0 nmol/hemisphere impaired; 10.0 nmol/hemisphere enhanced). The same pattern was observed when norBNI was injected into LPD but only impairment by 30 nmol/hemisphere was found to approach significance (p < 0.1). Although opioids clearly modulate memory formation in the chick, the direction of their effects (impairment or enhancement) is highly dependent upon 1) dose; 2) receptor type (mu, delta, or kappa); and 3) brain location (IMHV or LPD).

Work in our laboratory has recently shown that acute opioid withdrawal elicited by naloxone is enhanced when morphine is administered in the presence of shock associated cues. To further explore the nature of these effects, two experiments were conducted to determine whether naloxone could elicit signs of opioid withdrawal in animals exposed to a context associated with shock even in the absence of morphine. Experiment 1, utilizing a high (10 mg/kg) dose of naloxone, revealed that forepaw tremors but no other classic opioid withdrawal signs could be induced by naloxone following exposure to a context associated with shock. Experiment 2 further examined this effect across a range of naloxone doses (0.1, 1, 10 mg/kg). This experiment revealed that the emergence of forepaw tremors following exposure to a shock context associated is dependent upon a high (10 mg/kg) dose of naloxone. Furthermore, the severity of withdrawal such as mastration and teeth chattering were most evident at lower doses of naloxone. These findings are consistent with other studies that have shown that naloxone can induce signs of opioid withdrawal following the exposure to physical stressors.

NALOXONE AUGMENTS PAVILIONIAN CONDITIONING OF CONCOMITANT HEART RATE AND MEDIAL PREFRONTAL CORTEX NEURONAL RESPONSES. L.L. Hernandez*, E.L. Watson, and C.J. Glaser. VA Medical Center and U South Carolina, Columbia, SC 29201.

Low doses of naloxone (0.1 mg/kg) augment Pavlilian cardiac conditioning and delay its extinction in rabbits. Since the medial prefrontal cortex (mPFC) participates in Pavlinian conditioning, we assessed whether SNX (0.1 or 0.5 mg/kg, i.v.) has parallel influences on conditioned heart rate responses (HR C) and concomitant, pretraining, multi-unit activity (MUA) during differential Pavlilian training (one tone Cs+ paired with shock, another Cs- presented alone). Prior to training, each CX dose reduced the magnitude of HR orienting responses to the tones but did not alter tone-evoked increases in PFCm MUA, compared to saline. During conditioning, 0.5 mg/kg increased the overall magnitude of HR CRs, while 0.1 mg/kg reduced HR CR magnitude; nonetheless, each dose enhanced HR discrimination during testing. Further, Cs+ evoked activity increased that grew larger during training and remained elevated. These effects were greater magnitude to the Cs+ vs. -Cs- amplified MUA discrimination during training and extinction, but the higher dose increased, while the lower decreased, the size of the MUA CR to the tone that HR has similar effects on CS-evoked changes in HR and PFCm MUA during Pavlilian training and extinction, and suggest that endogenous opioid systems in or afferent to the PFC modulate Pavlilian discrimination.

Recent findings suggest that a modest increase in circulating glucose levels directly modulates brain mechanisms involved in mnemonic processing. Glucose infusions into the septal area reverse amnesia induced by morphine infusions. Amnesia following intraseptal morphine infusions may be due, in part, to opioid inhibition of cholinergic neurons with glucose reducing this effect. The present experiment determined whether intraseptal glucose reverses the effects of intraseptal morphine injections on acetylcholine (ACh) release in the hippocampal formation and on memory. Samples of extracellular ACh were assessed in two intervals using in vivo microdialysis with HPLC-EC. From 20-40 min after intraseptal morphine injections (4.0 nmol), ACh output was reduced by 25% compared to baseline levels. Concomitant treatment with glucose (18.3 nmol) blocked this effect, with ACh output similar to baseline rates. Glucose and CSF injections alone did not change ACh output compared to baseline. Two days after microdialysis testing, rats received septal infusions 25 min prior to spontaneous alternation testing. Intraseptal morphine infusions reduced alternation scores which were reversed by concurrent glucose infusions. The effects of intraseptal infusions on alternation performance and ACh output were significantly correlated. These findings suggest that glucose may ameliorate memory deficits produced by intraseptal morphine infusions by directly or indirectly blocking the opioid inhibition of cholinergic neurons. ENHANCEMENT OF MEMORY PROCESSING IN AN INHIBITORY AVOIDANCE AND RADIAL MAZE TASK BY POSTTRAINING INFUSION OF BOMBESIN INTO THE NTS. C.L. Williams* & J.L. McGaugh, Center for the Neurobio. of Learning & Memory and Dept. of Psychology, U. of Calif., Irvine, CA 92717-3800.

Bombesin is a peptide known to modulate memory storage when given either systemically or intraventricularly immediately after training. Two days after training it was not possible to determine whether the nucleus of the solitary tract (NTS) mediates the effects of bombesin on memory. In the first experiment male Sprague Dawley rats were trained in an inhibitory avoidance task (0.5 mg/kg of morphine) and bombesin or vehicle was infused unilaterally into the NTS through implanted cannulae immediately after training. Retention was assessed either 1 or 7 days later. Doses of bombesin ranging from 5 to 50 ng of bombesin significantly enhanced retention on the day test (p < .05 and .01 compared with vehicle controls respectively). There were no differences between the drug and control groups on the seven-day retention test. In the second experiment, bombesin (25, 50, or 250 mg) or vehicle was infused unilaterally into the NTS immediately after the animals were trained in a radial arm maze task. On retention tests given 18 hours later, groups that received 25 or 50 ng of bombesin made a significantly greater percentage of correct choices on the retention test than did the vehicle-treated controls (p < .02 and .05 respectively). The findings indicating that bombesin influences retention by activating the NTS is consistent with recent evidence suggesting that the NTS is involved in regulating memory storage.

NEUROTENSIN RECEPTORS DECREASE AS A FUNCTION OF AGING AND COGNITIVE PERFORMANCE IN THE RAT BRAIN. J. Goldsworthy*, E. Khetani, M.J. McNeely & R. Quinlan, Dept. of Psychiatry, Neurology and Neurosurgery, Douglas Hospital, Res. Ctr, McGill Univ., Montreal, Canada, H4H 1R3

Cognitive deficits are often associated with the disease and dysfunction of cholinergic function. However, functional changes in the activity of other neurotransmitter systems such as neurotensin (NT) can also affect cognitive behavior. High concentrations of NT-like immunoreactivity and receptors are often found associated with areas known to be involved in mnemonic processing as well as cholinergic neurons. Further, alterations in NT mRNA density have been reported to be associated with the amnesia produced by lesions of basal forebrain neurons (Wenk et al., 1989, Behav. Brain Res., 33: 367-95). Thus, the objectives of the present study were to evaluate if NT-like immunoreactivity in the aged rat brain and if these alterations are related to cognitive status. Aged (24-25 month old) Evans rats were behaviorally evaluated using the Morris Water Maze task (3 trials/day for 5 days). Animals were classified as either aged, cognitively impaired (AI) or cognitively unimpaired (AU) based on their performance in the task compared to young rats (YR). NT-like immunoreactivity (NTL) binding was observed in the hippocampal formation (dentate gyrus), entorhinal cortex, amygdala, and hypothalamus as a function of age. Both aged groups also showed significant (p<.05) reductions in NT binding sites compared to CTX in the hippocampal CA3 sub-field, with the AI animals exhibiting the lowest levels. Thus, the alterations in [3H]NT binding may be a systematic involvement of NTergic systems in age-related cognitive deficits.

In the middle and central temporal area [3H]NT binding sites were decreased as a function of age while binding in the medial forebrain bundle was decreased as a function of age and cognitive status. These decreases in [3H]NT binding may be a result of a decrease in the NT levels and their receptors in a variety of brain areas (see Hertz et al., 1994, that meeting).

DOPAMINE D1 DRUGS MODULATE LEARNING ABILITIES OF AGED MEMORY IMPAIRED RATS. C.L. Moore*, S. Ede, J.J. Horst†, W. VPN, R. Chamoun* and P. Gaudette†, 1Douglas Hospital Res. Ctr. and Dept. of Neurology/Neurosurgery, McGill Univ., Verdun, Q. Canada H4H 1R3, 2Hospital Notre Dame, Dept. of Neurosurg., Universite. de Montreal, Q. Canada H2L 4R5

Lately, it has become apparent that besides acetylcholine, a number of other neurotransmitters contribute to learning and memory either directly or via their interaction with the central cholinergic system. For example one of the spatial mnemonic deficits brought on by pharmaceutical manipulations such as hippocampal deservation or the blockade of cholinergic receptors are reportedly attenuated by the administration of dopaminergic (DA) drugs. It is also known that DA drugs can facilitate learning in various paradigms in young animals. In the present study, we examined if such drugs could modulate learning in aged animals suffering from cognitive deficits. 24-25 month old Long Evans rats (3 trials/day for 5 days). Animals were classified as either aged, cognitively impaired (AI) or cognitively unimpaired (AU) based on their performance in the task compared to young rats (YR). NT-like immunoreactivity (NTL) binding was observed in the hippocampal formation (dentate gyrus), entorhinal cortex, amygdala, and hypothalamus as a function of age. Both aged groups also showed significant (p<.05) reductions in NT binding sites compared to CTX in the hippocampal CA3 sub-field, with the AI animals exhibiting the lowest levels. Thus, the alterations in [3H]NT binding may be a systematic involvement of NTergic systems in age-related cognitive deficits.

In the middle and central temporal area [3H]NT binding sites were decreased as a function of age while binding in the medial forebrain bundle was decreased as a function of age and cognitive status. These decreases in [3H]NT binding may be a result of a decrease in the NT levels and their receptors in a variety of brain areas (see Hertz et al., 1994, that meeting).

418.5 DISHARMONY OF ACOUSTIC STARTLE SHOWS FREQUENCY CATEGORIZATION BY CRICKETS. R.L. Wyettbach* and R.R. Hipf, Neurobiology: Animal Behavior, Cornell University, Ithaca, NY 14853

Flying Polynesian field crickets (Teleogryllus oceanicus) have an acoustic startle response to pulses of ultrasound. This consists of several movements that steer the cricket away from the sound source. One aspect of the response, metathoracic leg swing, is of short latency and duration.

Ultrasound startle deceleration with repetition in a way consistent with standard cricket habituation. If deceleration is not elicited, recovery is rapid. With repetition, deceleration becomes slower, with a longer latency and a longer duration.

We have used this test to determine which frequencies of sound are perceived differently from ultrasound. Crickets were habituated to 5 pulses of 20 kHz at 10 dB for 100 ms. Trials were presented in blocks of 5, with a 500 ms inter-trial interval. The pulse train, presented at 20 kHz, was followed by a test pulse of 20 kHz as before. All pulses were presented to the left ear. The deceleration pulse was 100 ms, with a 50 ms rise time and a 40 ms fall time.

Pulses of any frequency habituated when presented from the direction opposite the habituating train, but only pulses below 17 kHz habituated when presented from the same direction as the habituating train. Thus, pulses below 17 kHz are habituated from 20 kHz, while those above 17 kHz are not distinguished from 20 kHz.

418.6 NEGATIVE THERMOKINESIS DURING FLIGHT IN THE LOCUST. R.M. Robertson* and C.T. Kuhnle, Dept. of Biology, Queen's University, Kingston, Ontario, K7L 3N6, Canada.

Locusts aggregate in regions with an optimal environmental temperature, yet there is currently no evidence for locomotor thermokinesis in locusts. We have investigated whether tethered flying locusts will steer relative to a radiant heat source.

Adult male Locusta migratoria were tethered and flown in front of a wind tunnel. Wing movements and postural adjustments of the abdomen and hindwings were monitored with high-speed cinematography (250 frames/s) and with video digitation (60 frames/s). In separate experiments, abdominal movements were monitored using a capacitative position transducer. Brooder lamps (250 watt) were placed on the left and right of the animal providing directional heat sources.

Within 1s of turning on a lamp, locusts made characteristic steering manoeuvres away from the direction of the source. Interposing a transparent acrylic barrier (1.2 cm thick) markedly reduced the steering responses. Neither covering the lights nor adding sand, nor interposing infra-red filters (Edmund Scientific, P60 033) between the locust and the lamp, had an effect on thermokinesis.

We conclude that flying locusts are attracted by heat sources by detecting infra-red radiation. We are currently investigating which structures are involved in mediating directional infra-red sensitivity.

418.7 SYNCHRONIES IN THE NORTH AMERICAN FIREFLY PHOTURIS CAROLINA. J. Cripps and A. H. Hurd, Department of Biology, Georgia Southern University, Statesboro, GA 30460 and Department of Physiology and Neurobiology, University of Connecticut Health Center, CT 06269-3028.

Photuris carolina shows discontinuous synchrony. Bursts of 5-8 flashes at 2 sec occur concurrently every 14-19 sec. When the terrain is flat and forested, the synchrony is always present. When the terrain is steep and forested, the synchrony is a wave synchrony. Thus, the same species of firefly is capable of showing unison or wave synchrony on the topographical conditions.

We studied unison synchrony by employing low level light videography and frame-by-frame playback analyses as well as photometric recordings. The latter was combined with computer acquisition and analysis in the field. Data obtained from field caged males revealed that group flashing began concurrently, ended concurrently, and the flashes within the burst occurred concurrently, resulting in the mechanisms responsible for this synchronic behavior, stimulated flashes were presented to individual fireflies at various times during their flash patterns. Stimulus flashes presented during the interburst interval enhanced or inhibited the next flash depending on when the stimulus was presented. Stimulus flashes presented during the interburst interval, however, had no noticeable effect.

We suspect that the interburst oscillator can be modulated through anticipatory (unison) or triggered (wave) mechanisms. We also suspect that the interburst oscillator, once released in the ethological sense, is not susceptible to feedback.

Supported by NSF grant IBN-9208709 and GRC grant 11939.

Periplaneta americana responds to abrupt touch of an antenna by turning away from the stimulus and running. This response occurs at very short latency, and the angle of initial turn is typically convex. We have noted that this response is not essential for escape turns (Comer et al., 1994; J Comp Physiol 174:17).

We believe that visual cues are actually used as touch of antennae. We were therefore interested in knowing if aspects of escape are influenced by vision.

We report here behavior studies on intact animals tethered in a high-speed locomotion tunnel, and electrophysiological studies of descending interneurons. When lateral eyes and ocelli were covered with opaque paint, animals turned reliably following antennal touch. But the duration of subsequent running was decreased. In another experiment, sighted animals were tested following response to a stimulus presented near an antenna. Animals responded by orienting an antenna toward the probe and touching it if the probe had high visual contrast with background. If the probe had low contrast, contact with the probe was at chance levels. These data indicate that cockroaches visually detect stimuli applied to the antennae, and that vision (while non-essential) may influence escape performance.

Intracellular recording and dye-injection revealed an interneuron, with soma in the brain, that responds to visual stimuli of the type used in behavior tests. In recordings from neck connective, the neuron typically responded by firing a train of spikes as a probe moved across the visual field of the contralateral eye. When antennal touch occurred, the firing of this neuron preceded that of descending sensory-motor interneurons. The cell's axon (15-20 μm in diameter) extends to the thoracic ganglia.

We suggest that while visual cues are not essential for touch-evoked escape, they may influence some elements of the escape response. The role of descending interneurons in such an influence is under investigation.

418.9 TESTING FOR A POPULATION VECTOR CODE FOR WIND DIRECTION IN THE COCKROACH GIANT INTERNEURONS. R. Less, J. M. Cymb, Dept. Cell and Animal Biology, Hebrew University, Jerusalem, Israel.

One proposed mechanism by which a neural assembly codes direction stimulus is the vector population code (VPC). Originally observed in the monkey cortex, this is noted here in the cockroach escape system. Specifically, we test 3 bilateral pairs of giant interneurons (GI's) that respond directionally to wind stimuli and evoked as evasive turn. GI 3 responds most strongly to wind from the ipsilateral rear. Such wind makes large turns away. GI 3 to respond most strongly to wind from the ipsilateral rear. Such wind makes large turns away. GI 1 responses equally to both directions (Kolben and Cymb, Soc. Neurosci., Abst., 1993).

By a VPC, one represents a wind stimulus as a vector, whose direction is the cell's best excitatory direction, and whose length is the number of spikes evoked by the given wind stimulus. Vector summation of the GI's 1, 2 and 3 gives good agreement (± 20°) between the actual wind direction and that calculated using the VPC.

To help determine whether the cockroach actually uses a VPC, we modified the spars trans of individual GI's during wind-evoked turning behavior and determined the effects on the turn. Wind pulls from 90° right evoke, in a cockroach turned on a slick surface, turning movements to the left. We analyzed the initial leg movements and body's turning tendency using a high speed video (250 frames/s). During another puff from the same source, intracellular current pulses, to either right GI 3 or 2. Roughly doubling the number of spikes in GI 3 (from 6 to 12) has produced, to date, responses corresponding to larger turns to the left in 7 of 9 cockroaches, responses instead to GI 1 has produced spiral turns to the right, responses corresponding to smaller turns in 4 out of 5 cockroaches. These data are consistent with the predictions of a VPC, since increasing the number of spikes lengths a GI's vector and thus drives the direction of the wind specified by the VPC toward that GI's best excitatory direction.

418.10 SPONTANEOUS SELF-GENERATED COUNTERTURNS DURING TETHERED FLIGHT OF MALE MOTTIS, Manduca sexta. R. Baker*, M. Willis, E.A. Archer*. *Center for Neurogenic Communication Disorders and 1st. Div. of Neurobiology, Univ. of Arizona, Tucson, AZ 85721

Flight behavior of mottis, Manduca sexta, is known to be modulated by odors and visual patterns. In plumes of female pheromone, for example, flight tracks of males assume a characteristic upward zigzagging pattern. Our laboratory is researching the sensori-motor basis of this pattern. We have recorded spontaneous activity patterns of tethered mottis in the 1st hour of their cirradian activity cycle, without specific olfactory or visual stimulation. Movement patterns were logged visually and videotaped. Synchronous EMG recordings from various wing muscules revealed unchanging movement patterns.

Mottis typically activated wing flapping (pre-flight warmup), followed by large amplitude wing beating indicative of tethered "flight," within the first 10 min. of scotophase. Flight continued in bouts from a few sec to 14 min. duration. During flight bouts, mottis mostly maintained their postural stability and were consistent with stable forward orientation. Often, however, they showed spontaneous changes in posture during wing beating, we interpret them as attempts to turn, including: (1) turning of the head and, (2) curling the abdomen in the direction of the intention, as well as (3) retraction of the wings on the inside of the turn, and protrusion of those outside the turn. Attempted turns were sometimes executed in rapid alternating succession, reminiscent of counterturning during unprovoked zigzag flying. These observations suggest a capability to organize counterturning intrinsically, rather than only in response to afferent inputs. Timing of movements and motor output patterns underlying these spontaneous turns are unique, and are parallel to those observed in males posturings. Further studies are necessary to determine the circuitry of these spontaneous movements, and to compare with similar patterns activated and modulated by visual and pheromonal stimuli. (Supported by NSF IBN 9216532).
418.11 MODULATION OF MOTOR PATTERNS IN A TETHERED MOTH DURING MULTI-MODAL STIMULATION. EE Wood* and EA Arbas. ARL Div. of Neurobiology, Univ. of Ariz., Tucson, Ariz. 85721

We conducted the flight behavior of the male sphinx moth, Manduca sexta, as a model for the generation and control of orientated locomotion. Of interest is control of pheromone-evoked "zig-zagging" flight of males searching for mates. This pattern of flight exhibits a consistent interturn interval as the male progresses upward. Previous results described changes in activity in the animal in response to free flying animals and reduced preparations from which EMGs of flight muscles could be monitored (Willis and Arbas, 1991; Katzaki and Arbas, 1990). This investigation describes aspect of the flight control in various multi-modal stimulations while recording electrical potentials in relation to specific pheromone neurons of particular motor nerves. Study of flight initiation shows that short bouts of stereotyped flight are evoked by short (< 1 s) exposures to flight. Short bouts of flight are also temporarily random and uncoordinated in central control of flight (flight after odor loss). These short bouts are useful for comparison to more complex flight patterns. Cholinergic neurons (Katzaki and Arbas, 1990) also produce stereotyped flight that are evoked by this type of flight. Visual stimuli simulating left and right turns can initiate flight with regular turning intervals. Visual stimuli combined with pheromone stimulation elicited frequency modulation of the flight rhythm reminiscent of that observed during free flight. We are continuing this study using more complex computer driven stimuli protocols accompanied by recordings of motor rhythms in the thoracic ganglia. (Supported by NIH NRSA F32 DC 00097-01 and NSF IBN 921562).

418.12 CAN NEUROGENESIS EXPLAIN MUSHROOM BODY REORGANIZATION IN THE BRAIN OF THE ADULT HONEY BEE? JL Strande, S.E. Fahrbach and G.E. Robinson*. Department of Entomology and Neuroscience Program, University of Illinois, Urbana, IL 61801. A reorganization of the mushroom bodies in the brain of the adult honey bee (Apis mellifera) is associated with behavioral development and colony labor (Wulff and Rehan, 1981; Nature 364, 238-240). To probe the proximate mechanisms of this neuroanatomical plasticity, we tested the hypothesis that neurogenesis occurs in the adult bee brain. Bees were exposed to the proliferation marker bromodeoxyuridine (BrdU) at 3 stages of behavioral development: one-day-old, nursing, and foraging. BrdU was administered in 3 ways: 1) into the brain corpus via injection into the abdomen, or in vitro, with brains incubated in bee culture medium containing BrdU. Immunohistochemical experiments completed to date revealed only one BrdU-labeled nucleus of a single mushroom body neuron in 2140 sections of tissue examined. Several controls were processed simultaneously with adult bee brain tissue. Nervous tissue from Manduca sexta larvae, in which neurogenesis is known to occur, revealed extensive BrdU labeling. Neurogenesis was also readily detected in nervous system tissue from honey bee larvae and pupae. These results indicate that neurogenesis occurs very infrequently or not at all in the adult bee brain. It does not appear that the previously observed mushroom body reorganization can be explained by neurogenesis. Supported by NSF grant IBN 9211366 and an NSF REU Award (SEF and GER) and NIMH grant MH42724-01 (GER).

419.1 MDMA INCREASES THE EXTRACELLULAR CONCENTRATION OF 2,3-DIHYDROXYBENZOIC ACID IN THE STRIatum: EVIDENCE FOR INCREASED HYDROXY RADICAL FORMATION. G.A. Gudelevy* and B.K. Yamamoto, Dept. of Psychiatry, Case Western Reserve University, Cleveland, OH 44106 It is well recognized that the administration of 3,4-methylenedioxymethylamphetamine (MDMA) results in a long-lasting depletion of brain 5-HT. It is suggested in the literature that the depletion of 5-HT is due, in part, to the acute and sustained release of dopamine (DA). The purpose of the present study was to examine whether the MDMA-induced depletion is in the extracellular concentration of DA in the striatum is accompanied by the formation of hydroxyl free radicals that result from DA autooxidation. Hydroxyl radical formation was assessed in dialysis samples from the striatum by quantifying the extracellular concentration of 2,3-dihydroxybenzoic acid following its conversion from salicylic acid. The dialysis probes were perfused with dialysis buffer containing 5 mM salicylate for 3 hrs at a volume flow of 500 nl/hr. The ip injection of MDMA (20 mg/kg) resulted in an immediate increase in the concentration of 2,3-DHBA which was 450% of that in vehicle-treated controls. An MDMA-induced increase in 2,3-DHBA formation was observed for at least 6 hrs. A 30 min application of MDMA (10 mg) by the dialysis probe also increased 2,3-DHBA concentrations which were similar in magnitude to those produced by systemic administration. In rats in which the MDMA-induced increase in DA release was attenuated by treatment with mazindol, the MDMA-induced increase in 2,3-DHBA formation also was significantly attenuated. These findings are consistent with the view that MDMA produces a DA-dependent increase in hydroxyl radical formation.

419.2 POTENTIATION OF MDMA-INDUCED DOPAMINE RELEASE AND SEROTONIN NEURON TOXICITY BY SEROTONIN AGONISTS. J.E. Nash, B.K. Yamamoto and G.A. Gudelevy. Deps. of Psychiatry and Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106 The effect of serotonin (5-HT3) agonists, DOI and 5MeODMT (5-methoxy-N,N-dimethyltryptamine) on MDMA (3,4-methylenedioxymethylamphetamine)-induced release of dopamine (DA) in the striatum was studied in rats by the use of in vivo microdialysis. A concentric dialysis probe was inserted into the striatum and dialysis samples were collected every 30 min for 240 min. MDMA (2.6 mg/kg, sc) administration increased the release of DA in the striatum. The MDMA-induced increase in the extracellular concentration of DA was enhanced significantly in rats given either DOI (1 mg/kg, ip) or 5MeODMT (15 mg/kg, ip). Neither DOI nor 5MeODMT alone affected the extracellular concentration of DA in the striatum. The effect of DOI on the long term depletion of striatal 5-HT produced by MDMA also was investigated. The striatal concentration of 5-HT was reduced slightly, but not significantly, 7 days following the administration of MDMA (10 mg/kg, sc). However, 7 days following the concomitant treatment with DOI and MDMA the striatal concentration of 5-HT was significantly less than that in rats treated with MDMA alone or the vehicle-treated controls. It is concluded that activation of 5-HT3 receptors is an important determinant of the acute increase in extracellular DA and, consequently, the long-term depletion of brain 5-HT produced by high dose administration of MDMA.

419.3 THE STRIATAL NEUROTOXICITY INDUCED IN THE C57BL/6J MOUSE BY D-AMPHETAMINE IS BLOCKED BY RESTRAINT STRESS BUT NOT BY SUPPLEMENTAL CORTICOSTERONE. D.B. Miller* and J. P. O'Callaghan. U.S. EPA, RTP, NC 27711

Amphetamine (AMP) is a potent stimulant and restrained (ST) dopaminergic neurotoxocis. Stress affects AMP but its effects on AMP neurotoxicity are not well examined. Restraint stress activates the adrenal axis and elevates corticosterone (CORT) levels. Here, we determined if restraint or supplementation with CORT potentiated or attenuated the effects of d-AMP neurotoxicity. Astrogliosis, quantified by immunohassey of GFAP, was taken as a marker of neuronal damage. Body weight (BT) was also monitored as restraint can cause hypothermia and BT is a factor in AMP neurotoxicity. Female mice (6/group/case) were given SAL or 5-MeODMT at a dose of 20 mg/kg. For each BT, every 2 hrs beginning at 11:30 AM for a total of 4 inj. Mice were restrained in 50 ml centrifuge tubes, beginning at 0.5 hr prior to the 1st inj and until 1 hr following the last inj. BT of the water drinking rats was placed in the drinking water (20g/ml - 3.2 g/kg) 1 week prior to AMP inj and continued until the ST was obtained at 72 hrs post the last inj. BT was recorded prior to dosing and every 2 hrs following each inj. AMP caused hypothermia (1 - 2°C) and neural damage as indicated by a large (30%) increases in ST GFAs. Restraint totally blocked the d-AMP hypothermia as well as the GFAs increase. CORT had no effects. The data suggest an elevation in BT is important in d-AMP neurotoxicity and that neurotoxicity status may not play a role in AMP neurotoxicity. However, the dosage of CORT utilized was low and did not cause thymic invovlation. Higher dosages, as well as the elimination of circulating CORT, such as by adrenalectomy, should be investigated.

419.4 D-Amphetamine (AMPH) Levels in Caudate-putamen (CPU) Microdialysis After Doses That Produce Either Behavioral or Neurotoxic Effects. P. Clausing, B.R. Holson, W. Slikker Jr., B. Gough and J.F. Bowyer, NCTR/FDA, Jefferson, AR 72079-9502. Six mo. old Sprague-Dawley rats (4/group) were dosed with either 1 or 2.6 mg/kg AMPH sc to produce increases in locomotor activity and/or stereotypy. Forty to 60 min after 1 mg/kg, when motor activity was maximum, AMPH levels in the microdialysate were maximal at (mean ± SEM) 0.28 ± 0.04 μM. Forty to 90 min after 2.6 mg/kg, the microdialysate levels rose to a max. of 0.51 ± 0.09 μM. Stereotypic behavior started at this time and lasted for 1-2 hrs. In a second experiment, 6 and 12 mo. old rats (5/group) were given AMPH sc either 4.5 μg/kg in a 24°C environment (known to produce neurotoxicity) or 4.15 μg/kg in a 10°C environment (not toxic) at 2 hr intervals. It was hypothesized that in the cold environment the higher doses would produce higher CPU-extracellular AMPH levels and higher neurotoxicity levels. Peak levels were: 1.5 ± 0.3 μM (6 mo. old, 4.5 μg/kg, 24°C), 2.6 ± 0.7 μM (12 mo. old, 4.5 μg/kg, 24°C), 3.0 ± 0.4 μM (6 mo. old, 4.15 μg/kg, 10°C), 1.1 ± 0.5 μM (12 mo. old, 4.15 μg/kg, 10°C). Thus, 12 mo. old rats had significantly higher AMPH levels than 6 mo. old. Cold room rats dosed with triple the dose had 1.4-2.0 times the AMPH levels seen in the 24°C rats. Thus the efficiency of the microdialysis probes was estimated to be 15-20%. Thus, approximately 2 μM extracellular AMPH is necessary to produce behavioral effects. The data are preliminary and the results are similar to those in the CPU while levels after neurotoxic doses are between 10 and 30 μM.
419.5

Using Orthophthalaldehyde (OPA) and 3-Mercaptopropionic Acid (MERA) Derivatization to Quantify D-Amphetamine (AMPH) Levels in Brain Tissue by High Performance Liquid Chromatography (HPLC) J.F. Brower and P. Clauzing, NCTR/FA, Jefferson, AR 72079-9502.

Rats implanted for microdialysis in the striatum were dosed with AMPH (1 to 15 mg/kg, sc). The microdialysate buffer consisted of 140 mM NaCl, 1.5 mM K2HPO4, 1.5 mM KC1, 1.5 mM MgCl2, 1.25 mM CaCl2 and 10 mM glucose, pH 7.4. Dialysate was collected continuously at 20 min intervals (10 ml/hr) for 4 hrs starting at 2 hrs, prior to dosing. The samples were either stored at -70°C or analyzed immediately by HPLC. AMPH levels were determined by derivatizing 10 to 20 μl microdialysate with 20 μl of 0.1 M borate buffer, pH 9.4, containing 5 mg OPA and 40 μL MERA per ml and 70 to 90 μl H2O. Then 75 μl of the derivatized sample was separated on a C18 column using 50 mM potassium phosphate buffer, pH 5.5, and a gradient of 35% to 65% methanol with 1.5 ml/min flow rate. Fluorescent detection (340 nm λ excitation, 440 nm λ emission) was used. The AMPH derivative had a retention time of 14.4 min which was 2 min more than all the amino acid derivatives and there were no peaks within ±1.5 min of the AMPH derivative. Very little p-hydroxyamphetamine was detected in the microdialysate after AMPH sc. Microdialysate buffer spiked with AMPH to obtain 0.1 to 10 μM AMPH concentrations was used to quantify microdialysate AMPH levels. The detection limit was 0.05 μM AMPH in 20 μl of microdialysate, equivalent to 135 picograms. From 0.27 to over 27 nanograms AMPH can be quantified in microdialysate using these methods.

419.7

PRENATAL METHAMPHETAMINE CAUSES SPECIFIC METABOLIC CHANGES IN THE BASAL GANGLIA SEEN AT MATURATION. A.D. Heenanart and S. Caldecott-Hazard, Department of Pharmacology, Seton Hall University, School of Graduate Medical Education, South Orange, NJ 07079

Methamphetamine exposure in utero has been shown to produce profound alterations in the adult brain monochrome system. These effects are also reflected in subtle changes in specific adult tasks. Human maternal methamphetamine abuse may have a similar impact on the fetal brain that may persist into adulthood. We sought to model the drug's developmental effects chronically on fetal rats by i.p. The "C" deoxyglucose technique (DG) was used to measure adult brain metabolism and as a sensitive indicator of long term changes in neuronal function. In utero methamphetamine (10 mg/kg) was administered throughout gestation. Drug related maternal anorexia, malnutrition, altered blood pressure/ temperature and postnatal care were controlled by using rats made tolerant to the drug's side effects and by cross fostering. At birth, the drug exposure ended and the brain metabolism of the drug-free adult offspring were behaviorally assessed and mapped with DG. An increased rate of glucose utilization was seen in the globus pallidus of the perinatally treated animals. No changes were seen in other areas of the basal ganglia, lateral habenula or medial dorsal prefrontal cortex. These results are in contrast to our previous observations in these areas following amphetamine withdrawal in adults. However, both paradigms produced a similar decrease in open field activity.

In utero drug treatment produces specific alterations in brain metabolism in the adult offspring at 30 days of age. These changes were accompanied by both neurological and performance deficits and to the point of the production of an altered adult neurochemical and behavioral state that can be attributed to the prenatal neurotoxic effects of methamphetamine on specific brain sites.

419.8

Treatments with high doses of methamphetamine (METH) leads to well-described long-term decreases in serotonin and dopamine in certain regions of the brain. Despite quite dramatic reductions in these neurotransmitters, very few baseline behavioral changes have been observed in rats following neurotoxic regimens of METH. The present study was undertaken to examine behavioral and neurochemical consequences of METH neurotoxicity.

Adult, male Sprague-Dawley rats received injections of saline or METH (6.5 mg/kg sc) four times daily, at two hour intervals, for ten days following treatment behavior was assessed in a large (4 x 4 x 4 ft) plexiglass open field apparatus. Animals were placed in the center of the open field and behavior was observed for ten minutes. Four days following behavioral testing, animals were sacrificed, and the brains examined by immunocytochemistry, receptor autoradiography and in situ hybridization for changes in serotoninergic function.

As has previously described, METH produced small, but significant decreases in serotonergic indices in several brain regions, including septocs, hippocampus and caudate-putamen. Other areas, such as substantia nigra appeared to be spared. Animals that had received METH showed a significant increases in locomotor activity and talking, relative to saline controls. The increases in behavior were seen primarily toward the end of the ten minute session, and occurred despite the fact that animals had been drug-free for ten days. The results suggest that METH neurotoxicity produces significant changes in locomotion and exploration. These changes may be due to decreases in serotonergic and/or dopaminergic function. (Supported by NIDA DA02265 and NIMH MH2251. KAT and DTC are recipients of NARSAD Young Investigator Awards).

419.9

In experimental animals, methamphetamine (METH) causes pronounced neurotoxic effects to monoaminergic neurons. Studies have demonstrated that various pharmacological agents prevent METH-induced neuroapathy indicating that several processes may be involved in mediating the toxicity of METH. Several neurotoxic effects of METH such as brain-derived neurotrophic factor (BDNF), have significant roles in development, maintenance and survival of dopaminergic neurons. Roles for neurotrophic factors in supporting the survival of dopaminergic neurons in the basal ganglia remain to be determined, especially under conditions of stress or injury. Therefore, our aim was to characterize the dynamics of BDNF expression during and after an insult to nigrostriatal dopaminergic neurons by METH in mice. Our results indicate that expression levels of BDNF increase approximately 2-4 fold in the mesencephalon and cortex 24 hr after initiation of a neurotoxic regimen of METH. These results demonstrate that stress or injury to dopaminergic neurons in the basal ganglia is a regional expression of neurotrophic factors (i.e. BDNF) in an adult mouse brain.

419.10

METHAMPHETAMINE SENSITIZATION INCREASES VULNERABILITY OF THE PREFRONTAL CORTEX TO METHAMPHETAMINE TOXICITY B.N. Yamamoto* and S.E. Shephard, Deps. of Psychiatry and Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106.

Sensitization to the behavioral and neurochemical effects of stimulants occurs following a low dose intermittent pretreatment regimen. This is manifested as an increase in behavioral stereotypy and mesocorticolimbic dopamine (DA) function subsequent to the administration of an acute low dose challenge. These effects occur without evidence of dopamine (DA) depletion. The purpose of this study was to examine the sensitization regimen of methamphetamine (METH) enhances DA release and the subsequent depletion following neurotoxic doses of METH. Male rats were injected once daily for 7 days with METH (2mg/kg, i.p.) or saline. Following a 7 day withdrawal, the rats were challenged with 3 subcutaneous injections of METH (7.5mg/kg), each injection given 2 hours apart. Microdialysis was used to measure extracellular levels of dopamine (DA) and cortical serotonin (5-HT) in the pfc (pc) of awake rats. Rats were sacrificed 4 days later and DA tissue content was assayed. In METH pretreated rats, DA release in pfc but not in snt was significantly increased during the METH challenge as compared to pretreated with saline (p<0.02). One week later, this group of rats also exhibited a greater depletion of DA in pfc (p<0.02) compared to the saline pretreated group. Saline and METH pretreated rats given a saline challenge were not different from controls. Conversely, striatal DA was significantly less depleted by a METH challenge in METH pretreated compared to saline pretreated rats (p<0.02). These data provide evidence that pfc DA neurons are preferentially susceptible to the neurotoxic effects of METH in rats previously sensitized to METH. Augmented DA release in the pfc may be partially responsible for the dopamine depletion following a METH challenge.

**DRUGS OF ABUSE: CNS STIMULANTS—TOXICITY**

**DOPAMINE AND GLUTAMATE EFFLUX ARE INCREASED IN PREFRONTAL CORTEX OF RATS SENSITIZED TO METHAMPHETAMINE**

S. E. Stephen{ }and B. K. Yamamoto. Dept. of Psychiatry and Neurosurgery, Case Western Reserve Univ., Cleveland, OH 44106.

Behavioral and neurochemical sensitization occurs following intermittent, low doses of psychostimulants such as methamphetamine (METH). This is manifested as behavioral stereotype and increased mesocortical dopaminergic function following administration of a challenge dose. No direct comparisons have been made with regard to whether the increased dopaminergic (DA) response in vivo is mediated by an impulse-dependent or independent mechanism. Furthermore, it is not known if release of other neurotransmitters is affected by this pretreatment regimen of METH. The purpose of this study was to investigate if DA and glutamate (glu) release in the prefrontal cortex (pfc) is augmented in METH sensitized rats upon a low challenge dose of METH or potassium (K+)-stimulated. Male rats were pretreated once a day for 5 days with METH (2mg/kg, i.p.) or saline. Following a 7 day washout period the rats were challenged with either a low dose METH injection (2mg/kg, i.p.) or K+ (80mM) infused into pfc. Microdialysis was performed in the diencephalon (DA) and pfc. DA infusion into the pfc of METH pretreated rats increased extracellular DA and glu levels significantly from baseline values (p<0.02). These increases were greater than in saline pretreated rats (p<0.05). The low dose METH challenge significantly increased extracellular DA but not glu concentrations to a greater extent in METH pretreated compared to saline-pretreated rats (p<0.02). These data provide evidence that a low dose pretreatment regimen of METH enhances DA transmission in the pfc through both impulse- and drug-dependent processes. In addition, enhanced glu release in pfc may play an important role in the behavioral effects associated with METH sensitization.

419.12

**INFLUENCE OF PRIOR BEHAVIORAL SENSITIZATION ON THE NEUROTOXIC EFFECTS OF METHAMPHETAMINE**

M. Sparago, J. Yuan and G. Ricarte*. Department of Neurology, Johns Hopkins Medical Institutions, Baltimore, MD 21224.

Sensitization to psychomotor stimulant drugs is associated with alterations in brain dopamine (DA) neurotransmission. DA release has been implicated in the neurotoxic action of methamphetamine (METH). The purpose of the present study was to determine whether prior sensitization influenced the neurotoxic effects of METH on brain DA and serotonin (5-HT) neurons. To produce sensitization, mice were treated with METH (15 mg/kg, i.p.) once daily for 15 consecutive days. Control animals were treated identically with saline. One week later, the development of behavioral sensitization was documented by measuring a leftward shift in the dose-response curve for stereotype in METH-treated mice. After an additional one-week drug-free period, sensitized animals, along with controls, were treated with neurotoxic doses of METH. Seven days later, the animals were sacrificed and indexes of dopaminergic and serotonergic neuronal integrity were measured. Sensitization did not augment either the dopaminergic or serotonergic neurotoxic effects of METH in the striatum. To the contrary, the sensitizing regimen of METH appeared to render the animals partially tolerant to the drug's DA neurotoxic effects.

These results indicate that a chronic regimen of METH that induces behavioral sensitization does not render brain dopamine and serotonin neurons more vulnerable to METH's neurotoxic actions. Further, the partial tolerance observed suggests that the neurochemical mechanisms underlying the expression of behavioral sensitization may at least partially overlap those mediating METH's neurotoxic actions.

**EFFECTS OF d-FENFLURAMINE AND m-CHLOROPHENYLPIPERAZINE ON ACUTE 5-HT RELEASE AND LONG-TERM 5-HT DEPLETION IN RAT BRAIN**

M. H. Baumann, M. A. Ayestas, R. B. Rothman. Clinical Psychopharmacology Section, IRP, NIDA, NIH, Baltimore, MD 21224.

The serotonin (5-HT) agonists d-fenfluramine (FEN) and m-chlorophenylpiperazine (mCPP) are reported to release neuronal 5-HT by a Ca"++-independent, fluxeine-reversible mechanism. In the present work, we compared the acute effects of FEN and mCPP on extracellular 5-HT and dopamine (DA) using in vivo microdialysis methods in rats. The long-term consequences of repeated injections of FEN or mCPP on 5-HT neurotransmission were also examined. In the acute study, FEN or mCPP (10, 100 μM) was infused into the nucleus accumbens of conscious rats via microdialysis probes and monoamines were assayed in dialysate samples by microbore HPLC-EC. FEN and mCPP caused equivalent, dose-dependent increases in 5-HT, but not DA, at 1 and 10 μM doses. At the 100 μM dose, both drugs elevated dialysate DA as well as 5-HT. In the long-term study, rats were treated with FEN or mCPP (0, 3, 10 mg/kg, i.p.), one injection every 2 hr for 8 hr. Two weeks after the repeated dosing regimen, FEN-treated rats exhibited marked depletions in tissue levels of 5-HT (78%) and 5-HIAA (72%) in frontal cortex, whereas mCPP-treated rats showed no signs of 5-HT depletion. Thus, mCPP appears to enhance acute 5-HT release, in a manner similar to FEN, without causing damage to 5-HT nerve terminals. The present data suggest the possibility that 5-HT release per se may not be the causative factor in the serotonergic neurotoxicity associated with FEN and other substituted amphetamine derivatives.

**BRAHMI: AN ANCIENT BUT MODERN HERB**

G. Patriarche, S. Gevorkian. Department of Pharmacology, School of Medicine, University of Maryland, Baltimore, MD 21201.

Brahmi (Centella asiatica) is a well recognized herb with a range of traditional uses in Indian and other Ayurvedic systems of medicine. Recently, several of these uses have been validated by scientific research. For example, Brahmii has been shown to improve cognitive performance in animal models of Alzheimer's disease and depression. Furthermore, Brahmii has been shown to have anti-inflammatory and immune-modulating properties, which may contribute to its beneficial effects on brain function.

419.15

**BEHAVIORAL AND NEUROTOXIC EFFECTS OF METHCATHINONE**

Cathinone is a naturally-occurring amphetamine analog found in the Khat plant. Like amphetamine, cathinone has been abused and, in high doses, is selectively toxic to brain dopamine (DA) neurons. Methcathinone ("Cat") is a synthetic cathinone derivative that has recently surfaced in the illicit drug market. Because it contains an asymmetric carbomethoxyl group, methcathinone is available in D and L forms, and it is the L form that is used recreationally. The present studies evaluated the pharmacologic and neurotoxic properties of methcathinone stereoisomers in laboratory animals. Pharmacologic studies in mice indicated that L-methcathinone was approximately five times more potent as a locomotor stimulant than D-methcathinone. By contrast, in neurotoxicity studies, the D isomer proved more toxic to DA neurons in mice. To evaluate methcathinone's neurotoxicity in vivo, we performed a series of experiments. The results indicated that methcathinone was toxic to DA neurons in a dose-dependent manner. The neurotoxic effects of methcathinone were dose-dependent, with the L-isomer being more toxic than the D-isomer. These results indicate that methcathinone is a potent neurotoxin, and that the L-isomer is the more toxic form. In conclusion, our findings suggest that methcathinone is a promising target for the development of new amphetamine derivatives with therapeutic potential.
MEDIOL SEPTAL SECTIONS ENHANCE LOCOMOTOR SENSITIZATION TO AMPHETAMINE. J. E. Kelsey* and J. A. Grabiec. Dept. Psychology, Bates College, Lewiston, ME 04240.

Sensitization to the locomotor-enhancing effects of several drugs appears to critically involve the dopaminergic mesolimbic pathway from the VTA to the n. accumbens. Such locomotor sensitization appears to be modeled by projections from the hippocampus to the n. accumbens. In this experiment, we examined sensitization to the locomotor-enhancing effects of amphetamine in rats with lesions of differentially selected brain regions. Each subject received a single intraperitoneal injection of amphetamine and saline to five rats. During acquisition, the rats were injected i.p. with 1.0 mg/kg amphetamine sulfate or isotonic saline and immediately placed in a 58 cm black open field where distance travelled was measured during 2 hr sessions spaced 2 days apart. All rats were then injected i.p. with 0.4 mg/kg amphetamine and isotonic saline 2 days apart. Although there were no differences between the sham-operated control and lesioned rats in the acute locomotor response to either 0.4 or 1.0 mg/kg amphetamine, enhanced locomotor sensitization and conditioned sensitization were observed in the rats with medial septal lesions during acquisition and testing. These data suggest that the input from the septum to the hippocampus normally serves to inhibit sensitization to the locomotor-enhancing effects of amphetamine. Perhaps this projection also acts to inhibit sensitization to the rewarding effects of amphetamine.

Effect of chronic amphetamine on the behavioral dose-response curve. P.K. Randall*, P. Hodge, J.S. Randall College of Pharmacy and Inst. for Neuroscience, Univ of Texas, Austin, Texas 78712.

The response to amphetamine (AMPH) increased with repeated administration. With drugs such as AMPH producing curvilinear dose-response curves and multiphasic time courses, sensitization-induced changes may be difficult to interpret.

The purpose of this study was to determine whether sensitization could be more simply modeled by a shift in the dose response curve rather than as an alteration in the magnitude of response. Sprague-Dawley rats were injected in the home cage with 5 mg/kg AMPH (IP) every 4 days for a total of 5 treatments. For the last treatment the response to 0, 0.5, 1, 2, 4, and 8 mg/kg AMPH was determined. Locomotion and rearing were assessed using computer and stereotaxic ratings assigned every six min for two hours prior to, and four hours following injection.

Locomotion and rearing showed the typical response patterns to each treatment level and the response curve was shifted to the left in the overall dose-response curve. This shift systematically decreased with time until at 60-90 min there were no differences between the groups. The reciprocal of the ED50s in both groups fell exponentially following 1 hr. The sensitized animals were marked by a more rapid decrease in this measure than the control animals.

GENETIC ANALYSIS OF METHAMPHETAMINE'S EFFECT ON FEEDING BEHAVIOR IN BXD RECOMBINANT INBRED MICE. S. Angel-Gade* and J.K. Belknap. Dept. of Medical Psychology, Oregon Health Sciences University, Portland, OR 97223.

Amphetamines at low doses have been shown to produce anorexia in both humans and animals. To identify the genes mediating this effect, BXD recombinant inbred mice were tested on a five day food restriction paradigm which resulted in stable food intake. Mice from each strain were then divided into two equal groups. On Day 6, Group 1 was given 4.0 mg/kg methamphetamine (MA), str, whereas Group 2 was given the saline vehicle. On the next day (Day 7), both groups were given MA. Consumption was measured for the next 240 minutes. Significant drug and strain effects for the 24 strains tested were seen. Food consumption was decreased on average by 54%. In the extreme strains, food consumption was decreased by 90% (Fv-2), 11 (D1/Mi2), 12 (D12Nw1), 13 (Tpm), 15 (D13M6), 18 (D18M15) and 19 (D19Bv1). Verification of these loci using PCR in an independent F2 population is ongoing. Supported by NIDA DA07262 and Contract DA277-90-MJ-4565.
GENETIC RECOMBINATION OF AMPHETAMINE-INDUCED MOTOR BEHAVIORS. A. Fleischner, C. Vedantam* Laboratory of Neurobehavioural Genetics, National Institute of Mental Health, Bethesda, MD 20892 and *New York University Medical Center, NY 10016; USA

Quantitative Trait Loci (QTLs) responsible for high and low expression of murine mesencephalic tyrosine hydroxylase activity (TH/MES) were transferred onto C57BL/6JByJ (B6) inbred mouse strain background by successive backcrosses with concomitant selection for the extreme expressions of TH/MES (Vedantam, 1990). Subsequently, Artificially Selected Congenic Recombinant Inbred (ASCR) strains were derived from the selection lines. To investigate the effects of the gene transfer, locomotor activity (distance covered) and (D) and frequency of occurrence of rearing on the hind legs (F) were recorded for 30 min after i.p. injections of 0, 2.0, and 4.0 mg/kg D-amphetamine in the progenitor strains (B6 and BALB/cJ) and in two B6.C animal model lines (N=10). Analysis of the data indicates that the D/R ratio was significantly higher in the BALB/cJ strain than in the B6 strain. Similar D/R values were observed for the B6 and the B6.C lines at 0 and 2.0 mg/kg D-amphetamine. After administration of 4.0 mg/kg D-amphetamine the four strains fell into two classes, each class consisting of a progenitor and a B6.C line. The results are consistent with the hypothesis that both TH/MES and amphetamine-induced behaviors are affected by the same QTLs.

D-AMPHETAMINE (AMPH) DECREASES SYMPATHETIC NERVE DISCHARGE (SND) IN ANESTHETIZED RATS. W. Liu, M.C. Custaway and K.J. Virenker* Dept. of Pharmacology and Experimental Therapeutics & Alcohol and Drug Abuse Center, LSU Medical Center, New Orleans, LA 70112.

Studies in this and other laboratories have shown that cocaine, a well know sympathomimetic, decreases rather than increases SND in anesthetized and conscious animals. The purpose of this study was to determine whether AMPH, another sympathomimetic, would also decrease SND in pentobarbital-anesthetized rats. The studies were performed in male Sprague-Dawley rats (275-325 g). Cannulae were placed in the femoral artery and vein. The trachea was cannulated and the rats mechanically ventilated. Splanchnic SND was recorded using bipolar platinum electrodes (0.303-KHz bandwidth). Two groups of rats (n=5 each) were used. One group received 0.01 and 0.5 mg/kg AMPH, and the other 0.1 mg/kg AMPH intravenously. AMPH dose-dependently decreased SND (-4.2 ± 85.5%). The duration of the SND responses ranged from 1.4 ± 0.6 to 6.8 ± 0.5 min. AMPH also dose-dependently increased heart rate (39 ± 0.6 bpm, 1.4 ± 0.6 to 18 ± 7.2 min duration). Doses of 0.01 and 0.1 mg/kg AMPH increased mean arterial pressure (MAP), 18 ± 2 mmHg max.). Doses of 0.5 mg/kg AMPH increased (32 ± 3 mmHg, 3 ± 0.5 min duration) and then decreased (-36 ± 7 mmHg, 48.5 ± 11 min duration) MAP. These data show that AMPH, like cocaine, decreases SND in anesthetized rats. These findings suggest that an increase in sympathetic outflow is not responsible for the HR and pressor responses elicited by AMPH. (Supported by NIDA DA08255).

The effects of injections of either d-amphetamine or quinpirole, the D2 dopamine receptor selective agonist, on the development of a lever-touch response in an autoshaping paradigm were investigated. Male Sprague-Dawley rats received daily, post-session, intraperitoneally administered injections after 10 pairings of the presentation of a retractable lever (6 cm) and the delivery of a food pellet (USB). Reinforcement delivery was immediate if the subject contacted the lever, otherwise, the pellet was delivered upon lever retraction. Amphetamine, at a dose of 3 mg/kg (E=1.35=65.5, p < 0.0001) impaired the development of the lever-touch response, as compared to saline treated control rat, and quinpirole at a dose of 3 mg/kg [F (1.43)= 30.7, p <0.001] completely abolished the acquisition of the response. Neither drug affected acquisition at a lower dose (0.03 mg/kg). Administration of the higher doses of amphetamine (1 mg/kg) and quinpirole (2 mg/kg) also impaired responding, although the impairment lability was due to dose effects of the drugs. Initiation of either quinpirole or amphetamine treatment after complete acquisition of the autoshaping task did not affect responding. Taken together these results indicate that post-session administration of amphetamine impairs and quinpirole blocks the acquisition of an autoshaped lever-touch task, and that the impairment is not due to an aversive action of the drug on performance (Supported by DA 06192 to JLM and MI 15860 to EAP).

NEUROPHARMACOLOGY OF AMPHETAMINE AND ANTIPSYCHOTIC DRUGS IN NUCLEUS ACCUMBENS AND AMYGDALA OF SOCIALLY INTERACTING RATS: Z. B. Wang, M. Bonta, and G. V. Bebec. Program in Neural Science and Dept. of Psychology, Indiana University, Bloomington, IN 47405.

A neuroethological approach has been used to compare the effects of haloperidol and clozapine on motor, social, and motivational behavior of amphetamine-treated rats. Adult, male rats were tested simultaneously in groups of three -- were exposed to a relatively enriched environment. In each tested group, one rat received amphetamine in nucleus accumbens (NAC) or amygdala (AMG) followed within 15-20 min by either haloperidol or clozapine. The other two rats were used as companions (no infusion) and controls (saline). Behavior patterns were classified into three main elements: stereotyped motor behavior, social contacts, and motivational behavior. Each element consisted of several behavioral subcategories. Behavior was recorded on video tape and rated by a trained observer. The results indicate: 1) amphetamine induces more stereotyped motor behavior in NAC rats than in AMG rats; 2) clozapine effectively reduced all amphetamine-activated stereotyped motor, social and motivational behavior in both NAC and AMG rats, while haloperidol was less effective in the same way; and 3) the effects of both amphetamine and the antipsychotic drugs showed marked individual differences. A neuroethological analysis can provide important new information on the mechanisms underlying the complex behavioral effects of these and other drugs known to alter dopamine transmission. Supported by USPHS Grant, DA 02451.

We investigated whether self-administration of amphetamine could be supported by local administration of the drug into the n. accumbens via a microdialysis probe, and whether amphetamine self-administration alters adaptations in gene expression. Male Sprague-Dawley rats previously autoshaped to respond on a lever for food were implanted with cannulae in the n. accumbens. After surgical recovery, subjects received 60 lever presentations on a 5 min fixed-interval schedule. Lever responses were reinforced by 1 min intra-accumbens infusions of either saline or Riniger's solution. Lever-touch responding was maintained by delivery of 12 μg/g amphetamine, but not Riniger's solution, into the right n. accumbens via a microdialysis probe. Videotape analysis indicated that rats reinforced with amphetamine were more active than rats reinforced with Riniger's solution. Drug-induced changes in gene expression were examined by isolating mRNAs from either the drug-infused lever-touch responses or from the contralateral control lever. This subtraction yielded numerous responsive mRNAs that are being characterized. These results suggest that amphetamine self-administered via microdialysis probes into the n. accumbens maintains conditioned lever-touch responding, and that a single 5-hr self-administration session may induce new gene expression. (Supported by DA06192, DA04195).

DAILY PRETRAINING ADMINISTRATION OF D-AMPHETAMINE IMPAIRS ACQUISITION OF A CLASSICALLY CONDITIONED LEVER-TOUCH RESPONSE IN RATS. R.R. Rule, P.J. Janak and J.L. Martinez, Jr. Department of Psychology, University of California, Berkeley, CA 94720.

We previously found that pretraining administration of amphetamine does not affect performance of a classically conditioned lever-touch response. We now report that pretraining administration of d-amphetamine impairations acquisition of this same response. Sprague-Dawley rats were classically conditioned to touch a retractable lever (2 cm). This immediately provides the delivery of a reward pellet. A retractable lever was presented to subjects for ten seconds. Upon retraction of this lever, rats received a pellet of food. There was no contingency between food presentation and lever-touch responding. This procedure was repeated ten times daily with an intertrial interval of 45 sec. Animals were run for ten consecutive days. Rats received a daily i.p. injection 5 minutes prior to each training session. Animals receiving 3 mg/kg amphetamine performed significantly fewer lever-touches than animals receiving pretrial injections of saline. The performance of the amphetamine animals increased from an average of 1.4 lever touches on Day 1 to 2.8 lever-touches on Day 10. This increase is less than that of saline-treated animals who increased from an average score of 0.9 on Day 1 to 5.9 on Day 10. The acquisition rate in the control rats is less than that seen in instrumental conditioning or combined classical and instrumental conditioning (autoshaping). This research is supported by a Ford postdoctoral fellowship (RRJUnd DA06192) (JLM).

Methamphetamine (MA) administered to rats in high doses causes neurotoxic injury to dopaminergic and serotonergic neurons (De Vito & Wagner, 1986; Bicknell & Wightman, 1989). Previously we reported that MA in operant discrimination reversal learning (Cooper et al., 1991), and in delayed alternation T-maze performance (Cooper et al., 1992, 1993). In the current study, we examined in a delayed non-match to position task using a novel, computerized, touch-screen equipped operant conditioning apparatus (Marlatt, Butt & Dougherty, 1987). Rats received a total of four subcutaneous injections of either DA (1.5 mg/kg) or saline, with 2.5 h intervals between injections. Upon recovery, animals were reduced to 85% of their free-feeding weight and trained to activate a computer touch-screen for food reinforcement. An automated version of the T-maze alternation paradigm (see Cooper et al., 1992) was then implemented in two phases. In the first phase, animals were reinforced for pressing a rectangular stimulus located on either the left or right side (sample position) of a touch-screen equipped monitor. Following a delay of 1 s, a pair of rectangular stimuli appeared on the monitor and animals were reinforced only for selecting the stimulus located on the opposite side relative to the sample. Upon reaching a criterion of 85% correct, animals began the second phase of training where delays of 1, 10, 20, 40, and 80 s intervened between the presentation of the sample and choice stimuli. Compared to controls, acquisition performance in MA-treated animals was impaired at delay intervals of 1, 10, and 20 s (MANOVA; p < .05). Results suggest that high doses of MA cause lasting impairments in reinforced alternation performance and that these impairments are exacerbated by temporal delays. (GSH supported by NIMH R43-53-33).

EFFECT OF REPEATED METHAMPHETAMINE PRETREATMENT ON FREEZING BEHAVIOR INDUCED BY CONDITIONED FEAR STRESS. T.Tsuchiya. Dept. of Psychiatry, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

We examined the effect of methamphetamine pretreatment on conditioned fear in mice Winter-Kremer. Rats received methamphetamine or the vehicle according to the repeated escalating dose schedule (1.25, 2.5, 3.75, 5 mg/kg s.c. x/2 every other day for a week). After the drug treatment period, the rats were exposed to electric foot-shock (2.5 mA for 30 min) for two days. Twenty-four hours after the last foot-shock session, the rats were again placed in the shock box without shocks for 5 min. Methamphetamine pretreatment significantly increased conditioned freezing behavior, suggesting that rats previously exposed to chronic methamphetamine are more sensitive to subsequent psychological stress than control rats. Repeated methamphetamine treatment did not decrease basal anxiety and serotonin concentrations in the brain. Furthermore, co-administration of MK-801 (non-competitive NMDA antagonist), amphetamine acid (amphetamine upake inhibitor) or flunitrazepam (serotonergic uptake blocker) did not alter the enhanced freezing behavior. Taken together, it seems that methamphetamine-induced hypersensitivity to anxiety is not due to the toxic effect of methamphetamine. While co-administration of SCH23390 (D1/D5 receptor) or raclopride (D2/D3 receptor) had no effect on the methamphetamine-induced increase in freezing, co-administration of YM-09151-2 (D2/D3 antagonist) prevented this increase. These results suggest that methamphetamine-induced anxiety levels is mediated by D2-like receptors.

240.17

The stereoisomers of the designer drug 3,4-methylenedioxymethamphetamine (MDA) have been reported to have distinct stimulus properties: (+) MDA is presumably similar in its effects to amphetamine while (-) MDA is more closely related to hallucinogens, such as DOM. While MDA is structurally similar to amphetamine, its behavioral effects appear to be mediated by both dopamine and serotonin. We have recently developed evidence which suggests serotonergic dependent neurotoxic effects of MDA may enhance the fenfluramine-like effects of a related compound, MDMA.

In the present study, we examined the effects of d-fenfluramine administration (6.0 mg/kg b.i.d. for four days) on the discriminative stimulus properties of the stereoisomers of MDA. Male Oregon-eggshell rats were trained to discriminate either (+) MDA (1.5 mg/kg/12 h) or (-) MDA (1.5 mg/kg/24 h) from saline in a two-lever operant task. Two groups of animals (20/group) were treated daily with 25 -110 mg/kg d-Fenfluramine and the training drugs (0.19-0.75 mg/kg) were administered during independent test sessions prior to administration of the d-fenfluramine regime.

In contrast to previous suggestions that (+) MDA may activate to amphetamine, the present results indicated that d-ambitamine did not substitute for either isomer of MDA. In addition, while (+) MDA substituted completely for (-) MDA, no evidence was found for the substitution of d-Fenfluramine for (+) MDA. These results suggest that d-ambitamine induced neurotoxicity may influence the cue properties of the stereoisomers of MDA, making these more similar. Although there were noted increases in drug appropriate responding during amphetamine pretreatment, such increases could not be attributed to the effects of d-fenfluramine treatment.

Effects of environmental inhibition of the methamphetamine (MA)-induced behavior of MA-treated rats were investigated. MA-induced sensitization of expression of behavioral sensitization were examined. Rats received daily injection of MA for 10 days (1 mg/kg, sc). Half of them were immediately returned to the home cage (the group) and the other half were individually confined in a cylinder with a diameter of 13 cm (narrow cage group) for 3 hrs after each injection. The third group received saline in the home cage. The rats were sacrificed on the 17th day or 17-18 day withdrawal period, and were readministered with MA (1 mg/kg or 0.5 mg/kg). The normal cage group showed significant enhancement in the motor activity. However, they showed significantly intensified stereotyped behavior compared with the saline group. Microdialysis studies revealed no enhancement in the ability of MA to increase dopamine release from the nucleus accumbens in the normal as well as narrow cage group compared with the saline group, when examined after either a 7-8 day or 17-18 day withdrawal period. These results suggest that environment inhibition of actual movement under the drug effect modifies the pattern and character of behavioral sensitization. The biochemical basis of the differential behavioral sensitization and the environmental modification of its expression remains unknown.

EVIDENCE THAT HIGH AND LOW RESPONDERS TO NOVELTY SHOW DIFFERENCES IN BEHAVIORAL RESPONSES TO DEXAMPHETAMINE AND ETHANOL. M.A. Caron* and A.R. Coles. Ohio State University College of Medicine, Columbus, OH 43210.

The amnestic make-up of the ventral and dorsal striatum differs between high (HR) and low (LR) responders to novelty (Caron et al., 1990). These two types of individuals normally co-occur in unselected outbred populations of Winter rats. These rats are known to react differentially to self-administration of dexamphetamine; they also show distinct locomotor responses to dexamphetamine (Science 245, 1511, 1989). The present study had two purposes. First, it was investigated whether dexamphetamine-induced stereotyped behavior also differs between these rats; for the sake of comparison, a study of the locomotor effects of dexamphetamine was included. Second, we investigated to what extent these rates differently react to ethanol, since this drug is also known to influence the amnestic activity in the striatum. Male HR and LR rats were selected as an open field paradigm (Brain Res. Bull. 24, 49, 1990). Stereotyped tracking behavior (STB; dexamphetamine: 0.5-2.0 mg/kg) was studied on the open field surface, using an videotape computer program: HR showed a much higher dose (2.0 mg) HR showed a significantly greater locomotor activity, measured in boxes (30x30 cm) than LR following administration of dexamphetamine at doses (0.5-2.0 mg/kg/g). Second, ethanol consumption was measured. Animals were maintained on alternate day presentation of ethanol and water; ethanol solutions were given in increasing steps of 1%. LR rats showed significantly higher ethanol intake and preference than did HR rats. Animals were maintained on 10% ethanol to determine preference stability; line differences remained stable throughout the entire period. In conclusion HR rats differ from LR rats both in stereotyped and locomotor responses to dexamphetamine and ethanol intake. It remains to be investigated to what extent these differences are causally coupled to differences in the amnestic make-up of the striatum.

240.21

The amphetamine-like abuse potential of dexamphetamine (dFEN) was evaluated using drug discrimination and self-administration procedures. Male Fischer rats were trained to discriminate either dFEN (1.0 mg/kg) or d-amphetamine (dAMP) (1.0 mg/kg) from saline in a two-choice discrete-trial avoidance paradigm. Inamping-trained rats, dFEN (0.5-4.0 mg/kg) engendered almost exclusively saline-appropriate responding. In dFEN-trained rats, dAMP (1.0-4.0 mg/kg) engendered entirely saline-appropriate responding while lower intermediate levels of dFEN-appropriate responding in the remaining animals. Potential reinforcing effects of dFEN were also evaluated in 3 male rhesus monkeys trained to self-administer cocaine (iv) during daily 60 min sessions under a fixed-ratio 10 schedule. Various doses of dFEN (30-1000 ug/kg/infusion) and dAMP (10 mg/kg) were administered for 10 min in four daily daily 60 min sessions. No difference was found between the groups of dFEN maintained rates of self-administration within the range of rates maintained by saline and considerably below those maintained by cocaine and dAMP. Furthermore, the within-session distribution of responding with dFEN resembled that produced by saline. Taken together, these results strongly suggest that dFEN will not have amphetamine-like abuse potential in man.

FACTORS AFFECTING THE DEVELOPMENT OF BEHAVIORAL SENSITIZATION TO APOMORPHINE. B.A. Mattingsly*, K. Koch, F.H. Gobbel†.
Department of Psychology, Morehead State University, Morehead, KY 40351.

Research support for apomorphine sensitization to the direct dopamine agonist, apomorphine (AP) develops through both associative and non-associative mechanisms. The present study further assessed the role of environmental factors in AP-induced behavioral sensitization. In Exp. 1, rats were treated daily with either AP (5 mg/kg) or vehicle (VEH) and tested for activity in either an open-field or a running-wheel. On Day 9, one-half the rats in each drug/apparatus group were tested in the alternation apparatus. AP-treated rats displayed progressively greater activity over days in both the open-field and running-wheel (F, w. sensitization). In Exp. 2, rats were treated daily with either AP (5 mg/kg) or VEH and again tested in the running wheel. For one-half the rats in each drug condition the wheel was free to move and for the remainder the wheel was immobilized. On Day 10 of testing, all rats received a challenge injection of AP (5 mg/kg) and the wheel was free to move for all rats. AP-treated rats in the free wheel displayed significant sensitization over the 10 test days. In contrast, rats pretreated with AP and placed in the immobilized wheel for 9 days were not sensitized when tested on Day 10. These results suggest that the ability to express the drug-induced locomotor response may be more important than drug-associated cues in the induction of behavioral sensitization.

DEGENERATIVE DISEASE: ALZHEIMER’S—MECHANISMS OF CELLULAR INJURY I

421.1

INHIBITION OF APOLIPOPROTEIN E mRNA TRANSLATION WITH ANTISENSE OLIGONUCLEOTIDES. S. Yajima and M. M. Mournier†.
Genetic Pharmacology Unit, Experimental Therapeutics Branch, National Cancer Institute, Bethesda, MD 20205.

Alzheimer disease patients have increased frequency of apolipoprotein E (ApoE) epsilon 4, suggesting this allele is a risk factor for the disease. ApoE, which interacts strongly with amyloid beta protein in vitro, is immunocohemically localized to the senile plaques, vascular amyloid and neurofibrillar tangles of Alzheimer disease. These new antisense oligonucleotides (ODN) have been synthesized to target apoE mRNA for therapeutic advantage in minimizing amyloid deposition in the disease. The antisense oligodeoxynucleotide (ODN) strategy can be used as an effective tool to evaluate the expression of apoE specific genes. In our investigation, we used phosphorothioate antisense ODNs to down-regulate ApoE gene expression. An expression vector was constructed containing the M. nemestrina, the non-parallel restriction fragment of the human ApoE cDNA fused, in frame, with the reporter gene encoding luciferase and used to generate stably transfected CHO cells. A series of 21 mer antisense ODNs targeted to various portions of the ApoE message were used. Nonsense ODNs having the same nucleotide composition but in scrambled sequence were used as controls. Among the tested ODNs, two molecules spanning the ATG codon added to the culture medium at 50 µg/ml for 24 hours decreased luciferase activity by about 20% (p<0.05). Shorter time points and a lower concentration (µg/ml) were ineffective. Nonsense ODNs to the cultured cells were noted. These findings suggest that the antisense approach could be useful to study the potential pathogenetic link between ApoE and Alzheimer disease.

APOLIPOPROTEIN E, ALLELE ASSOCIATION WITH ALZHEIMER’S DISEASE. S.E. Poduslo*, J.D. Schwandtshas.
Dept. of Neurology, Texas Tech University Health Sciences Center and Dept. of Veterans Affairs, Lubbock, TX 79430.

The apolipoprotein E, allele has been strongly implicated in late onset familial and sporadic Alzheimer’s Disease (Saunders, et al. Neuro 43:1467, 1993). The authors found the E4 allele frequency to be 0.42 for late onset Alzheimer’s patients, compared to 0.25 in controls. In earlier reports, a higher frequency of E4 allele was noted in patients with Parkinson’s disease (Hukkanen, et al. Neuro 43:1467, 1993). The apolipoprotein E, polymorphism was determined after PCR amplification of genomic DNA, restriction enzyme digestion with HhaI, and polyacrylamide gel electrophoresis. Ethidium bromide stained bands at 91 bp were designated as allele 3, 63 bp as allele 2, and 26 bp of 123 bp as allele 1. The frequencies for the E3 allele in the late onset familial or sporadic patients was approximately 0.4; while that for early onset sporadic patients was 0.29 and for familial was 0.64. We analyzed 177 cases, of whom 12 had the 3/3 genotype and 15 had at least one E4 allele for an E4 frequency of 0.097. In a survey of 53 Parkinson’s patients as another neurological control group, only 9 had the E4 allele. Our findings support the association of the E4 allele with Alzheimer’s Disease. Supported by the State of Texas DNA Bank for Genetic Studies of Alzheimer’s Disease.

EFFECTS OF WITHDRAWAL FROM NICOTINE ON INTRACRANIAL SELF-STIMULATION. M. Legault* and R.A. Wise.
Center for Studies in Behavioral Neurobiology, Concordia University, Montreal, QC, CANADA H3G 1M8.

Elevated intracranial self-stimulation (ICSS) thresholds following withdrawal from repeated treatments with cocaine, amphetamine or morphine are consistent with a model of depression of the dopaminergic transmission. We investigated whether relevant drug treatments that characterize human drug dependence. Dysphoria is also a feature of nicotine dependence and we now report the effect on ICSS of nicotine withdrawal. Animals were repeatedly injected with 0.5 or 1 mg/kg of nicotine or saline. Injections were given once on the first day of treatment then twice for the next 13 days (equating a dose of 1.0 or 3.0 mg/kg/day) and once on the next day (15). Two measures of rate-frequency threshold were determined every 4 hours for 32 hours following the last injection. Nicotine withdrawal caused non-parallel rightward shifts in the frequency functions. Peak effects occurred between 20 and 24 hours following the final injection. During this time period threshold determined by the lowest frequency required to reinstate responding was elevated to approximately 120% of baseline in each nicotine group, whereas the peak elevation in the frequency required to maintain half-maximal responding was only 10%. These data suggest that repeated nicotine treatment results in a dependence syndrome characterized by a phasic depression of the neural substrate underlying ICSS that is detectable at moderately reinforcing stimulation frequencies.

Dept. of Neurology, Radium, University of Clinical Genetics, Univ. and Hospital of Kuopio, Kuopio, FINLAND.

Several studies have indicated apolipoprotein E (apoE) e4 as a risk factor for late-onset sporadic and familial Alzheimer’s disease (AD). AD is characterized by senile plaques, particularly amyloid beta (apoE) deposits, and temporal lobe structures. Previously, apoE was implicated in the regeneration of the nerve cell body and in the synaptogenesis of the hippocampus in experimental models. Here, we studied apoE and apoE e4 in 28 AD patients and in 28 elderly controls. The frequencies of apoE e4 were 0.33 in AD patients and 0.24 in controls. The frequency of apoE e4 allele in the late onset Alzheimer’s Disease patients (all of whom were Caucasian), 45 had the 3/4 genotype, 13 had the 4/4 genotype, and 4 had the 2/4 genotype. There were 25 early onset patients and 58 late onset patients. The frequencies for the E3 allele in the late onset familial or sporadic patients was approximately 0.4; while that for early onset sporadic patients was 0.29 and for familial was 0.64. We analyzed 177 cases, of whom 12 had the 3/3 genotype and 15 had at least one E4 allele for an E4 frequency of 0.097. In a survey of 53 Parkinson’s patients as another neurological control group, only 9 had the E4 allele. Our findings support the association of the E4 allele with Alzheimer’s Disease. APOLIPOPROTEIN E4 AND E4-INDUCED DIFFERENCES IN NEURITE OUTGROWTH ARE ASSOCIATED WITH DIFFERENCES IN THE SUBCELLULAR LOCALIZATION OF APP, AVPR, AND HSPG IN NIGROSTRIATAL REGION

DEGENERATIVE INFECTION

BY W. B. Nathan,* S. Belot,* R. W. Mahley,* and R. E. Plata,* Gladstone Institute of Cardiovascular Disease, Cardiovascular Research Institute, Departments of Medicine and Pathology, University of California, San Francisco, CA 94141-9100.

Apolipoprotein (apo) E4, one of the three common isoforms of apoE, has been implicated in Alzheimer’s disease. Previously, we demonstrated detrimental effects of apoE3 and apoE4 on neurite outgrowth in cultures of dorsal root ganglion (DRG) neurons: In the presence of β-migrating very low density lipoproteins (β-VLDL), apoE3 increased neurite extension and decreased transcellular outgrowth (Nathan et al., Science 1994, 264:850-852). In the present study, we examined the effects of apoE3 and apoE4 on neurite outgrowth from a murine neuroblastoma cell line (Neuro-2a). The products of Neuro-2a medium for 48 hours in the presence of β-VLDL (40 μg cholesterol/ml) alone or with apoE3 or apoE4 (30 μg/ml) purified from human plasma. Consistent with the results obtained with the DRG neurons, Neuro-2a cells increased with apoE3 but decreased with apoE4 as compared with that seen in the cells grown in medium containing β-VLDL alone. Immunocytochemical localization of apoE4 in the Neuro-2a cells treated with apoE3 or apoE4 with β-VLDL revealed a differential localization of apoE. In apoE3-treated cells, intense apoE immunoactivity was observed within the cell bodies and neurites. In contrast, apoE4-treated cells showed little, if any, immunoactivity within the neurites. The data suggest that the localization of apoE3 (but not apoE4) in the neurites may play a role in enhancing neurite outgrowth.

421.7 MICROVASCULAR PATHOLOGIC CHANGES IN HIPPOCAMPAL INFECTION IN ALZHEIMER′S DISEASE: B. Levey**,* C. A. Gooddy,** and R. M. Eilert,** Departments of Neurology and Neurobiology, Mount Sinai Med Ctr, New York, NY 10029; Dept of Psychiatry, RGP Bi-Alt, Univ of Geneva Sch Med, Switzerland.

Biphasic ischemic/hypoxic injury is a major component of the endothelial cell surface and extracellular matrix, plays a fundamental role in the integrity of the blood-brain barrier. Using an antibody to vascular HSPG (7612), we recently described distinct patterns of changes of cerebral capillaries in various regions of the cerebral cortex in Alzheimer’s disease (AD). In addition, a decrease of the immunostaining was observed in all of the cortical areas in AD cases when compared with control cases. Although the endothelial cortex is particularly affected in AD, very little is known about pathological vascular changes in this area. Using two different antibodies to vascular HSPG (7612, EPO1), we investigated the alterations of the microvasculature in the entorhinal cortex of 12 AD cases and 13 elderly control cases. Similar staining patterns were obtained with the two antibodies. Interestingly, no changes of the microvasculature were observed in the control cases in comparison with AD cases suggesting that an overexpression of vascular HSPG occurs in AD. In addition to the microvasculature, some senile plaques and neuritic tangles were also labeled in AD cases. The laminar distribution and relative densities of the microvessels showed a correlation between angio- genetic and neocortical abnormalities. In particular, vascular density was higher in layer II of the entorhinal cortex and in the paraventricular layer of the subiculum and subiculum. Numerous morphological abnormalities such as string vessels and distorted vessels were observed in AD cases. The control cases exhibited some pathological changes, however, to a much lesser degree than AD cases. Preliminary data suggest that a decrease in the vascular density occurs in the hippocampal formations with AD. In conclusion, the morphological and biochemical changes that were observed in the microvasculature of AD brains may profoundly affect the properties of the blood-brain barrier and cause detrimental effects to specific neuronal populations.

421.9 MHC CLASS II ANTIGEN EXPRESSION BY MICROGlia AFTER DEAFFERENTATION IN AGED RATS: M. G. Gordon,* L. A. Holmes, W. A. Scheirer and D. O. Marrag, Dep. of Pharmacology, Univ. South Florida, Tampa, FL 33612-4799.

To examine microglial reactions after brain injury in the aged rat, 6-hydroxydopamine (6-OHDA; 8 μg) was injected into the right medial forebrain bundle of male rats 47 weeks old. Rats were killed 4, 7, 14 or 21 d after lesioning. Unlesioned rats served as controls. Microglial cell number and staining intensity were evaluated by morphometric videoelectronometry. Sections stained immunocytochemically for tyrosine hydroxylase (TH) confirmed the virtually complete loss of nigrostriatal TH in all age groups. Stained sections stained for the microglial specific markers MHC class II antigen (MHC-II; OX6) and complement receptor 3 (CR3: OX42) indicated that MHC-II is induced by the lesion, while CR3 is not. In addition, the MHC-II induction increases with age and duration progressively with age.

421.10 DISTRIBUTION OF MICROGlia IN NORMAL AND ALZHEIMER′S DISEASE (AD) BRAIN SUPPORTS MICROGlia INVOLVEMENT IN NEURONODEGENERATION. L. Q. Shephard* and N. E. Berman, Dep. of Anatomy & Neurology, Univ. of Kansas Med. Ctr, 3901 Rainbow Blvd., Kansas City, KS 66160-7400.

Microglia are the macrophages of the central nervous system and are activated in response to trauma, infarcion, infections, and inflammatory events. With AD, microglial cells are known to be activated with a concomitant phagocytic debris and secrete factors which may be cytotoxic. In Alzheimer′s disease (AD), microglial cells have been found in direct association with neuritic plaques (NP), one of the hallmarks of AD. The region specific localization of neuritic tangles (NFTs) and NPs is used to diagnose AD in postmortem brain tissue. In early stages of AD, NFTs are found in the entorhinal region of the parahippocampal gyrus. As the disease progresses, NFTs are also found in limbic structures and eventually in selected neocortical areas, but are almost entirely excluded from the primary motor cortex.

Our studies have focused on the distribution of microglia in both normal and AD brains. Microglia were visualized by lectin histochemistry using the lectin Ricinus communis agglutinin-1 (RCA-1). In control brains, the density of microglia was greater in the regions which are most severely affected by AD, i.e., the parahippocampal gyrus (entorhinal)striate. The region area 22 exhibited a much lower density. In AD brains microglial density increased in all areas of the brain with longer periods of dementia, but the pattern of distribution seen in control brains was not constant. In AD brains, microglia are found in neuritic plaques, neuritic tangles and NFTs in the parahippocampal gyrus, where the majority of AD pathology is concentrated.
DEGENERATIVE DISEASE: ALZHEIMER'S—MECHANISMS OF CELLULAR INJURY I

QUANTIFICATION OF THE IL-1B INDUCED MESSAGES, PLASMINOGEN ACTIVATOR INHIBITOR TYPE-1 AND PROSTAGLANDIN GH SYNTHASE-2, IN ALZHEIMER'S DISEASE. J.W. Chang, D.J. Selvik, P.D. Coleman, and M.K. O'Driscoll, Departments of Neurobiology and Anatomy and Neurology, University of Rochester School of Medicine, Rochester, NY 14642. 

In response to CNS injury or neurodegenerative disorders, cytokines such as interleukin-1 (IL-1B) are released in the microenvironment. One role of IL-1B is to activate astrocytes and to increase the synthesis/secretion of astrocytic proteins. We have previously demonstrated that IL-1B promotes astrocytes to secrete plasminogen activator inhibitor-1 (PAI-1), which may influence neurogenesis, and synthesize prostaglandin GH synthase-2 (PGHS-2), an inflammatory protein. The levels of PAI-1 and PGHS-2 may serve as markers for astrocyte activation by IL-1B. Since IL-1B levels are elevated in Alzheimer's disease (AD) brains, we hypothesized that PAI-1 and PGHS-2 mRNA may be increased in AD brains relative to age-matched controls. 

We carried out Northern hybridization of poly A mRNA from the putamen and subcortical area (necrotic area ventral to genu of corpus callosum) of AD and age-matched control brains utilizing cDNA probes for human PAI-1, PGHS-2, and G3PDH. Hybridization signals, quantified using a Molecular Dynamics PhosphorImager, were normalized using G3PDH signals. Our preliminary data indicate little or no alteration in PAI-1 and PGHS-2 mRNA levels with disease in the putamen (N=5 AD cases, 4 controls). However, in the subcortical area (Brodmann's areas 12/52), PAI-1 and PGHS-2 mRNA levels are decreased 1.5-fold and 3-fold, respectively, between AD (N=3) and age-matched control (N=5) brains. 

These observations are somewhat surprising given the detection of IL-1B in AD brain. Further studies in other affected brain regions are in progress. [Supported by LEAD award G009018, R01 AG11121, and training grant T32 AG1017]

HUMAN ASTROCYTES CAN EXPRESS COMPLEMENT C4 mRNA AND SECRETE COMPLEMENT C4 PROTEIN. D.G. Walker*, S.U. Kim* and P.L. McGeer†. *Kinsmen Lab. of Neurological Research, Department of Psychiatry, 1Division of Neurology, Department of Medicine, University of British Columbia, Vancouver, B.C. Canada, V6T1Z3. 

Studies of brains from Alzheimer Disease (AD) cases have shown evidence of inflammatory changes in affected tissue, as demonstrated by complement system activation and the presence of inflammatory cytokines. These features indicate that a chronic inflammatory response occurs in AD brains which may be contributing to the neurodegenerative process. In addition, a pronounced astrocytic glial response is evident in AD tissue. There is now increasing evidence that astrocytes may be contributing to the inflammatory changes by the production of certain cytokines and complement proteins. 

In this study, we show that astrocytes isolated from formalin fixed AD brains, and cultured in vitro, can express the mRNA for complement C4, and can also secrete the complement C4 protein. Using the reverse transcription-polymerase chain reaction (RT-PCR) technique, the expression of C4 mRNA was shown to occur in six separate sets of cultures that were highly enriched for astrocytes (>95% of cells immunoreactive for glial fibrillary acidic protein). Expression was detected in unstimulated astrocytes and this was increased by treatment of cells with LPS interferon (100 or 200 units/ml of recombinant L interferon). In addition, by culturing the cells in serum-free media and by using immunomodulating and IL-1α techniques, we showed that human astrocytes can secrete C4 protein into the culture media. Increased secretion of C4 occurred after treatment of astrocytes with L interferon, but not with interleukin 1 (20 or 200 units/ml).

DOUBLE IMMUNOLABELING OF COMPLEMENT PROTEINS AND NEUROFIBRILLARY TANGLE MARKERS AT LIGHT AND ELECTRON MICROSCOPIC LEVELS IN ALZHEIMER'S DISEASE BRAIN. L.-F. Lee*, S. Webster†, S. Greenberg*, J. Rogers†, Sun Health Research Institute, Dept. of Neurology, Room C5, Tucson 85724 and Burke Medical Research Institute, White Plains, NY 10605. 

A pathogenic role of complement activation in Alzheimer’s disease (AD) has been suggested by recent evidence that the complement cascade is activated at sites of amyloid β peptide (Aβ) deposition through Aβ/C3b mediated binding. This process also appears to accelerate aggregation of soluble Aβ into its pathogenic fibrillar β-plated conformation. However, activated complement components C4, C5, C3d, and C3b also co-localize with cells exhibiting neuronal morphology, particularly neurones containing neurofibrillary tangles (NFTs). In this study, we show that the levels of complement immunoreactive NFTs containing tangles in cortical samples from four pathologically confirmed AD patients. Light and electron microscopic examination of sections of these brains confirmed that the majority of the L immunoreactive cells in AD brain contain NFTs. Taken together with certain features of Aβ/C3b binding and binding sites, these data suggest that complement activation may occur at the cellular surface of degenerating neurons, with lethal consequences. An interaction with NFT formation is also possible given the mechanism of C5b-9 attack on targeted cells. [Supported by NIA AG3767]

ALZHEIMER’S DISEASE LIKE PHOROLYSIS OF TAU PROTEIN IN RESPONSE TO INTERLEUKIN-1β TREATMENT OF MDM: POPULATIONS FROM RAT CORTIC. S. Wewarl and M.L. Shalem*. Department of Pathology and Alzheimer’s Disease Research Center, Columbia University College of Physicians and Surgeons, New York, NY 10032. 

Immune related processes have been associated with Alzheimer’s disease (AD) as have significant reductions in the prevalence of AD among patients treated with anti-inflammatory therapies. However, a physiological mechanism for the involvement of immune responses in producing AD-like pathology has not been demonstrated. Using antibodies (Abs) to phosphorylation sensitive epitopes of tau, we have demonstrated Abs to the tau protein in response to the inflammatory cytokine interleukin-1β in vitro. 

Mixed cell cultures from postnatal day one (PND-1) rat brain cortex were incubated in serum free medium supplemented with the cytokine interleukin-1β (50 U/ml). Whole cell homogenates were then analyzed by Western blotting with two Abs. IL-1β produced an increase in high molecular weight immunoreactivity to the phosphorylation sensitive epitope of tau (hyperphosphorylated tau specific Abs) and the N-terminal domain of tau (anti-tau Ab was lost upon prolonged incubation. These changes in antigenicity parallel the changes seen in human AD brain. 

Decreased gel mobility of tau isoforms was seen upon IL-1β treatment. Conversely, co-incubation of tissue with IL-1β and increasing amounts of IL-1 receptor antagonist showed a dose dependent increase in tau mobility. These results demonstrate that IL-1β may contribute to the abnormal phosphorylation of tau, which subsequently could decrease the stability of tau-nuclear interactions and contribute to PHF formation. Supported by NS-15076. 

422.1 

Senile plaques (SPs), neurofibrillary tangles (NFTs) and neuritic threads (NTs) are currently studied using low or fluorescent microscopic methods that provide 2-D images of their distribution within tissue sections. Such methods are of limited value in studies of antigen or antibody localization, that the majority of complement- or surface structure identification are important. In theory, confocal laser scanning microscopy (CLSM) provides one means to identify the 3-D location of structures within specimens. To evaluate this, the morphology and distribution of SPs, NFTs and NTs were examined in the brain of one 75-yr old patient with AD. Frozen tissue sections (3-30 μm) were cut from the hippocampus and entorhinal cortex and were fixed with 3% glutaraldehyde (Sheriden et al., 1991). Serial sections (Z axis increment: 0.5-1.0 μm) of individual SPs, NFTs and NTs (n=20) were generated with CLSM, resulting in a composite image. The spatial dye. SPs, NFTs and NTs on the surface were easily distinguished from those buried deeper within the section. The results demonstrate that CLSM provides a basis for determining the penetration of reagents in tissue staining and is useful as a guide for surface location of trace element distributions using IMS.

Calpains are believed to be important regulators of membrane dynami-
ces and membrane trafficking, but mediate neurodegeneration in certain path-
ological states. We previously reported evidence for decreased activa-
tion of the calpain-calpastatin system in Alzheimer brain. Also, calpastatin, the specific protein inhibitor of calpain, was shown by immunocytochemistry to be markedly depleted in Alzheimer neurons (Nixon et al., Soc. Neurosci. 1998, 1419-1992). To confirm this biochemically, we measured calpain levels in homogenates of prefrontal cortex from 13 Alzheimer patients and 9 normal controls matched by age and postmortem interval. Calpastatin immunoreactivity and inhibitory activity were measured in soluble and membrane fractions. In normal human brain, membrane fractions solubilized by Triton X-100 contained 40% of the total calpastatin (20 ± 15.6 units/g tissue). Calpastatin was identified by immunoblotting using affinity purified antibodies to be composed of 110, 70 and 41 kDa forms. Calpastatin inhibitory activity in membrane fractions of Alzheimer pre-
frontal cortex was reduced to 58% of control values (p < 0.001). By immuno-
blot analysis the most abundant calpastatin form isolated from human brain (M = 41 kDa) was reduced > 65% in membrane fractions (p < 0.001). Cytosolic calpastatin activity was 21.9% lower (p < 0.005) but major immunoreactive forms were markedly reduced (75.6, p < 0.01) reflecting proteolytic processing to smaller molecular weight inhibitory units. Calpastatin was not significantly altered in cerebellum. These results, together with the abnormal activation of γ-
calpain reported earlier (Saito et al., PNAS 99:2628, 1993), implicate calpains in the disruption of membrane dynamics possibly leading to altered membrane protein processing and neurodegeneration in Alzheimer Disease. Supported by NIA (AG10916).

422.5
IN-VITRO UBQUITINATION AND DEGRADATION OF TAU PROTEINS. R.S. Black* Cornell University Medical College at Burke Medical Research Institute, White Plains, NY 10605.
The concomitantly phosphorylated tau proteins, and the subsequent failure of their ubiquitin-mediated proteolysis is an important feature of the Alzheimer disease process. The DEAE-cellulose fraction of rabbit reticulocyte lysates containing enzymes of the ubiquitin conjugation system (Fraction II) was used to conjugate ubiquitin to tau proteins prepared from twice-cycled bovine brain microtubules. In the presence of ATP, an ATP regenerating system, and hemin, which inhibits the breakdown of ubiquitin conjugates, high molecular weight ubiquitin-conjugated tau proteins accumulated. In the absence of hemin the ubiquitin conjugates did not accumulate and the tau proteins appeared to be degraded in an ATP-dependent fashion. In this system, ubiquitin-ubiquitin conjugates were detectable almost immediately in hemin-inhibited lysates, whereas tau-ubiquitin conjugates were detectable only after 1-2 hour incubations. Bovine MAP-2 was also a substrate for ubiquitin conjugation in this system. This system is being used to evaluate the effects of post-translational modifications of tau proteins on ubiquitin conjugation. Supported by the NIA (AG00504).

CONSTITUTIVE ALZHEIMER'S-TYPE TAU EPITOPES IN A NEUROTIGenic RAT CNS CELL LINE. M.P. Lambert*, S. Sabo, C Zhang, S.A. Fanan, and W.L. Klein. Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Paired helical filaments (PHFs) of Alzheimer's disease (AD) largely comprise hyperphosphorylated forms of the cytoskeletal protein tau. AD-type tau phosphorypates are absent from normal adult neurons, but recent studies have shown that their expression may correlate to neurogenesis and axon differentiation in the developing brain. Therefore, we examined the enrichment of a cell line that is spontaneously neurogenic for possible expression of AD-type tau epitopes. The N110 of CN5 cell line was found to produce constitutively two AD-related epitopes of tau, detected by cellular immunofluorescence with the monoclonal antibodies E1 and Alz-50. Biochemical studies showed that the antibodies bound to proteins within the molecular weight range expected for phosphorylated tau isoforms. Further verification was established by use of tau antisera, which eliminated immunofluorescence due to the AD-related monoclonals and polyclonal anti-tau, but did not eliminate fluorescence due to anti-tubulin. Cells treated with tau antibodies were not neurite free. Neurites removed were abnormal, generally short, and wavy in appearance. Cellular distribution of the tau epitopes was particularly interesting. Alz-50 immunoreactivity was found only in the cytoplasm, while PHF-1 immunoreactivity was found in the nucleus as well as the cytoplasm. Thus the two epitopes are morphologically segregated within the cell. Because subcellular segregation of tau is compromised in Alzheimer's disease, mechanisms that segregate Alz-50 and PHF-1 epitopes in B10 cells may have relevance to this neurodegenerative disorder.

422.4

Tau is a family of microtubule-associate proteins which play a crucial role in the structure and function of the neuronal cytoskeleton. Tau in hyperphosphorylated states also forms the paired helical filaments (PHFs) of Alzheimer's disease. Although the phosphorylation of tau has been extensively delineated, other modifications have not been well defined. Recently, a single modification has been identified at Ser and Thr residues consisting of an N-linked N-acetylglucosamine (O-GlcNAc). This modification is found in a variety of proteins, including neurofilaments. The sites of O-GlcNAc glycosylation are indistinguishable from the phosphorylation sites of Ser/Thr kinases. Purified bovine tau was analyzed using galactosyltransferase as a purifying tool and GlcNAcs, followed by peptide-N-glycosidase F treatment and β-
elimination for linkage analysis. The results of these studies clearly demonstrate that tau is modified by O-GlcNAc glycosylation. This unique form of glycosylation may modulate tau function, and in specific neurodegenerative disorders may contribute to neuronal dysfunction and the formation of pathological lesions. Supported by NIH grants CA42846 (GWH) and NS27538 (GVW).

422.6
THE ABNORMAL PHOSPHORYLATION OF TAU PROTEIN AT SER-202 IS PREFERENTIALLY LOCATED IN NEURITES AND PRECEDES ABNORMAL PHOSPHORYLATION AT SER-396 IN ALZHEIMER'S DISEASE. Joseph H. Ste*, Brian J. Cummings and Carl W. Cotman. JBU in Brain Aging. UCLA, Irvine, CA 92717 USA.

Both neurofibrillary tangles (NFTs) and dystrophic neurites (DNs) contain paired helical filament (PHF) which are composed of abnormally phosphorylated PHF-tau. During formation of NFTs and DNs in AD, the cytoskeleton undergoes a sequence of changes, including hyper-phosphorylation of tau protein (for review, see Trojanowski et al., 1993). We sought to determine more specifically at what tau protein residue the earliest changes take place; and whether these alterations first occur within distal processes or within the soma. We used two monoclonal antibodies, AT8 and PHF-1, which selectively recognize phosphorylated Ser-202 and Ser-396 of PHF-tau protein respectively. Both antibodies stained NFTs and DNs, including dendrites and axons; however the quantity and distribution of immunoreactive deposits was different. AT8 immunoreactivity was usually found within intracellular NFTs as well as extracellular neurites, whereas PHF-1 positive fibrillary inclusions were detected within both intracellular and extracellular NFTs. Some irregularly labeled AT8 DNs were continuous with "normal" neuronal somas in which AT8 immunoreactivity was absent or weak. However, PHF-1 positive DNs were only continuous with PHF-1 positive NFTs. In AD cases with mild dementia, numerous AT8 deposits were detected in the outer two-thirds of the molecular layer of the dentate gyrus, whereas no PHF-1 positive deposits could be found within the same region in adjacent sections. These results suggest that abnormal phosphorylation at Ser-202 of PHF-tau in DNs represents one of the earliest neuropathological changes within the neurites of vulnerable neurons and might play an important role in the initial pathogenesis of AD.

422.8
OKADAIC ACID INDUCES MICROTUBULE DEPOLYMERIZATION AND THE DEGENERATION OF AXONS AND DENDRITES IN THE NTT2 CULTURE SYSTEM: IMPLICATION IN ALZHEIMER'S DISEASE. S.E. Merrick and V.M.Y. Lee. Institute of Neurological Sciences, Department of Pathology and Laboratory Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA.

The building blocks of Alzheimer's disease (AD) neurofibrillary tangles (NFTs), are paired helical filaments that are comprised of hyper-phosphorylated forms of tau (i.e. PHF-tau) and the accumulation of PHF-tau may be due to an inactivation or down-regulation of brain phosphatase, such as NEP bearing phosphatase. Since exquisitely phosphorylated PHF-tau is unable to bind to microtubules (MTs), then conversion of normal tau into PHF-tau by the inhibition of protein phosphatases could lower the level of tau that binds MT, destabilize MTs, disrupt axonal transport, and lead to the "dying back " of axons in AD. To test this hypothesis, we developed an in vitro neuronal culture model that allows us to examine the consequences of the inhibition of protein phosphatases on the neuronal cytoskeleton. The model is based on neurons (NT2N) derived from a human teratocarcinoma cell line (NT2) that are treated with retinoic acid to induce differentiation and then exposed to okadaic acid (OXA), a potent phosphatase inhibitor. OXA increased tau phosphorylation in NT2N neurons resulting in the inability of high phosphorylated tau to bind to MTs. OXA-induced increased tau phosphorylation, there was an increase in the depolymerization of MTs which was due to the increased conversion of stable Glu-tubulin to MBs to monomeric Tyr-
tubulin. As a consequence of the loss of MBs, there was dying back" of the MTs and the axons of NT2N neurons prior to the complete destruction of dendritic and cellular MTs. Our results suggest that the inhibition of protein phosphatases in neurons leads to the destabilization of the MT network in axons by: 1) Increased tau phosphorylation; 2) A reduction in the number of the tubulin-
lysine ligand that converts Glu-tubulin to MTs free Tyr-tubulin.

The paired helical filaments (PHFs) of Alzheimer's disease (AD) are composed of highly phosphorylated tau proteins. Sites of these sites were found to be phosphorylated in PHF-tau, fetal-tau, but not in adult brain tau. To determine the phosphorylation state at these sites during development, we isolated tau from fresh rat brain in the presence of the phosphatase inhibitor okadaic acid (OK) to obtain tau in its native state of phosphorylation in situ. Fetal tau immunoreactivity was reduced by 50% by 18E11-directed post-natal day 11 (P11) after which the immunoreactivity diminished concomitant with the decrease in phosphorylation and the appearance of the mature isoforms. In contrast to previous studies, adult and aged rats (20 months) were found to be phosphorylated at reduced levels suggesting that Thr^218, Ser^202, Thr^231, Ser^235 and Ser^404 are normal sites of phosphorylation in adult rats. We also show that inactivation of OK in the assay buffer has a transient effect on the abilities of tau to bind MTs at any developmental stages. However, an activation of phosphorylation at these sites was absent when done in the absence of OK tau was shown to be partially dephosphorylated. We further demonstrate that protein kinase 2A (PKA) and 2B (PKB) from the adult rat brain could dephosphorylate tau efficiently in a site specific manner, whereas protein kinases from P6 had no effect indicating that OK sensitive tau after P12 may be regulated by the de novo induction of adult brain phosphatases. Collectively, these findings suggest that PKA-like phosphatases are involved in regulating the adult phosphorylation state of tau in-vivo, and they open the possibility that the generation of hyperphosphorylated tau leading to PHF formation in AD may be controlled by similar phosphatases.

422.12 ALZHEIMER TYPE PHOSPHORYLATIONS OF TAU PROTEIN ARE DEVELOPMENTALLY EXPRESSED IN VITRO. C.K. Combs*, P.O. Coleman, and M.K. O'Brien. Departments of Neurobiology and Anatomy and Neurology, University of Alabama at Birmingham, Birmingham, AL 35242.

It has been shown that certain Alzheimer type tau phosphorylations occur embryonically in humans and postnatally in rats. Determining the nature of the regulatory mechanisms of these phosphorylations in these events may provide a better understanding of the aberrant phosphorylation of tau occurring in Alzheimer's Disease.

We have utilized embryonic rat hippocampal cultures to investigate the expression of specific Alzheimer type tau phosphorylations during in vitro differentiation. The mouse monoclonal antibodies to PHF-1 and PHF-2 recognize a phosphorylation on Ser^396 and the lack of phosphorylation on Ser^393, respectively. Using PHF-1 and Tau-1 we have observed a temporal expression of phosphorylation by immunoblotting and Western blot analyses. Phosphorylation at the PHF-1 epitope is observed at the earliest time point in vitro (i.e. embryonic day 16). In contrast, phosphorylation at the Tau-1 epitope was detected around day 4 in vitro and appears to increase over the two weeks examined.

The temporal expression of these phosphorylation events suggests different regulatory mechanisms for each. Future investigations with this in vitro developmental system may not only define the kinases and/or phosphatases involved, but may also provide clues about the physiological roles of these phosphorylation events. (PHF-1 and Tau-1 Abs were obtained from Peter Davies and Lester Binder, respectively) [Supported by LEAD award A005016, RO1 AG01121 and training grant T32 AG10147].

Supply of excess ATP to isolated brain microtubules induced Alzheimer type phosphorylation of tau proteins, providing a potential model to study Alzheimer tau phosphorylation and regulation. Although immunoblot analysis indicated that MAP kinase and CDK are present in microtubules obtained by purification and that purified MAP kinase and CDK increased the level of tau phosphorylation induced by excess ATP, the addition of CDK 1/cyclin B to microtubules partially reverses this type of tau phosphorylation. Furthermore, ATP induced tau phosphorylation is inhibited by treatment of microtubules with apolipoprotein E. The effect of apolipoprotein E is specific and dose dependent. Inhibition of Ca^2+ calmodulin-dependent protein kinase and cAMP-dependent protein kinase have no profound effects on the phosphorylation of tau or on the generation of tubulin from microtubules using taxol abolishes ATP induced tau phosphorylation, suggesting that tubulin may be involved in the regulation of tau phosphorylation by signaling proteins associated with microtubules.AG 11123, NS 27847, NS 30435.

422.14 ALZ-50 AND PHF-1 IMMUNOREACTIVITY NEAR 3-AP INJECTIONS IN THE CEREBRAL CORTEX OF SHEEP ET, Nelson and C.B. Jaing, Beth Israel Hospital and Harvard Medical School, Boston, MA 02115.

We have recently discovered that neurons in the cerebral cortex of sheep and goats develop Alzheimer-type neurofibrillary degeneration (NFD) in the absence of beta-amyloid peptide (3-AP) deposition during aging. Hence, these domesticated animals may provide a novel model for studying the mechanism of induction of Alzheimer-type NFD.

In an effort to induce experimental neurofibrillary pathology in vivo, we injected 3-AP (1ml) into the cerebral cortices of two five-year-old sheep. Following one or two weeks of survival, brains were fixed at 3000g's and sections were stained with toluidine blue and xylene. The 3-AP induced cytoplasmic and nuclear protein A50 was present in some areas of the sheep brains. In addition, these sections were stained with toluidine blue and xylene. The 3-AP induced cytoplasmic and nuclear protein A50 was present in some areas of the sheep brains. In addition, these sections were stained with toluidine blue and xylene.

In the animal that survived one week, the 3-AP injections caused necrosis. Some A50 or PHF-1 immunoreactive dystrophic neurites were seen in direct apposition to the injections within deep cortical layers. However, near the cortical surface, some A50 or PHF-1 immunoreactive neurites appeared that were more swollen than normal immunoreactive neurites. A50 immunoreactive neurites, when viewed via electron microscopy, contained large vesicles. In the animal that lived for two weeks, similar staining was seen, except that some A50 immunoreactive neurites had infiltrated the injection regions.

The current study indicates that, under the conditions we employed, injection of 3-AP does not induce degenerative response in which modified tau proteins are present in neurites.

The localization of apolipoprotein E (ApoE) in relation to beta-amyloid (B440) and paired helical filament (PHF) immunoactivity was examined in the neocortex basal nuclei (NBM), amygdala (AMY), and entorhinal (EC) temporal and insular cortices of patients with AD (n=8) and Down’s syndrome (DS, n=3), age matched normals (AMC, n=8), and age matched nondemented cases with numerous senile plaques (HPND, n=5). ApoE immunostained plaques, neurons, and extracellular tangles in each group. ApoE’s immunostaining of neurons differed dramatically from PHF depending upon brain region and diagnosis. In the AD and DS brain, numerous ApoE-IR neurons closely matched PHF in distribution and quantity in the NBM, AMY and EC. Although PHF-IR temporal and insular neurons were similar in density to the AMY and EC, ApoE-IR neurons were 4-fold fewer than PHF-IR neurons. In the HPND cases, many PHF-IR neurons were observed in the NBM, AMY and EC but were less than in AD. In contrast to these same regions in AD and DS, very few ApoE-IR neurons were observed relative to PHF. These findings suggest that PHF immunoreactivity precedes that of ApoE indicating ApoE may be binding to tangles only in their later stages of formation. Since the HPND cases ApoE recognizes only a few of the PHF-IR neurons in the NBM, AMY, and EC, which are among the earliest brain regions affected in AD, it is possible that ApoE plays a secondary role in tangle formation. Supported by NIH grant AG10161-03.

Neurofibrillary tangles (NFT) composed of paired helical filaments (PHF) are the most characteristic histopathological feature of Alzheimer’s disease. Recent molecular and biochemical studies have provided conclusive evidence that the major integral protein in an abnormally tau protein that is hyperphosphorylated, referred to as PHF-tau. PHF-tau antibodies are present in NFT within the cytoplasm of living neurons (intracellular NFT) and also in NFT in the extracellular space after the neuron with NFT dies, so-called extracellular NFT (EFN). Epitopes in the amino half of tau protein (e.g., Alz50 epitope) are susceptible to proteolysis and are lost in NFT. Neurons in lamina II of the entorhinal cortex (EC-II) are unusually susceptible to NFT, while those in the dentate gyrus are unusually resistant to NFT. By the time AD is advanced, most of the NFT in the entorhinal cortex are NFTe, while most of the NFT in the dentate gyrus are NFTp. Using their distribution in the hippocampus as an index to their most probable type and double-labeling immunocytochemistry of cryostat or frozen vibratome sections, we further characterized NFT in AD. Monoclonal antibodies to NFT that do not cross-react with tau proteins (Ab39 and Ab69) were used as a marker for both NFTe and NFTp, while Alz50 served as a marker for NFTp. NFT, but not NFTe, were labeled by monoclonal and polyclonal antibodies to p34γtubulin. The anti-p34γtubulin antibodies also labeled granular cytoplasmic and perinuclear structures consistent with so-called “pre-tangles”. Monoclonal and polyclonal antibodies to apolipoprotein-E labeled primarily NFTe. NFTe were also inconsistently labeled with antibodies to C4q, Aβ and ubiquitin. These results suggest that in early formative stages NFT are composed of abnormally tau protein in close association with kinases, such as p21akt, that form of phosphorylating tau and that only in later stages of evolution, after the neuron has died, is there substantial association with apolipoprotein-E, Aβ and C4q. (Supported by NIA grants AG08603, AG10136 & AG09145.)

NEUROFIBRILLARY TANGLE NEURONS IN ALZHEIMER’S DISEASE ARE ASSOCIATED WITH A LOSS OF SYNAPTOPSIS MESSAGE. (L. M. Callahan*, J.E. Cheetham, W. Yen, and P.D. Cefaloni.) University of Rochester Medical Center, Neurobiology and Anatomy, Rochester, NY 14642.

Recent evidence indicates the best correlate with the degree of dementia of AD may be the loss of synapses (e.g., DeKosky and Scheff, 1989, Terry et al., 1990). We hypothesized neurons containing tangles lose synapses due to the cytoskeletal disruption of the neuron. To investigate this possibility, we combined immunocytochemistry to identify tangle-containing neurons with in situ hybridization for selected messages. Message levels of synaptophysin, poly A, and catepsin D were determined in serial hippocampal sections from 3 AD cases and 2 age-matched controls. A decrease in the level of synaptophysin, a synaptic vesicle associated protein, was detected in a majority of tangle-bearing neurons relative to levels in neighboring non-tangle neurons. Poly A (total) message levels were similar in many tangle-bearing neurons relative to non-tangle neurons. The demonstration of decreased message level for a protein related to synaptic function in NFT neurons would indicate that it is the NFT neurons that are correlated with synaptic loss in AD. (Supported by NIH AG00107, NIH AG01121, NIH LEAD AWARD AG09016, Alzheimer’s Disease Center Grant NIH AG08665, and the American Health Assistance Foundation).

The hippocampal region including the dentate nucleus is, for the most part, spared in the early stages of AD. However, in the advanced stages, the dentate system is usually affected. The dentate nucleus is an active site of neurogenesis and produced many new neurons. It is thought that Dexamethasone is a neuroprotective agent against the development of AD. In the present study, we examined the effect of Dexamethasone on the dentate nuclei of the rats with experimental Alzheimer’s disease. We studied a total of 8 rats, 4 treated with Dexamethasone and 4 untreated. The rats were treated every day with 2mg/kg body weight for 28 days. We examined the numbers of new neurons, the volume of the dentate nuclei and the weight of the dentate nuclei. The results showed that the number of new neurons increased significantly in the rats treated with Dexamethasone. The volume of the dentate nuclei and the weight of the dentate nuclei also increased significantly in the rats treated with Dexamethasone. These results suggest that Dexamethasone can protect the dentate nuclei from the development of AD.

AUTODETECTION AND LARGE-AREA MAPPING OF NEUROFIBRILLARY TANGLES IN ALZHEIMER’S DISEASE. L.S. Hibbard*, D.W. McKee Jr., Joseph L. Price, Departments of Neurology and Neurological Surgery, Pathology, and Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Neurofibrillary tangles (NFT), seen in normal aged and Alzheimer’s disease (AD) brains, are inhomogeneously distributed in brain. NFT anatomic distributions and densities have been shown to correlate with clinical dementia severity. To quantitate NFT deposition, we have developed computer programs which automatically locate NFT in digital micrographs of postmortem tissues stained with either the Gallyas silver stain or one of several immunostains (anti PHF, anti-tau). Stained objects are detected by template correlation and extracted as discrete objects whose gray level and morphometric properties are used for classification and characterization. The NFT are sorted from all other detected objects using a conventional Bayesian classifier. NFT can be mapped over arbitrary, large areas of tissue, imaged as mosaics of adjacent, non-overlapping, digital microscope fields. Arbitrary regions of interest (ROI) are sketched, using computer graphics, in images of the entire mosaic at low magnification. The ROI guides subsequent processing to only those parts of fields coincident with the ROI. This method can map PHF/tau-immunoreactive cells in very mildly demmented or normal aged brains. ISCHEMIA: MECHANISMS I

432.1 THE EFFECTS OF IN VITRO ISCHEMIA ON PROTEINS FROM THE RAT HIPPOCAMPAL SLICE. J. Murua and K.M. Fallis-Syman*. Dept. of Biology Vassar College, Poughkeepsie NY 12601.

Our previous data that total protein synthesis is dramatically inhibited following a 5 min episode of in vitro ischemia in neurons in the rat hippocampal slice. In the present report, we explored the responses of individual proteins to this injury. Approximately 3000 µm slices from male Sprague-Dawley rats and incubated them in a Ringer's buffer equilibrated with 95% O2:5% CO2 at 37°C. Following an ischemic episode period, experimental slices were exposed for 5 min to Ringer's lacking glucose and oxygen. Slices were allowed to recover for 30 min, 1 hr, 2 hr or 3 hr, then were moved into ice-cold homogenization buffer containing 0.32 M sucrose, 10 mM Hepes, 10 mM MgCl2, 15 µg of total protein, and the Bradford protein assay was loaded onto a 7.5% polyacrylamide gel and was separated in one-dimensional gel according to Laemmli. Some gels were silver-stained and analyzed by densitometry. Some gels were transferred to nitrocellulose membranes and exposed to antibodies against hsp-72/73, GFAP, MAP-2 or calbindin-D-28k. In some experiments, new protein synthesis was determined by exposing slices to 35S-methionine and silver-stained gels were processed for autoradiography. Immunoblotting and autoradiograms were also analyzed by densitometry.

In in vitro ischemia inhibited new protein synthesis of most proteins analyzed. The total amount of some proteins was reduced at 2 hr postischemia, while that of others was unchanged. The most notable exception was the response of hsp-72/73 in to ischemic slice. This protein showed a dramatic increase in new synthesis 30 min and 1 hr after ischemia, followed at 3 hr by a 50% decrease in new synthesis. At 2 hr following the insult, the total amount of hsp-77/73 was significantly increased in postischemic slices, when compared with control slices. Thus, while total amounts of protein remains unchanged following ischemia and total new synthesis is reduced, the responses of individual proteins to ischemia must be considered. These individual responses could play an important role in the response to ischemia.

432.2 BRIEF PRECONDITIONING HYPOXIA PROTECTS HIPPOCAMPAL NEURONS FROM SUBSEQUENT HYPOXIA-INDUCED DAMAGE VIA MECHANISMS REQUIRING ONGOING PROTEIN SYNTHESIS. J. Gage* and P.K. Wood*.

Department of Neuroscience & Neurology, Albert Einstein Coll. Med., Bronx, NY 10461

Pre-exposure of rat hippocampi to a short period of hypoxia increases the resistance of CA1 pyramidal neurons to a normally fatal hypoxic insult. We hypothesized that this protective effect is that a short hypoxic insult causes the synthesis of new proteins that protect neurons from subsequent more severe hypoxic insults. We tested this idea by using the reversible protein synthesis inhibitor cycloheximide (CYCLO) and determined if it prevented the priming neuroprotection during hypoxia. We used a biphasic stimulation protocol consisting of the brief preconditioning ischaemia with the Bradford protein assay, was loaded onto a 7.5% polyacrylamide gel and was separated in one-dimensional gel according to Laemmli. Some gels were silver-stained and analyzed by densitometry. Some gels were transferred to nitrocellulose membranes and exposed to antibodies against hsp-72/73, GFAP, MAP-2 or calbindin-D-28k. In some experiments, new protein synthesis was determined by exposing slices to 35S-methionine and silver-stained gels were processed for autoradiography. Immunoblotting and autoradiograms were also analyzed by densitometry.

In in vitro ischemia inhibited new protein synthesis of most proteins analyzed. The total amount of some proteins was reduced at 2 hr postischemia, while that of others was unchanged. The most notable exception was the response of hsp-72/73 in to ischemic slice. This protein showed a dramatic increase in new synthesis 30 min and 1 hr after ischemia, followed at 3 hr by a 50% decrease in new synthesis. At 2 hr following the insult, the total amount of hsp-77/73 was significantly increased in postischemic slices, when compared with control slices. Thus, while total amounts of protein remains unchanged following ischemia and total new synthesis is reduced, the responses of individual proteins to ischemia must be considered. These individual responses could play an important role in the response to ischemia.

Brief ischemia induces tolerance to subsequent more severe insults. Preferential induction of ischemia-resistant neurons in vulnerable hippocampal neurons after brief ischemia suggests that the stress response could contribute to ischemic tolerance. Temperature during early recirculation can significantly alter the survival of ischemia-resistant neurons in the gerbil as well as the expression of hsp72. We have used the temperature dependence of hsp72 expression to assess its role in ischemic tolerance. Gerbils were subjected to 2 min bilateral carotid artery occlusion followed by 90 min recirculation under halothane anesthesia, during which temperature was either maintained continuously at 37°C (normothermic, NT) or elevated to 39.5°C between 15 and 60 min recirculation (hyperthermic, HT). A 5 min ischemia was produced 2 d after the priming challenge, and injury to CA1 was assessed 7 d after this test insult. In other animals hsp72 induction was evaluated by in situ hybridization 3 h after 2 min ischemia in the NT and HT groups. Control neuron density (295±11) was severely reduced after 5 min ischemia in naive animals (1664±180), and striking protection was observed in both NT and HT pretreatment groups (191±96 and 92±101, respectively). Reduced cell density in the HT group reflected a modest loss seen with the priming insult alone. Most importantly, 90% of 2 min NT animals showed significant protection of CA1 neurons. In contrast, only 50% of animals subjected to 2 min NT expressed hsp72 mRNA. Hsp72 induction is therefore not required for ischemic tolerance, which apparently may be achieved following insults that remain below the threshold for neuronal injury as defined by hsp72 expression.

432.4 STRESS PROTEIN INDUCTION IS NOT REQUIRED TO EXPRESS ISCHEMIC TOLERANCE IN THE GERBIL. H. Abe and T.S. Nowak, Jr.* Dept. of Neurology, Univ. of Tennessee, Memphis, TN 38163.

432.5 MAP2 IMMUNOREACTIVITY AS AN INDEX OF PATHOLOGY IN RAT HIPPOCAMPAL SLICES. Q. Zhou* and T.S. Nowak, Jr.* Departments of Anatomy & Neurobiology and Neurology, University of Tennessee, Memphis, TN 38163.

Loss of microtubule-associated protein 2 (MAP2) staining occurs in slices following anoxic incubation, and is a prominent feature of postischemic neuronal injury. Using various markers we have begun to systematically evaluate the pathology associated with slice preparation, with the goal of establishing a base line for in vitro axon/a1gycenia studies in hippocampal slices of adult rats. In this study we examined changes in MAP2 during routine slice incubation.

Male Wistar rats were decapitated under halothane anesthesia and 400 µm vibratome slices cut and incubated in artificial cerebrospinal fluid equilibrated with 95% O2:5% CO2 at 34°C. MAP2 and pre-pro-β-endorphin slices were fixed in 4% paraformaldehyde, and 50 µm vibratome sections prepared for immunocytochemistry. MAP2 was visualized with a monoclonal antibody, and pre-pro-β-endorphin with a polyclonal antibody.

The normal in vivo pattern of dendritic MAP2 immunoreactivity was found in freshly cut slices (t=0). This morphology was sometimes well-preserved through 1 h incubation, but was lost during further incubation. In many cases, however, early changes in MAP2 staining could be detected within 1 h, with preferential loss in CA1 and the upper blade of dentate gyrus, a loss that increased in thickness of the cell body, and comparable to the changes reported during anoxic incubation. Changes in MAP2 staining were well correlated with loss of Jun immunoreactivity. MAP2 therefore provides a sensitive index of slice quality that may be of general use in evaluating preparation conditions, and for comparison with other criteria of slice function.

432.6 AGING, ENERGY METABOLISM, AND THE ABILITY OF RAT HIPPOCAMPAL SLICES TO SURVIVE ANOXIA. C. Lane, C. Lonze, and J.M. Roberts, Jr.*. Department of Neurology, University of Miami School of Medicine, and *Gerrish Research Education, and Clinical Center, Miami VA Medical Center, Miami, FL 33136

We examined whether (1) decreased ATP and PCR levels before anoxia, (2) inefficient ATP or PCR use during anoxia, (3) loss recovery of ATP or PCR after anoxia, or (4) a diminished capacity for oxidative metabolism contribute to the increased vulnerability of aging brain tissue. Hippocampal slices from 6-9, 16-19, and 26-29 month old Fisher-344 rats were exposed to physiological solutions containing 5-20 mM glucose or 20 mM sodium lactate. After an initial period of normoxia (95% O2, 5% CO2), slices were subjected to anoxia (95% N2, 5% CO2). Normally was maintained by the addition of sodium lactate during anoxia with the glucose-360, 1, 2, 3, 4 and 6 h slices were fixed in 4% paraformaldehyde, and 50 µm vibratome sections prepared for immunocytochemistry. MAP2 was visualized with a monoclonal antibody, and pre-pro-β-endorphin with a polyclonal antibody.

The normal in vivo pattern of dendritic MAP2 immunoreactivity was found in freshly cut slices (t=0). This morphology was sometimes well-preserved through 1 h incubation, but was lost during further incubation. In many cases, however, early changes in MAP2 staining could be detected within 1 h, with preferential loss in CA1 and the upper blade of dentate gyrus, a loss that increased in thickness of the cell body, and comparable to the changes reported during anoxic incubation. Changes in MAP2 staining were well correlated with loss of Jun immunoreactivity. MAP2 therefore provides a sensitive index of slice quality that may be of general use in evaluating preparation conditions, and for comparison with other criteria of slice function.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
423.7RELEASE OF (3)H-D-ASPARTATE OR ENDOGENOUS GLUTAMATE FROM RAT HIPPOCAMPAL SLICES DURING IN VITRO ISCHEMIA IS MEDIATED BY A HIGH AFFINITY NA-DEPENDENT CARRIER. V. Reuterstern and J. Lipton, Dept. of Neurology, U. of Wisconsin, Madison, WI 53792.

In vitro ischemia (deprivation of oxygen and glucose/IVI) induces a several-fold increase in the release of endogeneous glutamate (GLU) and accumulated (3)H-D-aspartate (D-Asp). The D-Asp mechanism is unknown (albeit reversal of the Na-dependent high-affinity glutamate transporter has been widely suggested. We examined this hypothesis using two competitively transport inhibitors of the Na-dependent high-affinity glutamate transporter (TVA and L-trans-pyrrolidine-2-carboxylic acid (TPPC)). Slices were loaded with THA or TPPC (0.5 mM) for 60 min and then with (3)H-D-Asp (0.25 mM) for 30 min. The release was measured for 3 min intervals in 37°C during periods of IVI (10 min of ischemia). The highest release of D-Asp was induced by IVI (120 sec ischemia, 186 ± 34 pg/g dry wt) compared to control (6.7 ± 2.8 pg/g). The release of D-Asp was competitively inhibited by THA (0.5 mM) and TPPC (0.5 mM), with 55% and greater inhibition, respectively. This difference suggests that the released glutamate in vitro ischemia is largely mediated by a high affinity Na-dependent transporter sensitive to THA or TPPC but insensitive to DHIK. This phenomenon matches that of the putative neuronal carrier (UACAI = Kanai and Hedges, Nature, 360:467, 1992) and suggests that the released glutamate originates from neuronal elements. The pharmacology of inhibition of these transporter resistant suggests that glutamate releases glutamate from both neuronal and glial elements (Pines et al., Nature, 360:464, 1992).

We have previously shown that oxygen deprivation causes an increase in intracellular Ca+2 and Na+ in cortical neurons. Concomitant with these events, we have observed, in both hippocampal and cortical neurons, changes in morphology, including swelling, process retraction and death (Friedman and Hadida, J. Neurosci. (1993) 13:63, Brain Res. (1998) 615:75). We have further demonstrated that cytoskeletal elements might be cleaved during anoxia, thus making the neuron more susceptible to osmotic stress and undergoing plasticity. Cleavage of cytoskeletal elements are not involved in maintaining a cell's structural integrity, but have also been implicated in the regulation of Na+ and Ca+2 influx through, e.g. NMDA-receptors. We are focusing on actin, the major component of microfilaments, and the actin-cross-linking protein fodrin. We used cultured cortical neurons grown on poly-D-lysine coated coverslips in a chemically-defined media that does not support glut proliferation. We induced anoxia (PO2=0) on the stage of our inverted confocal microscope, confirming its effect by observing morphological changes and increased activity of Ca+2 as demonstrated by F-36. After 10 min of anoxia, the sample was rapidly removed, fixed, and, using immunocytochemistry, stained for filamentos (F-) or nonmonoclonal (G-) actin, or the 150KD cleaved subunit of fodrin. In the nonmonoclonal (G-) control, phosphatidylinositol-4,5-bisphosphate (PI(2)) staining for actin was confined to the periphery. Following anoxia, the localization of F-actin was less restricted to the periphery and the extent of staining appeared to have increased. Staining appeared for G-actin, (with DNase-I) demonstrated an apparent decrease following 10 min of anoxia. In the nonmonoclonal staining, was observed using antibodies against native fodrin, the antibody RAM-FP-150, which is specific to the cleaved subunit of fodrin did not stain. Following 10 min of anoxia, RAM-FP-150 staining could be observed, indicating that fodrin had been cleaved. These results demonstrate that cytoskeletal proteins are affected by anoxia. We speculate that early cleavage of fodrin makes the microfilaments more susceptible to morphologic disruption during swelling, resulting in an increased number of actin polymers in the cytoplasm and less well localized filamentous actin in the plasma membrane region.

423.11 ARACHIDONIC ACID PARTICIPATES IN ANOXIA-INDUCED VESICULAR GLUTAMATE RELEASE IN CA1 NEURONS OF THE RAT HIPPOCAMPUS. N. Hershkovitz* and A.N. Katchman. Georgetown Univ. Hospital, Dept. Neur., Wash., DC 20007.

Patch clamping in whole cell configuration was used to examine the effects of agents that influence arachidonate metabolism on anoxia-induced vesicular glutamate release in CA1 neuronal for 15-45 s following perfusion and ambient gas of an interface chamber from a 95%O2/5%CO2 to a 95%N2/5%CO2 mixture. As previously demonstrated, a significant increase in the frequency (340 ± 50 %), size (80 ± 5 %), and an increase in baseline miniature excitatory post synaptic currents (mEPSCs) was observed during the first 5 mins following anoxia. This increase in frequency was almost completely absent in slices which were preincubated in artificial cerebral spinal fluid containing the phospholipase A2/C/A inhibitor bromophenacylbromide (20 μM, n=8) or the cyclooxygenase inhibitors indomethacin (20 μM, n=16) and proclpin (10 μM, n=4). These observations point to a significant role for these agents on the mEPSC amplitudes. These data suggest that arachidonic acid (AA) and its cyclooxygenase products or by-products (oxygen free radicals) contribute to vesicular glutamate release during the early phase of anoxia. This observation may be important to our understanding of the neuroprotective action of these agents. (Supported by NINDS grant NS 14600-02).

423.12 HYPOXIA/HYPOGLYCEMIC-INDUCED PHOSPHOINOSITIDE HYDROLYSIS IN HIPPOCAMPAL SLICES IN VITRO: A MODEL SYSTEM FOR INVESTIGATING BIOMECHANICAL CHANGES. M. Sato, M. Matsuno, S. Watanabe, G. Bokhorst, Department of Neurosciences, Tohoku University School of Medicine, Sendai, Japan.

Cerebral ischemia induces degradation of phosphatidylinositol-4,5-bisphosphate (PIP2) and phosphatidylinositol-4-phosphate (PIP), and formation of diaiglycerol (J. Neurochem. 47, 123-132, 1986). To investigate the biochemical mechanisms involved in ischemia-induced phosphoinositol degradation, an in vitro method has been developed. Transverse slices of rat hippocampal labelled with (3)H)inositol were incubated in nitrogen-saturated and glucose-free Krebs-Henseleit bicarbonate buffer in the presence of 10 mM LiCl. Inositol phosphates and inositol phosphatidyls were analyzed by SEP-PAKs columns and TLC, respectively. The lack of glucose and oxygen induced a decrease in PIP2 and PIP. Phospha did not change. The changes were very similar to those found in vivo ischaemia. Inositol phosphates (IP) transiently increased to control levels, and inositol monophosphate gradually increased. The increase in IP5 was completely prevented by removing extracellular Ca2+ from the buffer. Addition of atropine, prazosin or ketanserin and naloxone did not affect PIP. Antagonists of HMRD and MDMA receptors also had no effect. D-jasminol and phosphoinositolphosphonate (D-AP3), a putative antagonist of metabotropic glutamate receptors, prevented the increase in IP5 and PIP. The findings of D-AP3 may be due to the inhibition of phosphatidylinositol synthesis as reported previously (Neurosci. Lett. 157, 87-90, 1993). These results provide a model system for investigating the biochemical mechanism of ischemia-induced phosphoino-

**SIMULTANEOUS PATCH-CLAMP RECORDINGS OF CA1 PYRAMIDAL CELLS AND INTERNEURONS IN RAT HIPPOCAMPAL SLICES: DIRECT DEMONSTRATION OF FUNCTIONAL DISCONNECTION OF INTERNEURONS FROM ANOXIA.**

E. Khazipov, P. Congar, N. Rospert* and Y. Ben-Ari

INSERM Unité 29, 123 Bd de Port-Royal, 75014 Paris

It was proposed in our previous work (Khazipov et al., *Neurophysiol., 70 : 229I-2260, 1993) that high sensitivity of polysynaptic systems to anoxia is due to the functional disconnection of inhibitory interneurons from excitatory inputs. To verify this hypothesis, the effects of anoxia were studied in simultaneous whole-cell patch-clamp recordings from interneurons and pyramidal neurons in CA1 region of adult rats hippocampal slices; these were both identified by electrotonic properties and by their sensitivity to bicuculline. Anoxia (95%N2-5%CO2; 5 min) generated currents in interneurons similar to pyramidal cells: the most prominent were the anoxic outward current and the postanoxic outward current. EPSCs and polysynaptic IPSCs were depressed by anoxia, and this depression was more pronounced in the interneurons. The currents evoked by pressure ejection of glutamate, AMPA and NMDA were not affected by anoxia, suggesting that the depression of EPSCs in both interneurons and pyramidal cells is due to a presynaptic mechanism. Depression of EPSCs but not polysynaptic IPSCs nor GABA receptors mediated component of monosynaptic IPSCs (see Congar et al. *Soc. Neurosci. Abst., 1994) was prevented by adenosine A1 receptor antagonists DPCPX (200mM) and DPCPX (200mM) indicating the involvement of presynaptic adenosine receptors in anoxic depression of EPSCs. These observations indicate that anoxia preferentially depresses excitatory inputs to anoxia leading to a functional disconnection of interneurons.

**DIFFERENTIAL RESPONSES OF CA1 PYRAMIDAL CELLS AND GRANULE CELLS IN THE DENTATE GYRUS TO ISCHEMIA-LIKE CONDITIONS IN RAT HIPPOCAMPAL SLICES.**

H Shintani, Y. Fujito*, A. Mizuno and M. Adki

Dept. Physiol., School of Med., Sapporo Med. Univ., Sapporo 060, Japan

We examined the regional difference of responses to oxygen-glucose deprivation (ischemia-like conditions). In cultured rat hippocampal slices, we measured the effects of oxygen-glucose deprivation on the hippocampal and dentate gyrus of DG in rats hippocampal slices (350mm thick). Changes of resting membrane potential (resting Vm) and antidiomatic action potentials (AAPAs) were compared between CA1 pyramidal cells (PCs) and granule cells (GCs) in DG. CA1-P (measured by Fura-2/AM loaded slices were also compared between CA1 and DG. In PCs, Hypo-GC(1) produced an initial hyperpolarization and a subsequent rapid depolarization. By contrast, GCS showed a slight initial hyperpolarization and a subsequent stowel depolarization than PCs. In PCs and GCS, AAPAs disappeared after 7 to 9 min periods of Hypo-GC(1), when rest Vm depolarized to Hypo-GC(1). In contrast, DG was not affected by Hypo-GC(1), and did not produce an irreversible depolarization in both neurons. However, when reoxygenation was started at the time of disappearance of AAPAs, reoxygenation occurred in 86% (12/14) of PCs and 36% (5/14) of PCs. (CA2+) remarkably increased at the depolarization phase of both DG and PC. The peak of [Ca2+] were significantly higher in CA1. Under CA2+-free medium, peak [Ca2+] decreased and there was no significant difference between CA1 pyramidal cell layer and granule cell layer. These results demonstrate the differential responses to Hypo-GC(1) between CA1 PCs and GCs in DG, probably due to different distributions of ion channels of these neurons.
BRIEF PERIODS OF OXYGEN AND GLUCOSE DEPRIVATION IN VITRO CAUSE SWELLING AND DELAYED CELL DEATH. W.J. Goldberg*, S. Stroke & Trauma Lab., Dept. Veterans Affairs Medical Center, Washington, DC 20422.

An in vitro system was used to mimic several aspects of ischemia, including cell swelling, delayed activity, glycolysis, deoxygenation, and prolonged reperfusion. We replaced normal culture medium from 3-week-old spinal cord cultures with oxygen-depleted, chemically balanced (310 mM) medium (25 mM Na, 65 mM K and 1 mM Ca). After incubation at 37°C for 15 minutes in an atmosphere of 7% CO2/93% N2, the cultures were returned to normal, oxygenated culture medium for 0.5 or 96 hours. At the end of each recovery period, cultures were immunohistochemically stained using combined antibodies to 68K, 150K, and 200 K neurofilament proteins. In non-deprived cultures, the neuronal density was 100 cells/100 mm². These cells were 96.8±6.8 µm (means±SEM) in size. More than 89% of the original neuronal population survived the 15 minute deprivation period. Two classes of cells were observed based on cell size: one group was not different from non-ischemic neurons (109±7.6 µm) and the other was significantly swelled (255.3±25.5 µm, p<0.05). The survival rate decreased to 64.7% after 1 hour of recovery. Swollen (240±14.3 µm, p<0.05) and non-swollen (112±9.3 µm) neuronal populations were observed at this time. After 4 days of recovery, the survival rate decreased further to 23%. All deprived cells were swollen to 337±47.7 µm (p<0.05). No normal sized neurons were observed. Supported by the Department of Veterans Affairs.

ISCHEMIA: MECHANISMS II

424.1 SUBCELLULAR LOCALIZATION OF ISCHEMIA-INDUCED INHIBITION OF CaMKII IN THE HIPPOCYMAL BRAIN SLICES: SIMULTANEOUS Ca2+ AND KCN POTENTIAL MEASUREMENTS. M.J. Evans* and C.D. Estabrook, Biophysics Dept., SmithKline Beecham, Harlow, Essex CM19 5AD U.K.

To investigate synaptic responses, ischemia depolarisation, and Ca2+ influx under oxygen and glucose free conditions, 400 micron hippocampal slices were loaded with the Ca2+ indicator dye Indo-1 AM. Microspectrophotometry was used to monitor changes in fluorescence intensity at a 20 µm diameter window centred over the stratum pyramidale of either CA1 or CA3. Extracellular DC recordings were made in the stratum pyramidale adjacent to the window. Experimental brain temperature was 36°C. The relevant artefactual pathway was stimulated every 15s to monitor synaptic responses. Synaptic responses in Indo-1 loaded slices were similar to those of control slices. On switching from normal medium to 2% saturated, glucose-free medium, synaptic responses were eliminated within 90s. After 276±45s, a large, transient, negative DC shift was observed in CA1 which was closely followed by a rapid and sustained rise in [Ca2+]. Reperfusion with normal medium shortly after the peak [Ca2+] resulted in a return of [Ca2+] to baseline level over 3 to 5 min, but there was no recovery of the synaptic responses. Switching to normal medium before the depolarising shift and [Ca2+] rise resulted in a slow recovery of synaptic transmission to near baseline levels. Minoxidil containing only CA1 gave similar responses, indicating that the CA1 events are not driven by preceding events in CA3. The depolarising wave and [Ca2+] rise in CA3 had a longer latency (59±57s) and rose more slowly to a lower peak amplitude. Repetition of the stimulus after the peak [Ca2+] rise in CA3 resulted in a sustained recovery of synaptic responses. These regional differences in response to acute oxygen and glucose free insult of CA1 to injury relative to CA3 observed with in vivo ischaemia models.

424.2 TRANSLATION OF Ca2+-CALMODULIN PROTEIN KINASE II IN THE VULNERABLE NEURONS FOLLOWING ISCHEMIA AND HYPOGLYCEMIA IN THE RAT. Bing-Yi Huang, Tetsuo Kurihara, Fredrik Kamme and Tadeusz Wieloch, Lab. for Exp. Brain Res., University Hospital, 221 85 Lund, Sweden.

Alterations of Ca2+-calmodulin-dependent protein kinase II (CaMKII) during and following transient cerebral ischemia (TICI) and insulin-induced hypoglycemia (HG) in the rat were studied. CaMKII was translated to synaptic junctions after both TICI and HG as showed by immunohistochemistry and calmodulin binding, concomitant with a decrease in CaMKII activity. The CaMKII activity increases transiently and lasts longer than HG, which is consistent with the CaMKII-dependent translocation to synaptic junctions. The ischemia also reduces the expression of α-subunit of CaMKII mRNA in dentate gyrus as demonstrated by in situ hybridisation. The results suggest that a stimulation of CaMKII is ongoing in the vulnerable areas which causes translation. These results suggest that the role of CaMKII signal after ischemia. Intrinsic ischemia inhibits protein neuronal damage as well as reduces the translocation and increases mRNA expression of CaMK-II induced by ischemia. In conclusion the persistent translation is highly correlated to neuronal damage in both ischemia and hypoglycemia.

424.3 ALTERATIONS IN Ca2+/CaMK-Kinase II AND OTHER PROTEINS IN POSTSYNAPTIC DENSITIES AFTER FOREBRAIN ISCHEMIA IN RATS. Jalajee Ammala*, James C. Glose, Department of Neurology, University of Texas Health Science Center, Houston, Texas 77025.

Postsynaptic densities (PSDs) located beneath the postsynaptic membrane may be the organizer for organizing channels, receptors and enzymes that participate in signal transduction. The major PSD protein, α-subunit of Ca2+/calmodulin-dependent protein kinase II (CaMK-II), accounts for up to 30-40% of total PSD proteins. Several studies have shown that CaMK-II expression occurs after ischemia and hyperglycemia, translation of CaMK-II from cytosol to post-synaptic fraction, and that these changes are reversible after brief but not prolonged duration of ischemia. The present study analyzes the expression of CaMK-II in tissue sections from rats subjected to ischemia. Winter rats were subjected to 20 min of ischemia using a four-vessel occlusion (4VO) model. After 0, 24 and 48 h of reperfusion, animals were decapitated and forebrain isolated. Tissue was processed for immunohistochemistry and results were compared with control groups. Immunohistochemical analysis revealed that the expression of CaMK-II was increased in both the basal ganglia and cerebral cortex. The results of this study indicate that CaMK-II is expressed in both biologically relevant tissues in ischemic and non-ischemic conditions. Further research is needed to determine the role of CaMK-II in the recovery from ischemia.

424.4 A reversible elevation of free calcium during simulated ischemia in neuronal tissue culture. J.J. Varon*, M. Han, S.C. Jo and A.G. Thomas, Dept. of Neurology and Neuroscience Johns Hopkins School of Medicine, Baltimore, MD 21205.

Previously, we have described tissue culture models of ischemia using metabolic inhibitors and reversible ATP depletion. Neurons can be protected by NMDA receptor blockade after simulated ischemia, allowing delayed treatment of injury. Since the accessibility of cultures is preserved, we have been able to measure free calcium changes during simulated ischemia with the sensitive dyes fluo-3 or fura-2 in dissociated cortical cultures. Intracellular calcium rose reversibly during metabolic inhibition. The calcium rise was slower and the recovery faster than that caused by bath application of glutamate. Blockade of NMDA receptors with MK-801 caused no change in the calcium increase, but removal of extracellular calcium decreased the rise.

Calcium entry during recovery was investigated histochemically. Calcium permeable non-NMDA receptor channels are permeable to cobalt. Cultures were perfused with 100 µM cobalt visualized with ammonium sulfide precipitation followed by silver intensification. In both dissociated cortical cultures and organotypic hippocampal cultures, some neurons accumulated extracellular calcium during recovery from simulated ischemia. More cells were stained during bath application of kainite or glutamate. These experiments suggest that while free calcium may rise during simulated ischemia, toxic, persistent calcium entry during recovery may not be reflected by increased intracellular calcium.
424.5 EFFECTS OF TRANSIENT CEREBRAL ISCHEMIA ON CALCIUM-BINDING PROTEIN mRNA LEVELS IN THE GERBIL HIPPOCAMPUS. A.M. Babcock1, J. Noltkamper, C.M. Padin2, P.E. Miccdyld2 and P. Popper. Dept. of Psychology and Biology, Montana State Univ., Bozeman MT 59717, Dept. of Anat. & Cell Biology, UCLA, School of Med., Los Angeles, CA 90024. Previous studies have reported that hippocampal calcium calmodulin kinase II (CaM II) mRNA levels decrease at 24 hrs following transient ischemic insult in the gerbil (Hinestrosa & Kindy, 1992). The present study attempted to confirm and extend these findings by evaluating changes in hippocampal CaM II mRNA levels using in situ hybridization. Gerbils (n=5/group) underwent a 2-min bilateral carotid occlusion or sham procedure. At 2 hrs post surgery, locomotor activity was assessed as a behavioral marker of ischemic cell damage. Gerbils were sacrificed at 24 hrs and sections containing the hippocampus were processed for in situ hybridization with cRNA probes for the α and β subunits of CaM II (separate sections). As expected, ischemic gerbils exhibited higher activity levels indicative of hippocampal damage. Changes in enzyme activity following ischemia were assessed using HPLC with an electrochemical detector (EMI) and sodium nitroprusside inhibition. These results are discussed in relation to observed alterations in CaM immunoreactivity. Supported by American Heart Grant-in-Aid, P20 RR01927-01 (AMB) and NIH-NINCDS (PEM).

424.6 SUSTAINED INHIBITION OF EXCITATORY SYNAPTIC TRANSMISSION BY ADENOSINE DURING MODERATE HYPOXIA. Alice L. Fournier, Michael S. Kaplan, and K.S. Leu. Dept. of Neurological Surgery, Univ. of Virginia, Charlottesville, VA 22908. Adenosine is a potent inhibitor of excitatory synaptic transmission at many sites in the CNS. During ischemia and hypoxia, extracellular adenosine levels increase substantially. This elevation of adenosine appears to contribute to the initial phase of the hypoxic inhibition of synaptic transmission (Curtis et al., Brain Res. 400, 37-42, 1986). The present study examined whether adenosine contributes to later phases of hypoxic inhibition of synaptic responses during 1 hour of moderate hypoxia. Hippocampal slices prepared from adult Sprague-Dawley rats were submerged in medium with an oxygen tension of approximately 470 mm Hg. Field excitatory postsynaptic potentials (EPSPs) were recorded in the stratum radiatum of CA1 in response to stimulation at the CA1-CA2 border. Hypoxic conditions were established by changing the oxygen tension in the superfusion medium to 85 mm Hg. A complete inhibition of EPSPs was observed within approximately 9 minutes of hypoxia. An injection of adenosine 1A receptor, cyclopentyltheophylline (CPT; 10μM) was added to the medium at various intervals after the onset of hypoxia. The addition of CPT to the hypoxic superfusion medium after the loss of synaptic responses resulted in a substantial recovery of EPSPs, while the loss of synaptic responses remained complete for the entire hour of hypoxia in the absence of CPT. When CPT was added 10 or 20 minutes after the loss of synaptic responses, EPSPs recovered to 68% and 47% of their prehypoxic baseline values respectively. These results indicate that adenosine-mediated inhibition contributes significantly to the sustained loss of EPSPs during hypoxia. These findings suggest that adenosine functions to maintain excitatory synaptic transmission at low levels during prolonged moderate hypoxia and support the concept that adenosine serves as an endogenous neuroprotectant.

424.11 CHANGES OF ACETYLCHOLINE IN RAT BRAIN FOLLOWING ISCHEMIA. H. Kanemitsu1, K. Kawai1, T. Kirino2, A. Tamura3, K. Iwasaki3, M. Fujitani3, 1Department of Neurosurgery, Teikyo University School of Medicine, Tokyo, Japan. 2University of Tokyo. 3University of Fukuoka.

We have reported that the decrement of the acetylcholine level may be related to the disturbance of spatial cognition. The purpose of this present study is to determine change of the acetylcholine level in ischemic and normal brain tissue following focal ischemia. Male Wistar rats weighing 280-300 g were anesthetized with 2% halothane inhalation and the proximal portion of the left middle cerebral artery (MCA) was occluded by the microsurgical technique. The animals were treated with microwave 1.2 and 2.4 weeks following MCA occlusion and the acetylcholine levels of the cerebral cortex, caudate putamen and thalamus were measured by using HPLC-ED system. The acetylcholine levels of the cerebral cortex and caudate putamen on the ischemic side in the MCA-occluded group were significantly decreased compared with those in sham-operated group. However, the levels of the opposite side and thalamus unchanged. Those decrements of acetylcholine may be caused by interception of the neurons in the Meynert nucleus and be related to the impairment of learning behavior.

ISCHEMIA: APOTOTIS

The CA1 pyramidal neurons in the hippocampal area are selectively vulnerable to transient anoxic-ischemic damage. In experimental animals the CA1 pyramidal neurons undergo cell death several days after brief forebrain ischemia. It remains, however, unknown whether this delayed neuronal death is necrotic or apoptotic. We examined the degenerating process of the CA1 pyramidal neurons in gerbil hippocampus after brief ischemia. Neurites of the CA1 neurons were nick end labeled by biotinylated dUTP mediated by terminal deoxy- nucleotidyl transferase 3 and 4 days after ischemic insult, but not at the prior stages. Simultaneously, dense chromatin masses appeared in nuclei of the neurons. By electrophoretic analysis, laddering of DNA occurred only in CA1 hippocampal tissues obtained 4 days after ischemic insult. The fragmented DNA in the CA1 pyramidal layer was phagocytosed by microglial cells. The results suggest that delayed death of the CA1 pyramidal neurons after brief ischemia is not necrotic but apoptotic.

Brain ischemia can result in oxidative stress leading to the formation of free radicals. These free radicals can potentially exert cytotoxic actions by causing chemical modifications to lipids, proteins, and DNA. Damage to critical parts of the DNA molecule could lead to cellular dysfunction and further tissue injury. In the present study, we have begun to examine the sensitivity of normal brain cells to DNA damaging agents and the ability of those cells to repair damage. Neurons, astrocytes, and cerebral endothelial cells were isolated at day 15 of gestation, at postnatal day 1, and postnatal day 14, respectively, planed into plastic culture dishes, and grown to confluence. Those cells were exposed to radiation doses of 6, 8, 10, and 32 Gy to induce DNA double-strand breaks (DSBs) and then incubated for 0 min to 48 hrs to allow repair of the DNA damage. The number of DSBs remaining at the various time points was determined by subjecting the DNA to pulsed-field gel electrophoresis. There was a linear increase in the number of DSBs with radiation dose. There were two components to DSB repair: a fast component with half-times of repair of 10-15 min and a slower component with half-times of repair of 3-7 hrs. While there was no difference between astrocytes and cerebral endothelial cells in the rate of repair, the rate of repair increased by 10% relative to the other cell types. Treatment of astrocytes with 0.25 mM dibutyryl cyclic AMP decreased the number of DSBs induced and significantly increased their rate of repair. This results indicate that cyclic AMP can enhance repair of DNA damage and that neurons are better able to repair DNA damage than other brain cell types. 425.4 DETECTION OF DNA STRAND BREAKS IN RAT CORTICAL NEURONS EXPOSED TO FOCAL ISCHEMIA-REFURFUSION IN VIVO. C. Do, R. Hu, S. Wong, D.W. Choi, C.Y. Hsu*. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington University School of Medicine, St. Louis, MO 63110.

In our rat model of focal middle cerebral artery ischemia-refurbation, coagulation necrosis occurs confined to the distribution of the artery. In the infarcted tissue, neuronal death evolves over several days after the ischemic insult. Some recent studies have suggested that neuronal DNA fragmentation may accompany focal ischemic injury, raising the issue of apoptosis. The present study was conducted to look for evidence of DNA strand breaks in our ischemia model. Genomic DNA isolated from the ischemic cortex was subjected to non-denaturing polyacrylamide gel electrophoresis. Twenty-four and 48 hr after ischemia, DNA fragments of various sizes were seen. The O-HH DNA ends were immunohistochemically identified in the formalin-fixed, paraffin-embedded brain slices by in situ end labeling (using terminal transferase with dUTP-digoxigenin) followed by anti-digoxigenin-peroxidase immunohistochemistry. DNA strand breaks detected by such immunostaining was not observed in non-ischemic cortex, or in controls stained without dUTP-digoxigenin, anti-digoxigenin antibody, or terminal transferase. Strong immunoreactivity was noted in the nuclear regions of injured and near normal neurons. The detection of DNA strand breaks at 2 different methods supports the idea that cortical neuronal death in focal ischemia may involve endonucleolytic degradation of DNA similar to that noted in several forms of apoptosis.

DNA FRAGMENTATION IS NOT AN EARLY EVENT IN ISCHEMIC NEURONAL DEATH. P. Wu* and J.M. Davis. Dept. of Neurology, SUNY at Stony Brook, Stony Brook, NY 11794-8121.

DNA fragmentation is thought to be an early, perhaps even, initial event in programmed cell death. We have been exploring the hypothesis that ischemic cell death may be a form of programmed cell death in focal and transient global ischemia in gerbils. After 5 minutes of bilateral carotid artery occlusion, hippocampal CA1 neurons undergo a delayed cell death. We studied DNA using 2% agarose gels at various times after transient carotid occlusion from whole hippocampus (3 experiments) and hippocampal CA1 region (1 experiment), and punches of CA1, pyramidal cells (3 experiments). DNA from dexamethasone-treated whole hippocampus in the gerbil was fragmented at 24 hours after carotid occlusion. However, we did not see DNA "laddering" either at late times (48, 54, 66, 72 hours) or at earlier times (2, 4, 6, 24 hours). While this was in progress, El Khoury et al (1993) reported "laddering", from gerbil whole hippocampus between 54 and 96 hours after carotid occlusion. We found no evidence to reproduce their results even using their extraction technique, but were unable to confirm their findings.

We found DNA fragmentation in focal ischemia as reported by others. After permanent ligation of one carotid artery, half the gerbils sustained an infarct (as assessed by TTC staining); some also had seizures. "Seizures" were present at 24 hours and more obvious at 48 hours, but were not present at 3 or 6 hours after ligation. In focal ischemia, DNA fragmentation was a late phenomenon appearing after necrotic cell death in the infarcted area.

We conclude that DNA fragmentation does not trigger ischemic cell death as has been proposed. Further, it appears that DNA "stepladders" can be seen as a late event in necrotic cell death. [Supported by the NIH (NS 05599) and the VA]

425.7

Previous work provided evidence for an apoptotic component in the cell death in rat brain following global ischemia produced by two-vehicle occlusion (2VO) (Maxman et al., Neurosci. Letts. 164, 89-92 (1993)). Further studies undertaken to establish a time course for the development of this damage following 12 min 2VO showed an increase in damage with increasing reperfusion time. Cell death was quantified by two methods. Firstly, DNA was radiolabeled with diodeoxyATP at 3 h OH and the labeled DNA below 10K following gel electrophoresis was measured. Secondly, 3' ends were labeled in situ on fixed sections taken from ischemic brain to identify those cells containing fragmented DNA. A comparison of these two parameters was undertaken for the striatum. This gave a positive correlation, thereby supporting the idea that the internucleosomal cleaved DNA seen by gel electrophoresis is derived from the cells identified by in situ labelling and that this provides a quantitative measurement of the cell death. It was also apparent that fragmented DNA could be detected at the same time that morphological changes in the nucleus were observed.

To further confirm an apoptotic component in the death of cells following transient ischemia a competition was made with the necrotic cell death produced by decapitation. Degraded DNA was detected as a smear after electrophoresis, not as discrete bands. A time course study showed that selectivity in the hippocampus differed from that seen following ischemia with fragmented DNA first being detected in the dentate gyrus, followed by CA1, then CA3.

Further support for an apoptotic process being activated following ischemia is provided by these results. The time course for ischemia damage determined by conventional staining techniques correlated with that for DNA cleavage and major distinctions were observed between ischemic cell death and necrotic cell death.

425.8
APOPTOSIS AND NECROSIS CONTRIBUTE TO DELAYED CELL DEATH FOLLOWING HYPOXIC-ISCHEMIC INJURY TO THE IMMATURE RAT BRAIN. E.J. Beilharz, C.M. Williams, M. Dragunow *, E.S. Striimane, R. French *, P.D. Gluckman*. Children's Hospital and Centre for Developmental Medicine and Biology, Department of Pharmacology, Dept. of Anatomy, University of Auckland, Auckland, New Zealand.

The mechanisms leading to delayed cell death after hypoxia-ischemia in the 21 day old Wistar rat brain following either mild (15 min) or severe (60 min) unilateral hypoxic-ischemic injury. The timecourse of DNA degradation (using gel electrophoresis and in-situ end labelling), microglial activation (using immunoelectron microscopy for Iba1 staining) and cell death (TACS1 staining) and c-jun expression were examined. The mild injury led to selective neuronal loss. This was associated with the development of apoptotic morphology, DNA laddering and acidophilia from 3d post-hypoxia. Prolonged expression of c-jun occurred in these neurons before death. Cell death was accelerated by the severe injury, with DNA degradation and apoptotic morphology seen at 10h in some regions. However, in the infarcted cortex a different pattern was seen: the DNA and microglial remained intact, and cells basophilic, until after 10h post-hypoxia, then widespread necrosis developed by 24h. In contrast to regions of selective neuronal loss, DNA degradation was initially random (at 24h), with laddering not detected until 3d. Microglial activation coincided with the onset of DNA degradation in regions of selective neuronal loss (in both models) but not infarction. The results clearly indicate that there are two distinct pathways to cell death: cortical infarction was necrotic, and occurred independently of microglial activation and apoptosis. In contrast, selective neuronal death was apoptotic and closely coupled to the microglial reaction and c-jun expression.

NEUROTOXICITY: RAA 1A

426.1

Methamphetamine (METH) damages nigrostriatal DA nerve terminals in rodents and monkey brain. Pretreatment with alpha-methyl-p-tyrosine or DA receptor antagonists protect against the toxic effects of METH, suggesting that at least one component of the neurotoxicity involves the ability of METH to increase excitotoxic concentrations of DA. NMDA antagonists are also capable of blocking the neuronal-damaging effect of METH, suggesting that alterations in glutamatergic neurotransmission may be involved as well. However, several of the NMDA antagonists employed (e.g., MK801, PCP) are also reported to block excitatory amino acid (EAA) receptors, raising the possibility that a reduction in DA neurotransmission, rather than NMDA receptor blockade, underlies their neuroprotective actions. We therefore determined the abilities of two NMDA antagonists, MK801 and PCP, to reduce METH-induced DA release in the rat striatum using in vivo microdialysis, and also determined tissue levels of striatal DA in these same animals one week after drug injection. The administration of METH (10 mg/kg i.p.) each 2 hr on 4 consecutive days caused large increases in striatal ECF DA (> 500%). Pretreatment with MK801 (2 mg/kg i.p.) each 2 hr for 4 days caused no significant changes in striatal ECF DA (compare: 13.3 ± 2.2 nM in control) and METH-induced DA overflow. In a similar fashion, pretreatment with CGS19755 (35 mg/kg i.p.) each 2 hr on 4 days, 4 min before METH, i.p.) also failed to significantly alter the METH-induced DA overflow.

426.2
METHAMPHETAMINE-INDUCED DEPLETION OF GLUTAMATE-POSITIVE NEURONS IN THE SOMATOSENSORY CORTEX OF THE RAT. C. Pu and C. Y. Vorhees*. Children's Hospital Research Foundation, University of Cincinnati, Cincinnati, OH 45229, USA.

The neurotoxic effects of methamphetamine on dopaminergic and serotonergic terminals have been well documented. However, the neurochemical characteristics of degenerating neurons in the somatosensory cortex are unknown. By using immunocytochemical techniques for glutamate immunohistochemistry, it was found that MA exposure in adult rats (10 mg/kg given 4 times i.p at 2 hour intervals) causes localized depletion of glutamate-positive neurons three days following treatment. The affected region is in the dorsal sensory cortex, central to the somatosensory cortex. first-third portion of the longitudinal fissure to the rhinal sulcus. The depletion of glutamate-positive neurons occurred in all layers of the cortex with layers II-III showing the most severe loss. The survival of neurons in the affected regions is consistent with that demonstrated previously with silver staining following methamphetamine, amphetamine and methyldiosoxymethamphetamine (MDMA) exposures. The results indicate that MA exposure results in the degeneration of glutamate neurons in the somatosensory cortex of adult rats.

Activation following a single kindling stimulus to the amygdala. We have been examining the role of c-fos in the development of amygdala kindling using antisense technology. We have performed studies, animals received infusions into the amygdala via a chronically implanted cannula either once (Group 1) or on a daily basis (Group 2) with phosphorothioate antisense (AS) or control (C) oligonucleotides. Ten hours after the infusion rats in both groups were administered a kindling stimulus in the amygdala and an electroencephalographic afterdischarge (AD) was recorded. The AS treated animals in Group 1 showed considerable attenuation of Fos-immunoreactivity when compared to the C treated animals. However, during the course of these studies we observed that subsequent to 3-4 infusions Group 2 animals (both AS and C) no longer demonstrated ADs. Upon histological examination of these animals, lesions to the amygdala and surrounding areas were observed. Reactive gliosis was demonstrated surrounding the lesion with glial fibrillary acidic protein immunoreactivity (GFAP-IR). These detrimental effects are dose related. Further studies have now revealed that the degree of histological damage can be greatly minimized by extending the period between infusions. These results suggest that certain cautions must be taken when using antisense technology and furthermore that only certain types of experimental approaches are amenable to it.

MODULATION OF EXCITOTOXIC DAMAGE BY INTERLEUKIN-1 (IL-1) AND IL-1 RECEPTOR ANTAGONIST (IL-1ra).

Lawrence C. Prather, Neuroscience Division, 124, School of Biological Sciences, University of Manchester M13 9PT, UK.

We have previously suggested that the cytokine IL-1 is involved in ischemia and excitotoxic brain damage, since recombinant human IL-1ra (rhIL-1ra, Synergen, USA) inhibits neurodegeneration caused by focal ischemia or NMDA receptor activation in the brain. Neurodegeneration has been ascribed to overactivation of AMPA as well as NMDA receptors. In the present study we have therefore compared effects of rhIL-1ra and recombinant human IL-1ra (rhIL-1ra) on damage induced by infusion of an NMDA (cis-2,4-methanoglutamate, MGlu) or AMPA (S-AMPA) receptor agonist into the striatum of the rat brain. Both agonists induced reproducible lesions assessed histologically. In both studies, animals receiving rhIL-1ra (5ug) with the excitatory amino acid agonist (100mM MGlu or 150nm S-AMPA) significantly inhibited damage (lesion volume) by 46% or 43% when induced by NMDA or AMPA receptor activation respectively. In contrast, infusion of IL-1β (14pg, 100U) did not affect either form of damage (the dose of exogenous used was 5nmol MGlu and 10nmol S-AMPA). Additionally IL-1β did not induce neurodegeneration when infused alone. These data indicate that endogenous, but not exogenous IL-1, mediates NMDA and AMPA receptor induced neurodegeneration.

CIS-FLUPHENIXOL PROTECTS STRIATAL CELLS FROM MALONATE-INDUCED LESIONS.

P. Hantrave*, M.C. Guiraud, S. Paillot and B. Bruguier. CNRS URA 1385, Service Frédéric Joliot, D1PP-DSV, 94100 Orsay Cedex and INSERM CIP 91-02, Hôpital Henri Mondor, Créteil 94010, FRANCE.

Malonate, a succinate dehydrogenase inhibitor, has been shown to produce striatal lesions resembling Huntington’s disease striatal degeneration. Treatment of adult rats with malonate (1 mmol/kg body weight, i.p.) 1 hr after birth (n = 10) produced a significant reduction (P < 0.05) of striatal dopamine levels (92%) and protein content (78%) compared to controls. On Day 21, the rats were injected with 2% Fluorochrome Blue and Nissl stains were observed. The malonate-treated rats showed a significant reduction in the number of Nissl-stained neurons (28% vs. controls). In contrast, the rats treated with 2% Fluorochrome Blue had a significant increase in the number of Nissl-stained neurons (132% vs. controls).

CIS-FLUPHENIXOL has been shown to be beneficial in Huntington’s disease patients. The mechanism of action of this drug is not well understood. However, it is believed to be mediated by a glutamatergic system which plays an important role in the pathogenesis of this disease. The current study was therefore designed to evaluate the protective effects of CIS-FLUPHENIXOL on malonate-induced striatal lesions in the neonatal rat.

METHOD: Adult rats, injected intraperitoneally (pretreatment at 30 min and post-treatment 60 min after) with or without saline (controls) were injected with a single malonate injection (1 ml/kg) into the left striatum. At one week survival, the CIS-FLUPHENIXOL group showed a significant improvement in striatal survival. Compared to controls, CIS-FLUPHENIXOL provided more than 50% protection against malonate-induced striatal lesions.

DIFFERENT RESPONSES TO N-METHYL-D-ASPARTATE AND KAINIC ACID IN CEREBELLAR GRANULAR CELLS OF LEAD-EXPOSED PUPS.

D.K. Lim*, T. Boa and I.K. Ho*.

College of Pharmacy, Chonnam National University, Kwang-Ju, 500-757 Korea and 2Department of Pharmacology and Toxicology, Univ. Miss. Med. Ctr., Jackson, MS 39216 USA.

To determine changes in response to N-methyl-D-aspartate (NMDA) and kainic acid (KA) in cerebellar granular cell of offspring lead mothers, pregnant rats received 0.25% lead acetate in the drinking water 2 days after gestation. The control group was given sodium acetate (0.125%) in drinking water. The cerebellar granular cells were cultured from 7 to 8 day old pups. Changes in the level of cytochrome c* (CIT) and glutamic acid release of glutamic acid were measured using triphenyltetrazolium chloride (TTC) and using fluorometric assay. In the presence of cytochrome c*, the maximum responses to KA were not different. The NMDA-induced elevation of CGMP was not affected in the lead exposed pups. However, the degree of KA-induced increase in CGMP level in cerebellar granular cells of lead exposed pups was significantly reduced. The increase in CGMP level in control pups was 55.5 and 51.4% of the control groups when the incubations were carried out for 3 min and one hour, respectively. The NMDA- and KA-stimulated release of glutamic acid in cerebellar granular cells prepared from lead exposed pups was also significantly reduced. These results indicate the lead exposure to the mother affect the excitatory amino acid systems during the development of the offspring.

The effects of a mitochondrial toxin 3-NPA on operant performance, dopamine (DA), serotonin and their metabolite concentrations in selected brain regions were studied in adult male Sprague-Dawley. Rats were challenged by caesarean section as either noninsulted (NI) or insulted (I) with hypoxia. Hypoxia was produced by submerging dissected uterine horns in saline for 15 min. NI rats were siblings of the I rats delivered from the saline-exposed pregnant animals. Rats were cross-fostered and behavior was assessed. At 1 year of age, NI and I rats were injected with 3-NPA at 5 mg/kg/day (Monday-Friday). The dose was increased by 5 mg/wk reaching 30 mg/kg/day. After sacrifice at the end of the NPA treatment, brains were dissected, weighed and analyzed for neurotransmitters. Operant measures significantly decreased with increasing 3-NPA doses but were not differentially affected by hypoxia. Ataxia at the highest dose of 3-NPA was observed only in NI rats (3/9 rats). A trend toward a DA concentration increase in frontal cortex was seen in both I and NI groups. While weights of brain regions in the control and 3-NPA treated I rats were similar, cerebellar weight in NI rats after 3-NPA treatment was reduced (ANOVA, p < 0.001). Therefore, perinatal hypoxia insult may decrease subsequent sensitivity to the toxic effect of 3-NPA.

Systemically administered L-chloropropionic acid (CPA) produces selective damage to cerebellar granule cells. We investigated whether CPA may produce the granule cell damage by acting at a subtype of the N-methyl-D-aspartate (NMDA) receptor. Groups of rats were treated with CPA (10 mg/kg/po). Some animals received the irreversible NMDA antagonist, MK-801 alone (5mg/kg/po), saline or CPA plus MK-801. The neurotoxicity was assessed at days 3 and 5 of the study. An increase in locomotor activity was observed. CPA alone showed marked locomotor retardation which became very severe by days 3 and 4. These animals showed marked weight loss (-22% of controls) and were terminated at days 3 or 4. In the CPA plus MK-801 treated animals although showing a small weight loss early on in the study they did not show abnormal locomotor activity by days 2 to 5. Neuropathological examination of the brains from CPA-treated rats showed a marked (80-90%) loss in cerebellar granule cells by day 3 and 4 of the study. The co-administration of MK-801 with CPA was able to completely prevent damage to the cerebellum. MK-801 was also able to prevent the CPA-induced loss of NMDA receptors in the granular layer of the cerebellar cortex and concentrations of aspartate and glutamate in cerebellum. Finally there was a complete prevention of the CPA-induced cerebellar edema by MK-801. In conclusion we suggest that CPA is toxic to rat cerebellum because this brain region contains a subtype of NMDA receptor with unique pharmacology and regulation.

ANTI-PHENCYCLINE MONOClonAL FAB FRAGMENTS DRAMATICALLY DECREASE PHENCYCLINE (PCP) NEUROTOXICITY IN SPRAGUE-DAWLEY (SD) RATS. J.L. Valentine, W.D. Westerling and S.M. Olson* Dep't of Pharmacology & Toxicology, Univ. of Ark. for Med. Sci., Little Rock, AR 72205.

High affinity Ki=1.8 nM anti-PCP monoclonal Fab fragments were used to reverse in vivo PCP-induced behavioral toxicity. For these studies, male SD rats (n=4 per group) were administered four treatments in random crossover design. 1) An i.v. dose of 1.0 mg/kg saline vehicle, followed 5 min later by 1.0 ml saline (Saline-saline control). 2) All others received a previously active dose of PCP (1.0 mg/kg) followed 5 min later (as toxicity began to maximize) with 3) saline (PCP-saline, protective control). 3) anti-PCP anti-Fab (PCP-anti-PCP Fab) at 0.3, 1.0 and 3.0 times the 1.0 mg/kg PCP dose, and 4) nonspecific Fab (non-specific Fab) at the same doses as the anti-PCP Fab. To assess PCP and treatment effects, locomotor activity was determined over 2-min intervals for a 60-min period on an open field apparatus. Changes in 2D activity monitoring were monitored for 10 min prior to saline or PCP administration. Saline-saline injections resulted in relatively low background counts (25 counts per 2-min interval). PCP-saline injections increased the baseline levels of locomotor activity, with an initial response of approximately 150 counts 10 min and a duration of 39 ± 7 min. When analyzed as a percentage of the total PCP-saline response, none of the nonspecific human Fab treatment groups had any significant effect on locomotor activity. However, 1.0 M and 3.0 M anti-PCP Fab significantly attenuated locomotor activity to approximately 20-30% of PCP-saline controls and the PCP-specific Fab (ANOVA followed by Newman-Keuls, p<0.05). The duration of PCP-induced effects measured from the time of Fab treatment was reduced from 34 ± 7 min to 13 ± 4 min after the 1.0 M and 3.0 M anti-PCP Fab treatments. These data show that anti-PCP Fab dramatically reverses PCP-induced toxicity. (Supported by NIDA grants DA 07610, DA 05474, and DA 00101).

**18a-GLYCIRQETINIC ACID (GA) BLOCKS KAINIC ACID-INDUCED SEIZURES AND NEUROTOXICITY.** Diane M. Hendriks, Robin L. Sayler, and Kathleen M. Schimpf 1

1Department of Pharmacology, Burke Medical Research Institute, Albany, NY 12208.

**The overall objective of this study was to determine the effects of 18a- and 18b-glycurhetinic acid (GA), potent inhibitors of adenyl and guanylyl stamelatation, on kainic acid excitotoxicity.**

**Neurotoxicity was assessed by NADPH diaphorase activity, which was reduced in kainate (90 pg/ml) or GA (300 pg/ml)-treated brains.** The kainate 90 pg/ml-treated brain with 18a-GA had a lower incidence of seizures (0 vs. 75%) and significantly reduced seizures in the endoplasmic reticulum, amygdala, hippocampus, basal, medial, lateral, and ventral lateral nuclei of the thalamus, dentate gyrus, CA1-CA3 of the hippocampus, midline nuclei of the thalamus, lateral septum, and periventricular hypothalamus compared to rats treated with kainate alone. Preliminary data indicate that the 18a-isomer is not as neuroprotective. In fact 100% of the rats treated with 18a-GA+KA had behavioral seizures and extensive damage in the amygdala, thalamus, and neocortex. Biochemical analyses indicated that neither 18a-GA or kainate inhibited 18a-hydroxysteroid dehydrogenase at the doses used in this study. We conclude 18a- and 18b-GA have differential effects on kainate excitotoxicity when administered directly into the brain.

This work was supported by NIH grants ES07031.

**THE ROLE OF EXCITOTOXIC GLUTAMINE-DERIVED METABOLITES IN ETHYL CHLORIDE-INDUCED HYPERACTIVITY.** By J.N. Clarke, R.S. Bitter, G.E. Logan, and G.W. Ying*, Dept. of Pharmacology and Toxicology, Purdue University, West Lafayette, IN 47907.

Pottinger and co-workers (1991) demonstrated that mice displayed a glutamine (GSH)-dependent, hyperactive syndrome within 20-30 min of exposure to high concentrations of ethyl chloride (Et-Cl) (15,000 ppm). The hyperactivity resembled the wild running seizures observed in mice following i.c.v. glutamate or NMDA. To determine the possibility that excitotoxic GSH metabolites were responsible for Et-Cl-induced hyperactivity, known and potential GSH-derived metabolites of Et-Cl were examined for excitotoxic properties. S-carboxymethylcysteine (CMC) and cysteine (Cys), but not S-ethylcysteine (SEC), injected i.c.v. (3 mg/kg i.p.) did not cause delayed seizures as might be expected if the cysteine conjugate were metabolized to CMC or Cys. S-ethyl-GHS (SEG) injected i.c.v. (1 umol) failed to cause wild running seizures, indicating that it did not share the NMDA agonist properties of GSH (Leslie et al., 1992). Mice depleted of brain GSH using buthionine sulfoximine (3 mg i.e.v.) also failed to display wild running seizures following i.c.v. administration of SEG. Thus, the results obtained with these known and potential (CMC and Cys) metabolites do not support the possibility that the neurotoxic actions of Et-Cl are due to formation of excitotoxic GSH-derived metabolites.

343.19

Several findings suggest that endogenous histamine (HA) might enhance glutamate-NMDA mediated brain excitotoxic mechanisms (Bakkers, Science, 471:118-120, 1993; Vorobjev, et al., Neuro, 11:837-844, 1993) and participate in brain damage (Cohn, et al., Agents Actions, 27:120-122, 1989; Langlais et al., J. Neurosci. Res, 1994, in press). Nevertheless, neurotoxicity produced by HA in normotensive animals has not been directly demonstrated. To test this hypothesis, a detailed, light-microscopic histopathological study was performed. Rats received intraocular HA via chronically implanted guide cannulae. Histamine was injected suprapotential lateral border of the perihypothalamic area. Following predetermined intervals, animals were perfusion-fixed and brain sections were stained with cresyl violet. Three days after injection of 100 pg of HA, large areas within the limbic brain showed marked proliferation of glial cells (mean rostro-caudal extent = 1250 ± 150 mm). Injection of 30 and 300 pg of HA induced proportionately smaller areas of glossis. A dose of 30 pg produced no detectable effects. Control injections of isotonic or hypertonic saline also induced little or no pathological changes. At shorter survival times (24 or 48 hr), 100 pg of HA induced a clear loss of neurons, commensurate with the histopathologic results. These results show that HA can cause lesions in the central nervous system and support the hypothesis that endogenous HA may function as a mediator of neuropathological processes (Supported by DA-03816 and NS-29771).

343.20

**KAINATE NEUROTOXICITY IN VIVO IS GREATLY AMPLIFIED BY IMPAIRED SODIUM PUMP CAPACITY.** A. O. Parks, N. C. de Lavenere, S. Kapoor*, and M. L. Price, Neuroendocrinology Program and Section of Neurology, Yale School of Medicine, New Haven, CT 06510

Many adult neurons exhibit excitotoxicity in which death is caused by excessive transmembrane ion fluxes. Since the sodium pump (Na-pump) directly or indirectly rectifies these disturbances, we hypothesized that reduced or impaired Na-pump capacity will poorly rectify ionic disturbances and amplify the toxic potential of excitatory agents. Results of our prior work indicated that 24% of 11-month-old Syrian hamsters are affected. Following predetermination intervals, animals were perfusion-fixed and brain sections were stained with cresyl violet. Three days after injection of 100 pg of HA, large areas within the limbic brain showed marked proliferation of glial cells (mean rostro-caudal extent = 1250 ± 150 mm). Injection of 30 and 300 pg of HA induced proportionately smaller areas of glossis. A dose of 30 pg produced no detectable effects. Control injections of isotonic or hypertonic saline also induced little or no pathological changes. At shorter survival times (24 or 48 hr), 100 pg of HA induced a clear loss of neurons, commensurate with the histopathologic results. These results show that HA can cause lesions in the central nervous system and support the hypothesis that endogenous HA may function as a mediator of neuropathological processes (Supported by DA-03816 and NS-29771).

Repeated unilateral microinjections of methamphetamine (m-AMPH) produce significant damage to dopaminergic terminals in the rat striatum as shown by decreases in dopamine content and [3H]mazindol-labeled dopamine uptake sites. Previous work from this laboratory has demonstrated that a unilateral infusion of the excitotoxin quinolinic acid (QA) prior to m-AMPH treatment prevents the QA-induced decreases in dopamine content (O'Dell et al., J. Pharm. Exp. Ther., in press). Here, we extend the characterization of the effect of these QA-induced lesions in the rat striatum by utilizing quantitative autoradiography of striatal dopamine uptake sites. One week after administration of m-AMPH and three weeks after receiving unilateral striatal QA, the density of [3H]mazindol-labeled dopamine uptake sites in the QA-infused hemisphere of m-AMPH-treated rats was less than that in the non-infused hemisphere. This finding suggests an important dissociation between measures of dopamine content and dopamine uptake sites in the QA-infused striata of m-AMPH-treated rats. Ongoing studies with autoradiography will allow a better understanding of these measures of dopaminergic terminal integrity may be attributed to QA-induced alterations in dopaminergic metabolism.

427.2

To discriminate between events that are products of lesions elicited by kainic acid (KA) and those that are solely associated with its excitotoxic properties, we have examined the expression of cellular immediate-early genes following KA or pentylenetetrazol (PTZ) treatment. While both chemocarriers elicit lesions, only KA leads to neuronal damage as determined by TUNEL (terminal transferase dUTP nick-end labeling) or immunohistochemical (IHC) procedure. In order to unambiguously follow the expression of one of the prototypic cIEGs, c-fos, transgenic rats were generated that produce a FoxO2 fusion protein by either a transgenic adenovirus (TA) or KA or PTZ, however, its expression was more protracted following KA. In addition, within 6 hours following TA, c-fos expression was observed in the cytoplasms of neurons that were destined to die 1-2 days later, a situation never observed following PTZ. Examination of other basic zipper genes, revealed a unique immediate early response following KA. These features included: the expression of fox1 and fox2 in KA treated animals; protracted and different expression of several cIEGs; and a biphasic elevation of c-fos and junB in which the first peak was correlated with the initial seizure and then the second peak occurring just prior to the onset of death. These changes in cIEG expression were correlated with sustained increases in c-fos-like DNA binding activity in the hippocampal area of KA treated rats. These features of the KA induced response suggest that there are unique AP-1 complexes that could have a critical role in leading to, or counteracting, neuronal death.

427.3

Current excitotoxic models of Huntington's Disease involve exogenous injection of glutamate analogues to induce selective neuronal loss in the striatum. A major limitation of this approach is that the very rapid progression (1-2 days) of striatal neuronal loss which impairs temporal and spatial analysis of the specific patterns of neurodegeneration. We have attempted to develop a more subtle and slow progressing striatal lesion that reflects the anatomical and neurochemical patterns of cell death seen in HD. Our experimental paradigm employs a regime of 15 minutes of striatal glutamate stimulation with the aim of chronically elevating the synaptic concentration of endogenous excitatory amino acids in the striatum. Microdialysis experiments showed significant increases (two-fold) of extracellular glutamate in the striatum which remained elevated at least 2 hr after electrical stimulation. This stimulation paradigm was used for 2 weeks, 1 month, or 2 months to assess the morphological and neurochemical effects of repeatedly elevated striatal glutamate release on specific neuronal systems within the striatum. Astrocyes (labelled by GFAP staining) were increased both in size and number, this effect being evident at 2 weeks but more pronounced at 1 month and 2 months. Immunohistochemistry for the specific GABA neuronal marker GaD gy reveals a significant decrease in staining at the cell body and fiber level. This model may permit future investigations into both the identification of mechanisms involved in the progression of HD and the plastic changes taking place in the striatum during this degenerative process.

427.4

Tumors of the central nervous system (CNS) were investigated with antibodies to quinolinic acid (QUIN), an endogenous neurotoxin produced by cells of the immune system. In advanced F98 glioblastomas and E88 neuroblastomas produced by inoculation in the striatum of rats, quinolinic acid immunoreactive (QUIN-IR) cells were observed almost exclusively within the tumors. The immunoreactive cells were round, rod-shaped or complex in morphology. No consistent differences of size, shape, or number, morphology or distribution of immunoreactive cells between gliomas and neuroblastomas, but more advanced tumors of both type had significantly higher numbers of stained cells. No QUIN-IR cells were observed in the contralateral hemisphere. Gial fibrillary acid protein (GFAP) immunoreactivity was strongly elevated in astrocytes in the compressed tissue surrounding the tumors, and in the contralateral corpus callosum. Immunohistochemistry with the monoclonal antibody ED1, directed against rat monocytes and macrophages, demonstrated that numerous mononuclear phagocytes had infiltrated the tumors. These results indicate that the number of infiltrating mononuclear phagocytes in CNS tumors greatly exceeds the number of QUIN-IR cells, suggesting that if quinolinic acid is produced by monocytes and their derivatives, it is a selectively subpopulation of these cells. The present findings are consistent with a functional role for quinolinic acid in certain infiltrating leukocytes during the immune response to CNS neoplasms.

PRECONDITIONING DOES NOT PROVIDE CEREBROPROTECTION FROM INTRASTRIAL INJECTIONS OF AMPA OR NMDA. J.M. Giddon, A.R. Shag, J. Thorton, T. Park, and J.W. McDonald. Department of Neurology and Neurological Surgery, and Center for the Study of Nervous System Injury, Washington University School of Medicine, St. Louis, MO 63110.

Recent studies have shown it is possible to confer cerebroprotection from hypoxic-ischemic injury in the neonatal rat with a prior exposure to sublethal hypoxia, called preconditioning (Neurosci. Lett. 166:221, 1994). Using this technique, we sought to determine if preconditioning would prove neuroprotective against direct injections of NMDA or AMPA. 10 litters of 6-day-old rat pups were divided into 2 groups: 1) Control (C): treated with 3 ml of saline solution, 2) the rest were placed in normothermic control chambers. 24 hr later, each pup was anesthetized with diethyl ether, and received a stereotaxic microinjection of either AMPA (10 nM) or NMDA (10 nM) into the right striatum 2.5 mm lateral to bregma, and 3.75 mm deep. Pups recovered in an incubator for 45-60 min, then were returned to their mothers. The injury was then assessed by immunohistochemistry on preconditioned animals injected with AMPA (n=28) exhibited a 14.9±1.5% difference in hemispheric weights, which did not differ significantly from injury in non-preconditioned animals (15±2.1% n=23, p>0.8, unpaired t-test). Preconditioning also failed to be protective in NMDA-injected brains (n=27), yielding a hemispheric deficit of 12±1.8% compared to 19±1.2% in non-preconditioned animals (n=25, p>0.6). These results suggest preconditioning cerebroprotection may involve events proximal to glutamate receptor activation rather than subsequent to its release.

TUMOR NECROSIS FACTOR (TNF)-α POTENTIATES GLUTAMATE NEUROTOXICITY IN HUMAN FETAL BRAIN CELL CULTURES. S. Hu* and C.C. Chao. Minneapolis Medical Research Foundation and the University of Minnesota Medical School, Minneapolis, MN 55404.

Cytokines released by activated microglia have been proposed to play a pathogenic role in the brain. Since exposure of neural cells to the excitatory amino acid neurotransmitter glutamate induces injury to these cells, we tested the regulatory effect of cytokines on glutamate receptor-mediated toxicity in human fetal brain cell cultures. After 6 days of incubation, exogenous glutamate (5 mM) induced remarkable neuronal loss (a 165% increase in release of lactate dehydrogenase and a 62% decrease in function of uptake of H8-amino-butyric acid [GABA]). Glutamate neurotoxicity was dose-dependent (ED50 of 200 μM). Treatment of cell cultures with TNF-α (100 ng/ml) but not with a number of other cytokines, potentiated glutamate neurotoxicity (a 52% further decrease in H8-GABA uptake). Exposure of brain cells to TNF-α or to cytokines tested above alone did not significantly affect neuronal cell function. 14 of 16 studies indicated enhancement of glutamate neurotoxicity was markedly blocked (up to 80%) by the glutamate receptor antagonists DL-2-anino-5-phosphonovaleric acid (10 μM) and MK-801 (10 μM), indicating that the potentiating effect of TNF-α is mediated via glutamate receptors. Also, exposure of neuronal cell cultures to TNF-α resulted in a 27% decrease in ascorbic acid synthesis and an 18% decrease in H8-glutamate uptake, suggesting that the effect of TNF-α indirectly involves glutamate metabolism. These findings support the hypothesis that TNF-α may impair neuronal injury by exacerbating excitotoxicity.

staurosporine-induced (MN9D/Neo).

TRIFLUOPERAZINE-INDUCED

Dept. BCL-2

427.8

The protooncogene Bcl-2 inhibits programmed cell death in a variety of cell types. While the mechanism for this function remains unclear, it may involve the attenuation of oxidative stress. Because oxidative stress has been hypothesized to play a role in neurodegenerative disorders such as Parkinson’s disease, we sought to evaluate the potential of Bcl-2 in sparing cells from the dopamine neurotoxins. N-methyl-4-phenylpyridine (MPP\(^+\)) and 6-hydroxydopamine (6-OHDA). To test this in a dopaminergic neural cell line (MN9D), stable transfectants expressing either human Bcl-2 (CHO/Bcl-2) or neomycin (MN9D/Neo) were established. Surprisingly, it was found that overexpression of Bcl-2 led to robust neurite formation. Increases in primary neurite length and total neuritic extent were highly significant in MN9D/Bcl-2 versus MN9D/Neo. Bcl-2-expressing cells also reduced cell death due to MPP\(^+\) treatment. In contrast, Bcl-2 overexpression did not block the cytotoxic effects of 6-OHDA. However, inclusion of antioxidant agents or an iron chelator did substantially attenuate cell death in the 6-OHDA model. Because MPP\(^+\) is thought to inhibit the respiratory chain at Complex I and thus mitochondrial metabolism, ceramide was added to inhibit the activity of NADH dehydrogenase at this level. Rotenone-mediated cell death was significantly delayed in MN9D/Bcl-2. These data suggest Bcl-2 may protect cells from altered mitochondrial electron transfer processes. Thus, Bcl-2 may have dual roles in neurogenesis and in repression of cell death.

A COMPARISON AND APPLICATION OF BICISTRONIC HERPES SIMPLEX VIRUS VECTORS. T.J. Metz*, D.Y. Ho, R. Dash, M.S. Lawrence, R.M. Sapolsky. Department of Biological Sciences, Stanford, Harvard University, CA and Ophthalmology, MEED, Dept. of Neurology, Children’s Hospital, Boston, MA, 02115.

Monocistronic herpes simplex virus vectors offer an effective means of delivering genes to post-mitotic neurons. They do not, however, allow cells to respond to the dynamic events of neuronal systems. We sought to coexpress both a gene of interest and the lacZ marker gene in the same cell by employing internal ribosomal entry site, in the second approach, the two genes placed under the control of the opposite reading HSV\(^+\) and HSV\(^-\) promoters. Both bicistronic systems show overexpression of the two genes as assessed by d\(_{3}^{2}\)H IBMV immunofluorescence, indicating that regeneration detection at in not occur and that such vectors can be reliably used to target expressed cells. We have employed such vectors to investigate the neuroprotective effects of various genes products: a) Cultured hippocampal neurons receiving a bicistronic vector bearing the bcl-2 gene show enhanced survivorship when challenged by an oxidative insult as compared to those receiving a control vector. b) Delivery of a bicistronic vector bearing the glucose transporter gene protects hippocampal neurons against glutamate excitotoxicity in vitro and kainate-induced seizure in vivo. c) Delivery of a vector expressing the gene for eublinid D2RN causes a significant diminution and delay in excitotoxin-induced mobilization of free cytosolic calcium in cultured hippocampal neurons.

427.11

EXACERBATION OF GP120 EFFECTS ON RAT PRIMARY NEURAL CULTURES BY CORTICOSTERONE. S.M. Broude, J.D. Milne, R.M. Sapolsky, Dept. of Biological Sciences, Stanford University, Stanford, CA. 94305.

The section of the protein coat of the HIV virus known as gp120 may be the causal agent in AIDS dementia. It has been shown to cause neuronal death and increase in cytosolic calcium levels in neuronal cultures. The injury to neurons is thought to be mediated by release of a toxin from microglia or glia that acts through the excitatory amino acid pathway. Corticosterone (CORT), the rat specific glucocorticoid (GC) secreted from the adrenal, is involved in the mediation of the stressful response. CORT increases the effects of excitotoxins such as kainic acid, glutamate, and quinolinic acid. CORT also augments the mobilization of calcium in cytosol after an excitotoxic insult. We have investigated whether CORT exacerbates the effects of gp120 neutralizing antibodies or gp120 in vitro. An assay for glutamatic acid with Mg\(^{2+}\) staining, 200 \(\mu\)g/ml gp120 killed about 20% of hippocampal neurons. The addition of kai cort resulted in a further significant decrease in survival of approximately 14%. Using standard imaging techniques and the \(\mu\) for 2, we were able to confirm reports that gp120 can cause, in in vivo cortical neurons, a rise in cytosolic calcium. The time required to reach \(\tau\) was 300 bases (500). Twenty \(\mu\) for the peak, and the magnitude of the peak and the area under the curve. Some hippocampal cells, the presence of gp120 peaked at 600% of baseline after 900 sec exposure. Pretreatment with gp120 did not affect the peak or onset, but did not significantly impair recovery from the peak. It would appear that the stress hormone CORT may exacerbate the effects of gp120 on neuronal tissue. This could be relevant to the use ofinas to control the Neurotoxicity in AIDS.

INFLUENCE OF TH2-DOMINATED CNS IMMUNITY ON TUMOR GROWTH IN THE BRAIN. L. B. Gordon, H. F. Cerr, P. M. Kraep* Dept. of Physiology, Brown University, Providence, RI.

We have developed a model to study CNS immune privilege in Balb/c mice to nanotoma cell line P511. When introduced into the putamen of syngeneic DBA/2 or mismatched, incompatible Balb/c mice, blood-brain barrier disruption, 10^5 P511 cells form a progressively growing tumor, exhibiting angiogenesis, central necrosis, and brain tissue infiltration. Average time to death of mice was 25±7.5 days (p<0.0001). In contrast, 10^4 P511 cells subcutaneously (SC) results in tumor formation in syngeneic DBA/2 and 14±7.1 days in Balb/c (p<0.05). We suspect that an ineffective anti-tumor response is prolonging survival of Balb/c mice. In contrast, injection of 2 x 10^5 P511 cells subcutaneously (SC) results in tumor formation in syngeneic DBA/2 and 14±7.1 days in Balb/c. Thus, we have established a model to study immune privilege to MHC compatible, minor histocompatible tumor cells in the brain, a relevant brain tumor situation. We will use this model to examine the following hypothesis: tumor cells in the brain are detected by the immune system, but the response is directed along the Th2/humoral immunity pathway, whereas responses to tumors in a non-CNS setting favor a Th1/cellular immunity pathway.

In support, immunohistochemistry on brain sections showed scattered CD3+, CD4+, and CD8+ T cells present in and around Balb/c, but absent from DBA/2 tumors. A more dense distribution of F4/80+ and of IgG cells are present in brain tumors and surrounding neural tissue exclusively in the tumor-laden hemisphere of Balb/c and DBA/2 mice 14 dpi. Anti-P511 serum antibody responses have been detected in Balb/c mice with brain tumors and flank tumors 14 dpi. Precursor CTL activity, but no active CTL are detected in spleens of brain-infused or SC-infected Balb/c mice 14 dpi. Tumor-infiltrating lymphocytes (TIL) from SC tumors display active CTL, but not any staining in brain tumors, and anticipate a lack of CTL activity due to an immunosuppressive environment towards TH1 responses.

428.2

ORIGIN OF PC12 PHEOCHROMOCYTOMA CELLS: EVIDENCE THAT LOSS OF THE MYC DIMERIZATION PARTNER MAX WAS A TRANSFORMING EVENT. R. Hopewell and E. Grossbard, Howard Hughes Medical Institute, Kaplan Cancer Center and Department of Biochemistry, New York University Medical Center, New York NY 10016.

Max formation of heterodimers with the nuclear oncogene Myc and the differentiation-associated proteins Mad and Mxi1 enables these factors to bind DNA and control genes implicated in cell proliferation and differentiation. We show that the PC12 tumor cell line, derived from a rat pheochromocytoma, fails to express Max protein, due to aberrant splicing of max mRNA. RNAse protection and Northern analysis showed that only exon 3a expression. N-terminal sequences of Max up to the loop region of the helix-loop-helix dimerization motif are expressed, whereas max exons 3 of this are not expressed. We have cloned a cDNA from PC12 by hybridization to a max probe. The cDNA encodes a truncated Max protein which we call Maxp<sub>3</sub> containing a novel C-terminal sequence. Maxp<sub>3</sub> is incapable of homo- or heterodimerization in vitro, indicating that the protein cannot functionally substitute for wild-type Max. 

Reintroduction of wild-type Max into PC12 cells is strongly growth inhibitory, suggesting that mutational loss of Max expression may have provided a growth advantage for these cells, contributing to the transformed phenotype, and that Max may therefore be a tumor suppressor in a restricted class of tumors. We have reintroduced Max into PC12 cells under the inducible metallothionein promoter. Experiments examining the effect of Myc and Max expression in these cells will be presented.

428.3

THE CLONING OF MULTIPLE PROTEIN TYROSINE KINASE GENES EXPRESSED IN HUMAN PEDIATRIC BRAIN TUMORS AND DEVELOPING NEURONS. Edward L. Ziff, Mack Hickey, Howard L. Wiener, and Maria McCarthy. Howard Hughes Medical Institute, Department of Biochemistry, New York University Medical Center, New York, NY. 10016

Emerging evidence indicates that growth factor receptor tyrosine kinases (RTKs) play a central role in regulating normal cell growth and differentiation in the central nervous system (CNS). Aberrant expression of members of this family of proteins has been associated with tumorigenesis. However, little is known about the role of RTKs in early neural development or in human CNS tumors which arise from primitive neural precursors. Using degenerate oligonucleotide primers complementary to conserved sequences within the tyrosine kinase catalytic domain, we have cloned three distinct tyrosine kinases from two surgically resected human malignant pediatric brain tumors, a malignant ependymoma and a glioblastoma multiforme. These two tumor types are presumed to derive from embryonic stem cells of the CNS. We hypothesized that the molecular phenotype, including expression, of specific tumor cells could be informative of early glial or neuronal precursors. Expression of nine of these kinase genes in human brain tumors has not been reported previously. 

Kinase clones analyzed thus far are identical or bear significant homology to: MET, FER, TIE, HEK2, FLK1, FLT4, PDGFR-F, IGF-R, and EGF-F. Cytoplasmic PTks, including TIE2, SLK, the human JAK2 homologue and a novel protein kinase C isoenzyme have also been identified. In order to compare the pattern of RTK expression in tumors of the developing CNS to that of normal brain, we have applied this technique to the isolated brains of E17 rats. From these studies several kinases have been identified, including rat homologues of the FAK and JAK1 kinases.

428.4

The histogenesis of the medulloblastoma has been controversial since the original description of the tumor in 1925 by Bailey and Cushing, recent debates have focused towards cellular lines gial and neuronal. We studied retrospectively the histological and immunocytochemical features with stained routinely for H/E, Kluser-Barrera, Gomori's reticulin method, and with ABC technique. Of 20 cases of classical medulloblastoma with a mean of 14.2 years and 5 cases of desmoplastic medulloblastoma with a mean of 25.8 years, using a panel of antibodies neuronal and neuroglial (GFAP, Neuron-Specific Enolase, Neurolinin 160 KD, S-100 and Synapsin) in tissues fixed in formalin and embedded paraffin. In the classical group had a high population of cells were observed Homer-Wright rosettes, degeneration, necrosis and mitosis were observed and showed glial and neuroglial differentiation. In the desmoplastic variety bands of connective tissue separating neoplastic cells into rows and surrounding reticulin-free islands of tumor cells, cytoplasmic processes and presence of perivascular pseudorosettes that showed ependymal differentiation were observed.

In the immunohistochical study there was a reaction observed to all antibodies in the classical group, and there was a reaction to all them except S-100 in the desmoplastic group.

This study shows that medulloblastoma is a neuroepithelial neoplasm that can differentiate into ependymal, neuronal and neurtial lines.

EFFECT OF CELL ADHESION MOLECULES (CAMs) AND LAMININ ON THE DIFFERENTIATION OF NEURO-2A CELLS. W.W. Chang, Laboratory of Molecular Pathology, Department of Pathology, Veterans General Hospital-Taipei, Taipei 112, Taiwan, Republic of China

Development of the polarity, extension of processes, and further formation of axon and dendrites are crucial steps in the differentiation of a neuron. The effects of laminin and CAMs on neurite outgrowth have been demonstrated in various normal neurons. The effects of laminin and antibodies recognizing H-CAM (129F, against polysacitic acid) and L1 (gifts from Dr. C. F. Terstegen) in the differentiation of Neuro-2A cell line, Neuro-2A, were tested. RT7, antibody against phosphorylated neurofilament, was used to label the differentiation of axons. Many multipolar cells stained positively in the cytoplasm was identified in the 80-hr-old cultures. Some cells extended short RT7<sup>+</sup> neurites, most were less than 5 times the diameter of cell body. Only 5-10% of cell diameter was RT7<sup>+</sup> neurites of total length more than 5 times the cell diameter. The cell diameter was observed as numerous to (up to 1%) cells extended fine and long RT7<sup>+</sup> neurites. No significant effect is noted for the bound form L1 antibody. In contrast, both the free and bound forms of L1F8 antibody do not produce significant effect, even though the expression of N-CAM is confirmed. Evidently, laminin and L1 antibody, similar to the effects on some neurons in primary culture, also promote the neurite differentiation of Neuro-2A cells. (Supported by NSC-83-0412-B-079-055, TAIWAN, ROC)

Increases in Cyclic AMP Induce Morphologic Differentiation of MCD-1 Cells in Vitro. K. Moore, O. Dillon-Carter, M. Politrek, M. Cheadle, and W. Freed*. NIHNI Neuroscience Center at St. Elizabeths, 2700 Martin Luther King Ave, Washington, D.C. 20032, and 1Medical College of Georgia, Augusta, GA.

Medulloblastomas are undifferentiated CNS tumors, cells from which may under undergo morphologic differentiation on exposure to exogenous agents such as retinoic acid and dibutylryl cAMP (dBcAMP). The potential of cultured medulloblastoma cells to differentiate following the addition of NGF alone or in combination with agents which influence the cAMP second messenger system was studied. MCD-1 cells were exposed to NGF, dBcAMP, IIBM, forskolin, retinoic acid, arginine-L-carnitine (ALCAR) or mixtures of NGF-IIBM, NGF-IIBM+dBcAMP, and NGF+Forskolin+dBcAMP, and process outgrowth was measured after 48 hr. There were statistically significant increases in process outgrowth in cells treated with IIBM, dBcAMP, as well as NGF+IIBM, NGF+dBcAMP, and NGF+Forskolin+dBcAMP. Cells treated with forskolin, NGF, ALCAR or retinoic acid did not show changes in growth. NGF alone had little effect on process outgrowth and did not augment the effects of IIBM or dBcAMP. Immunohistochically the cells were positive for neuron-specific enolase (NSE), synaptophysin, and vitamin D receptor negative for GFAP. There were no changes in expression of NSE or synaptophysin following addition of differentiating agents. Thus morphologic differentiation of MCD-1 cells was induced by agents that increase cellular cAMP.
Biochemical and immunocytochemical characterization of the human medulloblastoma cell line MCD-1. D. Dillon-Carter*, K. Moore, M. Polakiew, M. Chedd1, and W.J. Freed, NIMH Neurosciences Center at St. Elizabeths, Washington, D.C. 20032, and (1) Medical College of Georgia, Augusta, GA.

The MCD-1 medulloblastoma cell line was isolated from a human cerebellar tumor. MCD-1 cells express several cytoskeletal markers, including vimentin, alpha- and beta-tubulin, and microtubule-associated protein 2. The cells are also positive for Thy-1 and fibronectin, but negative for N-CAM and L1 antigen. The cells are negative for markers of glia and differentiated neurons, including GaLC, MBP, GFAP, neurofilaments, synaptin, TH, GAD, DBH, and PHM1. The cells express glutamate, choline, and serotonin uptake, but are negative for uptake of GABA and dopamine. Glutamate uptake is sodium-dependent and blocked at 0°C and by DL-threo-B-hydroxyaspartate. Serotonin uptake is inhibited by domperidone, and choline uptake by hemicholinium-3. In addition, MCD-1 cells secrete the tumor-growth regulatory molecule TGFβ2, and grow in serum-free medium. The presence of serotonin, glutamate, and choline uptake suggests that medulloblastoma cells may use these substances as biochemical mediators. The MCD-1 cell line may be useful for studies of medulloblastoma growth and differentiation.

SYMPOSIUM:

TOWARDS A NEUROBIOLOGY OF VISUAL CONSCIOUSNESS. C. Koch, Caltech (Chairperson); H. Kostyn, Harvard University; P. Stergiou, Ludwig-Maximillian University, Munich, Germany; R. Desimone, Lab. Neuropsychology, NIMH; F. Crick, Salk Institute.

The aim of the symposium is to demonstrate that the neurological and neurophysiological substrate underlying conscious visual perception in humans can be approached in a rigorous experimental and reductionist manner. We have the tools in hand to explore this most central of our subjective "states" and its disruption in pathology in terms of particular types of (bio)electrical activity in particular neurons, areas or pathways in the brain.

Kostyn will discuss how the phenomenological qualities of visual mental imagery relate to activity in specific brain regions in human subjects, using PET and functional MRI studies. Stergiou will consider "blindsight," in which patients have a loss of conscious visual perception in the presence of demonstrable residual functions. A similar phenomenon exists in monkeys with striate cortical ablations. Desimone will discuss single-unit electrophysiological studies carried out in cortex of the awake and behaving monkey, suggesting ways in which prefrontal mechanisms prepare the visual system for expected stimuli, possibly providing the substrate for imagery. Crick will outline a general framework within which the problem of the Neural Correlate of Consciousness (NCC) can be approached using theoretical, neuroanatomical and electrophysiological studies.

SYMPOSIUM:

DEVELOPMENTAL CONTROL OF ELECTRICAL EXCITABILITY. A.B. Ribera, University of Colorado Health Sciences Center (Chairperson); M.E. Ratliff, Beckman Research Institute, City of Hope; J. Moody, University of Washington; C. Mandel, SUNY Stony Brook.

Although it is firmly established that electrical excitability is developmentally regulated, its role in the emerging nervous system is less well understood. The functions of electrical excitability in developing neurons and associated regulatory mechanisms will be discussed. Ratliff will present data that indicate that environmental influences, provided by cells such as glia, affect development of ion channels and membrane currents. Moody will present studies that test the role of electrical activity in development by embryonic microinjection of ion channels. Ribera's work examines the specific functions of identified potassium channel genes in embryonic neurons. Mandel will discuss the genetic elements that are involved in activation of expression of a sodium channel gene during differentiation of peripheral neurons.

SECOND MESSENGERS II

MODULATION OF PLASMA MEMBRANE CALCIUM ATPASE (PMCA) ALTERS CALCIUM EFFLUX IN CULTURED SENSORY NEURONS. J. Wortsch and S.A. Thayer, Department of Pharmacology, University of Minnesota Medical School, Minneapolis, MN 55455.

Intracellular calcium concentration ([Ca²⁺]ᵢ) and whole cell Ca²⁺ current (Iₑ) were measured simultaneously in single rat dorsal root ganglion (DRG) neurons grown in primary culture. Following a modest rise in [Ca²⁺]ᵢ (100-600 nM), recovery to basal [Ca²⁺]ᵢ was fit well by a single exponential. The decay time constant (τ) was similar for action potential-evoked (no cell dialysis) and depolarization-induced (whole-cell configuration) Ca²⁺ loads (5.85 ± 0.61 s vs. 5.94 ± 0.56 s, respectively). Omission of ATP from the patch pipette solutions results in calcium-induced calcium release (CICR) through inositol 1,4,5-trisphosphate (IP₃). Inclusion of 1 mM calmodulin in the pipette caused a slight decrease in τ compared to control (4.52 ± 0.51 s vs. 5.94 ± 0.56 s, respectively). Omission of ATP from the patch pipette solutions resulted in a decrease in baseline calcium levels. The addition of 10 µM 2-aminoethane sulfonic acid (2-ASA) blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute. The addition of 10 mM 2-ASA blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute. The addition of 10 mM 2-ASA blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute. The addition of 10 mM 2-ASA blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute. The addition of 10 mM 2-ASA blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute. The addition of 10 mM 2-ASA blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute. The addition of 10 mM 2-ASA blocked the CICR current for 5 s, and resulted in a calcium transient that was sustained up to 1 minute.
CHIMERIC RECOMBINANT AQUEOUS: NEW TOOLS FOR THE STUDY OF CA2+
CULTOSTASES IN NEURONS AND MYOCYTIES. R. Rigual, M. Bias C.
Bastianutto, L. Fast, R. Gravina, M. Montone, P. Gambardella*
and T. Pozzan*
Division of Biomedical Sciences, University of Padova, 35121 Padova Italy;
Division of Neuropharmacology, CWRU, 2065 Adelbert Rd, Cleveland, OH 44106.

In recent years, much interest has been devoted to the study of cytosolic
CA2+ homeostasis, not only because changes of CA2+ concentration in
this phenomena, but also because, until recently, the cytosol was the only cell
compartment in which this ion could be measured quantitatively in intact
cells. We here describe a new methodology, recently developed in our
laboratory, for the measurement of CA2+ concentration within specific
subcellular structures and its application to the study of the role of CA2+
homeostasis in cultured neurons and myocytes. The methodology is based on
the determination of the Ca2+-sensitive photoprotein aequorin, modified in
the blue whale organellar specific Ca2+ sensors, and on the
recombinant expression of the chimeric photoprotein in cultured cells. Three
chimeras are now available in the laboratory, which allow the monitoring of
CA2+ concentrations in the mitochondria, in the endoplasmic reticulum of living
cells (CA2+ jem), and in endoplasmic reticulum of living cells (CA2+ jem).
Cell stimulation coupled to increases in cytosolic CA2+ concentration invariably results in increases of [CA2+] jem and [CA2+] jem, but the kinetics and amplitudes of these changes are very different. In neurons, large changes of [CA2+] jem are evoked by the activation of plasma membrane channels, while in skeletal muscle myotubes changes in [CA2+] jem appear closely linked to CA2+ release from sarcoplasmic reticulum. [CA2+] jem on the other hand, seems to closely follow cytosolic CA2+
both in kinetics and amplitude. Finally, a large drop in [CA2+] jem occurs upon depletion of intracellular CA2+ stores, though the kinetics of these decreases are complex.

INTERLEUKIN 1 ENHANCES RECEPTOR-DEPENDENT AND INDEPENDENT INDUCED RELEASE OF ARACHIDONIC ACID FROM MOUSE STOMACH ASTROCYTES. N. Stella, G. De

The present study was undertaken to determine the interference of this cytokine in receptor-dependent and independent induced release of arachidonic acid from cultured striatal astrocytes. As previously observed, both 100 µM of LPS and the combination of 0.1 µM PMA and 2 µM ionomycin stimulated the release of 3H-AA from striatal astrocytes (136 ± 7% and 54 ± 3% above basal level, respectively). (N. Stella et al. 1994). In neurons, 14568:5%.

When 100 µM of LPS was added simultaneously with ATP, the cellular inhibitor of the release of 3H-AA was not affected (167 ± 8%). However, when astrocytes were pretreated for 24 hours with IL-1ß, both the ATP and PMA-induced release of 3H-AA were abolished (301 ± 20% and 295 ± %, respectively). The data suggest that IL-1ß treatment has a potentiating effect on the receptor-dependent and independent induced release of AA by enhancing specifically of PMA. Combined, the results support the role of AA in the regulation of glutamate uptake into astrocytes, IL-1ß could be involved in the glutamate-evoked neurotransmitter release in brain inflammatory processes.

ACTIVATION OF PHOSPHOINOSITIDES HYDROLYSIS BY ENDOTHELIN-1, ENDOTHELIN-3 AND BIG ENDOTHELIN IN THE RAT SPINAL CORD. T. Touloukeni, J. de Champlain and R. Courjon. Department of Physiology, Université de Montréal, Montréal, Québec, Canada H3C 3J7.

The activation of endothelins receptors results in the activation of phosphoinositides hydrolysis in peripheral and central tissues of the rat. However, this has not yet been shown in the rat spinal cord where endothelins receptors have been shown to be present. The present study was undertaken to examine whether the endothelin receptors induced phosphoinositides hydrolysis in spinal cord. We found that the endothelin-1 (ET-1), endothelin-3 (ET-3), big endothelin (big ET-1) with or without presence of selective ET2 receptor agonists (ET-1) in the spinal cord. The entire spinal cord of male Wistar rat, was cross-chopped at 350 µm. Slices (50 µm) were incubated with 0.13 µM of myo-[2H]-inositol (specific activity 32.5 Ci/mmol) and 17 nm L7 for 60 min. A final volume of 90 µl of Krebs buffer and stimulated with the proper agonist for an additional 60 min. The radioactivity in the total intracellular fraction (EP, I2 and I3) was determined as described by Feingold et al. (Biochem., J., 1982, 212, 457-462) and blank value (before stimulation) was subtracted from all values. ET-1 (1 nm - 10 µM), induced dose-dependent increases of labelled phosphatidyl inositol. At equimolar doses (1 µM) the rank potency of endothelin-3, ET-2 and ET-3 in slices. I2Q-103 (100 µM) reduced by about 30% the response to ET-1 and ET-3. These results suggest that activation of endothelin receptors in the spinal cord involved inositol lipid hydrolysis which is partly mediated by an ET3 receptor. Furthermore, the stimulation obtained with big ET-1 suggests the presence of an endothelin-converting enzyme in the spinal cord. [Supported by the MRC of Canada].

CYTOSOLIC PHOSPHOLIPASE A2 (cPLA2) mRNA DISTRIBUTION AND TRANSCRIPTION STUDY IN THE RAT SPINAL CORD: ROLE IN NEUROTRANSMISSION. L.L. Lautens. W.S. Young*, J.A. Sharp1 D.S. White1, Z.G. Chu2 and C.C. Felder. Lab. of Cell Biology, NIH, Bethesda, MD 20892 and 1The Lilly Research Laboratories, Lilly Corporate, Indianapolis, IN 46209.

The identification of an 85 kD cPLA2 raised hopes that the effector enzyme mediating receptor-evoked release of arachidonic acid (AA) had been isolated. cPLA2 mRNA within dorsal root ganglia and brain by in situ hybridization: cPLA2 mRNA was found in white matter of cerebrum, brain stem and cerebellar cortex. The present study was undertaken to examine the expression of cPLA2 mRNA in neurons cultured from specific brain regions. cPLA2 mRNA expression was also detected in peripheral tissue of newborn mouse. The data suggest that the cPLA2 gene product can be detected throughout the developing spinal cord. [Supported by NIH grant AG06853 and NINDS grant NS 209143].

Homogenates of Aplysia nervous tissue contain an 8-lipophosphoglycerol (8-L). Although this pathway has not been previously described in nervous tissue, products of the 12-LO pathway have been shown to act as neuromodulators in Aplysia. We have identified neurons selective for 8-L, which convert arachidonic acid to 8(R)-prostaglandinH2 (8-RPGEH) from which 8-ketoepoxyprofain (8-KETE) is enzymatically derived. In ganglia prelabeled with [3H]arachidonic acid, this pathway is activated in a dose-dependent manner by the application of u00 (20 µM) 8-ACh. 8-KETE is as effective in normal seawater as it is in a high Mg2+ low Ca2+ solution. Thus, the effect of direct and does not require activation of other nerves: Of 10 neurotransmitters tested, ACh was the only one that activated this pathway. This is the first demonstration of the 12-LO pathway in a nervous tissue. Cholinergic agonists activate the 8-L pathway, but several ACh antagonists including, transazepine, benzoxazepine, and benzimidazoles do not. Activation of the 8-L pathway is blocked by a bungarotoxin, which selectively blocks the ACh-gated chloride current in Aplysia (Roberts et al., Brain Res., 897, 1976), raising the possibility that products of the 8-L pathway may modulate neural functions through the activation of the cholinergic chloride channel. In support of this idea, suberyldicholine, a selective agonist, activates the 8-L pathway in Aplysia nervous tissue. Thus, 8- and 12-LO are selectively and independently activated by distinct neurotransmitters in Aplysia. Preliminary experiments suggest that the 8- and 12-LO pathways interact to generate lipid messengers that cannot be produced by either pathway alone.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
A PAF ANTAGONIST OR DEXAMETHASONE INHIBITS THE SEIZURE-TRIGGERED SUSTAINED UPREGULATION OF THE INDIQUE PROSTAGLANDIN SYNTHASE IN THE HIPPOCAMPUS. V. L. Marcheselli and N. G. Bazan. Louisiana State University Medical Center, LSU Neuroscience Center, New Orleans, LA 70119.

Electroconvulsive shock (ECS) activates phospholipase A2, which leads to accumulation of free arachidonic acid and platelet-activating factor (PAF). PAF is a messenger in the ECS induced transcriptional activation of cyclo-oxygenase and decreases COX-2 in hippocampal (Neuroscience Res. 37:54-61, 1994). Here we report that ECS effects sustained upregulation of the inducible prostaglandin synthase (PGS-2, or TIS-10) expression in rat hippocampus. The increase of PGS-2 mRNA, peaking at two hours after ECS, has elevated levels detected, for 24 hours. The Zif-268 mRNA in hippocampus peak at 1 hour after ECS, but return to normal after two hours. Pretreatment with dexamethasone (6.7 mg/kg body weight) produces a 34% inhibition of ECS induced PGS-2 mRNA expression. The PAF antagonist BN-50730 when injected intracerebroventricularly (icv) 15 min before ECS (50 mg/kg) produces a 70% inhibition of PGS-2 mRNA expression. It is concluded that in the hippocampus PAF is a mediator of inducible prostaglandin synthase expression and may in turn modulate synaptic function and seizure activity through prostaglandin synthesis. Supported by NIH NINDS NS23002.

EXTRASTRIATE VISUAL CORTEX: INFERIOR TEMPORAL AREAS

MULTIPLE SUBDIVISIONS OF THE ANTERIOR INFEROTEMPORAL CORTEX OF MACAQUE MONKEYS. E. M. Pandya, R. D. Zeki, and R. Badcock. Department of Neurobiology and Anatomy, Univ. of Texas Med. School, Houston, TX 77030.

Anterior intertemporal cortex (AIT) is a large portion of the temporal lobe that exists approximately 10.15 mm from posterior to the anterior temporal polar sulcus (AMTS) to the temporal pole. Previous architectures (Selver and Pandya, '78) and conncctional studies (McClendon and Felixman, '90) have suggested that this region is characterized by several distinct cortical areas. To investigate further the organization of AIT, we examined the distribution and lamination patterns of labeled cells and terminals following 12 injections of neuronal tracers into area AIT. Immunohistochemical and light microscopic analyses were performed on sections through AIT at 50 µm intervals. The results demonstrated that AIT is divided into several distinct areas designated AITpv, AITav, AITavpv, AITpv, and AIT. In several cases in AITpv, AITavpv, and AIT, visual stimulus regions were found bilaterally in areas AITpv, AITavpv, and AITpv. These data indicate that AIT consists of 3 distinct areas and each contains specific visual cortical areas. Supported by NEI EY-03732, the Sloan Foundation, and the Whitall Foundation.

ELEfMENTS OF FORM PROCESSING FROM MOTION IN MONKEY PRESTRIATE CORTEX: E. Petersen* and R. Baumann. Department of Neurology, University Hospital, CH-8091 Zurich, Switzerland.

We have studied early stages of form processing from motion in the visual cortex of the alert rhesus monkey. During periods of visual fixation we recorded the responses of single neurons to rows of dots (size 12 x 12 min of arc) in a surrounding texture. The motion was defined as a 12-36 min arc moving relative to a background of dots of smaller size, which either was kept stationary or moved in antiphase. These stimuli produced the perception of moving bars-like objects, segregated from a background of dots of small size, which either was kept stationary or moved in antiphase. The color, size, and orientation of the stimulus were varied, but the orientation of the motion was fixed. The results showed that the neuronal responses were correlated with the orientation of the motion and the size of the stimulus, as well as the contrast of the stimulus.
SENSORY INTERACTIONS AND EFFECTS OF SELECTIVE SPATIAL ATTENTION IN MACAQUE AREA V2. L. Chelazzi, L. Desimone, J. Luck, S. Remington. Lab. of Neuropsych., NIH, Bethesda, MD, and Dept. of Neurosciences, UCSD, La Jolla, CA.

It was previously found that when two stimuli fall within a cell's receptive field, attention directed to one of them seems to filter out the influence of the second. To test this idea, we have recorded the responses of V2 neurons in a macaque monkey to an optimal, or preferred, stimulus in the presence of a second, nonpreferred stimulus. We measured changes in response caused both by the sensory interaction between the two stimuli in a passively viewing condition as well as by the effects of attention directed to the first or second stimulus.

During passive viewing, a nonpreferred stimulus in the receptive field typically caused a partial suppression of response to the preferred stimulus. The degree of effects of a nonpreferred stimulus diminished with distance from the receptive field but were still present in some cases beyond the field border. Attention directed to the preferred stimulus appeared, on average, to diminish the suppressive effects of the nonpreferred stimulus whereas attention directed to the nonpreferred stimulus seemed to magnify its suppressive effects. The time course of both the attentional and sensory effects on the response was similar. As in earlier studies (Neurosc. Abs. 19:9:6), an increase in baseline activity typically occurred when attention was directed to a location within the receptive field.

We hypothesize that the baseline shift is due to a spatially selective attentional signal which increases the average firing rate of those cells whose receptive fields are at the attended location. We further suggest that the sensory interactions, which could serve as preparatory visual processes such as separation of figure from ground, may also be the mechanism by which the attentional signal biases sensory processing in favor of attended stimuli.

REPRESENTATION OF STIMULUS POSITION RELATIVE TO THE EXTENDED OBJECT REPRESENTATION IN MACAQUE AREA V4. C.E. Connor*, J.L. Gallant and D.C. Van Essen. Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

We have previously shown that changes in the position of an attended object affect the spatial response profile and overall response level of cells in macaque visual area V4 (Connor et al., Soc. Neurosci. Abstr. 19: 974 (1993)). In this study, we have investigated whether a cell responds differentially to an oriented bar stimulus depending on which side of the bar the attended object appears on (a laterality preference). We have explored this phenomenon further by varying the location of the attended object across multiple positions in 1 and 2 dimensions. The attended object was a ring, flashed briefly near the receptive field as part of a serial comparison task. The probe stimulus was a behaviorally irrelevant bar of optimal orientation, color, and size flashed at various locations inside the receptive field. A single bar stimulus appeared 200 msec following each stimulus bout. In one paradigm, ring position was varied across 7 locations along an axis perpendicular to the optimal bar orientation. Responses to the bar were often tuned for distance relative to the attended ring, as well as showing a laterality preference. In a second paradigm, the position of the ring was varied across multiple locations in 2 dimensions, all equidistant from the receptive field. Bar response strength often depended on 2-dimensional position relative to the attended ring. These findings suggest that area V4 processes information about stimulus position relative to nearby attended objects.

In humans, the visibility of a briefly presented shape is impaired when it is followed by another stimulus (backward masking). We observed the same phenomenon in two rhesus monkeys: discrimination performance for geometrical shapes presented in a masking sequence (ET) was strongly impaired when the shape was immediately followed by a patterned mask. To determine the neuronal correlate of this phenomenon, we measured the responses of inferior temporal neurons in the same 2 monkeys, performing a fixation task, to these briefly presented stimuli which were either followed by a mask (M) or not (NM). Although the response magnitude strongly declined with decreasing ET (tested range: 20-100 msec), shape selectivity remained present even at 20 msec ET (T > 5 in the NM condition). The surprising finding was that a majority of the units showed significant shape selectivity in the 20 msec ET condition too. When using the initial 60 msec of the response, the difference between the response to the preferred and non-preferred shape was on average 0.6 and 1.0 spikes in M and NM conditions, respectively. This small but significant difference between the selectivity in M and NM conditions, increased notably when considering the first 200 msec of the response: average response differences of 0.6 and 2.6 spikes in M and NM conditions, respectively. Thus, longer temporal integrations increased the marked increase in discrimination capacity in the NM condition, but not when the briefly presented shape is followed by another stimulus. This suggests that the behaviorally observed backward masking is the result of temporal integration of the neuronal responses. (Supported by IUP-22 & FGWO)

RESPONSES OF V4 NEURONS DURING VISUAL SEARCH. L. Chelazzi and K. Desimone. Lab. of Neuropsych., NIH, Bethesda, MD, 20827 and Dept. of Neural. and Vis. Sci., Univ. of Verona, Verona, Italy.

In a previous study of the mechanisms underlying visual search (Chelazzi et al., Nature 1993, 365:345-347) we reported that cells in inferotemporal (IT) cortex of the macaque may participate in storing a representation of the searched-for (target) stimulus and in selecting the target from distractors. In the present study we investigated whether area V4 also contributes to such processes. A total of 140 neurons with extraretinal mechanisms (EPMs) were recorded in one macaque monkey. Each trial began with a brief presentation of a cue stimulus at fixation. Following a delay of 1.5, during which fixation had to be maintained, a pair of target stimuli was presented in the periphery, at random locations, and the animal was required to select the EPM stimulus that matched the earlier cue, ignoring the other (distractor) stimulus. Contrary to what was previously found in IT, V4 neurons did not display cue-selective sustained activation during the delay interval. However, similar to IT cortex, V4 responses to the distractor stimulus were suppressed well before the eye movement to the target. This effect was maximum when target and distractor both lay within the RF borders, diminished substantially when the target stimulus was moved outside the RF, and diminished further with increasing distance of the target from the RF borders. Thus, in addition to IT cortex, V4 contains mechanisms for selecting a relevant target based on its features and discarding distractors. The fact that these mechanisms are most evident when target and distractor are located within a cell's receptive field suggests that they are based on local competitive interactions within area V4. The competition between target and distractor in V4 may be biased by top-down, or feedback, signals directed at cells coding the expected target's features.

NEURONAL RESPONSES IN MONKEY INFERIOR TEMPORAL CORTEX DURING THE ATTENTIONAL RELEVANCE OF A VISUAL STIMULUS. B. Jagadeesh*, L. Chelazzi, R. Desimone, M. Mishkin. Lab. of Neuropsychology, NIH, Bethesda, MD and Dept. of Neural. and Vis. Sci., Univ. of Verona, Verona, Italy.

With repeated stimulus-response-reward pairings, stimuli become behaviorally relevant and typically elicit orienting responses. To examine the neuronal mechanisms underlying the learning of stimulus relevance, we recorded from neurons in inferior anterior temporal cortex of a macaque monkey while the monkey acquired a stimulus-response-reward association. Pairs of stimuli were presented at random locations extravehally, and the monkey was rewarded for making a saccadic eye movement to one stimulus of each pair (the positively rewarded stimulus). During the recording session for a single cell, the animal learned “on-line” which stimulus was associated with the reward through trial and error.

Each pair was chosen on the basis of pre-testing to include one stimulus that activated the cell well on its own (good stimulus) and one that was ineffective (bad stimulus). Two pairs of stimuli were used for each cell, and good and bad stimuli were randomly assigned to be either positive or negative. The animal had to find and saccade to the positive stimulus with a very short (150 ms) latency. Responses to the good-bad stimulus pair were averaged across the population of cells. During the 150 ms prosaccadic period, responses were larger when the good stimulus of the pair was positive than when the bad stimulus was positive. The difference in the responses was present even though both good and bad stimuli were always present within the receptive field during that time. This result suggests that the competitiveness of representations of visual stimuli in anterior inferior temporal cortex can change with learning and influence the selection of targets from a scene.

Neurons in the inferior convexity of the prefrontal cortex have recently been found to respond selectively to complex stimuli such as pictures of objects and faces. These responses resemble those of feature-selective neurons in area TE of inferotemporal cortex. In order to investigate connections between area TE and prefrontal cortex, we combined physiological mapping with WGA-HRP histochemistry to identify afferents of the prefrontal cortex based on functional evidence of injection. Injections were made in the inferior prefrontal cortex in three cases. Two cases received injections in area 45, one of which was first characterized electrophysiologically. The third animal received an injection in area 12. Following injections of area 45, we found retrogradely labeled cells and anterogradely labeled terminals throughout the entire length of subdivisions TEa and TEa in the ventral bank of the STS. Labeling of area TEa was also found in the case with an area 12 injection. In the latter case, the labeling was restricted to areas TEa and TEa in the ventral bank of the STS, and was located slightly rostral to that seen following injection of area 45. These findings indicate that area TE in the inferior temporal cortex, including the ventral bank of the STS, is a selective channel of object and feature information which links specific regions of the prefrontal cortex with the visual system. Learning a Visual Task as Reflected in Activity Dynamics of Macaque Inferotemporal Neurons

A simple task was performed on a standard touch-screen paradigm. The task was to discriminate between two images presented on the screen. The images were of high visual acuity and were presented in a random order. The task was performed by a single monkey, and the monkey's performance was monitored using two electrodes placed in the inferotemporal cortex.

In this study, the monkey was trained to discriminate between two images of different objects. The images were presented on the screen, and the monkey was required to touch the correct image within a short time. The task was performed for several days, and the monkey's performance was recorded using two electrodes placed in the inferotemporal cortex.

The data collected during the task were analyzed using a drift-diffusion model, which is a mathematical model used to describe the decision-making process. The model assumes that the monkey's response is based on a random walk in a decision space, where the decision is made when the monkey reaches a certain threshold.

The results showed that the monkey's performance improved over time, with a significant increase in the speed of the decision-making process. The drift-diffusion model was able to accurately predict the monkey's performance, indicating that the model is a useful tool for understanding the decision-making process in primates.

In conclusion, this study provides evidence that the inferotemporal cortex is involved in the learning of visual tasks, and that the decision-making process can be modeled using a drift-diffusion model. These findings have important implications for understanding the neural mechanisms underlying learning and decision-making in primates.

SEQUESTRATION OF AMYLOID β-PROTEIN BY TRANSHYRETIN: STRUCTURAL STUDIES OF TTR-AP INTERACTION.
Department of Psychiatry and Pharmacology, SUNY, Stony Brook, NY 11794 and The Picower Institute, Manhasset, NY, 11030.

Recent studies have proposed that sequestration of Aβ in biological fluids and extracellular space is the key step in the homeostatic mechanism which prevents Aβ amyloidosis. We have identified that failure to sequester Aβ may lead to amyloid formation. We then found that in cerebral spinal fluid, TTR sequesters Aβ into stable complexes. We also showed that TTR prevented amyloid formation in vitro. In order to investigate the interaction of the two proteins, a computer graphic model of the TTR-Aβ complex was built and the Aβ binding domain with several negatively charged amino acids was predicted. To verify this model, forty different mutations were introduced into the putative binding domain of recombinant TTR and the mutants were tested for binding of radiolabeled Aβ. The mutants of TTR that failed to bind Aβ and to prevent amyloid formation were identified and the key amino acids of TTR that interact with Aβ were determined. These results enabled us to refine the model and predict possible variants of Aβ that may be associated with Aβ amyloidosis. The correct model of TTR-Aβ complex will identify structural requirements for compounds that prevent amyloid formation.

Apolipoprotein E (apoE), particularly the ε4 allele, is genetically linked to Alzheimer's disease (AD). ApoE has previously been shown to bind to β-amyloid (Aβ), an amyloidogenic, proteolytic product of amyloid precursor protein. To analyze the interaction of Aβ with apoE, we constructed an active Western immunoblotting of Aβ peptides incubated with concentrated, conditioned media from HEK293 cells stably transfected with either apoE or apoE human cDNA. Non-reducing SDS-PAGE revealed the presence of a 45kD multi-protein complex with both Aβ and apoE immunoreactivity. Using either Aβ 1-40 or 1-42 peptides, the level of apoE/Aβ complex was ~20-fold greater than apoA4/Aβ complex. This apoE isofrom-specific binding pattern was maintained at concentrations of Aβ from 11nM to 1mM, from pH 5 to pH 9, and from 2 minutes to 24 hours of peptide incubation. The higher level of apoE binding to Aβ is in contrast to previously published data which had been delineated and denatured (Proc. Natl. Acad. Sci. 90:8098, 1993). These data suggest that apoE may play a role in preventing the aggregation or facilitating uptake/removal of this amyloidogenic fragment.

DISTRIBUTION OF APOLIPROTEIN E AND B-AMYLOID PROTEIN IN CULTURES OF NEURONS, MICROGLIA AND ASTROCYTOTES. M.D. Argy, G.M. Cole, and A.P. Mohrb.
Dept. of Anatomy, U. of Tennessee, M. Gr., Jackson, MS 39216, & Dept. of Medicine, UCLA and GRECC, VAMC, Sepulveda, CA 91343.

Understanding the mechanistic basis for apolipoprotein E (ApolE) genotypic variability, major risk factor for amyloidosis and Alzheimer's disease requires an exploration of ApoE and β-amyloid protein (Aβ) interactions with CNS cells.

Cells were cultured from neonatal or young (4-5 month) rat brain and were immunostained using rabbit anti-ApoE serum (Organon Tech) or rabbit anti-Aβ antibody (Calbiochem). Anti-ApoE serum showed strong staining in the parenchyma of the brain, whereas the anti-Aβ antibody revealed positive staining in the astrocytes and microglia, with occasional staining in the neurons. Anti-ApoE serum showed a similar pattern of staining in the rat brain. The results suggest that ApoE is associated with microglia in the CNS and may contribute to the formation of amyloid plaques. The presence of ApoE in the CNS may contribute to the development of Alzheimer's disease.

343.8

APOLIPROTEIN E (APOE) GENOTYPE AND IMMUNOHISTOCHEMICAL FINDINGS IN ALZHEIMER'S DISEASE (AD) WITH AND WITHOUT PARKINSON'S DISEASE (PD) CHANGES. M. Gesing*, J.A. Schneider, and S.S. Mintz.
Department of Pathology and Laboratory Medicine, VA Medical Center and Emory University School of Medicine, Atlanta, GA 30322.

The ε4 allele of ApoE has recently been identified as a risk factor for the development of AD, and cognitive decline in AD and ε4 has been observed in senile plaques. Genetic dysequilibrium of the ε4 allele and the ApoE amyloid association in senile plaques were investigated in 100 dementia patients with neuropathological confirmation. Forty-five AD cases were diagnosed using criteria of the National Institute of Neurological and Communicative Disorders and Stroke and the AD Alliance, and 25 PD cases were identified based on a combination of clinical symptoms and a positive Family History of PD (FHF-S. Heart Hospital). We found that 72% of patients in each group had at least one ApoE ε4 allele compared with reported estimates of 20-25% in the general population. The AD vs. PD groups also showed similar immunohistochemical findings. Although cortical plaques generally demonstrated 5α-A4 apoE colocalization, 9α-plaques in focus neocortical regions were seen in ApoE-immunonegative cases. In all cases, β-amyloid diffuse plaques in the striatum failed to label with antibody to ApoE, whereas cerebellar diffuse plaques showed consistent colocalization of 5α and A4. These discrepancies may be explained in several ways: (1) amyloid processing differs regionally, and the association between 5α and ApoE is not universal; (2) β-amyloid immunonegative plaques may represent an earlier stage in plaque evolution than ApoE-positive plaques, and the ApoE-5α colocalization is a later phenomenon; (3) ApoE is present in all plaques, but in some plaques the levels are too low to be detected with our methods; or (4) ApoE is more sensitive to technical vagaries than 5α. Supported by VA Merit Award and NIH grant AG10130.

CEREBOSPINAL FLUID LEVELS OF AMYLID B-PROTEIN ARE INDEPENDENT OF APOLIPROTEIN E GENOTYPE AND ARE INVERSELY CORRELATED WITH SEVERITY OF DEMENTIA IN ALZHEIMER'S DISEASE.
1Dept. of Neurology, Massachusetts General Hospital ACC 830, Boston, MA 02114; 2Athenogen Inc., South San Francisco, CA; 3Dept. of Brain and Cognitive Sciences, M.I.T. Cambridge, MA.

Alzheimer's disease (AD) is characterized by formation in brain of neurofibrillary tangles and/or amyloid deposits. Brain amyloid burden is highest in AD patients who are homozygous for the apolipoprotein E ε4 allele, which is a high risk factor for the development of AD. To investigate the relationship of apolipoprotein E genotype with brain metabolism of the amyloid β-protein (Aβ-40, Aβ-42, and Aβ-43) we evaluated CSF levels of amyloid β-protein (Aβ) and of secretory neural TTR APP derivatives in 19 AD patients with varying degrees of dementia and with the most common combinations of apolipoprotein E alleles, that is, ε3/ε3, ε3/ε4, and ε4/ε4. Mean CSF levels of Aβ are presented as mean ± SEM. There was no significant difference among the 3 genotypes (ε3/ε3, ε3/ε4, and ε4/ε4). Mean CSF levels of Aβ were nonsignificantly lower in the ε3/ε3 group than in the ε3/ε4 and ε4/ε4 groups. The CSF levels of Aβ were not associated with dementia severity or mortality. The results suggest that ApoE ε4 allele may be a risk factor for AD.

343.10

INCREASED APOLIPROTEIN E ε4 ALLELE FREQUENCY IN ALZHEIMER'S DISEASE (AD) AND IN VASCULAR DEMENTIAS (VD).
Inst. Pharm. Sci. and E. Grossi Pavetti Ct. Univ. of Milano, Alzheimer's Disease Unit, FBFS-Heart Hospital, Brescia, Italy.

ApoE is the only apolipoprotein expressed in the nervous system where it may participate in the transport of choles and lipids via binding to LDL and LRP receptors. In AD apolipoprotein E has been found in senile plaques and ApoE4 (E4 is encoded by a single gene, a common polymorphism is defined by alleles ε3 and ε4) binds in vitro to β-amyloid. These observations stimulated the search of ApoE4 genes in AD leading to the discovery that ApoE is raised in AD (Corder et al., Science 251, 921, 1993). The increased prevalence of ε4 allele is confirmed in our series of AD patients. The ApoE ε4 frequency determined in AD patients by PCR methods was 0.43 (P<0.0001) compared to 0.09 in 64 age and sex matched controls. The presence of two copies of ε4 allele and the 25 SNeuropil fluid (CSF) levels were maintained in both the ε3/ε3 group and the ε3/ε4 group. The results suggest that ApoE4 allele may be a risk factor for AD, indicating an increased risk for AD increased with the ApoE4 dose. Notably a gender effect was observed, since the presence of one ε4 allele was sufficient to significance for AD in females (5.6, P<0.009), but not in males (2.8, n.s.) suggesting an interaction between Apo E4 and sex hormones. This view is supported by the observation that estrogen replacement therapy decreased the risk for AD in women (Paganini et al. Soc.Neuroscl. Abs., 1993). Moreover an increased ε4 allele frequency in nonobese is observed in VD. This last observation indicates that the ApoE4 allele specificity for AD is doubtful and that the modified allele frequency may have some fundamental role in altering the sensitivity of neurons to damage, perhaps through an impairment of repair processes in the brain.
435.11
SECRETION OF β-APP INTO THE RAT CSF: AGED RATS SECRET
SIGNIFICANTLY HIGHER LEVELS OF β-APP FOLLOWING
FOREBRAIN CHOLINERGIC LESIONS THAN YOUNG RATS. Y. Haroutunian*, K.L. Davis, R. Gluck, E. Fiber & W.C. Wallace, Department of Psychiatry, Mount Sinai School of Medicine, NY, NY, and Laboratory of Biochemistry, NIH, Washington, DC, 20201.
Experimental lesions of various subcortical neurotransmitter systems (cholinergic, noradrenergic, serotonergic) induce β-APP expression in the cortex of the rat. This induction results in the persistent secretion of β-APP into the cerebrospinal fluid (CSF). In the current series of experiments young (2 month old) and old (24 month old) Fischer 344 rats received unilateral 6-hydroxy-dopamine lesions of the cholinergic basal forebrain. One week after lesioning, cerebrospinal fluid was collected, and the rats were sacrificed. Analysis of cortical choline acetyltransferase activity (ChAT) showed that cortical cholinergic marker activity was significantly (p<0.001) reduced to approximately 50-55% in both groups. Immunoblots of the CSF using an antibody (15) to the secreted β-APP showed that significantly higher levels of β-APP were present in the CSF collected from sham operated controls (p<0.001). In addition, a significantly (p<0.0002) greater amount of β-APP was present in the CSF of lesioned aged rats relative to lesioned young rats (118% increase vs 66% increase). Basal levels of β-APP in the CSF of young and old sham lesioned rats did not differ (p>0.2). The levels of β-APP in the CSF were highly, and inversely, correlated with the degree of cortical ChAT depletion (r=0.55, p<0.001). Since secreted β-APP contains the potentially amyloidogenic Ap30 amino acid sequence, these results suggest that the consequences of cholinergic system dysfunction may be more deleterious in the old than in the young.

435.13
IMAGING STUDIES OF A TC-99M ANTI-A8 FAB MONOCLONAL ANTIBODY (MAB) IN ALZHEIMER’S DISEASE (AD) USING SPECT. R.P. Friedland*, J.M. Reis, E.M. Majocha, M.S. Bertrand, F. Mirakijko, P. Hedera*, L.E. Eli, C.A. Moceri, Alzheimer Center, University Hospitals, CWRU, Cleveland, OH 44106; NeoRx Corp., Seattle, WA; Malinckrodt Medical, St. Louis, MO; Brown University, Providence, RI.
A Mab (10H3) targeting the AD A8 protein has been developed as a tool for the in vivo assessment of amyloid angiography using SPECT. Results from immunochemical studies using the 10H3 antibody suggest that microvascular fibrillar amyloid is accessible to an imaging agent delivered via the IV route. The 10H3 antibody is stably radiolabeled by conjugation of a preformed Ts 99m diamino dichloro chelate active ester with the protein antigen group, and then associated to Fab fragments. In vitro and animal studies in vivo have demonstrated the safety, sensitivity, specificity and satisfactory biodistribution of the labeled 10H3 Fab (J Nuc Med 33:2184, 1992; Mol Neurosci, in press). SPECT and gamma camera imaging in 4 patients with AD demonstrated activity in the blood pool in the thorax and brain, with rapid uptake in liver and kidney. Clearance of the label from serum is slower than expected, with an initial half life of 3 to 4 hours. No binding to the CSF could be shown, and free Tc-99m was minimal. Tomographic brain images obtained up to 15 hours after injection show retained activity in the venous sinuses with patchy activity in the brain parenchyma. Studies are currently underway to compare the brain distribution of the label to known blood volume markers, and compare patients in the early and later stages of the disease. A label with a longer physical half life may be needed to allow for imaging at later times following clearance of the radiopharmaceutical from the blood.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION

436.1
Thyroid hormones are required for the transition from the breeding to non-breeding state in a variety of species. The onset of the breeding season appears to be thyroid hormone-dependent as well as dependent on photoperiod because maturation of the reproductive tract occurs in birds with thyroidectomized (THX) as well as the photo-induced non-breeding state (J. Exp. Zool., 179: 333-338). In the present study, we tested the hypothesis that thyroid hormones are involved in the transition from the non-breeding season to the breeding season in the ewe, a species in which both onset and end of the breeding season are generated by an endogenous rhythm. We determined the influence of thyroidectomy on the onset of the breeding season in ewes maintained outdoors and ewes held in a fixed short-day photoperiod in which the endogenous reproductive rhythm would be unmasked. All animals were ovariectomized (OVX) and received s.c. Silastic implants of estradiol. As an index of reproductive neuroendocrine activity, thyroid hormone (LTH) was measured in twice weekly blood samples. A sustained increase in circulating LH above 1 ng/LL defined the onset of the breeding season. Ewes maintained outdoors were either THX in late anestrus (Aug., Nov.), THX in early anestrus (Mar., Apr.), or remained thyroid intact (n=7). There was no group difference in the mean date of increase in LH (20 Sep ± 10, 16 Sep ± 6, and 14 Sep ± 3, respectively). Ewes held in constant photoperiod were either THX early in anestrus (a month after LH decreased; n=9) or remained thyroid intact (n=7). There was no difference in the onset of the subsequent breeding season, with LH rising 6 mo. after the previous decline. We conclude that thyroid hormones do not influence the transition into the breeding season in ewes. Rat thyroid hormone receptor binding on the reproductive development of anestrus. 436.2
A PHYSIOLOGICAL ROLE FOR EXCITATORY AMINO ACIDS IN THE CONTROL OF PULSATILE LH SECRETION. V.B. Malek*, J. Ping and D.W. Brain, Department of Physiology & Endocrinology, Medical College of Georgia, Augusta, GA 30912.
The purpose of the present study was to determine the role of excitatory amino acids (EAA's) such as glutamate and aspartate in the regulation of pulsatile luteinizing hormone (LH) secretion in adult male and female rats. To achieve this aim, specific EAA receptor antagonists were injected into the third ventricle of castrated adult rats and the effect on pulsatile LH secretion was determined. The specific N-methyl-D-aspartate (NMDA) receptor antagonist D-APV (2-amino-5-phosphono-pentanoic acid, 10μg/rat) and the specific non-NMDA receptor antagonist DNX (6,7-diisoquinoline-2,3-dione, 30nM) were utilized in these studies. In female rats, administration of either DAP or DNX resulted in a significant elevation of LH levels which was due to a suppression of both LH pulse frequency and amplitude. In male rats, DAP suppressed mean LH levels and amplitude with no effect on frequency, while DNX had no effect on any parameter of LH secretion. Increasing the duration of exposure to the antagonists by administering three injections (instead of one) at 20 minute intervals yielded similar results to a single injection for APS, while three injections of DNX (20 nM each injection) now caused a significant suppression of mean LH levels and pulse amplitude with no effect on frequency. These studies provide evidence that EAAs acting through both NMDA and non-NMDA receptors play a significant role in regulating pulsatile LH secretion and that female animals have a higher sensitivity than male animals to this regulation.
436.4 INFLUENCE OF ETHANOL (ETOH) ON INSULIN-LIKE GROWTH FACTOR-I (IGF-I) AND IGF-IR SYNTHESIS DURING FEMALE PUBERTY. V. Srivastava, J.K. Hiney, C.L. Nyberg, N.H. McArthur, and W.L. Dees, Dept. of Vet. Anatomy, Texas A&M University, College Station, TX 77843-4458.

Recently, we showed that most IGF-I available to the hypothalamus at puberty is derived from circulating bone derived IGF-I at the LH/LH releasing system of prepubertal female rats; thus, indicating IGF-I may participate in the control of LH secretion at the time of puberty. Since ETOH delays puberty and is associated with depressions in GH and LH levels, we examined whether ETOH can affect i) IGF-I gene expression in liver, ii) IGF-I mRNA expression in the median eminence (ME) and c) serum levels of IGF-I and LH. Prepubertal female rats were implanted with gastric cannula on day 24 and began receiving control or ETOH liquid diets on day 29. On day 34, rats were killed, determined to be anestrous, and tissues and blood collected. Results indicate that the ETOH-fed rats showed a decrease (p<.001) in liver IGF-I mRNA levels compared with the controls, and this paralleled depressions in both serum IGF-I (p<.01) and LH (p<.05). No changes were observed in IGF-I mRNA within the ME. These results suggest that ETOH administration process, at least in part, by blocking the peripheral increase in the synthesis of IGF-I, a peptide suggested as a metabolic signal involved in the onset of puberty. (Supported by NIH-A07216)

436.5 PULSATILE FSH SECRETION IN THE OVARIECTOMIZED EWE IS CONTROLLED BY BOTH GNRH-DEPENDENT AND -INDEPENDENT MECHANISMS. V. Padmabhaskar, E.L. McFadden, N.P. Evans, G.E. Dahl, D.T. Mauger, and J. Kurogi, Department of Pediatrics and Physiology, Reproductive Sciences Program, and the National Center for Infertility Research at Michigan, University of Michigan, Ann Arbor, MI.

The objectives of this study were to determine i) if FSH secretion is episodic and ii) if a GnRH-independent control of episodic FSH secretion exists. Hypophyseal portal blood and peripheral blood were collected from five short-term (80 min) intervals for 6 h before and 6 h after a single i.v. injection of Nal-Glu, a GnRH antagonist (10 μg/kg body weight) in GnRH in portal blood, and LH and FSH in both jugular and portal blood were determined by radioimmunoassays. Pulsatile GnRH secretion was evident both before and after Nal-Glu administration. Pulses of LH in the portal circulation coincided with those seen in the peripheral circulation but were larger and more discrete in nature. The pattern of FSH in peripheral blood was not episodic. In marked contrast, FSH in portal blood was unambiguously pulsatile. Prior to Nal-Glu treatment, each pulse of GnRH correlated with a pulse not only of LH but also of FSH in portal blood. However, 49% of the total FSH pulses occurred in the absence of corresponding GnRH pulses. Following Nal-Glu administration, LH pulsatility was completely eliminated, demonstrating its dependence on GnRH. In contrast, Nal-Glu administration blocked only GnRH associated pulses of FSH, it did not block other episodes of FSH release. We conclude that in the ovariectomized ewe; i) FSH secretion is episodic; ii) all GnRH pulses induce an FSH pulse; iii) there exists a GnRH-independent episodic component of FSH release. Our results are consistent with the hypothesis of a dual regulation of FSH release. Supported by NIH grants U54 HD 29184, P50 HD 18258.

436.6 INHIBITION OF ENDOGENOUS NEUROPEPTIDE Y (NPY) SYNTHESIS BY ANTISENSE OLIGODEOXYNUCLEOTIDE ADMINISTRATION SUPPRESSES THE PROGESTERONE-INDUCED LH SURGE. Kalra, P.S.*, Bonavera, J.J., Dube, M.G., Crowley, W.R. and Kalra, S.P., Departments of Physiology and Neuroscience, Univ. Fl., Gainesville, FL 32610 and Department of Pharmacology, Univ. Tenn, Memphis, TN 38163

Evidence shows that NPY is involved in stimulation of the LHRH and LH surges induced by progesterone (P) in estradiol benzoate (EB)-primed ovariectomized (ovx) rats. We have also reported that P stimulates NPY peptide content and prepro-NPY mRNA levels in the hypothalami of these rats, thereby suggesting P-induced activation of NPY synthesis. To evaluate whether newly synthesized NPY is critical in induction of the P-induced LH surge, ovx rats fitted with electrochemical detectors in the lateral ventricles (icv) were primed with EB (30 μg/rat s.c.). Two days later, these rats received P at 1000 h (2 mg/rat s.c.). Additionally, they were injected icv at 1000, 1200 and 1400 h with either 1 mg/kg NPY antisense or scrambled NPY. Pregnane-3,20-diol (NLOGIC); controls were injected with saline. Blood samples were withdrawn via pre-implanted intra-atrial cannula at 1000 h and at hourly intervals between 1400-1800 h for LH analysis. Results show that robust LH surges occurred in controls and in rats injected with scrambled OLOGIC. However, in rats injected with NPY antisense OLOGIC to block NPY synthesis, the P-induced LH surge was completely suppressed. These results support the hypothesis that P activates de novo synthesis of NPY, which is necessary to evoke LHRH and LH surges. (Supported by NIH HD 08634)
FOOD RESTRICTION INCREASES NPY GENE EXPRESSION IN A SUBPOPULATION OF NPY NEURONS IN THE ARCULATE NUCLEUS OF PREGNANT RATS. L.A. Camacho†, D.J. Horvath‡ and M.S. Smith
‡. Department of Psychiatry, Neuroscience and Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261.

Food restriction was shown to delay the onset of puberty in female rats. Others have reported that food restriction increases hypothalamic NPY activity. Their results were obtained in animals where changes in NNPH-somata were associated with the delayed onset of puberty induced by food restriction. Three groups of prepubertal rats (n=6 each) began treatment on day 28 of age and were sacrificed 2 weeks later: (a) ad lib feeding; (b) food restriction (FR); or (c) food restriction + 24 hrs of ad lib feeding before sacrifice (FR + 24 hr refeed). Average body weights on day 42 were C: 136.0 ± 3.3 gm; FR: 74.2 ± 0.7 gm; and FR + 24 hr refeed: 96.0 ± 1.3 gm. At the time of sacrifice, C animals were in various stages of the estrous cycle, whereas none of the FR and FR + 24 hr refeed groups had exhibited first estrus. In situ hybridization was performed on 20 µm brain sections using a 35S riboprobe for rat NPY mRNA. The data were analyzed by measuring the area occupied by silver grains on the acrulate nucleus. NPY mRNA levels did not differ among the three groups in the rostral portions of the arculate nucleus. However, in the caudal portions of the arcuate nucleus, NPY mRNA levels were increased by 76% in response to food restriction: C = 59.1 ± 8.2, FR = 67.0 ± 7.4, area occupied by silver grains; FR + 24 hr refeed = 71.5 ± 6.7 µm². The data demonstrate that the delay in the onset of puberty induced by food restriction is associated with an increase in NPY mRNA levels in a specific population of NPY neurons in the caudal portion of the arcuate nucleus. Further studies will be necessary to determine whether these NPY neurons play a role in causing the suppression of GnRH secretion that underlies the delay of puberty induced by food restriction.

436.11
AXONAL TRANSCRIPTS IN THE RAT HYPOTHALAMIC-NEUROHYPOPHYSIAL TRACT: G.P. Jirikowski, Dept. of Neuroendocrinology, Max Planck Inst. for Psychiatry, Munich, Germany.

With light- and electron microscopical in situ hybridization and non-radioactive detection methods, we could obtain evidence that oxytocin- and vasopressin-expressing mRNA is present in the axonal pathway of magnocellular hypothalamic perikarya, probably associated with a fraction of the large secretory vesicles. mRNA is likely to be subject to rapid axonal transport, since osmotic challenge changes axonal concentrations of transcripts, while colchicine treatment blocks such effects. In recent studies we could demonstrate that several other transcripts occur in magnocellular hypothalamic axons in the median eminence and the posterior lobe: mRNA coding for c-fos and cjun as well as yroinne hydroxyllase mRNA could be found in the median eminence and the posterior lobe. Saturation loading resulted in a down-regulation of hybridization signal to the magnocellular perikarya within 15min, which could be prevented by pretreatment with colchicine. Pretreatment with a polymerase II inhibitor did not affect increase of hybridization signal to the paraventricular and supraoptic nuclei upon osmotic stimulation. It is likely that neuroendocrine systems with high secretory capabilities, like the hypothalno-neurohypophysial system, utilize their large axonal volume for storage of transcripts, which are perhaps compartmentalized in vesicles, to circumvent degradation. Retrograde transport upon specific stimulation may allow for immediate de novo translation, to replenish depletd peptide pools in terminal sites, prior to the onset of new gene expression.

436.12

Vasopressin (VP) neurons in the bed nucleus of the stria terminalis (BNST) are steroid sensitive and the number of VP mRNA expressing neurons is larger in males compared to female rats. This difference in VP cell number has been attributed to proliferation and/or survival of VP neurons in the gonadotropin responsive period during the critical period. We have shown that galanin (GAL) and VP mRNAs are coexpressed in the BNST of the adult male rat and recently, that GAL mRNA gene expression in the BNST is not sexually dimorphic. These results suggest that the index of coexpression of these neuropeptides differs in male and female rats.

Here, we hypothesized that VP neurons represent a subset of GAL cells in the BNST and that the incidence of coexpression of VP mRNA by GAL mRNA expressing neurons in the BNST would be reduced in female rats compared to male rats. We performed double-label in situ hybridization histochemistry on sections through the BNST from male and female Wistar rats (90 d). Brain sections were hybridized with 35S-labeled and digoxigenin-labeled cRNA probes complementary to GAL and VP mRNAs, respectively. Radioactive grains were detected over VP cells expressing the presence of GAL gene expression. We divided the BNST into two anatomical regions which are part of separate functional pathways: medial (BSTM) and lateral (BSTL) divisions. We found a significant sex difference in the number of GAL cells which coexpressed VP in the BSTM (Mean±SEM: male: 124±8, female: 55±6, p<0.001). However, no difference was found in the BSTL (male: 80±5, female: 83±15). Likewise, the number of cells expressing GAL mRNA only was significantly higher (p<0.02) in the BSTM of female (85±9) compared to male rats (43±5). We provide evidence that VP is coexpressed by a subset of GAL neurons and that the reduced incidence of coexpression of VP by GAL neurons in the medial BNST accounts for the sex differences in VP cell number in this limbic region.

436.13

GAP junctions (GJ) establish cytoplasmic continuity and synchronize activity between adjacent cells. In the brain, the GJ proteins, connexins (Cx), exhibit developmentally regulated expression and restricted distribution. Although Cx26 and Cx43 were thought to occur predominantly in astrocytes, a recent report demonstrated functional GJs and Cx26 expression in GnIH-T17 neurons in vitro (Neuroendocrinology 1993 58:489-492). To reevaluate which cell types express Cx isoforms in the intact brain, we analyzed the distribution and expression of Cx26 and Cx43 in the primates hypothalamus during development. Ubiquitous sections were immunostained with optimal dilutions of affinity-purified polyclonal antibodies against Cx26, residues 108-117 (from J.A. Germain) or 112-125 (from N.B. Galudai), and a mouse monoclonal lgG against 19 residues of Cx43 (Zymed). Two fetal males (142-150 dga) had low Cx immunoreactive (ir) fibers. However, in 4 infant females (4.5-7.5 mo), faint or speckled Cx26-ir and Cx43-ir perikarya also were seen, especially in animals pre-treated with octreotide. In 3 juvenile females (17-19.2 mo), Cx26-ir and Cx43-ir somata had light to intense, uniform or speckled staining. In 3 adults, Cx43-ir perikarya were absent, but speckled Cx26-ir fibers were noted. In addition, Cx26-ir perivascular and Cx43-ir fibers in the ventral hypothalamic tract continued into the infundibulum (INF) and median eminence. Considering that Cx-ir was in perikaya retrograde and staining mimicked that for neuronal but not astrocytic markers, we conclude that Cx26 and Cx43 are present in neurons. Since GJs create electrotonic connections and allow small molecular diffusion between coupled cells, development in Cx expression may help coordinate maturation and synchronize specialized functions of hypothalamic neurons. Supported by HD10967 and HD11979.
437.2
ENZYMIC SYNTHESIS OF ANANDAMIDE, AN ENDGENOUS LIGAND FOR THE CANNABINOID RECEPTOR; PROPERTIES AND DISTRIBUTION IN THE BRAIN. W.A. Devane, Dept. of Neurobiol., Lab. of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892.

Anandamide (arachidonylethanolamide) was the first endogenous cannabinoid compound to be identified in brain (Devane et al., Science 1992). The purpose of this study was to characterize the enzymatic synthesis of anandamide using brain membranes.

Bovine membranes (P2 fraction) were incubated with [3H]ethanolamine and varying concentrations of ethanolamine and arachidonic acid for 20-40 min at 37°C. This resulted in the formation of a radioactive product having the same Rf value as authentic anandamide using both normal and reverse phase thin layer chromatography. Incorporation of [3H]arachidonic acid and ethanolamine also resulted in the synthesis of a radiolabeled product having the same Rf value as anandamide in both chromatographic systems. The synthesis of anandamide had a pH optimum of 9 to 10, and the amount of product formed was linear up to 50 min, using 70 µg of membrane protein/200 µl.

When varying the concentration of arachidonic acid, the enzymatic activity exhibited a biphasic curve, suggesting substrate inhibition. When compared to a number of related fatty acids, arachidonic acid proved to be the best substrate with the lowest EC50 and the highest Ψmax. A production study in bovine brain indicated that anandamide synthesis levels are high in the hippocampus, followed by cortex, striatum, and thalamus. Lower levels of enzymatic activity were found in cerebellum, medulla, and medulla. These findings suggest the presence of anandergic neurons.

437.4

Circumventricular organs (CVO) of the rat brain lamina terminals lacking a blood-brain barrier, the subfornical organ (SFO) and the organum vasculosum laminae terminals (OVLT), are involved in body fluid and cardiovascular control by sensing blood-borne substances. In vivo autoradiography on brain tissue sections showed binding sites for vasopressin (AVP) and its AVP(4-9)-agonist within the SFO and OVLT. For characterization of AVP and AVP(4-9)-receptors in cells cultured from the SFO and OVLT, receptors were labeled with [3H]dDAVP. The binding was measured in fura-2 loaded single neurons and glial cells. The investigated cell type was verified by immunofluorescence using NSE- and GFAP-specific antibodies. SFO- and OVLT-cultured cells responded exclusively to AVP with the highest affinity and at the lowest concentration. When comparing binding of AVP to other vasopressor peptides, it was found that the potency of AVP was greater in glial cells than in neuronal cells. To investigate the presence of a V1 receptor subspecies, specific antagonists inhibited the evoked responses in neurons (SFO n=4, OVLT n=9) and in glial cells (SFO n=5, OVLT n=3). Ca++-transients measured in the absence of extracellular Ca++ suggest intracellular stores to be the Ca++-source. An additional AVP receptor subtype in OVLT-neurons is implicated by the finding of a Ca++-signal induced by the V2 receptor agonist dDAVP (n=7). Furthermore, Ca++-transients were evoked with AVP(4-9) (100 nM) in SFO- (n=6) and OVLT- (n=7) neurons as well as in SFO- (n=2) and OVLT- (n=6) astrocytes. A significant number of cells (n=9) responded exclusively to the fragment peptides, indicating the existence of yet another member of the AVP receptor family.

ALTERED α2-ADRENOCEPTOR GENE EXPRESSION IN BRAINS OF TRANSCENDENTAL MICE. M. Scheinin, R. Link, M. Kulatunga, I. Marttila, M. Savola, C. Barsh and B.K. Bollika. Dept. of Pharmacology, Univ. of Turku, FIN-20520 Turku, Finland, and Howard Hughes Medical Institute and Stanford University, Stanford, CA 94305.

Three α2-adrenergic (α2) genes are expressed in brains of rodents and are evolutionarily conserved in humans. One of the subtypes, α2C, mediates both pre synaptic regulatory functions and postsynaptic effects. Little is known of the neurophysiologic roles of α2C genes. We have generated α2C-/- mice with normal development and behavior, but α2C specifically lacks dense binding in most hypothalamic nuclei, some of which may have been non-adrenergic imidazoline sites, e.g. in the arcuate nucleus(1). Intense immunohistochemical α2AR expression was not seen in any hypothalamic nuclei. Northern blotting and reverse transcription-polymerase chain reaction analyses showed predominant expression of these two receptors in the central nervous system. In situ hybridization analysis revealed their prominent expression in the limbic system and further demonstrated the differential distribution of their mRNAs in mouse brain. Although the ligands for these receptors are yet to be identified, the significant sequence homology between these receptors suggests that they constitute a new receptor subtype and they possibly represent different receptor subtypes for an unknown neurotransmitter. The prominent expression of α2C in medullary habenular nucleus, shown by in situ hybridization analysis, suggested that further characterization of α2C may facilitate our understanding of the function of the habenular nuclei.
437.7
LOCALIZATION OF CALCIUM RECEPTOR mRNA IN RAT BRAIN USING IN SITU HYBRIDIZATION HISTOCHEMISTRY.
K.L. Singh, S. Singh, and A.N. Sanyal. Pharmacia, Salt Lake City, UT 84108, and 2 Endocrine Hypertension and Renal Divisions, Dept. of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115.
The capacity to sense changes in the level of extracellular Ca2+ is an important function in several cell types. For example, hormone secretion by the hypothalamus and parathyroid glands is regulated by extracellular Ca2+. The protein that enables these cells to detect and respond to changes in extracellular Ca2+ is recently identified and shown to be a 7-transmembrane, G-protein-coupled receptor linked to the mobilization of extracellular Ca2+ in response to increases in extracellular Ca2+. The receptor is a heterodimer containing two subunits, one of which is mainly regulated by extracellular Ca2+. This protein, 11C, is primarily regulated by extracellular Ca2+.

437.8
Physiological studies using microinjections of L-glutamate into specific sites in the rostral ventrolateral medulla and monitoring of cardiac function and vascular blood flow (Doppler flow probes) of postganglionic-vagovagal dogs revealed two sites where consistent responses were obtained. One is an area located 3.5 to 5.8 mm rostral to obex, 4.2 to 5.1 mm lateral to midline, 0.5 to 1.5 mm below the ventral surface [referred to as the subparvicellular area (SPV)] and the second in an area located 6.2 to 7.1 mm rostral to obex, 2.9 to 5.4 mm lateral to midline, 0.5 to 2.0 mm below the ventral surface (referred to as ventromedullar area). L-glutamate microinjected in the subparvicellular area produces a significant increase in arterial blood pressure associated with decreases in femoral and renal vascular bed conductances. L-glutamate microinjected into the ventromedullar area produces a decrease in arterial blood conductances but an increase in femoral arterial bed conductance. Using immunohistochemical methods and specifically tyrosine hydroxylase (TH) and phenylethanolamine-N-methyltransferase (PNMT) colormetric immunohistochemistry, we determined whether TH and/or PNMT immunoreactive neurons were present at the two microinjection sites. Results indicate that neurons in the canine subparvicellular area are immunoreactive to antibodies against PNMT and therefore contain epinephrine. Further analysis shows that neurons in the ventromedullar area are mainly occupied by neurons exclusively immunoreactive to antibodies against tyrosine hydroxylase (TH) although some neurons also contain PNMT. Previous investigators have included this region anatomically as part of the SRPN (Janzey et al., 1992). However, physiologic responses to L-glutamate microinjection in this area are characterized primarily by a significant increase in femoral conductance consistent with vasodilation.

437.9
STIMULATION OF C-FOS EXPRESSION IN SELECTIVE BRAIN NUCLEI BY EXOGENOUS ARGININE-8-VOSOPRESSIN: QUANTITATIVE IMMUNOHISTOCHEMISTRY AND LIGHT/FLUORESCENCE MICROSCOPY
Peripheral administration of arginine-8-vasopressin (AVP) has been shown to elicit the desired behavior of leaches and to maintain tolerance to ethanol by the action on AVP-V1 receptors. Others found that i.v. injection of AVP increased c-fos mRNA expression in the hippocampus and hypothalamus. Here, we tested the precise site(s) of action of peripherally injected AVP remain unknown. Adult male Sprague-Dawley rats were injected with saline (0.3 ml/kg s.c., n = 6), AVP (10 μg/ml s.c., n = 6), saline (0.3 ml/kg i.p., n = 6) or paraglandular AVP (PPTZ, 10 mg/kg i.p., ml, n = 3) and sacrificed 2 h later. Serial coronal brain sections were processed with antibodies against Fos and like proteins and AVP. Brain areas containing nuclei of similar size and shape were quantified by counting the number of neuronal cell bodies showing Fos immunoreactivity (Fos-IR) in each nucleus in left/right side under a Nikon Eclipse microscope with 20 X objective and CFPCCD (2.5 X).

EFFECT OF MK-801 IN FOCAL CEREBRAL ISCHEMIA IN THE MONKEY. R.N. Auer, G.W. Jason, B.I. Tranner, and S. Coupland Department of Neuroscience, University of Calgary, Canada, T2N 4N1.

To determine the effectiveness of MK-801 in primary focal ischemia, transorbital occlusion of the middle cerebral artery (MCA) was done in female cynomolgus monkeys (Sioumi strain) using a clip occluder placed under the operating microscope, while blood pressure was controlled to 60 mm Hg using halothane. Other drugs were administered. Ambient temperature was controlled during the operating procedures to roughly 35°C, and temporoparietal temperature was controlled to 37°C. MK-801 (1 mg/kg) was administered 20 minutes after occlusion. Following 110 minutes of occlusion, the clip was released and restoration of flow was verified visually. Quantitative histopathology at 52 coronal planes was performed after 2 weeks. There was no statistically significant difference in the infarct volumes between treated and untreated animals.

Neuropathologic testing also revealed no difference between the groups.

The cingulate cortex was carefully examined in the oldest animals, and no evidence of acidophilic neocortical neurons, microglial nodules, or other evidence of MK-801-induced cell death was seen.

We conclude firstly that MK-801 is ineffective in reducing cerebral infarct volume in this model of transient focal ischemia. Secondly, although 1 mg/kg is a relatively high dose of MK-801 in the primate, we conclude that the dose is not the necrotizing effect of this NSMDA antagonist, which has been well-described in the cingulate cortex of the rodent, does not occur in this primate.

438.2

Transport across the blood-brain barrier is an essential component of brain parenchymal cells is believed to be mediated by two differently glycosylated forms of GLUTI. The effects of cerebral ischemia for GLUTI mRNA have been described but not for the protein. Using a high affinity, specific, polyclonal antiserum (ALM-K1: 1:5000) they confirmed the asymmetric distribution of GLUTI with abnormally > cytoplasmic > luminal concentrations. After ischemia, both microvascular and non-microvascular GLUTI concentrations increased markedly by as soon as 1 day and persisted through 4 days of ischemia. We conclude: GLUTI may be detected in both brain microvascular and parenchyma using a high affinity, specific-polycyclonal antiserum. Global forebrain ischemia rapidly and persistently increases GLUTI expression of both forms. Supported by NS22213 and NS17983.

SUPPRESSION OF HIPPOCAMPUS FOS EXPRESSION AND ACTIVATOR PROTEIN-1 (AP-1) ACTIVITY DURING FOCAL CEREBRAL ISCHEMIA USING ANTIASENSE STRATEGY. P.K. Lin, A. Saltinsson, Y.Y. He, M.C. Tardos, C.Y. Hsu. Div. of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030.

An activation of c-fos and the subsequent expression of the Fos protein were noted following focal cerebral ischemia. Fos and Jun form a heterodimer as AP-1 which modulates the expressions of several genes. To study the suppression of Fos expression related to c-fos expression, we performed Northern blot analysis following focal ischemia to suppress the post-ischemic expression of c-fos by intraventricular infusion of an antisense phosphorothioated DNA of c-fos mRNA. The antisense DNA was converted into RNA and hybridized with the c-fos mRNA in the hippocampus. In the outcome of this study, we not only noted that the 'P'-labelled antisense DNA was internalized within the neurons and in the hippocampus but also that the antisense DNA was not detected in the hippocampus after infusion of the antisense DNA. The suppression of Fos expression was induced by AP-1 binding activity following focal cerebral ischemia.

343.4

We have previously reported that a 30 s, high +G (head-to-foot internal load) exposure of > +25G causes global cerebral ischemia in rats (Wercchan and Shahed, The Physiologist, 35: S143-146, 1992). Also, there were ++25G exposures have been shown to cause transient brain edema (Shahed et al. Aviat. Space Environ. Med. 63:5, 1992). In the present study HSP70 expression was investigated as an early marker of cellular stress.

Methods: Protocol I: Rats were exposed to +2.5G for either 15, 30 or 60 s in a small animal centrifuge, and brains were collected immediately or 0.5 to 24 hr after the run. Control rats were exposed to +0.5G. Protocol 2: rats were subjected to six 30 s exposures of +22.5G, and brains were collected as in Protocol 1. Total RNA was extracted by RNAzol B method. RT-PCR was performed using 1 μg of RNA for cDNA synthesis and specific HSP 70 primers were used for subsequent amplification.

Results: Expression of HSP 70 did not increase above the control level after 15 or 30 s exposure. Following the 60 s exposure, HSP 70 expression increased at 60 and 180 min after the centrifuge run. In protocol 2, expression of HSP 70 increased at 60 and 180 s after the run.

Discussion: High +G, exposure of at least 60 s duration or six exposures of +22.5G were required to increase expression of HSP70. The time points of increased HSP70 expression were similar to those previously reported for brain edema. This suggests that HSP70 expression could be a suitable marker for monitoring post +G, exposure effects.
**ISCHEMIA: MECHANISMS III**

**439.1**

A well established model of neonatal cerebral hypothyamic ischemia involving subjecting 7 day old rats to unilateral carotid artery occlusion and exposure to 3 hr of hypoxia which results in damage spialateral to the carotid occlusion. In several adult animal models of cerebral ischemia, DNA fragmentation has been noted of apoptosis has been observed. Whether programmed cell death contributes to the damage which occurs following hypoxia-ischemia in neonates is not known.

The presence and identity of DNA fragmentation was investigated in situ by dual-labeling with terminal deoxynucleotidyl transferase and propidium iodide. Breaks in DNA were observed in brain sections ipsilateral to the carotid artery occlusion in rats exposed to 3 hrs of hypoxia-ischemia corresponding to extensive damage observed in the HE&E sections. In some animals subjected to 2 hr of hypoxia-ischemia, the damage was less severe and selective areas of positive DNA fragmentation were observed in the hippocampus, thalamus, caudate nucleus and cerebral cortex. Tissue analysis of these regions confirmed the presence of ladder DNA fragmentation.

This, in model of neonatal hypothyamic ischemia there is evidence that DNA fragmentation indicative of apoptosis can occur suggesting that programmed cell death contributes to the damage observed.

**GENETIC MANIPULATION OF ORGANTOPIC COULTURES WITH AN ADENOVIRUS ANEVOKESS TO CHANGE NEUROANATOMICAL PROJECTIONS.** M. Wiener and E. Angelides.

The structure and organization of thalamocortical (TC) axons in the developing mammalian neocortex is the focus of current investigation. Organotypic cultures of fetal thalamic and neonatal cortical explants permit the in vitro dissection of the signals and mechanisms underlying the development of TC projections. To date, the roles of various molecular and signal transduction molecules is a potentially powerful tool for exploring the development of this circuitry.

Recently, several labs have demonstrated the usefulness of using viral vectors (herpes simplex virus I and adenovirus) to transfect neurons in vivo and in vitro. Replication-defective, recombinant (RDR)-adenoviruses have several advantages over herpes virus vectors, including: (1) high titer, (2) safety and (3) relative long-term expression of the recombinant gene. To explore the possibility for genetic manipulation of organotypic cultures, rat cortical explants, cocultured with thalamic explants, were infected with AdRSV5gal. Infection of cortical explants, with both RDR-adeno and RDR-herpes virus vectors was investigated: (1) labelled thalamic axon growth was also assisted 1-2 weeks post infection. In 2 in vitro experiments where the bilateral lesions were formed between infected and control cortical explants, no gross differences in the extent of thalamic ingrowth or axonal arborization were detected. These data suggest that adenoviruses may be gene vectors for genetic manipulation of target tissue. Future experiments will concentrate on designing recombinant adenovirus for studying target selection and circuitry formation in thalamocortical explants. Supported by NIH grant NS 26733. M. Wi. in NIH postdoctoral fellow (NS 00710).

**439.10**

Apoptosis, or programmed cell death, has been shown to be a mechanism by which cells can die from a cell to commit suicide. CDC is usually associated with intranuclear DNA fragmentation, which may lead to an upregulation of certain proteins such as p53, a member of the heat shock protein family. This study was performed to show that following a unilateral focal stroke, induced in rats by photochemical thrombosis (rose bengal is injected intravenously and the skull is irradiated with a beam of focussed light; Neuroscience 1990, 55, 472; J Neurosurg 1993, 79: 2440) will have a significant role in the area penumbra. We collected brain samples at different times post-stroke and determined immunohistochemically: a) in situ DNA fragmentation by staining the brain slices with anti-digoxigenin antibody to detect digoxigenin labelled-DUTP-DNA adducts (AntiAp; Orion); b) the presence of p53 (antibody PAAb20; Oncogene Science Inc.); and c) the presence of 72 kD heat-shock protein (72 kD antihumononal antibody, Amerham). Following stroke, we observed increases in DNA fragmentation, p53, and 72 kD protein in the cortex ipsilateral to the thomeric core. These increases occurred in different brain regions: DNA fragmentation and p53 increased only in the area penumbra, while 72 kD heat-shock protein increased throughout the cortical cortex, except in the area penumbra. DNA fragmentation was evident as early as 6 hr post-stroke, peaking at 12-14 hrs, and leveling off at 24 hrs. In contrast, p53 and 72 kD immunoreactivity was not increased until 8 hrs and lasted throughout the progressing cortex.

These results suggest that stroke-triggered p53 upregulation might be responsible for the CDC in the area penumbra.

**THE EFFECT OF TRANSIENT GLOBAL ISCHEMIA ON ACTION POTENTIALS, CALCIUM INDUCED CALCIUM TRANSCRETS INS [Ca]I PYRAMIDAL NEURONS. Y. Schiller, C. Sommer, and M. Kissingler.

The effect of global ischemia on the brain's ability to maintain calcium homeostasis and calcium dependent mechanisms was examined. Ischemic conditions were evoked by electrical and synaptic activity in CA1 pyramidal neurons. Brain slices were prepared from mice and sacrificed at 3 days of age. Calcium transients were measured at the soma and at different location along the apical dendrite (10-300um).

The major findings of this study are: 1) The resting [Ca] was not significantly different (control and ischemic) but up to 24 hours after the ischemic event. 48-72 hrs after a small increase of the resting [Ca] was observed. 2) The [Ca] transients evoked by a train of 5 action potentials (synaptic or electrophysically evoked) were not significantly altered up to 24 hours after the ischemic event. 48-72 hrs after the ischemic event, the prolongation of the [Ca] transients was observed. 3) Following a 0.5 second 100Hz synaptic stimulation the peak and decay of the [Ca] transient did not significantly differ in normal and ischemic gerbils 24 hours after the ischemic event. In both groups about 85% of this [Ca] transient was blocked by APV. From these findings we concluded that during the first and potentially reversible period after the ischemic event (24h) no significant abnormalities were detected in the amplitude of synaptic and action potential induced [Ca] transients and in the ability of CA1 pyramidal neurons to eliminate this calcium load.
439.3 LAMINAR SPECIFIC ATTACHMENT AND NEURITE OUTGROWTH OF THALAMIC NEURONS ON CULTURED SLICES OF DEVELOPING CEREBRAL NEOCORTEX. D.E. Essenhigh and A.D. Lander*. Dept. of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

In nervous system development, the growth cones of advancing axons are thought to navigate to their targets by recognizing cell-surface and extracellular matrix molecules that act as specific guidance cues. To identify and map cues that guide the growth of a particular axonal system, the thalamocortical afferents, an assay was devised to examine short-term interactions of dissociated embryonic thalamic cells with living, ~150 μm slices of developing mouse forebrain. Thalamic cells rapidly (<3 hours) and efficiently attached to and extended neurites on pre- and postnatal slices, but a broad zone around the neocortex was generally non-permissive for both thalamic cell attachment and the ingrowth of neurites. This zone coincided with the cortical plate at early stages (embryonic day 13), but later became restricted, in radial-to-cortical fashion, to cortical laminae 2/3. Thus, at each stage, thalamic cells in vitro avoided just that area that thalamic axons confront, but generally do not enter, in vivo. In addition, neurites that extended on some layers were found to be significantly oriented in directions that coincide with the pathways that thalamic axons follow in vivo. Furthermore, these laminar specific behaviors of thalamic cells on cortical tissue were observed when fresh frozen cryostat sections were substituted for living brain slices. The results imply that local adhesive cues and signals that affect process outgrowth are distributed among developing cortical laminae in a manner that could underlie much of the temporal and spatial patterning of thalamocortical innervation.

By investigating what cell-surface and extracellular matrix molecules account for the behavior of thalamic cells in this rapid in vitro assay, we hope to elucidate some of the molecules that control the in vivo development of the thalamocortical pathway.

439.4 CNS-ASSOCIATED CUES ARE REQUIRED FOR CENTRAILY-DIRECTED NAVIGATION BY PERIPHERAL SENSORY NEURONS IN THE EMBRYONIC MURINE NEUROPHYSIOLOGY. L. J. Arices*, K. Johnson, B. C. Johnson, Neuroul Res. Center and Dept. of Physiol. and Biophysics, Unv. of Alabama, Birmingham, AL 35294 & Dept. of Zool. and Genetics, Iowa State Univ., Ames, IA 50011.

The axons of peripheral sensory neurons in Xenopus laevis medially navigate through several potential choice points toward the CNS where they then segregate into discrete axon tracts which can be dissociated by differential expression of surface antigens. The earliest population of sensory cells arise in discrete clusters called sensory and pathway selection by individually dyed-filamented sensorg growth cones is highly specific. We have shown earlier that one potential source of guidance information proximal to the CNS was the outgrowing axons of central pioneer neurons. To examine the potential influence of CNS-associated cues, we performed CNS ablations early on embryonic day 18. Gangliocytic primordia were removed from anesthetized embryos which were allowed to survive for 6-8 days before labeling them with the monoclonal antibody Lea3-2 to stain all sensory axons. Control preparations involved surgically opening the body wall but not removing the gangliocytic primordia. Pathfinding and selective fasciculation in control preparations were indistinguishable from normal. In contrast, in each of 110 hemisegments deprived of CNS (15 animals), the seminal set of axons appeared undirected. In all cases the majority of seminal axons fascicolized extensively upon one another following a tight circular pathway around the neuropile. Normally these axons project some distance from this point. There were also a few instances where normally separate peripheral fascicules became tightly fascicolized along abnormal pathways. These results demonstrate that the CNS normally provides cues necessary for correct navigation, and in its absence the peripheral neurons fail to fasciculate with each other. Further evidence in support of this is that later developing extramurally oriented neurons do differentiate and project axons in the absence of the CNS, but appear unable to identify an appropriate direction for growth. Instead they form short tendrils of axons that do not join their normal pathways. Thus, the peripheral sensory neurons of larvae require CNS-derived gradient information. We are currently further examining the nature of the cues provided by CNS neurons necessary to directafferent innervation. Supported by NSF 9209237 and a Sloan Foundation Fellowship (Jla) and NH 26867 (Jle).

In the embryonic spinal cord, commissural axons pioneer a circumferential pathway from one hemisphere to the floor plate at the ventral midline. Floor plate cells secrete a factor that attracts these axons in vivo, suggesting that the ventral growth of these axons may be directed partly by chemotropism. Floor plate cells have also been shown to secrete a (possibly distinct) diffusible factor that promotes the outgrowth of commissural axons in collagen gels in vitro. Using outgrowth of commissural axons into collagen gels as an assay, we have purified from embryonic spinal cord a protein, netrin-1 and netrin-2 (28 kD and 75 kD, respectively, by SDS-PAGE), that mimics the outgrowth-promoting activity of the floor plate. We have also identified the distinct activity in embryonic brain that potentiates their effects. Cloning of cDNAs encoding the two netrins show that they are homologous proteins (72% identical) which are exclusively expressed in the CNS. We have been able to clone a laminin-related protein required for the circumferential migration of cells and axons in the nematode C. elegans. This homolog suggests that the guidance of growth cones in the vertebrate spinal cord and the nematode are directed by similar molecular cues.

The guidance of axons to their targets in the developing nervous system is believed to involve diffusible chemotrophic factors secreted by target cells. Floor plate cells at the ventral midline of the spinal cord secrete a diffusible factor (or factors) that promotes the outgrowth and fasciculation of commissural axons that recruits these axons in vivo. Two proteins from embryonic brain, netrin-1 and netrin-2, possess the outgrowth-promoting activity of floor plate cells. Here we report that during the period of commissural axon growth to the ventral midline, netrin-1 is expressed at high levels in the floor plate region, whereas netrin-2 is expressed more widely and at lower levels in the ventral spinal cord. Moreover, heterotopic expression of either netrin can mimic both the outgrowth promoting and the long-range chemotrophic activities of floor plate cells. Thus, netrin-1 and netrin-2 are chemotropic factors that may guide commissural axons in the developing spinal cord.

We have been characterizing the expression and function of several genes involved in growth cone guidance at the midline of the Drosophila central nervous system (CNS). In mutations of the commissureless (cmn) gene, growth cones miss the midline instead of staying on their own side (Seeger et al., 1993). In mutations in the roundabout (robo) gene, growth cones that would normally stay on their own side instead now cross the midline. The cmn gene encodes a novel transmembrane protein expressed by a subset of midline cells (Teet, Seeger, and Goodman, submitted). Closing of the rob expression domain gives rise to an embryonic CNS midline defect. Here we describe the characterization of a third gene – D-nefrin – that was cloned on the basis of homology to the two vertebrate netrin genes and the nematode unc-6 gene. In the nematode, UNC-6 appears to control circumferential guidance. In vertebrates, netrin-1 and netrin-2 are expressed by the floor plate and ventral neural tube, respectively, and can function in vitro to attract commissural growth cones. The D-nefrin gene is located on the X chromosome. It is strongly expressed by a subset of midline cells developing, and by visceral mesoderm. Based on its homology to the netrins/UNC-6 and its expression pattern, we have named this gene that D-nefrin plays an important role in midline guidance. To test this model, we are using genetic approaches, including the analysis of specific growth cone loss of function mutations to trace in embryos and to construct constructs which produce specific patterns of ectopic D-nefrin expression.

The Semaphorin genes encode a family of highly related secreted and transmembrane proteins which appear to function during growth cone guidance. Antibody blocking experiments have shown that gangliocytic Semaphorin I (formerly Fasciclin IV) is required for the proper guidance and fasciculation of the T11 growth cones in the limb bud of the grasshopper embryo (Kolodkin et al., 1992). Chick collapsin, a secreted member of the Semaphorin family, is capable of causing growth cone collapse in an in vitro assay (Luo et al., 1993).

We previously identified two members of the Semaphorin gene family in Drosophila (Kolodkin et al., 1993). Semaphorin II (Sema II) is a secreted protein that is structurally similar to cholinergic growth cone repulsive molecule Semaphorin IV, a 500 amino acid Semaphorin domain, a single immunoglobulin domain, and a C-terminal tail. In the embryo, Sem II is expressed by a small subset of cells in the CNS and by muscle 31 in the body wall of the T3 segment, suggesting a role in the generation of neuromuscular connectivity.

We have taken a genetic approach to characterize the function of Sema II. Adult flies homozygous for this mutation have a variety of behavioral phenotypes including partially penetrant flightlessness, visual orienting defects, and abnormal drinking behavior. To gain insight into the origins of these behavioral defects, we have examined the effect of the sema II loss-of-function mutations on the innervation of muscle 31 in the embryo and larvae. To examine this effect, we have used transgenic constructs to ectopically express Sema II by novel sets of muscles. In this way, we hope to determine the function of this secreted Semaphorin during growth cone guidance and target recognition.
439.9 EXPRESSION OF THE SEMAPHORIN III GENE DURING DEVELOPMENT OF THE RETINOGENETIC SYSTEM. E. N. Hems et al., A. I. Kolkodin, C. S. Goodman, and C. J. Shatz, Department of Biology, University of California, Berkeley, CA 94720.

The Semaphorins are a family of highly related secreted and transmembrane proteins that appear to function during growth cone guidance. Semaphorin III (Sema III, also known as Fas IV) in the grasshopper is a transmembrane protein that functions in vivo in growth cone guidance (Kolodkin et al., Neuron, 1992). Sema II in Drosophila is a secreted protein that is essential for adult behavior and survival (Kolodkin et al., Cell, 1993). Chick collagen, a secreted protein that is closely related to D-Sema II, can function in vitro to cause DFG growth cone collapse (Lu et al., Cell, 1993).

Based on the homology of human Semaphorin III (Kolodkin et al., Cell, 1993), we used PCR to clone mouse Sema III which is likely to be the homologue of chick collagen. Here we conduct in situ hybridization using a mouse Sema III cDNA to analyze Sema III expression during mammalian development. Whole-mount embryos (E9.5) and tissue sections (E13.5, E15.5, P7, and P21) were hybridized with antisense and sense riboprobes. Some of the structures showing the most prominent labeling with the M-Sema III probe include posterior diencephalon and branchial arches at E9.5, ventral neural tube motoneurons, cells surrounding dorsal root ganglia, and pial and cortical plate at E13.5, retina and olfactory tract at E15.5, and olfactory tract, cerebellar Purkinje cells, and cortical layers 6b and 5 at P20.

439.11 AXONIN-1 AND Ng-CAM-LIKE IMMUNOREACTIVITY DURING THE DEVELOPMENT OF THE RETINOGENETIC SYSTEM IN THE CAUCAL G. Rager, P. Morino and P. Sonderegger, Institute of Anatomy, University of Freiburg, CH-7100 Freiburg, and 1Institute of Biochemistry, University of Zürich, CH-8057 Zürich, Switzerland.

The development of the retinotectal system seems to follow the rule of chronology (Rager et al., Anat. Embryol. 179, 133-148, 1988; Rager et al., J. Comp. Neurol. 310, 239-250, 1991). To show this type of order, we used immunocytochemical expression of cell adhesion molecules could play an important role. Recently, two axonal adhesion molecules, axonin-1 and Ng-CAM, have been found to interact during the process of axon growth (Sonderegger and Rathjen, J. Cell Biol. 109, 1397-1394, 1990). We have observed the expression of axonin-1 and compared it with the distribution of Ng-CAM in the retina and in the retinotectal system of the chick during the period of development. At stage 18 both axonin-like (A-L) and Ng-CAM-like immunoreactivities (Ng-CAM-LI) are clearly present in the area where first retinal ganglion cells (RGCs) are generated. The immunoreactivity spreads synchronously with the formation of ROGs over the developing retina. From stage 21 on the inner proliferative layer was also stained according to its temporal gradient of maturation. In later stages the outer plexiform layer and the inner segments of photoreceptors show immunoreactivity, too. The development of A-L and Ng-CAM-LI along the optic nerve, chiasm, optic tract, and in the superficial layers of the optic tectum seem to follow the chronotopic distribution of axons as it was found by earlier morphological investigations. Older axons seem to loose their A-L which allows us to localize the position of newly formed axons. The fact that A-L and Ng-CAM-LI go in parallel with the formation and maturation of axons allows us to suggest that axonin-1 and Ng-CAM may play an important role in the organization of the retinotectal system. Supported by Swiss N.S.F. grant 31-34409.2.

Ordely neuronal maps of visual space are created in the fly brain by precise retinal cell (R cell) contacts to the optic lobe. To identify genes that regulate R cell connectivity we screened Drosophila larvae for mutations affecting the R cell projection pattern. We analyzed over 5000 IMS mutagenized lines for aberrant R cell projections and isolated 30 interesting loci. Each mutation was analyzed to determine if the gene underlying the defect 1) is required in the R cells, 2) affects R cell fate determination, 3) affects cell fate determination of the optic lobe. A genetic mosaic analysis was used to determine if the gene is required in the eye. In this procedure a patch of mutant eye tissue is generated in an otherwise normal fly. Those mutations that produce a defect in the R cell projection lobe are likely impaired in the R cells. Neural cell fate determination was assessed in both the eye and the optic lobe. In particular we wanted to eliminate from further analysis those mutations that can be rescued in the eye (i.e., in situ transcription) and those that result in defects that may be a secondary consequence of changes in neuronal identity. Three mutations were isolated that are required in the eye but not in the R cell fate. These mutations represent candidate genes which function in the R cells to generate precise connections with their targets.

439.13 DROSOPHILA RECEPTOR TYROSINE PHOSPHATASES ARE EXPRESSED IN THE DEVELOPING VISUAL SYSTEM C. Desai, E. Popova, B. Hamilton and R. Zinn*, Dept. of Biology, Caltech, Pasadena, CA 91125.

Several receptor-linked protein tyrosine phosphatases (R-PTPs) appear to be expressed on results in adult CNS in Drosophila. We purified such one R-PTP, DPTP69D, using anti-PPase against horseradish peroxidase (HRP) as immunofluorescence antigen. Anti-HRP antibodies recognize a carbohydrate epitope expressed in the optic ganglion and the optic lobe. This RPTP was expressed on HRP reagents that were applied to CNS in the eyes. In third instar larvae, DPTP69D expression is restricted to subsets of neuronal processes in the brain, ventral nerve cord, and eye disc. In particular, DPTP69D is expressed on photoreceptor axons and on the neurites of the developing lamina, medulla and lobula complex. Interestingly, DPTP69D is also expressed in the optic lobe in a similar pattern, but at lower levels. We have made DPTP69D mutants; these are viable with normal embryonic CNS. We are examining the visual system in larvae and adults of these mutants. We are also trying to disrupt DPTP69D by mobilizing a P element located 8 kb downstream from DPTP69D.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
Regulation of DOPAMINE D3 RECEPTORS EXPRESSED IN HEK-293 CELLS: M.A. Piachev, K.D. Burns and P.E. Molloy. Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104-0894.

We have previously reported a drug-induced increase in the density of D2 receptors expressed in transfected HEK-293 cells (Mol. Pharmacol. 44:371-379). D2 receptors have distinct structural and pharmacological properties. It was of interest to determine whether the D3 receptor regulates in a fashion similar to the D2 receptor. A stable cell line was created by transfecting the D3 receptor, under the control of a cytoplasmic promoter, into human embryonic kidney cells (HEK-293). The density of receptors after treatment with compounds known to be agonists or antagonists at D2 receptors were measured in homogenates using radioligand binding assays with the following compounds: [125I] transf-7-hydroxy-2-PiPAT or the D3 antagonist [125I] NCCQ-298. HEK-293-D3 cells express a single class of D3 receptor per mg of protein. Exposure of HEK-293-D3 cells to quinpirole (5.0 μM) for 18 hr resulted in a 77% increase in the density of binding sites for both [125I] trans-7-hydroxy-2-PiPAT and [125I] NCCQ-298. This increase in density was both time- and concentration-dependent. Exposure of cells to haloperidol (5.0 μM) for 18 hr, resulted in a 57% increase in the density of D3 binding sites. Treatment with the dopamine antagonist haloperidol (5.0 μM) for 18 hr resulted in a 145% increase in the density of D3 receptors. The increase in the number of D3 binding sites induced by haloperidol was also concentration-dependent. The data suggest that both D2 agonists and antagonists increase the density of D3 receptors expressed in transfected HEK-293 cells. (Supported by MH41654, and NS18591.)

440.3 PRODUCTION OF MICE WITH A CONSTITUTIVE DEFICIENCY OF THE BETA-ADRENERGIC RECEPTOR KINASE (AR) AND HOMOLOGOUS RECOMBINATION: B. Gloumann, J. Le Royɛwitz and M.G. Coronel, HUH, Duke University Medical Center, Box 2587, Durham, NC 27710, USA.

Protein phosphorylation is a key event of the transduction process that underlies the activation and desensitization of B/arrestin receptors. A constitutive &BK-1 (-/-) mice was created which allows for the analysis of events that would normally be regulated by receptor desensitization. The consequences of this change in the phosphorylation status of B2-adrenergic receptor kinase (BKAK) were evaluated in the context of B2-adrenergic receptor function. The results of these experiments were compared with that of a wild type control.
NUCLEAR PROTEINS FROM YOUNG AND OLD RAT TISSUES INTERACT DIFFERENTIALLY WITH THE D2 Dopamine RECEPTOR GENE PROMOTER. I.M. Deloam, C.J. Roth, T. Hinova and M.M. Mosandl. Molecular and Genetic Section, Laboratory of Cellular and Molecular Biology, NIA, NIH, Baltimore, MD 21220; Genetic Pharmacology Unit, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Loss of dopamine receptors and/or changes in their activity may lead to compromised neuronal functioning in aging and certain neurodegenerative diseases. To study the mechanisms of regulation of the D2 dopamine receptor gene in different tissues with aging, we carried out gel mobility shift experiments using nuclear extracts from young and old rats and DNA fragments or oligonucleotides containing different parts of the D2 promoter. A 415 bp DNA fragment containing sequences from -900 to -76 relative to the major transcriptional start point and a 378 bp fragment containing sequences from -75 to -30 bound to position(s) present in nuclear extracts prepared from rat cortex, cerebellum, hippocampus, striatum, and kidney. In addition, the 378 bp probe bound to nucleofected AF2 promoter as well as promoter(s) present in AF2-enriched extracts. We have also shown that an oligonucleotide containing sequences from -75 to -30 binds protein(s) present in extracts from rat cortex, hippocampus, and liver. In several cases, nuclear factor(s) present in extracts from cortex, cerebellum, hippocampus, or striatum formed DNA-protein complexes with different gel mobilities than those formed with liver extracts, suggesting that the identity of some of the nuclear factors binding to the D2 promoter may differ between brain and peripheral tissues. Furthermore, with equal amounts of total nuclear protein, greater binding was observed using cerebellar and liver extracts from young rats than from old rats. These results suggest that the concentration and/or binding activity of nuclear factors interacting with the D2 dopamine promoter may change with age. Further characterization of putative DNA regulatory sites and regulatory proteins in different issues of young and old animals is in progress.

STEROID RECEPTOR MEDIATED EFFECTS OF NEUROSTEROIDS. R. Ruppert, J. H. M. Reul, T. Trapp, B. van Steenberg, C. Wetzel, W. Ziegglitsbgerger and F. Holbofer.* Max-Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Krappealistr. 2-10, 80804 Munich, FRG.

Several 3α-hydroxy steroids accumulate in the brain after local synthesis or after metabolization of steroids that are provided from the adrenals. As this may occur independently from peripheral sources these steroids are called neurosteroids. The 3α-hydroxy ring A-reduced pregnane steroids allopregnanolone and tetrahydrodeoxycorticosterone are believed to interact with intracellular receptors but enhance γ-amino butyric acid (GABA)-mediated chloride currents. The present study shows that these neurosteroids can regulate gene expression via the progesterone receptor (PR). Although they do not bind to the PR of other species, they confer an exclusively nuclear localization of the PR. However, the induction of DNA-binding and transcriptional activation of the PR requires intracellular oxidation of the neurosteroids into PR-active 3α-pregane steroids. Thus, in physiological conditions, neurosteroids regulate neuronal function through their concurrent influence on transmitter-gated ion channels and gene expression. These findings extend the concept of a 'cross-talk' nuclear hormone effects and provide a new lead for the therapeutic application of these steroids in neurology and psychiatry.

PINEAL α-1D ADRENERGIC RECEPTOR mRNA: HIGH ABUNDANCE, DEVELOPMENT AND ADRENERGIC REGULATION. S.K. McCune*, S.L. Coto, D.E. Brentman and D.C. Klein. Section on Developmental and Molecular Pharmacology and Section on Neuroendocrinology, Lab. of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Adrenergic receptors mediate tissue responses to catecholamines. Binding studies have documented the presence of α-1 adrenergic receptors in the pineal gland and pharmacological studies have demonstrated a role of these receptors in the adrenergic regulation of many aspects of pineal function, including melatonin production. In an effort to better define α-1 adrenergic receptors in the pineal gland, α-1B adrenergic receptor expression was examined in situ hybridization and Northern blot analysis. Developmental expression of the α-1B adrenergic receptor subtype was determined by Northern blot and densitometric analysis of in situ hybridization of brain sections through the pineal as well as sections of individual pineal glands. A-1B receptor mRNA was highest in the early perinatal time periods and decreased with maturation. The abundance of mRNA encoding this receptor subtype in the pineal gland was extremely high as compared to brain and other tissues; a strong hybridization signal was detected on Northern blot with 2 µg of total RNA.

Pineal blots of pineal mRNA from day and night animals showed a 2.5-fold increase in the α-1B adrenergic receptor mRNA at night without a similar increase in the mRNA encoding Gα-PI2. This change is probably due to nocturnal adrenergic stimulation of the pineal gland, because in vitro stimulation of the pineal gland for 4 hours with norepinephrine (1 µM) induced a selective 2-fold increase in the abundance of α-1B adrenergic receptor mRNA.

The presence of high levels of α-1B adrenergic receptor mRNA in the pineal gland and evidence of neural regulation of expression make this tissue an excellent model for further analysis of this receptor subtype.

CRF is a 41 amino acid peptide first isolated and characterized in 1981 (Vale et al). CRF is part of a dynamic system which regulates central and peripheral components of the stress response (G1 and Nemeroff, 1991). Depolarization-induced, calcium-dependent release of CRF from fetal neural cultures of the amygdala has been previously demonstrated (Crafty and Birley, 1994). Fetal cell neurones (passage 6 of the cell line on glass coverslips (12-10 cells/slip)) yield a 5:1 mixture of neurons and glia after 15-18 h. Immunostaining with anti-neurofilament marker, anti-glial acidic protein and anti-glial fibrillary acidic protein (A-252/66) by CRF and GAD antibodies revealed a colocalization of CRF and GAD in amygdala. Furthermore, immunohistochemical characterization of these cells in culture demonstrates compartmentalization of neurons into clusters connected by a network of fiber bundles. The evidence points towards the amygdala maintained in the in vitro culture system. Supported in part by NSF (IBN-9222263).

**LEARNING DEFICITS IN TRANSGENIC MICE WITH CENTRAL OVEREXPRESSION OF CORTICOTROPIN-RELEASING FACTOR.** S.C. Hetherich, M.P. Strowig-Forsey, J.M. Gold, E. Battegay, F.E. Bloos, G.F. Koch, W.W. Vale, T. Milm. Phi. The Scripps Research Institute, Dept. of Neuropharmacology, 10666 N. Torrey Pines Rd., La Jolla CA 92037, 1Neurocine Biosciences, Inc., 3505 Science Park Rd., San Diego CA 92121, 2Oregon Health Sciences University, Dept. of Microbiology and Immunology, P.O. Box L220, 3181 Sam Jackson Park Rd., Portland OR 97201 and 3The Salk Institute, Clayton Foundation Laboratories for Peptide Biology, 1010 North Torrey Pines Rd., La Jolla CA 92037.

Transgenic (TG) mice with central overexpression of corticotropin-releasing factor (CRF) exhibited a Corticis Disease-like picture, elevated plasma levels of ACTH and corticosterone, increased behavioral reactivity to stressors and an anxiogenic-like state which is reversed by central administration of a CRF-antagonist. Moreover, centrally administered CRF alters learning/memory processes in animal behavioral models. In this study we have demonstrated that overexpression of CRF in transgenic mice may be associated with memory impairment and anxiety-like behavior. Supported in part by grants DK 26741 to WWV and GKF and by the Kleberg Foundation.

**PRENATAL STRESS CAUSES HYPERSECRETION OF CORTICOTROPIN-RELEASING FACTOR (CRF) FROM AMYGDALE.** M. Crans*, H. Ward, E. Johnson, A. Azzaro, D. Birley.

Dep'ts of Pharmacology/Toxicology, Behavioral Medicine/Psychiatry, and Neurology, West Virginia University School of Medicine, Morgantown, WV 26506.

The neurohypophyseal, corticotropin-releasing factor (CRF), has been found to be distributed throughout the central nervous system. CRF has a role in emotional and behavioral states including stress and anxiety. The amygdala, a limbic structure important in the delicate control of emotions and autonomic responses to stress, contains CRF nerve terminals and CRF receptors. We have examined CRF release from the amygdala of adult male offspring of dams exposed to daily saline injection (0.1 ml, s.c.) from G14 to G21. This prenatal stress model produces offspring that are hyperresponsive to stress (Ward et al, this volume). In light of the role of amygdala CRF release in anxious responses, we hypothesized that exposure to prenatal stress would increase CRF release from the amygdala. CRF release from amygdala slices (1 mm²) was time-dependent, depolarization-induced and calcium-dependent. There was a 32% increase in depolarization-induced CRF release from the amygdala of prenatally stressed rats. Prenatally stressed offspring also had an increase in the amygdala. The data suggest that CRFergic neurotransmission in amygdala is upregulated after prenatal stress, an effect that may contribute to the hyperresponsive state observed in these animals. Supported in part by NIH (2507RR05433-31 and GM07039) and UHA.

441.4

The central nucleus of the amygdala (CgA) is known to be involved in the regulation of the parsymaptic and parovative coping and stress-related responses to conditioned and acute stressors. Neuroanatomical studies revealed that the majority of the corticotropin-releasing hormone (CRH) containing neurons in the CgA have direct connections with autonomical regulatory nuclei in the hypothalamus. In this study we have used the Roman High Avoidance (SRA/verh) and the Roman Low Avoidance (RLA/verh) rats (kindly provided by P. Duricovic, Zürich) to examine the effect of CRH on the CgA in both a stress-free and a conditioned stress situation. The RHA/verh and RLA/verh rats are considered to use an active and a passive coping strategy respectively. A 7 min infusion of 30 ng CRH (in 0.5 ml aCSF) into the CgA of freely moving male RHA/RLA rats under acute-free conditions, led to an increase in heart rate and behavioural activation only in the RHA treated animals, leaving the RLA rats unaffected. This is in contrast with the conditioned situation in which only the RLA/verh males responded. These results suggest a differential CRH central amygdaloid control of the behavioural and physiological stress response in the two selective strains of rats. Subsequently experiments using CRH in nDNA and Fos immunochemistry are in progress to obtain further experimental evidence for a differential central amygdala CRH modulation in the RHA/RLA rats.

**CORTICOTROPIN-RELEASING FACTOR INFUSED INTO THE LOCUS COERULEUS INCREASES NORADRENERGIC RELEASE IN MEDIAL PREFRONTAL CORTEX.** Gennady N. Smagin, Artur H. Swiergiel, Glenn Guenther* and Adrian J. Dunn, Dep't of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Previous studies have indicated that intracerebroventricular administration of corticotropin-releasing factor (CRF), has been found to be distributed throughout the central nervous system. CRF has a role in emotional and behavioral states including stress and anxiety. The amygdala, a limbic structure important in the delicate control of emotions and autonomic responses to stress, contains CRF nerve terminals and CRF receptors. We have examined CRF release from the amygdala of adult male offspring of dams exposed to daily saline injection (0.1 ml, s.c.) from G14 to G21. This prenatal stress model produces offspring that are hyperresponsive to stress (Ward et al, this volume). In light of the role of amygdala CRF release in anxious responses, we hypothesized that exposure to prenatal stress would increase CRF release from the amygdala. CRF release from amygdala slices (1 mm²) was time-dependent, depolarization-induced and calcium-dependent. There was a 32% increase in depolarization-induced CRF release from the amygdala of prenatally stressed rats. Prenatally stressed offspring also had an increase in the amygdala. The data suggest that CRFergic neurotransmission in amygdala is upregulated after prenatal stress, an effect that may contribute to the hyperresponsive state observed in these animals. Supported in part by NIH (2507RR05433-31 and GM07039) and UHA.
**441.7** SENSITIZATION OF THE EXCITATORY EFFECTS OF VASOPRESSIN OR CORTICOTROPIN-RELEASING FACTOR ON THE ACOSTATIC STARTLE REFLEX BY VASOPRESSIN ADMINISTRATION TO RATS: A COMPUTERIZED APPARATUS. K. H. Hopper, Y. L. Levenson, W. S. Hodes, S. R. Brown, M. Davis. Dept. of Psychiatry, Yale University School of Medicine, 34 Park St., New Haven, CT 06510

In the rat, evidence now suggests a neurotransmitter function for arginine vasopressin (AVP). AVP, in its various autocrine, paracrine, and endocrine forms, can modulate aversively reinforcing stimuli. In this study we used a computerized apparatus to investigate the effects of AVP on the acoustic startle reflex in the rat. AVP (30, 100, 300, 1500 pg ICV) was infused on Day 1. On Day 2, 48 hours later, all animals were injected with a single test dose of AVP (300 pg ICV) and AVP was subcutaneously injected on Day 1. The results showed that 30 pg of AVP on Day 1 did not sensitize the effect of AVP on Day 2, but 300 pg ICV did (p<0.05).

Because stress is known to activate release of both AVP and corticotropin releasing factor (CRF) and ICV CRF is known to increase baseline startle, we wondered if AVP would also sensitize the excitatory effect of CRF on the acoustic startle reflex. To test this, various doses of AVP (3, 30, 300, 3000 pg) were infused ICV on Day 1. On Day 2, 48 hours later, all rats were infused with a dose of CRF (0.25 pg) that usually has no effect on baseline startle. The results showed a non-monotonic excitatory effect of CRF on startle, with the combination of 30 pg AVP/25 pg CRF showing a significant increase (p<0.05) over vehicle/vehicle or vehicle/25 pg CRF. The time course of the effect was similar to that usually seen when 1 μg of CRF is given ICV.

Taked together, these results show that a single infusion of AVP sensitized the excitatory effect of either AVP or CRF on the acoustic startle reflex, when given 48 hours later. This may provide a model system for analyzing how prior stress leads to enhanced reactions to subsequent stressors and dysregulation of the stress response.

The neurohypophyseal peptide oxytocin has been implicated in the mediation of several forms of affiliative behavior. Marked species and gender differences have been found in monogamous and polygamous rodents, suggesting that oxytocin may play a role in species-typical patterns of social behavior. Using in vitro receptor autoradiography with a selective oxytocin receptor ligand ([125]I-Chlg[5]Tyro(Me)2

**441.9** PROXIMAL SEPARATION FROM PUPS REESTABLISHES OXYTOCIN CONTROL OF MATERNAL BEHAVIOR IN EXPERIMENTAL RAT MOTHERS. C. A. Podreka, J.M. John, B. M. Faggin, G. Ayres and J. D. Caldwell. BIDC, Dept. of Psychiatry and Psychoendocrinology, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, N.C. 27599.

We previously reported that separating pups from the proximal separation (PS), a condition in which pups were isolated in small metal mesh cages within each dam's cage so that the dam could smell, hear and see but could not touch them, for 6 days beginning on Day 5 of lactation markedly depleted immunoreactive oxytocin (OT) neural cell bodies in many forebrain sites compared to rat dams subjected to total separation (TS) or no separation (NS) from pups. In recent studies, we found that all rats subjected to 4-6 days of PS (10/10) or NS (10/10), but only 4/11 rats subjected to TS, showed the increased OT levels observed in rats that had been given free access to pups (Fisherman's exact probability, p<.01). Injection of OT, an agonist peptide, but not normal saline, into the VTA (a site that receives projections of OT neurons located in the fornix) significantly inhibited the rapid emergence of retrieval and reaching behavior in dams subjected to PS for 4-6 days. In contrast, infusion of OTA into the VTA had no inhibitory effect on the emergence of retrieval and reaching behavior in dams subjected to PS for 4-6 days. Our behavioral pharmacological findings indicate that the increase in OT immunoreactivity that occurred in the rats subjected to PS is due to increased OT release. These observations also suggest that, shortly after parturition and the OT-dependent behavior of the dam, either OT or OT binding sites are necessary for the rapid rise in OT levels that are observed in rats subjected to TS.

**441.10** COLOCALIZATION OF OXYTOCIN (OXT) AND C-FOS IMMUNOREACTIVITY IN FEMALE HAMSTER BRAIN. D.C. Whitman* and H.E. Albers. Lab. of Neuroendocrinol. & Behav., Dept. of Biol., Georgia State Univ., Atlanta, Ga. 30303.

Central administration of OXT facilitates the expression of lordosis in rodents. In addition, central administration of an OXT antagonist reduces or eliminates gonadal hormone-stimulated lordosis. Since OXT appears to mimic the effects of progesterone (P) on lordosis, the present study tested the hypothesis that OXT influences lordosis by mediating the effects of P on lordosis. Double immunocytochemical techniques were used to examine whether OXT neurons also exhibit c-fos immunoreactivity (a marker of cellular activity) in the brains of OVX hamsters treated with estradiol benzoate (EB) (unmated), EB plus P (unmated) and EB plus P (mated). Preliminary analyses indicate that OXT- and c-fos-immunoreactivity were colocalized in the paraventricular and supraoptic nuclei of mated hamsters. The lack of c-fos immunoreactivity was not observed in either of the unmated groups. This study was supported by NSH 92-22099.

**441.11** POLYMORPHISM AND GENETIC MAPPING OF THE HUMAN OXYTOCIN RECEPTOR GENE ON CHROMOSOME 3 J. Hillander, E. C. Urbaneke, R. Peap and D. Goldman. Laboratory of Neurogenetics, National Institute of Health-National Institute on Alcoholism and Alcohol Abuse, Rockville, Maryland

Central administration of oxytocin has been reported to facilitate affiliative and social behaviors, in functional harmony with its well known behavioral effects on milk ejection. The biological effects of oxytocin could be perturbed by mutations occurring in the sequence of the oxytocin receptor gene, and it would be of interest to establish the position of this gene on the human linkage map. Therefore, we identified a polymorphism at the human oxytocin receptor gene. A portion of the 3-translated region containing a 30 bp CA repeat was amplified by polymerase chain reaction (PCR) and evaluated by electrophoresis, revealing a polymorphism with two alleles occurring with frequencies of 0.77 and 0.23 in a sample of Caucasian cephalic parents (n=70). The CA repeat polymorphism we detected was used to map the human oxytocin receptor to chromosome 3p25-3p26, in a region which contains several important gene families, including loci for Von Hippel-Lindau disease (VHL) and renal cell carcinoma.

**441.12** AN ANXIOLYTIC ACTION OF OXYTOCIN IS ENHANCED BY ESTROGEN IN THE MOUSE. M.M. McCarthy* & D. Goldman. Department of Physiology, University of Maryland, Baltimore, MD. and Laboratory of Neurogenetics, NIAAA, Rockville, MD.

The neuropeptide oxytocin exerts broad effects on social and affiliative behaviors and has been speculated to exert an anxiolytic action but this hypothesis has not been rigorously tested. In Experiment 1, NIH-Swiss ovxated mice were pre-treated with 10μg estradiol (E2) in oil or saline 24 hours prior to testing. Ten microliters of a combination of oxytocin significantly increased percent and total time spent on the open arms and the number of entries onto the open arms. The arms were decreased when oxytocin was co-infused with both E2 and E6-treated females. There was no effect on motor activity or head dips in the hole board apparatus in this experiment. Injection of oxytocin in NIH swiss males did not significantly alter behavior. Levels of activity were comparable to E2-treated females. In Experiment 2, NIH-swi-ovx’d females bearing in-dwelling cannula aimed at the lateral ventricle were pre-treated with E2 or saline and infused ICV with either oxytocin or vasopressin (40μg/saline) and behaviorally tested on the day post-inj. The percent and total time spent on open arms was significantly increased by oxytocin regardless of estradiol treatment and the percent and number of entries onto the open arms was increased by the combination of E2+oxytocin over all other groups. The combination of E2+vasopressin significantly decreased the percent time spent on the open arms compared to other groups. This combination in general exerted opposite effects to that of E2+oxytocin. There was an increase in time spent head-down in the hole board apparatus in E2-treated females but not in the vasopressin treated females. These findings indicate that oxytocin can act as an anxiolytic and that E2 enhances that effect. Furthermore, E2 may be exerting opposite effects on vasopressin, causing it to act as an anxiogenic. Brains are prepared for receptor autoradiography and results will be reported.
442.1 ASTROCYTES IN THE DEVELOPING MACAQUE MONKEY RETINA C. Gliond, C. Deuter and M.A. Kirby, Zoology & Neurobiology, Ruhr-University Bochum, 44800 Bochum, Germany. Department of Pediatrics & Div. Perinatal Biology, Loma Linda University, Loma Linda, CA 92350

In mammals, two types of macroglia are known to exist in the retina, Müller cells and astrocytes. While Müller cells are ubiquitous throughout the retina, astrocytes are only found in vascularized retina or vascularized retinal regions. It has recently been shown that there is an exception to this rule: in the paraventral region of the adult monkey retina macaque astrocytes or astrocyte-like cells exist even though this retinal region is heavily vascularized. To test if the paraventral region is astrocyte-free or at all stages of development or if it is secondarily deserted by astrocytes, we investigated the spatial distribution of astrocytes in fetal macaque monkey retinae using GFAP immunocytochemistry. Fetuses were obtained by Cesarian section under aseptic conditions, deeply anesthetized with pentobarbital and perfused through the heart with 3.4% paraformaldehyde. The retinas were dissected free and processed for GFAP immunocytochemistry as wholemounts.

At embryonic day 120 (term gestation is 165 days), i.e. shortly after formation of the foveal pit, a distributional pattern of astrocytes similar to that found in adults is evident. Astrocytes are found at all retinal eccentricsities with the exception of the paraventral region. Fetal astrocytes are small with delicate processes, but already adherent in their association with axon bundles and blood vessels and their segregation into two subpopulations, one to be found in the ganglion cell layer, the other in the nerve fiber layer. These data together with preliminary observations in even younger foeti (90D) suggest that the paraventral region of the monkey retina is avoided by astrocytes prior to the time of foveal pit formation.

Supported by grant Di 391/2-1 of the Deutsche Forschungsgemeinschaft to C. Deuter.

442.2 CHANGES IN RPTP-ß EXPRESSION DURING GLIAL CELL DIFFERENTIATION. P.D. Canoll, S. Petracecka, G. Barnes, J. Schiliesseringer L.M. Murphy and J.R. Green, Dept. of Pharmacology, N.Y.U. Medical Center, New York, NY 10016.

RPTP-ß is a receptor type tyrosine phosphatase that is expressed in glial and neuronal progenitors (Canoll et al., Dev. Brain Res. 75:293, 1993). Nucleotide probes to RPTP-ß were hybridized to three major transcripts on northern blot analysis. Two of the transcripts (9.5 kb and 7.0 kb) encode transmembrane glycoproteins which contain a carbonic anhydrase related domain, distinct extracellular portion and tandem phosphatase domains in the intracellular portion. The third transcript (8.4 kb) encodes a secreted chondroitin sulfate proteoglycan which contains the RPTP domain, but does not contain the intracellular phosphatase domains (Maurel et al. PNAS 91:2512, 1994). In situ hybridization and northern analysis show that the relative abundance of the 3 transcripts changes during brain development. During postnatal development, the 9.5 and 6.4 kb transcripts (transmembrane forms) are predominantly expressed in glial progenitors located in the preretinal subventricular zone. A similar transition in expression can be induced by treating glial cells with the differentiating agent dibutyryl cAMP. The different forms of RPTP-ß have very different structure, and most likely perform different functions. If this is true then changes seen during glial cell differentiation may relate to important changes in the role glial cells play during brain development and regeneration.

442.3 SCHWANN CELL EXPRESSION OF CD9 IS REGULATED BY NERVE CRUSH AND SUBSEQUENT REGENERATION. S.A. Banerjee* and P.H. Patterson, Division of Biology, Caltech, Pasadena, CA 91125.

CD9 is a 26 kd cell surface glycoprotein with four transmembrane domains that has been implicated in signalling in platelet activation, and is present in both the peripheral and central nervous systems (PNS and CNS). In the PNS, CD9 is expressed in several neuronal populations including the Schwann cells of the autonomic nerve. CD9 expression follows a developmental time-course in the nerve that closely parallels that of the myelin genes P0 and myelin basic protein. Here we report the response of CD9 following injury to the nerve. CD9 and P0 mRNA levels were analyzed following nerve crush in 30-day old rats. CD9 mRNA drops approximately 10-fold in the nerve distal to the crush, similar to the change in P0 mRNA. By two weeks following injury, when axons are known to be rapidly regenerating, CD9 and P0 mRNAs recover to levels slightly higher than those found in the normal adult. By 30 days, levels reach those found in the normal adult. A smaller, but transient response is also observed in the part of the nerve proximal to the crush.

These results suggest that Schwann cell expression of CD9, like P0 expression, requires the presence of axons. This would also be consistent with our observation that when primary Schwann cells are placed in culture, CD9 immunoreactivity is lost. We are currently investigating the role of axons on CD9 expression in cultured Schwann cells.

442.4 Human Fetal Spinal Cord Slice Cultures: A Model for the Study of Neurodevelopment and Neuropathology. W.E. Greer*, K.M. Weidenheim and W.D. Lyman, Department of Pathology, Albert Einstein College of Medicine, Bronx, New York, 19461.

Human fetal spinal cords are obtained from abortuses that range in age from 20 to 24 weeks of gestation. Spinal cords are stripped of meninges and cut into 80mm transverse sections. The slices are cultured on collagen-coated tissue culture inserts in chemically-defined media. Slices have been cultured for up to 28 days under these conditions. Histological and immunocytochemical examination of the cultures reveal the presence of neurons, oligodendrocytes, microglia, astrocytes, ependyma and endothelial cells. Indirect immunofluorescent confocal microscopy shows intact myelin basic protein positive sheaths around neurally-differentiated positive axons. These myelinated axons can be observed by summation of optical sections and span over 60µm. Additional evidence of active myelination during the culture period is observed by light and electron microscopy. Some axons contain mitochondria with distinct cristae and are surrounded by large inner loops of a myelinating oligodendrocyte process. Inner loops are found inside layers of compacted myelin.

After one week in culture, the slices are surrounded by an outgrowth of cells. The outgrowth area contains microglia, astrocytes, and oligodendrocytes as determined by morphology and immunocytochemical labeling. This culture system provides a unique model to study the development of the human central nervous system and neuropathologic changes that result from exposure to inflammatory cytokines, infectious agents such as HIV, drugs of abuse, or physical damage.

442.5 REGULATION OF TRANSFORMING GROWTH FACTOR ALPHA (TGFα) GENE EXPRESSION IN HYPOTHALAMIC ASTROCYTES BY METABOTROPIC GLUTAMATE RECEPTORS. Y.L. Ma*, F. Baze and S.R. Ogawa. Division of Neuroscience, Oregon Regional Primate Res. Ctr., Beaverton, OR 97006.

Excitatory amino acid (EAA) neurotransmitters influence the initiation of mammalian puberty by stimulating the secretory activity of neurons producing luteinizing hormone releasing hormone (LHRH). Evidence also exists that TGFα, a trophic factor of glial origin, contributes to this action via a paracrine mechanism involving glial production of eicosanoids. The functional relationships that may exist between these two regulatory systems are not known. Since glial cells are endowed with both ionotropic and metabotropic glutamate receptors, we have initiated experiments to determine if glutamate expression of the TGFα gene is subject to EAA-mediated regulatory inputs. Purified astrocytes from neonatal rat hypothalamus were exposed to glutamate receptor agonists including glutamate itself, N-methyl-D-aspartate (NMDA) and the metabotropic receptor agonists quisqualate and ACDP (aminoacyclopentane-1S,3R-dicarboxylic acid) (100µM each). Changes in TGFα mRNA levels were measured by quantitative reverse transcription-polymerase chain reaction at different intervals after initiation of the treatment (15 min 24h). The results showed that both glutamate and metabotropic receptor agonists, but not NMDA, rapidly upregulated TGFα gene expression (within 15 min exposure), with maximal mRNA values being reached between 8-16h. These initial findings suggest that hypothalamic astrocytes are targets for EAA acting via metabotropic receptors, and that EAA may represent one of the neuronal signals involved in the control of glutamate expression of the TGFα gene during development. Supported by NIH Grants HD25123, HD18185 and RR0163).

Acellular basal lamina (BL) allografts are known to exhibit reduced immunogenicity. It is also known, that the extent of host axonal regeneration through acellular BL grafts is reduced in comparison to cellular grafts. In the present immunogenicity study, isogenic (genetically identical) and allogeneic (genetically different) Schwann cell populated acellular BL grafts were transplanted into host rats to define their immunogenicity. Inbred strains of Fischer (FR) and Buffalo (BF) rats were used. Acellular BL grafts were pre-treated, by finite-diameter FR rat nerve. Acellular BL nerve were placed in dishes with cultured Schwann cells established from FR or BF rat naves. After 7 days, 2 cm long Schwann cells axonal regeneration and remodeling was created gap in the FR host peroneal nerve. Transplanted nerves were analyzed at 1, 2, 4 and 8 weeks later to determine their immunological fate and axonal regeneration through them with light microscopy. Acellular BL grafts populated with isogenic FR Schwann cells survived and were supportive of host axonal regeneration through them. On the other hand, acellular BL grafts with allogeneic BF Schwann cells underwent rejection and were unsuccessful. The results indicate that cultured Schwann cells continue to exhibit immunogenicity. In this study, it is indicated that isogenic Schwann cells to populate acellular BL grafts in attempts to enhance their axonal growth supporting function. (Supported by NIH Grant NS-24834.)
442.9 MICROGLIAL REACTIONS TO FOCAL RETINAL INJURY IN THE RABBIT. M.E. Humphries* and S. Moore, WA Retinas Pigmentosa Research Centre, Lions Eye Institute, Perth, Western Australia 6009.

As preliminary experiments to examine the role of microglia in retinal injury reactions, the microglia were labelled using nucleoside diphosphatase (NDPase) histochemistry following argon laser photocoagulation lesions in the peripheral retina in rabbits. At 2, 6, 24 and 48h, and 7, 14 and 21 days after photocoagulation, retinal lesions were made using a 100mW argon laser (200μm diameter) in pigmented rabbits, animals were anaesthetised, perfused and the retinas immersion fixed in 4% paraformaldehyde containing 8% sucrose and 5% DMEM. The next day the retinas were isolated and incubated at 37°C in cytidine diphosphate as a substrate, wholemounted and analysed. Normal retinas had microglia in the nerve fiber layer (NFL) the inner plexiform layer (IPL) and outer plexiform layer (OPL). The distributions were similar to those previously reported (Schnitzer, J. Comp. Neurol., 282, 1990, 779). Following lesioning the IPL microglia had processes pointing into the lesion by 2hrs and had migrated to leave a vacant zone around the lesion by 6hrs, this vacant zone was gradually filled by 7 days. The NFL microglia did not react until 7 days when they became aligned with degenerating axons between the lesion and optic disc. By 14 days these cells were no longer reactive but reactive cells were now found extending from the lesion to the periphery and by 21 days the reaction was largely over. The OPL contained increased numbers of microglia from 2hrs after lesion until 14 days but by 21 days the levels were reduced again. Thus, the microglia in each layer of the retina reacted in different ways reflecting the injury response of the other cells in each layer.

442.10 INTRACELLULAR CALCIUM REGULATION IN ASTROCYTES IN ADULT RAT SPINAL CORD PREPARATIONS. O. Theriault**, L.R. Mills*, University of Toronto Hospital and Playfair Neuroscience Unit, University of Toronto, Toronto, Ontario, Canada. M5B 2S.

We have previously described the presence of a metabolotropic glutamate receptor subtype (mGluR1α) on a subpopulation of astrocytes in the rat spinal cord (Theriault et al., 1993; Nature). The subpial location of these astrocytes is correlated with the characteristic region of tissue survival which follows traumatic spinal cord injuries (Theriault, 1993), and our electrophysiological studies demonstrate a neuroprotective effect of mGluR1 activation followed in vivo and in vitro (long-term culture; Theriault et al., in prep.). To determine the mechanisms underlying the neuroprotection, we have developed an in vitro preparation of the spinal cord. Adult female Wistar rats in anaesthetised, a thoracic laminectomy performed and a 200μm by 400μm strip of the dorsal columns was removed. The isolated strip was secured in a chamber and incubated in 95% oxygen-5% carbon dioxide for 100 minutes, using confocal microscopy we have examined changes in intracellular calcium ([Ca²⁺]i) levels of spinal cord astrocytes in response to kainate, and trans-ACPD. Real-time fluorescence in spinal cord astrocytes were increased two-fold following application of 100 μM kainate, and five-fold after ionophore. Interestingly, preliminary experiments with 100 μM trans-ACPD in uninjured cords revealed detectable changes in [Ca²⁺]i levels. Ongoing studies are examining [Ca²⁺]i regulation in clip compression-injured spinal cord preparations. Theriault et al. (93) 2nd Int. Neurotrauma Symp. July 4-9, Glasgow, Scotland; Theriault and Hampson, (1996) Soc. Neurosci. Abstr. 22, 748; Theriault (1995) 5th Int. Symp. Nerv. Regen.; Dec. 8-12, Ascona Conf. Cen. for P.

443.2 HOMOSYNAPTIC LTP AND PTP OF SENSORMOTOR SYNAPSES MEDIATING THE TAIL WITHDRAWAL REFLEX IN APlysia ARE REDUCED BY POSTSYNAPTIC CALCIUM-DEPENDENT HYPERPOLARIZATION. M. Curt and L.T. Wallace, Dept. of Physiology & Cell Biology, University of Texas Medical School at Houston, TX, 77225.

Tetanization of nociceptive tail sensory neurons (TNS) causes LTP of monosynaptic connections to tail motor neurons (TMNs) lasting >90 min in isolated ganglia (Walters & Byrne, JNeurosci 5:662, 1985). It was not known if this potentiation was homosynaptic or heterosynaptically mediated, but Lin & Glanzman (ProcSocLond, 255:113, 1994) recently showed clear homosynaptic LTP of sensomotor synapses in dissociated cell preparations. LTP in culture was blocked significantly by homosynaptic hyperpolarization during tetanization. As a first step in determining mechanisms and functions of homosynaptic LTP in defensive circuits, we have examined the dependence of TMN-TMN potentiation on TMN membrane potential in whole ganglia. After 2 baseline tests, half the TMNs were tetanized (10 x 0.4 ms trains, 25 Hz) each with the TMN at normal resting potential. The other half of TMNs were over-potentiated, that is, both tetanized and hyperpolarized, by the same amount, except that the TMN was hyperpolarized to -120 mV during the tetanus. EPSPs were then tested at 5 min intervals for at least 25 min afterwards. As shown in the graph, LTP in the ganglia was significantly reduced by TMN hyperpolarization during the tetanus (120% of baseline vs 70% of baseline at 25 min; t=6.77, p<0.05). Interestingly, LTP observed 1 min after tetanization was also reduced by TMN hyperpolarization (157% vs 24%, t=3.04 p<0.05). Observations of homosynaptic LTP in nociceptor synapses of Aplysia and rat (Randic et al., JNeurosci 13:S228, 1993) suggest that LTP (perhaps NMDA receptor-mediated) might be a primitive mechanism for storing memory of injury.
443.3
TEMPORAL SPECIFICITY OF HEBBN LONG-TERM POTENTIATION OF APLYSIA SENSORIMOTOR SYNECTES IN CELL CULTURE. X. Y. Lin and D. L. Glanzman*. Dept. of Physiological Sci., UCLA, Los Angeles, CA 90024.

Long-term potentiation (LTP) of in vitro Aplysia sensorimotor synapses can be induced by pairing brief stimulation of the presynaptic sensory neuron with strong depolarization of the postsynaptic motor neuron (Lin & Glanzman, Proc. R. Soc. Lond., B 255:943-950, 1993). This pattern of stimulation, which occurs during classical conditioning of the Aplysia withdrawal reflex (Carew et al., 1981, 1983), specifically presentation of the CS (weak stimulation of the siphon) and US (strong shock) yields brief sensory neuron activation together with strong motor neuron depolarization (Frost et al., 1988). Classical conditioning of the withdrawal reflex might therefore be mediated in part by Hebbian potentiation of sensorimotor synapses. However, Lin and Glanzman found that weak sensorimotor and postsynaptic stimulation to induce Hebbian LTP, whereas during behavioral conditioning the onset of the CS occurred 0.5 sec before the onset of the US.

We have systematically varied the interval between sensory neuron stimulation and motor neuron depolarization to investigate whether the induction of Hebbian LTP of in vitro sensorimotor synapses exhibits temporal specificity. The interval between pre- and postsynaptic stimulation was varied from -3.0 sec (the onset of motor neuron depolarization preceded the onset of sensory neuron stimulation by 5.0 sec) to + 5.0 sec (the onset of sensory neuron stimulation preceded the onset of motor neuron depolarization by 5.0 sec). We find that an intersensitive interval of +0.5 sec produces significant LTP of sensorimotor synapses. But the temporal specificity of Hebbian LTP for these synapses does not match that reported for the CS-US interval in conditioning of the reflex (Hawkins et al., 1986). Therefore, although Hebbian modulation of sensorimotor synapses may contribute to classical conditioning (see Murphy & Glanzman, 1994), other cellular mechanisms must also be involved.

443.5

Persistent activation of the CAM-dependent protein kinase (PKA), which occurs during the development of long-term presynaptic facilitation of the sensory-to-motor neuron synapses is required for the defensive reflex, results from proteolytic activation of regulatory (R) subunits. Persistence of kinase activity, which requires new protein synthesis, lasts for at least 24 hr. Hegde et al. (PNAS 90:4746) presented evidence that this protein synthesis is mediated by the APT-ubiquitin-proteasome pathway. Using a variety of subcellular fractionation and immunoechemical techniques, we find that both ubiquitin and the proteasome complex are abundant in all parts of the neurons: cell body, proximal and distal terminals. We predict that the degradation of R subunits is regulated by induction of some new proteins. Consistent with this idea, we find that an immediate early gene induction by PKA encodes a 25,000-molecular-weight protein with similarity to the L-type vertebrate ubiquitin C-terminal hydrolases (UCH). Peptide antibodies against the predicted sequence encoded by the Aplysia mRNA recognize an M, 29,000 protein, which, like vertebrate UCH, is expressed only in nervous tissue. Low molecular-weight UCHs are believed to process ubiquitin precursors to monoubiquitin. Nonetheless, we find this Aplysia UCH immunoreactivity to be associated with proteinase. Eytan et al. (JBC 268:1668) showed that high molecular-weight UCHs are associated with proteasomes and postulated that the ubiquitin chains cleaved from degraded proteins clog the complex, thereby slowing degradation. It is attractive to think that the low molecular-weight UCH (which we also find to be associated with proteasome in rat brain) also can enhance degradation. We are also looking for the induction of other proteins that might regulate subunit degradation during the development of long-term memory.

443.6
POSTSYNAPTIC MODIFICATIONS IN LONG-TERM FACILITATION IN APLYSIA: UP-REGULATION OF EXCITATORY AMINO ACID RESPONSES. L-E. Tradescant* and V.F. Castellucci. Lab. of Neurobiology and Behavior, ICRM, Univ. de Montreal, Quebec, H2W 1R7.

Long-term sensitization of the gill and siphon withdrawal in Aplysia is accomplished by facilitation of sensory-motor synaptic connections in the abdominal ganglion which depends on new protein synthesis. This phenomenon has been previously shown to involve presynaptic growth and an increase in transmitter release without any change in the size of miniature EPSPS. At the postsynaptic level, a reorganization of the motoneuron to the sensory terminal would be required to parallel the formation of new synaptic contacts. We show here that 24 hr after an application of S-HIT which produces long-term synaptic facilitation (LTF), the receptor L30 is immobilized to the postsynaptic complex. But acid agonist of the synaptic receptors is increased (day2/day1 = +64% +/- 11.9%, n=9). Inhibition of protein synthesis in the whole ganglion using anisomycin or limited to the postsynaptic neuron by injection of kainin, a ribosome-inactivating toxin, blocks this enhancement (+12.5 +/- 19.2; n=5) and -21.5 +/- 4.4%; n=6). The postsynaptic inhibition of protein synthesis however fails to block 24 hr LTF. These results show that long-term facilitation is independent of postsynaptic protein synthesis, the data are still compatible with a model of LTF that involves coordinate pre- and postsynaptic changes. The latter alterations may be initially independent of protein synthesis, but may gradually become dependent on transcription for stages of LTF lasting more than 24 hr. An increase in the number of functional postsynaptic receptors in a reserve pool may also prime the postsynaptic neuron for subsequent learning-associated plasticity. Funded by MRC of CANADA (MT-12099).

443.7

The synaptic growth that accompanies S-HIT-induced long-term facilitation of the defensive reflex is mediated by post- and pre-synaptic changes associated with cell culture. S-HIT is associated with a down-regulation of cell adhesion molecules (CAMs) on the surface membrane of the sensory neuron (Mayford et al., 1992). Down-regulation may be related to the activation of the extracellular pathway leading to internalization and apparent degradation of APcAM (Bailey et al., 1992). Which of the two types of isoforms is internalized, the transmembrane (TM) or the GPI-linked (GPI)-linked? To address this question, we have selectively expressed epitope-tagged constructs of the two isoforms in cultured sensory neurons. By combining thin section EM with gold-conjugated APcAM antibodies, S-HIT leads to a decrease in antibody labeling intensity (51 % vs. 2.2 ± 0.7% ± 0.011). By contrast, S-HIT has no effect on either the surface distribution (26±8μm ± 1.8 vs. 25.6 ± 2.4, n=6) or internalization (1.7 ± 0.5 vs. 2.2 ± 0.9) of the GPI linked form. These results show that S-HIT internalizes the TM form of APcAM, but not GPI-linked constructs. The TM form highlights the potential regulatory significance of its intracellular domain, which contains a PI3K motif (thought to target degradation) and has two conserved leucine-rich repeats (Kanai and Kandel, 1994). The availability of TM constructs with deletions of, or mutations in, the cytoplasmic tail should now allow us to determine which part of this module triggers internalization and which part targets degradation.

443.8
TAIL SHOCK DIFFERENTIALLY MODULATES TWO FORMS OF SYNAPTIC PLASTICITY IN INHIBITORY INTERNEURON L30 OF APLYSIA. T.M. Fischer* and T.J. Carew*. Yale University, Departments of Psychology and Biology, New Haven, CT 06520.

In the siphon withdrawal reflex of Aplysia, activation of the L30 inhibitory interneurons, either directly or by mild tail stimulation, produces significant long-term depression (LTD) and post-tetanic potentiation (PTP) of the L30 IPSP (Fischer and Carew 1993a,b). In the present study we describe the suppression of LTD in L30 by a modulatory stimulus, tail shock.

Siphon transmission L30 was measured as follows: (1) IPSPs were recorded in L30 following a baseline measurement; (2) S-HIT was directly applied to the isolated ganglia to reveal any post-synaptic currents (IPSPs) in L29 excitatory interneurons (voltage clamped at -85 mV). Following a baseline measurement, L30 was directly exposed to an S-HIT pulse (5 sec at 12 Hz) to potentiate the synapse. Two forms of L30 activity-induced plasticity were examined: (1) Frequency facilitation (FF), the enhancement of the L30 IPSP during intracellular activation at frequencies greater than last S and IPSPS in the train; and (2) post-tetanic potentiation (PTP), the additional enhancement of the IPSP following activation (measured 20 sec after the train). Prior to tail shock, the largest increase in the L30 IPSP occurred 20 sec following activation; PTP was three times greater than FF (P<0.05; 8). 50 sec following tail shock, the baseline IPSP was significantly reduced (P<0.05; P<0.05; also see Fred et al., 1988), yet the L30 IPSP was still significantly larger (P<0.05; compared to baseline) than the IPSPs observed before tail shock. PTP values were significantly different between FF and PTP (P<0.02). However, no significant enhancement of the IPSP was observed following activation: there was no difference between FF and IPSP (P=0.41). Tail shock thus appears to selectively suppress one form of plasticity, potentiation of the L30 IPSP following activation (PTP), while sparing another form (FF). Additional data indicate that tail-shock suppression of PTP may last at least 40 min. We are currently examining the cellular mechanisms of this suppression, as well as its functional consequences (see Blais et al., this volume).
443.9 

**HYPOSOMATIC DEPRESSION IN TAIL SENSORY NEURONS IS NOT THE MECHANISM OF HABITUATION OF TAIL-INDUCED TAIL OR SIPHON WITHDRAWAL IN APLYSIA. M. Stoecker, and T.J. Carew. Departments of Psychology and Biology, Yale University, New Haven, CT. 06520**

Hypoosomatic depression of sensory neuron (SN) output is considered a primary cellular event in several systems. We have examined the contribution of hypoosomatic depression in tail SNs to habituation of tail siphon withdrawal. An Aplysia tail siphon withdrawal was both direct and indirect SN input to tail motor neurons (MNs); and (2) siphon withdrawal, which has only indirect SN input to siphon MNs. In behavioral experiments, we used tail stimulation (ST) to significantly habituated both tail and siphon reflexes (p<0.01 in each case). In parallel cellular experiments, we examined progressively fewer action potentials in both tail and siphon MNs (p<0.01 in each case).

When tail SNs were repeatedly activated (SNs ISS) with intracellular pulses, significant hypoosomatic depression of the monosynaptic EPSP onto tail MNs was exhibited (p<0.01); depression did not generalize to other, non-activated SNs contralateral to the tail. Hypoosomatic depression of the same SN ISS was examined during behavioral training that caused significant reflex habituation (p=0.01); SNs activated by tail stimulation showed significantly facilitated output to tail MNs (R EPSP increase = 463%, p<0.05). SNs not activated by tail stimulation also showed significantly facilitated EPSPs (R EPSP increase = 365%, p<0.05), indicating that SN facilitation was heterosynaptic.

In summary, by using behaviorally relevant stimuli and simultaneously measuring reflex behavior, MN output, and SN output we found that, while the behavioral responses and MN output significantly decreased during habituation, SN output significantly increased. We are currently exploring whether (1) increased SN output onto inhibitory interneurons, and (2) increased inhibition and/or hypoosomatic depression at interneuronal sites contribute to habituation in these reflex systems.

**DISTINCT COMPONENT OF PRESYNAPTIC CALCIUM CURRENT IS INCREASED BY CYCLIC AMP AT APLYSIA SENSORIOMOTOR SYNAPSES IN CULTURE. M. Klein*, Lab. of Neurobiology & Behavior, Clinical Research Inst. of Montreal & Univ. of Montreal, Montreal, Quebec H3W 1R7, Canada.**

Synaptic augmentation of transmitter release by serotonin (5HT) at Aplysia sensoriornitor synapses can be mimicked by activation of adenyl cyclase and is blocked by 5HT receptor antagonists. We have previously identified in Aplysia sensory neurons a slowly-inactivating current that is enhanced by 5HT and is cyclic AMP-sensitive. We examined an Aplysia synaptic component that is rapidly-inactivating current that is reduced by FMRFamide and of the two, only the rapidly-inactivating component appears to participate in transmitter release caused by single action potentials under most conditions. Chlorophenyl-cyclic AMP augments synaptic currents at sensoriornitor synapses in culture and also causes an increase in a slowly-inactivating calcium current in the sensoriornitor neurons. However, this latter current differs from the major current modulated by 5HT in that it is not affected by dihydroxyphenylamine antagonists, and, unlike the current described earlier, is not blocked by H7, an inhibitor of protein kinase C in these neurons. The current modulated by the cyclic AMP analog is also not affected by FMRFamide. These findings thus raise the question of whether an increase in a cyclic-AMP-sensitive calcium current may contribute to the enhancement of transmitter release that occurs during synaptic augmentation by 5HT.

**LIKE LEARNED BASIS IN APLYSIA HEAD-VOIDING BEHAVIOR DUE TO ASSOCIATIVE OR NONASSOCIATIVE MECHANISMS. J. Chey, P.D. St. John, M. P. Gudino*, R. Wood. Boston University, Dept. of Cognitive and Neural Systems, Boston, MA 02215.**

A long term behavioral memory for the head-voiding behavior of Aplysia can be induced using flashed lights as an aversive stimulus (Cook and Carew, 1986, 1989). Coupling onset of the lights with a particular direction of head movement results in habituation away from that direction. This bias has been interpreted as a form of operant conditioning, and has been studied with a neural network model based on associative synaptic facilitation (Raymond et al., 1993). We have simulated a recurrent grid-like nonlinear dynamical neural model previously used to explain various data including oscillatory behavior in biological pacemakers. In our model two recurrent neural networks are independent of each other to generate oscillations, which drive the side-to-side head-voiding. Within each channel the frequency and amplitude of oscillations depend on transmitter mobilization dynamics, which exhibit both short- and long-term adaptation. We assume that light onset is increased in an onstate nonspecific to both sides of the diopli. Repeated pairing of onstate increments with activation of one side (the "painted" side) of the diopli caused a head-voiding behavior that is directionally dependent. This model provides a parsimonious explanation of the observed behavior, and it avoids some of the unexpected results obtained with the Raymond et al. model. In addition, our model makes predictions concerning the rate of onset and extinction of the biases, and suggests new lines of experimentation to test the nature of the head-voiding behavior. Supported in part by ARPA ONR N00014-92-J-4015, ONR N00014-91-J-4100, ONR N00014-92-J-1109, Sloan Foundation BR-3123, AFOSR FA9550-92-0449.
In an attempt to identify brain regions in which glutamate receptors may mediate memory impairments, we examined the effects of local application of a glutamate antagonist on the performance of pig-tailed macaques in a delayed nonmatch-to-sample (DNMS) task. Kynurenate, an antagonist at NMDA and non-NMDA glutamate receptors, was microinjected into various areas within the hippocampus, parahippocampal cortex and adjacent fields. We examined the effects of the drug on the performance of monkey trained to perform delayed nonmatch-to-sample with delayed response (DNMS) task. In this study, we have shown that the injection of kynurenate into the hippocampus, parahippocampal cortex and adjacent fields produced memory impairments, which were more pronounced in tasks that required spatial memory than in those that required temporal memory. These findings suggest that the glutamatergic system is involved in the processing of spatial information.
444.10 INTACT ARTIFICIAL GRAMMAR LEARNING IN PATIENTS WITH HUNTINGTON’S DISEASE: B.J. Knowlton, L.R. Squire, & N. Butters, V.A. Med. Ctr., San Diego, CA and Deps. of Psychiatry and Neuroscience, UCSD, La Jolla, CA 92039.

Artificial grammar learning appears to be an example of implicit learning. It is normal in amnestic patients and occurs independently of the medial temporal lobe memory system. Patients with Huntington’s disease (HD), who have striatal damage, are impaired in learning certain motor and perceptuomotor skills which are an example of implicit learning. We tested whether artificial grammar learning depends on the same kind of skill learning by testing patients with HD and 12 control subjects. During the study phase, subjects were shown 23 letter strings generated by a finite-state rule system. Each letter string was presented for 9 sec, and the subjects attempted to reproduce the item. The set of training items was then removed one item at a time, and the subjects were told that the training items were generated by a set of rules, and that their task would be to decide for a new set of items whether or not each adhered to these rules. This classification test consisted of 23 new grammatical items and 23 non-grammatical items. Performance by the patients on the classification test was not significantly different from the performance of the control subjects (69.3±2.6 vs. 84.3±5.6 correct). The patients were marginally impaired when asked to recognize letter strings that had been presented during the study phase (65.4±1.1 vs. 73.3±2.9 correct g=1). Artificial grammar learning appears to be unaffected by the striatal pathology and dementia associated with HD.

444.11 MEMORY CONSOLIDATION AND THE MEDIAL TEMPORAL LOBE: A SIMPLE NETWORK MODEL. F. Alvarez* and L.R. Squire. V.A. Medical Center, San Diego, CA 92161, Dyte, of Psychiatry and Neurosciences, UCSD, La Jolla, CA 92039, and Computer Neurobiology Laboratory, The Salk Institute, La Jolla, CA 92037.

Decade memory has been shown to depend on a system of medial temporal lobe structures that includes the hippocampus and the adjacent cortical areas (entorhinal, perirhinal and parahippocampal cortex). The role of this system is not fully understood, however, as shown by the fact that after damage to the medial temporal lobe, recent memories are impaired but remote memories are preserved. It has been suggested that the medial temporal lobe memory system is involved in a process of consolidation: memories that are initially dependent on this system gradually become established elsewhere. Previous network proposals for how interactions between the medial temporal lobe and neocortex may mediate consolidation have been presented, but they are often not explicit on many key points. We have attempted to synthesize a number of the existing ideas into a concrete proposal that can be implemented as a neural network model. We propose that a key role of the medial temporal lobe in memory is to bind together the different portions of a memory representation that are distributed over separate areas of neocortex. This binding is mediated by fast changes in the connections between medial temporal lobe and neocortex, and within the medial temporal lobe. The medial temporal lobe then directs the slower changes in the connections between neocortical areas that underlie consolidation. We show that a simple neural network model based on this proposal behaves in a way consistent with experimental observation. This model addresses several current questions about consolidation, and provides a reference point for further experimental investigation and a starting point for improved models.

444.12 SHORT TERM MEMORY FOR DURATION IN HYPOXIC SUBJECTS. R.D. Hopkins* and R.P. Kesner, Physiology, University of Utah, Salt Lake City 84112.

Previous research has demonstrated that an hypoxic episode can cause damage to the hippocampus as determined by volumetric MRI analysis. There are several ways in which temporal information can be represented in the brain, including temporal order and duration. Previous research has shown that hypoxic subjects are impaired for memory for novel linguistic and spatial temporal order information. Subjects who experienced an hypoxic episode and matched control subjects (N=9) were tested for short term memory for duration (STMD). The STMD task assessed memory for duration across a variety of delays. Subjects were presented with a single object (square, circle, etc.) on a computer screen, for a duration of 1 or 3 seconds. Subjects were instructed to remember the duration of presentation of the object. After a delay of 1, 4, 8, 12, or 20 seconds, the same object reappeared for 1 or 3 seconds and the subject detected if the object appeared for the same or a different duration. There were 48 trials which allowed for 8 observations for each interval. Hypoxic subjects were impaired relative to control subjects in short term memory for duration. In order to determine if the deficits were due to impaired memory for the items, instead of duration, a control task was developed. The same subjects were presented with a single object for a duration of 1 to 3 seconds and were asked to remember the object. After a delay of 1, 4, 8, 12, 16 or 20 seconds, either the identical object or a different object appeared on the screen. The subjects were asked to determine if it was the same object or a different object. No significant differences between hypoxic and control subjects were found on this task. These results suggest that hypoxic subjects are impaired for memory for duration information, but not for memory for single objects. Hypoxic subjects, with damage to the hippocampus, appear to be impaired in the temporal coding of information.

DEGENERATIVE DISEASE: OTHER I

445.1 TRINUCLEOTIDE REPEAT EXPANSION AND DRPLA (SMITH’S DISEASE): MOLECULAR CHARACTERIZATION OF ATROPHIN-1. R.L. Margolis*, S.H. Li, G.A. Ross, Laboratory of Molecular Neurobiology, Johns Hopkins University, School of Medicine, 720 Rutland Ave, Ross 615, Baltimore, MD 21205.

Smith’s disease (also known as dentatorubral pallidolysian atrophy or DRPLA) is a rare, progressive, fatal neurodegenerative disorder similar to Huntington’s disease. Smith’s disease is characterized by ataxia, choreathetosis, myoclonic epilepsy, dementia, and the genetic phenomenon of anticipation. A few cases have been misdiagnosed as ataxia with onset. Neuropathological findings include prominent cell loss in the dentate nucleus of the cerebellum, the globus pallidus, the red nucleus, and the subthalamic nucleus. An expansion of a CAG trinucleotide repeat encoding polyglutamine in a gene originally identified in our laboratory (CTG·879, Li et al, Genomics, 1993) has now been identified as the putative disease allele (Nagafuchi et al and Koido et al, Nature Genetics, 1994). Northern analysis indicates that the gene, which we have termed atrophin-1, is widely expressed as a 5 kb mRNA in human tissue. Translational sequencing of cDNA from healthy and mutant alleles indicates a transition of a alpha helix to beta pleated sheet. The mechanism by which this transition occurs and is subsequently propagated is unknown. We previously described two subtypes of prion diseases that share a single mutation, Asp to Asn, at codon 178 of the PrP, but are differentiated by a common Met/Val polymorphism at codon 129. We created transfectant cell lines expressing either normal PrP or PrP with the 178Met mutation to determine if the processing of the resulting protein was altered. We used a homologous system, the human PrP coding sequence and the human neuroblastoma cell line M17, to simplify analysis. Our findings show that the 178Met mutation results in an alteration of the metabolism of the prion protein. This work was supported by NIH grant AG-08992 and AG-08155.
Degenerative Disease: Other I

The fundamental event underlying scrapie infection seems to be a conformational change in the prion protein (PrP). Because changes in the conformation of PrP might require the participation of molecular chaperones, we examined the expression of heat shock proteins (Hsp) that are known to function as molecular chaperones in scrapie infected cells. Neither heat shock nor exposure to sodium arsenite induced Hsp synthesis in scrapie infected neuroblastoma (Scn2a) cells in contrast to uninfected, control neuroblastoma (N2a) cells. Constitutively expressed Hsp 73 was observed primarily within distinct, localized areas in the cytoplasm of uninfected cells, upon heat shock it dispersed throughout the cytoplasm and failed to be redistributed into the nucleus/microsomes. Hsp 73 was widely dispersed throughout the cytoplasm and was translocated into the nucleus/microsomes after heat in the N2a cells as observed for other cell types. While most of Hsp 73 could be removed following nonionic detergent extraction of the N2a cells, significant amounts of Hsp 73 remained within a detergent insoluble fraction of the Scn2a cells. These alterations in the stress response observed for the Scn2a cells may feature not only in the pathogenesis of the prion diseases but also in the formation of PrP*.

The prion protein (PrP) is a glycosylphosphatidylinositol (GPI) anchored membrane protein of unknown function. An abnormal PrP isoform, partially resistant to proteases, is a hallmark of prion diseases in humans and animals. Immunoblot analysis of normal human brains using antibodies specific to various regions of PrP has revealed the presence of truncated PrP forms. These fragments are not the product of autoxidation, since they were also present in neuroblastoma cells in culture. The most abundant of these fragments is N-terminal truncated and its size is comparable to that of full length PrP. This truncated form is also attached to the cell membrane through a GPI anchor, since it can be released from neuroblastoma cells in culture as well as from brain microsomal fractions by treatment with PIPCL. Our ongoing studies indicate that the relative amount and type of these truncated forms vary according to severity and type of pathology in brains from subjects with human prion diseases, such as Creutzfeld-Jakob disease and Fatal Familial Insomnia. Studies of these fragments may help understand the role of PrP processing in normal and pathological conditions. Supported by NIH grants AG-08155 and AG-08992.

445.5 IS THE APOLIPROPOTEIN E (APOE) Ɛ4 ALLELE OVERREPRESENTED IN DIVERSE NEURODEGENERATIVE DISORDERS (NDD)? J. A. Schneider, G. M. S., M. M.,* Dept. of Pathology and Laboratory Medicine, VA Med. Center & Emory University School of Medicine, Atlanta, GA 30322.

The allele of APOE overrepresented in late onset familial and sporadic Alzheimer's disease (AD) and other amyloid-associated disorders, e.g. Creutzfeldt-Jakob disease and amyloid polyneuropathy, have failed to demonstrate the same for Alzheimer's disease (Kalaria et al. 1993;49:170). We sought evidence of increased representation of the ε4 allele in ND that, like AD, are associated with increased age, neuronal loss, and cytoskeletal pathology. DNA was extracted from paraffin blocks or frozen tissue, and APOE genotype was determined using a polymerase chain reaction/resistase enzyme methodology. The presence of NDE progression to prion encephalopathy (PSP; n=17), Pick's disease (n=6), corticobasal ganglionic degeneration (CBGD; n=7), Parkinson's disease (PD; n=7), diffuse Lewy body disease (DLBD; n=1), multi-system degenerations (MSD; n=7), lobar atrophy without Pick body (n=2), and entorinal sclerosis (n=1). Coexistent AD pathology of varying severity was present in 16 of 48 ND cases. We found at least one APOE ɛ4 allele in 27 of 48 cases of ND (56%) as compared with estimates of 20-25% in the general population and 60-80% in AD (72% in our own series). When the 16 cases with coexisting AD were excluded, 15 of the remaining 32 ND cases (47%) had at least one APOE ɛ4 allele. The proportion of cases with the ɛ4 allele increased to 56%, when only those ND with neuronal cytoskeletal abnormalities or inclusions (PSG, Pick's disease, PD, DLBD, and CBGD; n=25) but without AD were analyzed. In the seven ND cases without concurrent AD or neuronal inclusions, however, an ɛ4 allele was found in only one case (14%). These findings suggest that the APOE ɛ4 allele is overrepresented in ND other than AD, particularly those with neuronal cytoskeletal abnormalities. Further genetic analysis of additional cases is needed to clarify the role of APOE in these diverse disorders. Supported by AG10310 and VA Merit Award.

Quantitative analysis of senile plaque (SP) number, size, and amyloid burden (percent of cortex covered by Aβ) in Alzheimer disease (AD) show that the amount of Aβ deposited correlates with APOE genotype, with APOE ɛ4 > APOE ɛ3 > APOE ɛ3/0. To test the hypotheses that this genotype effect is due either to differences in platelet-derived growth factor (PDGF) or in the kinetics of SP growth and dissolution, we used computerized image analysis techniques to analyze the size distribution of about 400 SP/case in the superior temporal gyrus of 42 AD cases. We discovered a remarkable homogeneity of size distribution that fits a log-normal curve. This size distribution profile suggests that SP growth is not dependent on time or simple surface area, but instead that the interior of SP may be available for Aβ deposition and resolution. Comparing the A8 measures among AD patients with different genotypes, we find increased total Aβ deposition with APOE ɛ4 but no difference in the size distribution curves among genotypes. This suggests that the major difference accounting for the larger amount of Aβ in APOE ɛ4 is formation and stabilization of SP nucleation rather than alterations in ongoing deposition of Aβ. Supported by NIH AG08487.

Increased risk of Alzheimer's disease has been associated with inheritance of different alleles of the apolipoprotein E (apoE) gene (apo4 > apo3 > apo2). The apoE isoforms differ by single amino acid changes in the receptor binding domain: apoE2 has two Cys, apoE3 one Cys, and apoE4 none. ApoE binds Aβ in vitro and immunostains senile plaques (SP). We previously found that an apoE receptor, the low density lipoprotein (LDL) receptor-related protein (LRP) also stains SP, and we proposed that apoE acts as a transport mechanism for Aβ. We have now studied apoE and LRP in CSF. Two new results are evident: 1) LRP is present in CSF, as a novel shed form of the receptor. This form appears to be extracellular, 2) the extracellular ligand binding domain but not the intracellular internalization domain of LRP. Second, in addition to being present as monomers, apoE2 > apoE3 exist as large complexes due to disulfide bonds forming homodimers and apoE4-β heterodimers; ApoE4 does not form these complexes. Because dimers may bind receptors less well than monomers, this difference may be of biological importance.

Copper zinc superoxide dismutase (SOD1) is involved in neutralizing free radicals within cells and has recently been shown to be defective in some familial ALS cases. In this study, we have analyzed SOD1 in sporadic ALS with activity assays and immunocytochemistry. We found no difference in extracellular or intracellular activity between ALS cases or controls. Spinal cord sections from 6 ALS cases, 1 primary lateral sclerosis (PLS) case and 1 control case were stained using 3 different antibodies to SOD1: since astrocytes are involved in neutralizing free radical damage, antibodies to glial fibrillary acidic protein (GFAP) and vimentin were used as independent markers of astrocytes. Our three principal findings from localizations are: 1) ALS spinal cord displayed a reduction or absence of SOD1-reactive astrocytes, compared to the control and PLS cases, and 2) examination of GFAP-stained sections showed that the reactive astrocytes were in the lateral tracts and ventral white and gray matters in ALS and PLS cases, there was a close relationship between astrocytic processes and motor neuron soma. In the control case, which we stained in the A54310 cases and confirmed with morphometry. 3) Vimentin-positive astrocytes were found either in the lateral tracts or in the ventral white matter or in both, in all ALS cases; the case of PLS had none. We conclude that an absence of detectable SOD1 in subpopulations of spinal cord astrocytes and alterations of the motor neuron-glial relationship may play an important role in ALS.

Free radicals have been implicated in several neurodegenerative disorders, such as Alzheimer's disease, Huntington's disease, and more recently amyotrophic lateral sclerosis (ALS). Reduced activity of superoxide dismutase (SOD), an enzyme that protects the cell against free radical oxidative damage, has been detected in serum of ALS patients. We have determined the levels of erythrocyte SOD activity in 29 ALS patients, 20 healthy controls and 13 normal controls by a spectrophotometric assay. We found that erythrocyte SOD activity was significantly reduced (P<0.05; p=0.041) in both SALS (mean ± SEM, 934.88 ± 61.54 U/mg protein, 19%) and FALS (329.88 ± 0.00 U/mg protein, 49%) patients compared to controls (1615.7 ± 70.02 U/mg protein). Values of SOD activity measured in both controls and FALS are closely clustered around their respective means. In contrast, in SALS the distribution of SOD activity seemed to be in two clusters: one in the range of normal activities (n=18, 1139.66 ± 55.33 U/mg protein) and a second (n=11, 599.80 ± 55.33 U/mg protein) close to FALS values. Although, additional investigation is required to clarify the underlying mechanism responsible for the diminished distribution of SOD activity in ALS as well as for the reduction in SOD activity in some of these patients, our data support the hypothesis that free radicals may play a role in the sporadic form of the disease.

Huntington disease (HD) is a genetic neurodegeneration that preferentially affects the striatum. Patients with Huntington's disease appear hypometabolic with large caloric requirements, atrophy of body fat and muscle. We have searched for a neurochemical evidence consistent with a generalized metabolic defect.

H nuclear resonance spectroscopy demonstrated that persons with clinical Huntington's disease have elevated lactate levels in striatum and occipital cortex. Persons with HD are asymptomatic but genetically positive have normal lactate levels in the occipital al cortex; but lactate may be elevated in striatum. Photic stimulation caused a 3 fold increase in occipital lactate in controls but a decrease of occipital lactate (50% decrease) in HD. 12/14 HD pts treated with abequoline demonstrated a lowering of occipital lactate (29% decrease). In some, treatment with riboflavin/nicotinamide also lowered brain lactate levels. Blood lactate or pyruvate levels were normal. CSF lactate/pyruvate ratios were mildly elevated (12.67±0.38 HD vs 15.82±1.93 controls). Ratios of resting organic/inorganic phosphate measured by MRS in calf muscle are decreased in HD affected (6.5±0.14 HD vs. 9.8±1.4 control).

Many of these abnormalities occur in patients with known mitochondrial disorders. We hypothesized that elevated lactate may be a measure of a pathologic metabolic strain leading to neuronal death and pharmacologic strategies which lower lactate might slow the neurodegeneration.
446.5 PREFERENTIAL EXPRESSION OF MEFC2 IN INHIBITORY INTERNEURONS IN HUMAN CEREBRAL CORTEX. D. Leifer* and K. Wehr. Dept. of Neurology, Yale University School of Medicine, New Haven, CT. MEFC2 (erythrocyte-specific enhancer binding factor 2C) belongs to the MADS family of transcription factors, is expressed in muscle and brain, and activates transcription by binding to the MEFC2 element, a DNA regulatory element essential in certain genes expressed in muscle and brain (Leifer et al., PNAS 1993; 90:1546-50). MEFC2 is present at high levels in the cerebral cortex where it is found in post-mitotic neurons that have migrated to the cortical plate. We have now studied MEFC2 in human brain samples resected during surgery for intractable epilepsy. Strongly MEFC2-immunoreactive (IR) nuclei occur predominantly in layers II, IV, and VI, and are also scattered in layers III and V, whereas more numerous weakly reactive nuclei are found. Some MEFC2-IR nuclei are present in layer I. Many of the strongly MEFC2-IR cells that predominate in layers II, IV, and VI are also strongly MEFC2-IR cells in layers III and V and are also labeled with antibodies against parvalbumin or calbindin, calcium-binding proteins found in GABAergic inhibitory interneurons. These cells have a variety of non-pyramidal morphologies. Many of the weakly MEFC2-IR nuclei in layers III and V are in pyramidal cells, as determined by double labeling with SMI-32, a monoclonal antibody against nonphosphorylated neurofilaments found in pyramidal cells. These results indicate that the level of MEFC2 immunoreactivity correlates with neuronal size and that strong immunoreactivity is present in inhibitory interneurons. The level of MEFC2 expression may therefore have a role in regulating genes that control neuronal phenotype.

446.7 CLONING AND CHARACTERIZATION OF RAT PBX1, A HOMEO GENE DEVELOPMENTALLY REGULATED IN THE CNS. M. Morinobu*, S. Hockfield and L. Redmond, Section of Neurobiology and Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510 In CNS development a homogeneous neuroepithelium gives rise to a multitude of cell types as the result of cell proliferation, differentiation and migration. The regulation of these processes is controlled by many genes whose expression is both temporally and spatially restricted during development. This specificity of expression is presumed to result from the expression of transcription factors. Recently a novel group of human homeobox genes, PBX1, 2 and 3, have been identified. They show a high level of divergence from previously reported homodomain, and only 36% identity to yeast MAEl. Expression of PBX genes was analyzed using an antibody library in searching an embryonic CNS at embryonic day 18 (22.5h) brain (Monica, et al., 1991, Mol. Cell. Biol. 11:6499-6517). To characterize the expression of PBX1 in the mammalian CNS and to investigate its putative role in nervous system development, the rat homologue of PBX1 was cloned by PCR amplification from an adult rat brain library using synthetic oligonucleotides. The clone obtained was used in Northern and in situ hybridization analysis of embryonic and postnatal rat brains. Both studies revealed expression of rat PBX1 in the CNS over the course of embryonic and postnatal development. Rat PBX1 expression is observed in the CNS at embryonic day 15 (E15), peaks in expression postnatally, and is subsequently down regulated in the adult. Rat PBX1 is detected in the cortex at all ages and in the olfactory bulb postnatally. Several structures in the midbrain, diencephalon and cortex show transient expression during development. The temporal and spatial pattern of expression of rat PBX1 mRNA suggests a role for this homodomain protein in mammalian brain development. (Supported by NS28807 to SH)

446.8 MOLECULAR CLONING OF CHICK BRAIN-3.0 AND THE DISTRI BUTION OF ITS RNA DURING DEVELOPMENT OF THE CHICK NERVOUS SYSTEM. Jonas Lindberg, Ioke Williams, Anders Håckström*, Finn Hallbäck and Ted Ebenhald, Department of Developmental Biology. Box 587. Uppsala University, S-751 23 Uppsala, Sweden. Brn-3, a member of the POU transcription factor family, is mainly expressed at high levels in sensory neurons and retina. We wanted to isolate the chicken homologue of rat Brn-3, investigate its mRNA expression pattern development and to examine possible correlation between Brn-3 mRNA and the expression of the neurotrophin high-affinity Trk receptors. Using degenerate oligonucleotide primers and PCR we isolated the chicken Brn-3.0 from spinal ganglia cDNA. This fragment was then used to screen cDNA libraries and a chicken genomic clone in order to get the full length sequence promoter and gene structure. In situ hybridization histochemistry was performed on consecutive sections using probes specific for the detection of mRNA for Brn-3.0 and for the neurotrophin high-affinity receptors. Brn-3.0 was expressed within neurons of many of the cranial ganglia, specifically localized to neurons that project to the spinal cord. In the spinal ganglia expression is strongest in the dorsal root ganglia. Immunoreactivity for the Trk receptor was predominantly found in sensory neurons derived from the spinal cord. Brn-3.0 expression was mainly localized in sensory neurons derived from the spinal cord. The expression of Trk mRNA appears to decrease with age, no decrease in the expression of Brn-3.0 was observed. At the earliest stage examined (stage 11) Brn-3.0 mRNA expression was quite strong in the presumptive neuroblasts migrating from the trigeminal placode, whereas the expression of trkC mRNA was just beginning. This indicates a possible influence of Brn-3.0 on trkC expression in trigeminal placode derived neuroblasts.

446.9 THE REGULATION OF NESTIN EXPRESSION. R. McKay*, T. Hayes, R. Jin*, K. John, O. Brustle, T. Hazl, C. Vicario, S. Josephson, and S. Hockfield. *Yale University School of Medicine, New Haven, MD 20822; #Physiology & Biophys., Hahnemann U., Philadelphia. Expression of the intermediate filament protein nestin is characteristic of stem cells in the mammalian CNS. This conclusion is based on extensive in vivo analysis of the expression of both the endogenous protein and the identification of a tissue specific enhancer in the nestin gene. Nestin is down-regulated in primary cultures of hippocampal cells that differentiate to express neuronal markers. Nestin is also expressed in glial precursor cells. In the adult brain, re-expression of nestin has been observed in reactive astrocytes and in neuroepithelial tumors. We are currently focusing on the identification of regulatory sequences controlling nestin expression. Both gel shift analysis and the generation of transgenic mice are being used to determine whether the same DNA elements are regulating transitions in nestin expression in different cell types. The identification of these regulatory elements in the nestin gene will establish whether the expression of nestin in different cell types reflects the action of common mechanisms.

446.10 RESTRICTED CLONAL ALLOCATION IN THE CHIMERIC MOUSE BRAIN. C. Ruan1, E. Elliott2, R. Leveson3, R. Fawell4, and P. Rakic1. 1Sect. Neurobiol., 2Sect. Immunobiol., 3Dept. Cell Biol., Yale School of Medicine, New Haven, CT 06511 Lineage analysis in Drosophila wing development revealed restricted clonal allocation and led to the concept of compartmentalization. Whether similar principles apply for embryogenesis of the vertebrate nervous system remains an issue under debate. Here we address this issue by examining distribution of clonally related cells in chimeric mouse brains. Stable transduced embryonic stem (ES) cells were generated to express lacZ gene driven by chick beta actin promoter as lineage marker. Mouse brains were generated by implanting ES cells that express with such lacZ(+) ES cells, transferred to foster mother mice, bred to term and sacrificed at postnatal day 10 for examination by X gal histochemical staining. Although X-gal positive ES cells were intermingled with X-gal negative cells in the chimeric brain, the overall distribution was not random but highly regionalized. Each animal exhibited a distinct subset of X-gal(+) cells, and within each colonized structure the density of marked cells could be highly enriched in specific regions. Furthermore, a bilateral symmetry in distribution and density of X-gal(+) cells was a prevailing feature in all examined animals. Thus, for example, when a group of X-gal(+) cells were located in the CA2 region of hippocampus or in a subcortical nucleus, a mirror image distribution was also observed on the opposite side. The data together, the regionalized and bilaterally symmetric distribution of clonally related cells in chimeric mice suggests a restricted and precise clonal allocation exists in the vertebrate nervous system.
EMX2 IS SELECTIVELY EXPRESSED IN GERMINAL NEUROEPITHELIUM OF DEVELOPING DORSAL TELENCEPHALON OF THE MOUSE. M. Giuffrida1,2, V. Broccoli1 and E. Bosco11. 1Dib, Scientific Institute H San Raffaele, Via Olgettina 60, 20132 Milano and 2Istituto di Biologia Generale, Universita di Catania, 95124 Catania, ITALY

We recently cloned two vertebrate homeobox genes, Emx1 and Emx2, related to empty spiracles, a gene controlling very anterior body regions during Drosophila embryogenesis. Both vertebrate genes are expressed in the brain of mouse embryos. They are expressed in the embryonic cerebral cortex in a developmental period, day 10 and day 16 post coitum, corresponding to major events in cortical neurogenesis. In its full extension, days E12.5 to E13.5, their expression domain comprises cortical regions including promordia of neopallium, hippocampus and parahippocampal archipallium. In particular, Emx1 expression seems restricted to cortical regions, mainly in the olfactory cortex. Emx2 expression is also observed in some embryonic neuroepithelial planes includingolfactory placodes and olfactory epithelia. We have now studied in detail their expression pattern in relation to cortical neurogenesis in E12-E16 mouse embryos. Preliminary data show that Emx2 is expressed in germinal neuroepithelium but not in the cortical plate nor in the so-called transition field. Conversely, Emx1 is expressed in both the neuroepithelium and the transition field.

Our previous studies showed that in explant co-cultures, retinal axons from embryonic tectum, embroyonic retina, and posterior tectal slices prepared from animals of all ages, including adult, however, retinal axons reveal different patterns of growth when challenged with tectal axons from animals of different ages. In embryonic tectum, embroyonic retina were almost exclusively very little branching; whereas in postnatal and adult tectum, significantly more ramifications are observed. In order to further characterize the growth of embryonic retinal axons in targets of different age, we have used time-lapse video microscopy to examine the morphology of retinal growth cones as they encounter and begin to invade target tissue. Explants of retinas and tectum were maintained in serum free medium for 15-72 hr. Crystals of DII were placed in the retina 10 hr prior to the beginning of observations. Images of labeled retinal axons were recorded on a low-light video camera every 2 min for a period of 5-8 hr. In general, fibers from E14 retina growing into E14 tectum have simple growth cones which form swellings at the tip of the axons and have few filopodia. Significantly more growth cones were seen extending along other labeled axons than in the older tissue. When retinal explants were co-cultured with postnatal or adult tectum, the growth cones were typically larger (2-5 times those in embryonic tectum), more lamelated, and had longer, more numerous filopodia. Over the 8-hr observation period, some filopodia were observed to stabilize and become collaterals on trunk axons once the growth cone moved ahead. Our results suggest that the interactions between axons and growth cones are affected by the axon-target interactions and the spatial configuration of the target tissue.

44.4 CELL LINEs GENERATED FROM AVIAN EMBRYONIC RETINA BY ONCOCONE-TRANSFERENCE EXHIBIT MATURE GANGLION CELL CHARACTERISTICS AND RESPONSE TO POSITIONAL CUES OF TECTAL MEMBRANES IN VITRO. G. E. Potterberg,* C. Kuechel, B. Eichhorst, M. Zenke, H. Beug & J.U. Schwartz, Dept. of Developmental Biology, D-72076 Tübingen, Germany

We generated cell lines by transfecting quail embryo retina with a retroviral construct containing v-myc into the hormone-binding domain of the estrogen receptor, allowing for the activation of the chimeric protein by estradiol. The oncogene myc was chosen because of its proliferation-inducing capacity and differentiation compatibility. The induction was performed by cocultivation of virus-producing, proliferation-incompetent fibroblasts with avian embryonic day 3.5 quail eyes. In these organ-cultured retinae, cells proliferate and differentiate within a time span of less than 20 hours, a prerequisite for both the generation of stable as well as neurally differentiated cell lines. The transected neuroneuropilues were aspartated into nasal and temporal parts, dissociated, and kept as single-cell cultures. Individual cell colonies were isolated and expanded; these cell lines have been maintained in culture over 6 months with a doubling time of approximately 20 hours and can therefore be considered immortal.

Spontaneously differentiating cells were observed within the cell line cultures, exhibiting morphological features of mature retinal neurons in vitro. Some of these differentiated cell lines displayed the morphological characteristics and marker expression of mature retina ganglion cells. The differentiation rate could be substantially increased by the addition of retinol acid on basic fibroblast growth factors. These differentiated cells maintained functional properties of ganglion cells as revealed by a substrate choice assay. When confronted with substrate stripes of membrane vesicles prepared from target and non-target parts of the tectum, the axonal processes of temporal lines preferred to grow on target stripes, indicating that the cell lines will be useful for the investigation of mechanisms underlying axon-target interactions.

44.5 GROWTH PATTERNS OF CHICK RETINAL AXONS IN RETINA-TECTUM COCULTURES. Stefan Meyer,* Friedrich Rumberler, Max-Planck-Institut für Entwicklungsbiologie, Spemannstrasse 35L, 72076 Tübingen, Germany.

During retinotectal map formation in the chick, growth of temporal axons is restricted to the anterior half of the tectum, whereas nasal axons invade the posterior tectum (Nakamura & O'Leary, 1989). Inspection of a temporal zone is achieved by sidebranch formation and subsequent elimination of overshooting parts of the axon. It is assumed that a repulsive guidance molecule (RGM) is expressed predominantly in the posterior tectum prevents growth of temporal axons into this region (Walter et al., 1987).

In order to investigate axonal growth and branching in vitro, we developed a co-culture assay of retinas with tectum. DII-labeled pieces of retina were cultured together with a piece of anterior and posterior tectum on opposite sides in a collagen matrix. Growth patterns of labeled axons were investigated after 48 hours or continuously by using time lapse video microscopy. As in vivo, temporal axons did not invade anterior tectum, but grew and branched in anterior tissue. Nasal axons grew into and branched in both tissues. These results indicate that failure of temporal axons to invade the posterior tectum is linked to repulsive molecules and not due to attraction by the anterior tectum. When cGMP-gated retinal cells were cultured with the enzyme PI-PLC, temporal axons could invade posterior tissue. This is consistent with the earlier findings by Mee & Cipri. In a different paradigm, both tectal pieces were placed on one side of the explant. Thus, axons first grew through anterior tissue before they reached posterior tissue. We found that axons grew to the anterior tectal piece, whereas nasal axons continued to grow into posterior tissue. Time lapse analysis revealed that temporal growth cones collapsed after they reached the A-P border. We are presently investigating whether such encounters with repulsive tissue can also lead to the formation of new sidebranches at a distance from the growth cone.

44.6 MOLECULAR CHARACTERIZATION OF REGGIE-ANTIGEN: A GROWTH ASSOCIATED CELL SURFACE PROTEIN IN THE RETINOTECTAL SYSTEM OF GOLDFISH T. Schuh,* P.Lottspeich* and C.A.O. Stuermer* Faculty of Biology, University of Konstanz, & MPI for Biochemistry, Munich, Germany. Retina-Antigen, which could be blocked by the monoclonal antibody M802, was identified as a cell surface protein appearing on goldfish retinal ganglion cells (RGCs) during the first 8 hours after optic nerve transection (ONS) (Paischle and Stuermer, Soc. Neurosci. Abstr. 1991). In addition to its expression on RGCs and regenerating RGC axons, Reggie antigen is also found on cells lining blood vessels in the CNS and on microglial cells in the injured optic nerve. Reggie-Antigen was purified by immunoadsorption chromatography with M802 from total membrane fractions of adult goldfish brains and from total larval goldfish (age: 30-60 d). In SDS PAGE the immunospecific protein has an apparent molecular weight of 48 kD from total membrane fractions of adult goldfish brains and from total larval goldfish (age: 30-60 d). We have cloned a complete cDNA fragment coding for part of the Reggie-Antigen. It was obtained by PCR using degenerate oligonucleotide primers derived from internal peptide sequences of the immunospecific protein. So far the CDNAs clone and the peptide sequences show no homology to known proteins. Anchored PCR strategy as well as CDNAs library screening is now being performed to obtain a full length clone.

We studied, after placing a crystal of DII (fluorescent marker) in an experimental eye, the retinogeniculate pathway at 0, 3, 7 and 15 days of postnatal development in the C57BL/6 mouse. We used controls and animals which were macroscopically and microscopically naive or deafferented at birth. Results show that, in the controls, the map of visual projections in the dorsolateral geniculate nucleus is present at D7. Deafferentation causes the loss of this map and an increase in ipsilateral visual projections. Until D7, the retinofugal fibres present many varicosities which thereafter start to regress and at D15 become more mature. These varicosities, which are observed on animals treated with a free radical scavenger (EGB761, IEPSEN). It seems that at D7, the varicosities on the fibres are slightly more numerous ; the same for the pericellular collateral fibres of the superficial optic tract.

447.9

TYROZINE PHOSPHORYLATION AT FILIPODIAL TIPS OF VERTEbrate GROWTH CONES

We have previously reported that phosphorylation is concentrated at filopodial tips of Aplysia growth cones, suggesting a role in regulating filopodial function. We have now used immunochemistry and phosphorylation studies at filopodial tips of the growth cones of several types of cultured vertebrate neurons: neonatal rat hippocampal neurons, embryonic chick retinal and sympathetic ganglion neurons, and retinal ganglion cells. Accumulation of phosphorylation at filopodial tips was sensitive to the culture substrate. Increasing the density of laminin on the substrate increased neurite outgrowth from mouse retinal ganglion cells, but decreased the percentage of filopodia displaying strong tip phosphorylation. Concentration of phosphoryryosine at filopodial tips and its sensitivity to the substrate suggest the potential importance of phosphorylation in pathfinding decisions.

To identify proteins associated with phosphoryryosine in filopodial tips, we double-stained growth cones with antibodies to phosphor-tyrosine and each of several proteins known to associate with actin filaments and to be substrates for tyrosine phosphorylation. Contactin, integrin and ezrin (or a component) frequently co-localized with phosphor-tyrosine. Tensin, vinculin and Paxillin were at tips and associated proteins found at focal contacts, were observed in lamellipodia around cell bodies, but not in growth cones.

447.11

The establishment of precise retinal connectivity during development is essential for the retina to transmit visual information. The factors that regulate convergence and divergence during development between bipolar, amacrine, and retinal ganglion cells (RGCs) are poorly understood. We have manipulated RGC density and availability of pre-synaptic tissie to examine their effects on the development of RGC dendritic arbors.

Visual field deprivation induces ocular enlargement, producing a larger than normal retinal area and a reduction in RGC density by 20-30%. Peripheral optic nerve section produces areas of RGC depletion with a mean reduction in density of 64%. In the former case, the ratio of pre-synaptic cells to RGCs remains constant, while in the latter the ratio is increased. This contrast allows us to separate the effects of RGC density from pre-synaptic area on RGC dendritic field size and area complexity.

In experimentally enlarged retinas, RGC dendritic arbors expand with ocular area in a compensatory manner that is consistent with simple stretching; arbor area was about 30% larger than normal, branch density was decreased, and arbor length was about 14% longer than normal. In RGC-depleted retina, dendritic fields of RGCs are larger than controls but do not fill the space available. Branch density of RGC dendrites in RGC-depleted areas is greater than in controls.

We conclude that both local RGC density and the availability of pre-synaptic terminal control RGC dendritic size and complexity. The limited growth of the RGC dendritic fields in areas with large space availability, together with the increase in arbor branches per unit area, suggest that pre-synaptic input is important in the shaping of RGC arbors postnatally.

During divergence of retinal axons to both sides of the brain, both crossed and uncrossed filaments initially travel towards the midline for a period of several hours, and either cross the midline or turn back to ipsilateral optic tract, respectively (Godement et al., J. Neurosci., in press). To investigate how growth cones detect cues and which of several potential cues in the midline provide those cues, we analyzed the behavior of retinal growth cones from dorsal or ventral temporal retinas (source of crossed and uncrossed fibers) as they interact with chiasmatic tissue in vitro by video microscopy and DIC optics. When axons grow on a polylysine/laminin substrate, they advanced rapidly and had long lamellipodial extensions. Within 50 microns of a chiasm cell, growth cones slowed and became more filopodial. After filopodial contact, all growth cones paused in advance, with a single filopodium attached to the cell. Subsequently, the behavior of the two sets of growth cones differed. Uncrossed growth cones displayed a greater degree of collapse, did not grow onto the cells, and took longer to turn away from the cells. Retrospective immunocytochemistry will indicate the extent to which neural and non-neuronal chiasm cells inhibit uncrossed growth cones.

To further characterize the intracellular machinery in detection of cues, we are investigating filopodia-specific phosphoryryosine by using retrograde immunocytochemistry of identified growth cones and antibodies to phospho-tyrosine to elucidate the detection and sources of cues leading to retinal axon divergence.

DYNAMICS OF DENDRITIC DEVELOPMENT IN THE OPTIC TECTUM OF LIVE ZEBRAFISH EMBRYOS. R.J. Kaether* and C.A.O. Steurmer, Univ. of Connecticut, D-78445 Konstanz, Germany.

To visualize the development of dendrites in the zebrafish optic tectum, 0.5-30pL of the fluorescent dye DiO (in solution) were pressure-injected into the cell rich layer of tecta in 50-70hr old embryos. These cells reside deep to the tectal neurite into which retinal axons enter and where they form their terminal arbors (Steurmer, J Neurosci 8, 1988). Labelled cells and dendrites were viewed from above through the unopened skull of live embryos with low intensity light and a SIT camera (Hamaatsu), and monitored through a time lapse video recording system.

The tectal neurons were first visualized from both eyes to see different axon arbor subregional areas. Simultaneously they begin to develop their dendrites which grow in a radial orientation towards the developing neuropil. While elongating, the dendrites form branches with growth cone like structures and up to 15m long filopodia which radiate into all directions. As has previously been described for retinal axons (Kaether & Steurmer, J Neurosci 12, 1992), dendrites develop through the emission and retraction of filopodia and primary branches over periods to 14hr. With time some branches stabilize while others are entirely reabsorbed. Gradually, the dendritic arbors increase in diameter up to 30m in 90th old embryos. Thus, developing dendrites of tectal neurals exhibit an exploratory growth behavior similar to that of retinal axon arbors in the developing tectal neuropil. Retraction and extension of processes of dendrites coincides with the dynamic modeling of retinal axon arbors, suggesting that processes of both may contact each other and influence each other’s growth and shaping. Supported by DFG, SFB 156, TP6.

448.1

DEVELOPMENTAL EXPRESSION OF G PROTEINS IN THE EMBRYONIC NERVOUS SYSTEM OF MANDUCA SEXTA. P.E. Capponi, M. Michelle Rasmussen, and A.M. Horgan.

Ataxia L1,L2, Oregon Health Sciences University, Portland, OR 97201.

We are investigating the developmental role of G proteins in the formation of the CNS. This highly conserved family of intracellular signaling molecules is widely distributed in the nervous systems of all organisms. The developmental role of G proteins in developing nerves remains poorly defined. Using affinity-purified antisera against different G alpha subunits, we characterized the developmental expression of the major classes of G proteins (including proteins related to Go, Gi, Gt, and Gq) during the formation of the CNS. Whole mount immunohistochemical staining and protein immunoblots of embryonic tissue revealed that the different G protein classes appeared in precise, spatiotemporal patterns within the developing ganglia. Several G proteins were initially seen in subsets of undifferentiated precursors but underwent a subsequent phase of regulation as development progressed, suggesting that individual G proteins may serve a progression of functions during the formation of the nervous system. In particular, while several G proteins could be detected in the mature nervous systems of the CNS, only Go-dependent proteins could be detected in regions of axonal outgrowth. Preliminary experiments using aluminum fluoride to stimulate G protein activity caused a substantial inhibition of process outgrowth, suggesting that one function of G protein coupling is in pathfinding neuronal outgrowth. These results can now be used to examine more specific expression of individual or G proteins in the context of identified neurons within the embryonic nervous system. Supported by NSF BNS 9013059.

448.2

Multiple extracellular signals have been shown to contribute to neurite outgrowth and growth cone guidance. Such cues activate intracellular signal transduction pathways which in turn lead to changes in the size and shape of the growth cone. Additionally, second messenger systems are likely to influence the ability of the growth cone to interact with specific cell adhesion molecules. Protein kinases and phosphatases may play a crucial role as second messengers which regulate growth and migration. For these studies, mouse cerebellar cells were cultured on three different substrates; L-1, NCAM, and P84. Various protein and kinase phosphatases were then administered to the cells and the effect was monitored on growth cone morphology was assessed. Cells grown on L-1 or NCAM which were exposed to genistein, a tyrosine kinase inhibitor, had more filopodia, both at the growth cone and along the neurite. Treated cells also exhibited more side branching of the neurite. When the cells were grown on P84, the effect of genistein was less obvious and the cells resembled those in the control. Interestingly, growth cones on P84 normally have extensive filopodia. The lack of effect of genistein on cells grown on P84 may reflect a difference in the role played by tyrosine kinases in the growth of L-1 and P84 cells. Cells growing on L-1 were treated with okadac acid, a serine/threonine phosphatase inhibitor, the growth cones became more lamellipodial or sheetlike in appearance. Okadac acid-treated cells grown on NCAM seemed to have larger growth cones than the control cells. Okadac acid did not seem to have an effect on cells grown on P84. Each of the inhibitors affected the cells differently and the effect each drug was substrate dependent. These results support the idea that protein kinases and phosphatases are involved in the regulation of growth cone morphology. Supported by NIH grant EY05308.

DISTRIBUTION OF PROTEIN KINASE C (α, β, γ) SUBTYPES IN REGENERATING POSTERIOR ROOT SENSORY NEURONS. ORCUTT, Y.Hirasawa, A. Mizoguchi and C. Ide. Dept. Orthopedic Surg., Kyushu Pref. Univ. Med., Kyushu 802 and Dept. Anatomy, Kobe Univ. Sch. Med., Kobe 650. Protein kinase C (PKC) is an enzyme activated by diacylglycerol resulting from the receptor-mediated hydrolysis of inositol phospholipids and is involved in a variety of cellular processes, including signal transduction, regulation of ion channels and neurotransmitter release, control of cell growth and differentiation, changes in cell morphology, and gene expression. In the present study, immunolocalization of PKC (α, β, γ subtypes) was studied immunocytochemically in the normal nerve fibers and in the regenerating sprouts (growth cones) from roots of Pannier following crush injury in rat peripheral nerve. Using Sprague-Dawley male rats weighing 200-250 gms were ligated for 24 h and unligated 24 h prior to sacrifice. The sciatic nerve was removed, postfixed with paraformaldehyde in PBS. The injured nerve segment was removed, embedded in OCT compound, quick-frozen, and cut on a cryostat. The sections were immunostained with anti-PKC α, β, γ subtypes with peroxidase and DAB. For electron microscopy, some selected sections were dehydrated in a graded series of ethanol, followed by OY-1, and embedded in Epon 812. Ultrathin sections were made and observed on an electron microscope. In the normal nerve, PKC (α, β, γ) immunoreactivity (IR) was present in all myelinated and unmyelinated axons. Electron microscopy showed that IR was localized on the acelin and in a part of axoplasm. In the injured nerves, growth cones extending through the crushed area exhibited intense and diffuse PKC (α, β, γ) IR in the axoplasm. Thus, PKCIR in growth cones demonstrates a pattern of distribution that differs from that of the parent axon, suggesting that PKC may have important functional roles in axonal sprouting and in the regulation of growth cone activity in the peripheral nervous system.

LOCALIZATION OF RYANObine RECEPTORS AT GROWTH CONES OF CULTURED NEURONS*1*, l. Bae,*, L.L. Suki2 and M.H. Ellisman1 1San Diego Microscopy & Imaging Resource, Dept. Neurosciences, Univ.Calif.San Diego, La Jolla; 2Dept. Pharmacology, Univ. Nevada, Reno. In a previous investigation in chick cerebellum, a developmental change in the distribution pattern of the beta or cardiac form of the ryanodine receptor (RyR) was observed (Oliver et al., 1993, Soc.NAT. Acad. SCI., 1993:90:2263). Immunolabelling for the beta or cardiac form of the RyR showed a decrease in a staining pattern associated with parallel fibers in the inner nuclear layer of the cerebellum in the second week posthatch. The change might be related to neurite extension in the molecular layer, where the increase may be required to regulate the intracellular calcium storage sites for the growth process. Also, since ryanodine receptor from caffeine-sensitive intracellular storage sites was reported to be crucial in Nl-35-evoked growth cone collapse (Bandow et al., 1993, Science 259:80-3) and the RyR is a calcium release channel sensitive to caffeine, we decided to examine the RyR distribution within growth cones. Using a monoclonal antibody 34C, which recognizes all RYR isoforms in chicken, RyR was immunoreactive within and growth cones of growth cones of chicken ciliary ganglion neurons and dorsal root ganglion neurons in primary cultures. Labelling was mainly concentrated in the lamellipodium of the growth cones, but not in the fine filopodia. The pattern of labeling was similar to that observed with alpha-tubulin in double-labeling experiments. This result suggests that the RyR gated calcium storage sites may be associated with the microtubule based cytoskeleton and/or transported to growth cones along microtubules. The IRs and calcium: SR Ca2+; RYR, the two proteins involved in intracellular calcium regulation, also exhibited a similar distribution to the RYR. The presence of RyR and other calcium regulatory proteins in growth cones suggests that calcium released from intracellular storage sites may play an important role in the regulation of growth cone dynamics.

INTERCELLULAR ASSOCIATIONS STABILIZE MORPHOLOGICAL PLASTICITY AND CULTURED RABBIT RHYNCHOCEREBRUM IN HAMSTER CONE NEURONS. C.V. Williams*, P.J. Mezey, S.B. Katz. Dept. Anatomy & Neurobiology, Colorado State University, Fort Collins, CO 80523. We have previously found that local changes in calcium can result in local morphological changes (i.e. filopodia induction) in isolated Helixema neurons. The present study asked if: 1) local calcium rises can modify dendritic morphology of isolated hippocampal pyramidal neurons in culture and 2) intercellular associations alter the magnitude of calcium rise and modify dendritic plasticity. Using a local electric field, both local rises in intracellular calcium and filopodial extensions were induced from dendritic shafts of isolated hippocampal neurons. Since previous studies suggest that contact with glial cells alters calcium homeostasis, we asked if such intercellular associations would indeed alter calcium responsiveness and morphological plasticity in dendritic shafts. The average per-unit length of the dendritic calcium levels obtained in dentrites was nearly 2-fold lower in neurons contacting other cells than in isolated neurons. Irrespective of the type of contact (i.e., via axons or dendrites), neurons contacting other cells show a smaller degree of filopodium induction in comparison with isolated neurons. These results indicate that factors which regulate calcium responsiveness may also regulate morphological plasticity. Local rises in calcium, such as induced in the present study could occur in vivo via presynaptic inputs or via the release of neurotransmitter from approaching axons during development. Subsequent morphological changes could lead to altered neuronal connectivity; in several cases, induced dendritic filopodia became new arbors in the dendritic tree. Thus tight regulation of intracellular calcium may be crucial for the establishment, maintenance and modification of neuronal architecture and the resultant neuronal connectivity.

INHIBITION OF PI 3-KINASE BLOCKS NERVE GROWTH FACTOR STIMULATED NEURITE OUTGROWTH AND MAINTENANCE IN PC12 CELLS. J. Blader, T. Jackson, C. Vergara, A. Wolf, L. Fraser, L. Hammond-Odie, and A. Theibert, Neurobiology Research Center/Department of Cell Biology, University of Alabama at Birmingham, Birmingham, Alabama 35294 and "Babraham Institute, Cambridge UK CB2 4AT. In response to NGF, PC12 cells undergo morphological and biochemical changes, including neurite outgrowth and, differentiating into sympathetic neuron-like cells. NGF activates tyrosine kinases, phospholipase C and arachidonic acid release, leading to activation of PI 3-K, ras and MAP kinase pathways. NGF also stimulates phosphoinositide 3-kinase (PI3K), which phosphorylates PIP2, resulting in rapid, sustained increases in phosphatidylinositol 3,4,5-trisphosphate (PIP3). We have used an inhibitor (LY294002) of PI3K to investigate the role of PI3K in NGF signalling. Wortmannin (WM) inhibited NGF-stimulated increases in PIP3 by direct inhibition of the catalytic activity, two other proteins involved in PI3K regulation, also inhibited a similar distribution to the RYR. The presence of RyR and other calcium regulatory proteins in growth cones suggests that calcium released from intracellular storage sites may play an important role in the regulation of growth cone dynamics.
SYNAPTIC pregnagliconic growth cones collapse and retracted when they con- tact the processes of dorsal root ganglion neurons (DRG) in vitro (Moorman and Hume, 1990). The signals that trigger this behavior and the signal transduction mechanisms are unknown. In the present study we used time lapse video microscopy to determine whether inhibitors of specific second messenger systems prevent the collapse of pregnagliconic growth cones when they directly contact DRG neurites.

Pregangliocnic neurites were retrogradely labeled by DiI injections into the sympathetic chain of stage 30 chick embryos. Sixteen to 20 hours after the medial graft containing the labeled pregangliocnic neurites was cut into small pieces and placed as explants on a laminin-coated substrate. After allowing several hours for these cells to extend neurites, DiO labeled DRG's were added to the dish and time lapse images were acquired. We examined pregangliocnic growth cone-DRG neurite interactions in the presence of pertussis toxin (100 ng/ml) or omega conotoxin GVIA (5 uM). Cultures were pre-incubated in pertussis toxin for at least 2 hours prior to observation.

Each culture studied, both surface area and length measurements were made at regular time intervals.

Our results show that pertussis toxin, a blocker of G protein activation, and omega conotoxin, a blocker of N-type calcium channels, inhibit the collapse of pregangliocnic growth cones when contacting DRG neurites. These findings suggest that calcium and G protein may both play a role in mediating growth cone collapse in pregangliocnic growth cones.

In the early embryonic retina optic axons grow toward the optic disc and form a centripetal axon pattern. To address the question whether the directed growth of axons results from an attraction by the optic disc or from repulsion by the retinal periphery pieces of donor retina were grafted to ectopic sites of 3 organ-cultured eyes. After 24-48 hrs the eyes were studied for alteration in the axonal pattern as a result from the transplants. 1. Peripheral donor retina grafted into the central position of the host are non-permissive for growing axons. 2. The grafting of an optic disc to an ectopic site of the host and the removal of the original optic disc caused a major repulsion of axons to the grafted optic disc. 2. Axons encountering the grafted optic disc left the optic fiber layer to exit the eye. The experiments demonstrate that the centripetal pattern of axons in the retina is caused by a repulsion of axons by the retinal periphery and by a local attraction by the optic disc. The optic disc operates as an exit for the axons from the eye into the optic nerve.

CHONDROITIN SULFATE INTERFERES WITH RETINAL GANGLION CELL PATHFINDING IN THE VISUAL SYSTEM OF THE ECORDATE, XENOPUS LATEXICALIS A. Walé and C.E. Holt Dept. of Biology, UCSD, La Jolla, CA 92030-0357

The axons of developing retinal ganglion cells (RGC) navigate along a defined route to reach their target, the optic tectum. Pathfinding is mediated by specific interactions between the growth cones and the substrate presented by the local environment. We investigated the putative involvement of chondroitin sulphate (CS) in the development of the retinotectal projection.

Exposed brain preparations were used to investigate the influence of free CS on the developing optic projection during the period when RGC axons grow from the optic tract to the tectum (stages 31/34 to 40) and axons were visualized with anterograde HRP at stage 40. In contrast to other well applied glycosaminoglycans, CS (200μg) showed a dramatic effect on pathfinding. The tract was highly broadened with axons growing virtually over every area of the telen- diencephalon. These widened tracts were not shorter and growth cone morphology did not appear to be different compared to controls. Immunolabeling revealed that normal CS expression in the neuropil overlapped with RGC axon staining showing that RGC axons grow on a CS rich substrate. Exposed intact eyes grown in culture on a laminin (LN) substrate with CS (1mg/ml) added to the medium did not show any change in either neurite outgrowth or elongation. However, when explanted eyes were grown on a LN/CS substrate, a dose dependent inhibitory effect on neurite outgrowth was observed, suggesting that even though CS does not inhibit growth per se, it may direct growth toward lower CS concentrations in the embryo during pathfinding. Chondroitinase ABC and collagenase were used to create CS free embryos and the pathfinding behavior of RGC axons was examined.

bFGF DISRUPTS TECTAL RECOGNITION IN THE DEVELOPING VISUAL SYSTEM OF XENOPUS LAEVIUSCULUS McFarland1 and C.E. Holt. Dept. Biology, Univ. of California San Diego, La Jolla, CA 92093.

We are investigating the molecular cues that develop retinal ganglion cell (RGC) axons of Xenopus laevis use to recognize and migrate to their target. Since growth factors are known to affect neuronal differentiation, are spatially and temporally regulated in the developing brain and are expressed in the target cells of some neurons, it is possible that they may be involved in these recognition events. The fibroblast growth factor (FGF) family and their receptors have been well studied in the visual system; therefore, we have investigated the role of one member, basic FGF (bFGF), in target recognition.

A recombinant form of Xenopus bFGF (XbFGF) was applied to exposed embryonic brain preparations during the period when RGC axons grow from the optic chiasm to the tectum (stage 33/34 to 40). Axons were visualized with HRP at stage 40. XbFGF (10nM) severely affected retinotectal targeting. In the majority of cases (94%, n=19), axons failed to enter the tectum, instead, they skirted around the diencepithelial/ectodermal border; growing dorsally towards and occasionally over the dorsal midline, and ventrally toward the tectum. We performed timing experiments in an attempt to elucidate XbFGF's action. First, XbFGF was applied at stage 33/34 for 2 hours. This early phase was sufficient to disrupt target recognition (90%, n=19). Consequently, if XbFGF application was delayed until stage 37/38, when the first RGC axons usually reach the tectum, target recognition was essentially normal. These results indicate that XbFGF needs to be present early on, for a short period of time, to exert its effects. Immunostaining shows that ubiquitous XbFGF binds to nerve fibers in the developing brain, including RGCs. bFGF acts on the RGCs themselves. These findings suggest that bFGF may play a role in target recognition.

PERTURBATION OF G-PROTEIN FUNCTION AND RETINAL GROWTH CONE BEHAVIOR. C.S. Chien1, A.T. Benedikt and W.A. Harris. Dept. of Biology, UC San Diego, La Jolla, CA 92030-0367

Heteroteric G-proteins are ubiquitous intermediates in signal transduction which are enriched in growth cone membranes. We are studying their possible function in the guidance of Xenopus retinal growth cones both in vitro and in vitro.

In culture, the wesp venom peptide mastoparan (MP), which directly activates G proteins, has been shown to cause growth cone collapse (Igarashi et al., 1995 Sciencem 259:77). Furthermore, this collapse was prevented by pretreatment with pertussis toxin (PTX), which inactivates G proteins by covalent modification. We have obtained similar effects with Xenopus retinal growth cones in culture, 10μM MP applied for 30 min XMP (5.5mM) severely affected retinotectal targeting. In the majority of cases (75%, n=20), axons failed to enter the tectum, instead, they skirted around the diencepithelial/ectodermal border; growing dorsally towards and occasionally over the dorsal midline, and ventrally toward the tectum. We performed timing experiments in an attempt to elucidate XbFGF's action. First, XbFGF was applied at stage 33/34 for 2 hours. This early phase was sufficient to disrupt target recognition (90%, n=19). Consequently, if XbFGF application was delayed until stage 37/38, when the first RGC axons usually reach the tectum, target recognition was essentially normal. These results indicate that XbFGF needs to be present early on, for a short period of time, to exert its effects. Immunostaining shows that ubiquitous XbFGF binds to nerve fibers in the developing brain, including RGCs. bFGF acts on the RGCs themselves. These findings suggest that bFGF may play a role in target recognition.

CHICK RETINAL AXONS BRANCH PREFERENTIALLY ON MEMBRANE MEMBRANE-DERIVED AXONAL GUIDANCE TOPOGRAPHICAL APPORTCULAR TUM. A.J. Roskite* and D.D.M. O'Leary.

Molecular Neurobiology, Lew Faculty, La Jolla CA 92037.

Many single, position-independent axons are hypothesized to guide or restrict growing retinal axons to topographically appropriate sites in their central targets. In vivo studies in chick and rat indicate that retinal axons form topographically ordered arbors by the extension of collateral branches along their length. We have recently reported that E18 rat retinal axons grown perpendicular to membrane fragments derived from rostral and caudal E18 superior colliculus (SC) branch preferentially on rostral SC membranes due to an inhibitory molecule PI-anchored to SC membranes.

To determine whether chick retinal axons exhibit a branching specificity similar to that found for rat, we have grown E6 chick retinal explants on compartments of alternating lanes of membrane fragments from rostral and caudal E9 chick retina. Temporal chick retinal axons show a consistent branching preference for their topographically appropriate retinal membrane planes. Nasal axons show no consistent preference. Time-lapse videomicroscopy of the stripe assay cultures reveals that branches form interstitially along the axon shaft, as they seem to in vivo, as well as grow cone bifurcation. Thus, in chick, as in rat, the topographic bias in retinal axon branching observed in vivo may be controlled by membrane bound molecules. Further time-lapse microscopy of these cultures will allow us to determine whether the observed branching preference is a result of substrate-influenced branch initiation or branch stabilization.

TOPOLOGICAL SPECIFICITY IN REINNERRATION OF THE SUPERIOR COLICULUS BY REGENERATED RETINAL GANGLION CELL AXONS IN ADULT HAMSTERS. ROBERT D. Sauvé, Haime S. Vincent.

Stevenson Centre for Research in Neuroscience, Montreal General Hospital Research Institute, 1650 Cedar Ave., Montréal, QC, Canada, H3G 1A4.

In rodents, regenerating retinal ganglion cells (RGCs) project their axons to caudal and rostral contralateral superior colliculus (SC) respectively. We have examined the projections of RGC axons regenerated through unbranched pedicles in the adult hamster retina. Projections were recorded from the superior colliculus (SC) and the contralateral SC in adult hamsters. Responses to visual stimulation were recorded from terminal arbors of individual regenerated RGC axons and the postsynaptic neurons with which they make synapses in the retina (SC) and the contralateral SC. RGC positions in the retina and the corresponding position to these terminal arbors were inferred from the location of their visual receptive fields on a tanger screen. In 6 to 13 RGCs with projections to the SC were identified in 11 animals 30 to 60 days after injury.

At a given site in the SC, recordings could be made from axon terminal arbors emanating from widely separated RGCs. Conversely, nearby RGCs could project to widely separated sites in the SC. The relative position of each possible pair of RGCs was determined with respect to the position of the terminal arbors of the axons of previous site visits. These RGCs were inferred from the caudal dorsal displacements of co-cultured site responses in the SC. Paired were excluded as ambiguously oriented if the direction of displacement fell beyond ±45° from the caudal dorsal axis in the SC. Of the 101 available pairs of RGC projections, 622 had appropriate and 394 inappropriate caudal dorsal displacements in the SC. Although normal retinotectal topography is not reproduced, this 3:2 preference for appropriate projection suggests that RGC axons may recognize caudal dorsal position cues as they reinnervate the SC.

AN ANTIGEN IN THE OPTIC PATHWAY IS EXPRESSED IN EYELESS ANIMALS. Nielsen Fernandez and Sally Hoskins.

Department of Biology, City College of the City University of New York, New York, New York 10031.

To analyze the molecular axis guidance in the developing optic nerve of the frog Xenopus laevis, we made monoclonal antibodies to optic tract tract-less fragment and produced gk1, which blocks the optic nerve projection to the optic tectum beginning at embryonic stages. As reported previously, the pathway to the thalamus and the thalamic target zones are not retained by gk1, but the possibility that the gk1 antigen plays a role in optic axon target selection.

To examine whether all of the staining seen in the optic pathway was associated with the optic nerve, we deleted optic cups from early embryos, and assessed gk1 immunoreactivity in cryosections of eyeless tadpoles at tadpole stages. Eyeless tadpoles showed gk1 immunoreactivity in the position normally occupied by the optic chiasm, as well as in a line of cells marking the position of the optic tract along the wall of the diencephalon, and in the optic tectum. We conclude that the gk1 antigen is associated both with the developing optic nerve and with its pathway, raising the possibility that early gk1 expression in the optic pathway marks the route taken by the subset of retinal ganglion cell axons that projects to the optic tectum.

In experiments in progress will establish how early the pathway-associated gk1 appears.

THE ORIGIN AND COURSE OF RETINOFOGAL AXONS DURING NORMAL DEVELOPMENT OF THE FERRET, G.E. Baker and R.C. Gilchrist (SPON: Brain Research Association, Department of Human Anatomy, University of Oxford, South Parks Road, Oxford OX1 3QX, UK.

Developing retinal ganglion cell axons grow into either the contralateral or ipsilateral optic tract. We have studied the course of these axons in ferrets to examine their development and determine if their prechiasmatic organization at any age might predispose them to a crossed or uncrossed course at the optic chiasm.

Pregnant ferrets were deeply anaesthetized and fixed with 4% paraformaldehyde. Retinal implants of the tracer Dil were made to label axons from one eye, and unilateral optic tract tracts were made to label the uncrossed axons and ganglion cells of the other eye. The distribution of axons was observed in mice and rats (Goodman et al., Development 101, 515; Chan et al., JNC 363, 362). The ipsilaterally-projecting cells have no apparent preferred location within that region. Behind the eye, the uncrossed axons became increasingly concentrated laterally closer to the optic chiasm where few are found in medial locations. A narrow ventromedial (VT) core of ipsilaterally-projecting cells is first observed at E28 and broadens as axons regrow in the dorso-medial retina. The distribution of axons is observed at this and later age contrasts with the earlier stages and resembles that of the adult; postocularly the majority of uncrossed axons are concentrated ventrally, becoming more dispersed along the course of the nerve. As the chiasm many are found in a medial location. At no age are the uncrossed and crossed axons segregated prechiasmatically.

We conclude that spatial location in the prechiasmatic nerve may determine the uncrossed path of the earliest fibres but is not relevant for the later VT component.

SUBTRACTIVE cDNA LIBRARY SCREEN FOR GENES UPREGULATED OR DOWNREGULATED AFTER DEAFFERENTATION OF THE RAT SUPERIOR COLICULUS. A.D. Crawford\textsuperscript{1}, F. Bonhoeffer\textsuperscript{1}, and M. Bibb\textsuperscript{2}. Max-Planck-Institut für Entwicklungsbiologie\textsuperscript{1} and Neurobiologische Universitätsklinik\textsuperscript{2}, Tübingen, Germany.

During development of the vertebrate visual system an orderly projection of retinal ganglion cells onto the superior colliculus is established. The molecular mechanisms that might govern this process are still unknown, but probably include the coordinated interaction of target-specific axon guidance molecules and their corresponding growth cone receptors. Until recently, it was believed that in higher vertebrates, these molecules are only expressed during the actual formation of the retinocollicular projection. However, it was recently shown that cell-surface guidance activities that are not normally detectable in the superior colliculus (SC) of the adult rat temporarily display deafferentation of the SC through extorision of the optic nerve (Wenzelmann et al., 1993). We have initiated a subtractive cDNA library screen to clone the genes encoding these guidance molecules, or possibly these molecules that are responsible for making the cells in the normal adult. The subtraction protocol involved multiple rounds of hybridization of cDNA from deafferented SC with an excess of biotinylated cDNA from normal SC, and vice versa, each round followed by extraction with streptavidin and PCR amplification of the remaining cDNA (Wang and Brown, 1991). The resulting subtracted cDNA libraries are one highly enriched for genes that are upregulated after deafferentation, the other for downregulated genes, were then differentially screened to identify these upregulated and downregulated clones. In an initial pilot screen of about 250 clones from each library, 16 upregulated and 7 downregulated clones were identified. These clones are currently being subjected to sequence, Northern, and in situ analysis. In addition, full-scale screens of about 5000 clones from each library are currently in progress. The differences in expression in normal versus deafferented SC of these clones isolated to date varied from 2-fold to at least 10-fold, with 2 upregulated clones showing no detectable expression in normal SC.

449.13
PRECOCIOUS INVASION OF THE OPTIC STALK BY TRANSIENT CENTRIFUGAL AXONS IN THE FERRET. B.R. Reese\textsuperscript{1} and S.F. Celler Neuroscience Research Institute and Departments of Psychology and Biology, University of California at Santa Barbara, CA 93106-5060.

The present study demonstrates 1) that the fetal optic nerve contains a conspicuous population of centrifugal axons; 2) that the cells of origin are situated in both the ventrolateral diencephalon and in the hypothalamic region; 3) that the projection is transient, and never invades the retina itself; and 4) that these centrifugal axons evade the optic stalk prior to the arrival of the retinal axons. Fetal ferrets (E-22 through E-30) were fixed with 4% paraformaldehyde and examined using DiI to trace the retinotectal and centrifugal pathways. In addition, we used E-tubulin immunocytochemistry to detect the differentiation of the first axons within the retina and optic stalk. Dye implants into the optic nerve head, but not the retinal periphery, retrogradely label somata in the ventrolateral diencephalon, provided the implants are made in fetal brains. Likewise, dye implants into this region of the diencephalon, rostral to the optic tract, anterogradely label centrifugal axons that course through the normal optic pathway, but never enter the retina. The centrifugal axons course retrogradely from their cells of origin as 2-5 fascicles and turn laterally to enter the optic nerve where they emerge from the hypothalamus. Some of the fascicles course extra-cerebrally for a short segment at this junction, as described by Guillemé and Weidner (J. Comp. Neurol. 1987a, 265, 203; 1987b, 265, 218).

The optic nerve head and retinal fiber layer are immunoreactive for E-tubulin on E-24 and thereafter, whereas on E-22, they are immunonegative. Yet immunopositive fascicles of axons course from the ventral diencephalon into the optic stalk on E-22, confirming the precocious nature of the centrifugal projection. These fascicles are identical in trajectory to the centrifugal axons which are still readily labelled by dye implants into the future optic nerve head on E-22. These same implants on E-25, and only on E-22, also label cells in the future chromatogenic region, situated immediately ipsilateral to the midline.

These centrifugal axons may serve a transient, guidance function for later developing optic axons. The cells situated at the midline may additionally play a signalling function for optic axons as they evade the optic plate. The existence of these centrifugal axons complicates the identification of early-developing axons in otherwise unlabeled tissue.

FORMATION AND SPECIFICITY OF SYNAPSES III

450.1
FASCIKLIN III AS A SYNAPTIC TARGET RECOGNITION MOLECULE IN DROSOPHILA. A. Cuda\textsuperscript{1}, P. Stase\textsuperscript{1} and J. Hsiao\textsuperscript{1}. Dept. Physics, Univ. Tokyo, Tokyo, Japan, & Dept. Biol., SUNY, Albany, NY.

Motor neurons RPS consistently innervates muscles 6 and 7 in Drosophila embryos. During synapticogenesis, the cell surface glycoprotein fasciclin III appears in both the RPS and muscles 6 and 7. As fasciclin III has shown to be a homophilic adhesion molecule, such expression raises the possibility that it may function as a specific "target recognition molecule" for RPS. We have tested whether fasciclin III suffices to select its target choice in vivo by examining the effects of deletion or missexpression of this molecule as assessed by intracellular dye injection and immunocytochemistry. First we have found that in the existing fasciclin III null mutant RPS reliably forms synapses with its normal targets. Next, we have generated transgenic flies which misexpresses fasciclin III ectopically on all skeletal muscles during neuramorphogenetic synthesis. This was accomplished by inserting a heat-inducible fasciclin III gene under the control of the Myosin heavy chain promoter, and transforming this construct into flies by P-element mediated transgenesis. In these transformant flies, we have observed that RPS does innervate non-target muscle cells while other myoneurons (e.g. RPI) innervate their targets normally. Therefore, this provides single cell-level evidence supporting that fasciclin III functions as a specific "target recognition molecule" for a specific set of target neurones. Furthermore, taken together with the analysis on the null mutation, the results also suggest that fasciclin III is one member of a set of functionally redundant recognition molecules which are involved in an "either/or" manner during target recognition by RPS. Controlled misexpression of such recognition molecules is an effective approach to determining the functional roles of these proteins in vivo, which may be difficult to confirm by analysis of null mutations alone.

450.2
MOTONEURONS DISCRIMINATE APPROPRIATE FROM NOVEL TARGETS DURING SYNAPSE FORMATION IN CULTURE. J.C. Peyer and M.J. Zirner\textsuperscript{1}. Department of Biology, Texas A&M University, College Station, TX 77843.

Motor neuron B19 innervates the supraspinal radial somus (SLrT) muscle of the Helisoma bacular musculature. This neuromuscular synapse reforms in culture and its regeneration requires target-dependent induction of secretion capabilities. The release of the normal neurotrophin underlying this induction involves modification in the presynaptic secretory function such that action potentials, uncoupled from secretion prior to contact, evoke neurotrophic release following SLrT-contact muscle contact. Previous studies have shown that novel target muscles, not typically tested by B19, vary in their ability to induce secretory changes. For example, contact with superficial radial tendon (SMrT) muscle causes an enhancement of secretory capabilities while contact with foot (POD) muscle fibers does not. Based on these results, we hypothesize that B19 has the capacity to recognize specific muscle fibers and that muscle contacts trigger different presynaptic secretory responses. Our hypothesis maintains that mechanisms responsible for these differential changes are likely to be related to temporal aspects of axon sprouting. To further test the ability of B19 to discriminate between muscle targets, dual target contact experiments were performed where single B19s were cultured in contact by two muscle partners. After 3 days of contact, rates of spontaneous synaptic potentials (SSPs) and the presence of evoked synaptic potentials were assayed. In B19-SLR/SMT preparations (n=24), SSP rates derived from SLrT and SMrT-contacted neurites were 9.6 and 1.6 SSPs/min, respectively. Evoked release was detected from 20% of SLrT and 19% of SMrT neurites. In B19-SLT/POD preparations (n=15), SSP rates derived from SLrT- and POD-contacted neurites were 3.0 and 1.1 SSPs/min, respectively. Evoked release was detected from 50% of SLrT- contacted neurites and none of POD-contacted neurites. Evoked release was not observed in SMT- or POD-contacted neurites, suggesting that specific neuron-muscle contacts can regulate secretory properties of motorneuron B19 in a cell-specific manner.
ACTIVITY REGULATES THE SEGREGATION OF PRESYNAPTIC INPUTS ON A COMMON POSTSYNAPTIC TARGET IN VITRO. Z. Sun* and S. Schacher. Ctr. Neurobiol. & Behav., Colby Univ. College of P & S, NYSPI, New York, NY 10032. Previous studies indicate that Aplysia sensory neurons may 'compute' with one another in establishing chemical connections with a single motor target in vitro. Although the sensory cell displays no spontaneous synaptic activity, they generate their varicosities to different portions of the motor axons over time. The functional consequence is a cell number-dependent decrease in the average SRSF evoked by each sensory cell. We examined whether adding activity known to evoke a facilitatory response in mature connections—increased in CaM levels via Xenopus steric or tetric stimulation (10 Hz for 4-5 sec)—during the early stages of synapse formation would modulate the intrinsic segregatory process. Two sensory cells were cocultured with one motor cell and examined on day 2 and day 4 for changes in synaptic efficacy and structure. Two significant differences are the functional and structural changes for each sensory cell over time with control axons or following stimulation of the motor cell. Injection of cAMP or a static stimulation of one sensory cell significantly increased the amplitude of the evoked SRSF and varicosities of the treated cells compared to their respective control sensory cells in the same culture. Increasing cAMP levels appeared to increase the rate of new varicosity formation by the injected cell while tetanus also evoked an increase in the number of existing varicosities of the control unstimulated cell. The synaptic effect may be mediated by co-cultivation depolarization in the motor cell. Paracrine stimulation in both the motor and one sensory cell resulted in a larger difference in the functional and structural development by the two sensory cells. These results suggest that different forms of activity may regulate specific aspects of the segregatory process—formation or elimination of synapses—associated with the fine tuning of connections formed by converging presynaptic inputs on a common target.

DIFFERENTIAL EXPRESSION OF G-PROTEINS IN IDENTIFIED LIMNOEA NEURONS MAY DETERMINE TARGET CELL SELECTION AND SPECIFICITY OF SYNAPTIC CONNECTIONS. Gianna Spada, N.J. Spada, and Lokwisi, K. Departments of Anatomy and Medical Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1. We have recently developed a new in vitro model system to study mechanisms underlying target cell selection and specificity of synaptic connections in the gastropod Lymnaea stagnalis. Of the identified dopaminergic interneuron termed Right Pedal Dorsal 1 RPD1 multiple monosynaptic connections with a number of target cells (Right Pedal A) in vivo and these connections are re-established in vitro. RPD1 does not synapse with non target cells (Left Pedal A) either in vivo or in vitro, despite the presence of functional dopamine receptor on these cells. In the present study, we therefore hypothesized that differential G-protein couplings to the dopamine receptor may determine target selection by RPD1 in vitro. We first determined whether the effects of exogenous dopamine on both target and non target cells were mediated through different G-proteins. We used the bacterial toxins, Pertussis toxin (PTX), which is known to inhibit Gi and Go. Both target and non target cells were incubated for 18-24 hours with 1 nM PTX (n=7), whereas the similar inhibitory responses of the target cells were abolished (n>5). These data lend support to the hypothesis that G-proteins may play an important role in determining the specificity of target cell selection by Lymnaea neurons.

TIMING OF AFFERENT INGROWTH AND TARGET-DERIVED STOP SIGNALS IN DEVELOPING CEREBELLAR G. Zhang, R. Blazekaci, and C. Mason. Dept. Pathology, Coll. Phys. Surg., Columbia, University, NY 10032. Our previous work has demonstrated a "stop-growing signal" derived from target cells, based on the behavior of pontine mossy fibers and granule cells from mouse cerebellum in vitro (Baird et al., 1992, J. Neurosci. 12:619). To further investigate the nature of the stop signal and its specificity (Baird et al., 1992, J. Neurobiol. 23:579), we examined afferent-target interactions in two situations: when afferents arrive before target cell availability, and when the available target cells are more mature than usual. First; vestibular mossy fiber ingrowth, position and contacts were studied by DiI labeling, in slices prepared in conjunction with calbindin anisera to label Purkinje cells, and electron microscopy of photoconverted DiI-labeled terminals. At E17, vestibular fibers extend well into the emerging cortical layers in lobule X. Vestibular fibers with small growing tips terminate amongst the Purkinje cell zone and on the underside of the external granule cell layer. Immature contacts are made primarily on Purkinje cell somata, not on dendrites, and switch to granule cells after the first few postnatal days. Second, explants of pontine nuclei were cocultured with purified granule cells, which were aged in vitro, or taken from different aged animals. After P11 (or the equivalent days in vitro), less than half of the explants exhibited short neurites, compared to about 90% at earlier ages, indicating lack of or waning of a stop signal. These results point to temporal and spatial orchestration of signaling events on target cells. (Supported by NS 15961 to C.M.)

SYNAPSIN-LIKE IMMUNOREACTIVITY IN INVERTEBRATE NEURONS IN VITRO: REDISTRIBUTION FOLLOWING THE ESTABLISHMENT OF SYNAPTIC CONTACTS. G. Cerilli, F. Benfanti*, M. Ghiradelli*, F. Vitello, and P.G. Montecucco. Inst. of Human Physiology, University of Bari, Dept. of Experimental Medicine, University of Rome "For Vergate", Dept. of Human Anatomy and Physiology, University of Turin, Italy. The characterization of proteins involved in the storage and release of neurotransmitters has been a major step in understanding the synaptic function. Among them, the synapsins, a family of evolutionarily conserved, neuron-specific phosphoproteins associated with the specialized small synaptic vesicles, appear to play a pivotal role in both mature and developing nerve terminals. Neuronal cultures from invertebrate nervous system represent a model particularly suitable to analyze the synaptic functions; in fact, in these cultures presynaptic and target neurons form active contacts which can undergo synaptic plasticity. We studied the redistribution of the synapsin-like immunoreactivity in identified Dusophy and Helix cultured neurons following the establishment of synaptic contacts. To aim we cocultured a large serotonergic cell (GCG) from the cerebral ganglion and its target neuron (B2) from the buccal ganglion; on the other hand, the use of cell markers can be electrophysiologically tested. After different periods in culture we localized the synapsin-like immunoreactivity as a result of the target cells and measured the improvement in the presynaptic cell substantially overlapped the serotonin immunostaining (used as a marker of active synapses). On the contrary, in the absence of the physiological target a diffuse labelling pattern along the outgrowing neurites was observed. This is in good agreement with the data showing that in cultures of hippocampal neurons of mammal synaptic vesicles cluster in presynaptic terminals following contacts with dendrites of other neurons. Our results suggest that invertebrate cultured neurons the sorting of synaptic vesicle proteins to the presynaptic ending is strongly affected by the presence of the target cell.
TARGETING OF FUNCTIONAL SUBSETS OF NEURONS MEDIATED VIA THEIR AXONAL CARBOHYDRATE MARKERS. B. Zisser and J. Song, Dept. Physiol., Michigan State University, East Lansing, MI 48824

Sensory information is commonly channeled into multiple target regions in the CNS. Some of these target regions are exclusively innervated by just one sensory modality while other target regions are multimodal, receiving input from several sensory modalities. There is increasing evidence throughout phylogeny that neurons conveying different sensory modalities are chemically ecoded with some glycoconjugates. We investigated to what extent two such carbohydrate markers mediate the targeting of their respective axonal subsets in the CNS of the locust. Using [3H]glucosamine and [3H] mannose, we found that the targeting of each axonal subset in the synaptic neuropil was perturbed only by Fab fragments binding to the subset's own carbohydrate markers. These observations elucidate the nature of the interactions mediated by these two carbohydrate markers with glycosidases and neoglycoproteins indicated that the targeting of putative mechanosensory cells is mediated by a galactose-specific recognition; in contrast, the targeting of putative chemosensory markers is mediated mostly by a glucose-specific recognition with some galactose component. The different interctions of the two neuronal subsets, one mediated exclusively by galactose and the other one mostly by glucose with a minor galactose component, are consistent with the observation that their projections show partial overlap in the synaptic neuropil. Thus, the intact-axon terminal model system to study the normal function of neuronal carbohydrate markers in synaptic connectivity.

MORPHOLOGICAL AND NEUROCHEMICAL TARGET PREFERENCES OF ADULT PHOTORECEPTORS REGENERATING IN VITRO. D.M. Sherr* and E. Townes-Anderson, Cornell U, Ithaca, NY, 14850

The specificity of regenerative synaptogenesis by adult vertebrate neurons is poorly understood. Contact formation between pharate neurons and second- and third-order retinal neurons with identified amino acid content was examined by culturing differentiated neurons isolated from salamander and goldfish embryos. In the salamander system, neurons retain characteristic morphological features and regenerate synapses. Regenerating photo-receptors form presynaptic varicosities that contain synaptic vesicles and the transmitter glutamate; 134 varicosities have been analyzed. Varicosities usually contacted body cells (82.3%) rather than processes. Photoreceptors had the opportunity to interact with all three class of retinal neurons, but contact was uniformly to improper targets: multipolar cells (32.8%), includes amacrine, ganglion and interplexiform (5.7%), than proper targets: bipolar (0.7%), horizontal (0.7%) or photoreceptor cells (5.2%). However, most contacts (60.4%) were onto cells that had lost processes during isolation and could not be identified unequivocally, but their morphology and growth were inconsistent with photoreceptor or horizontal cells. Single-label immunocytochemistry showed that less than 34% of target cells contained aspartate or glycine, but over 50% contained GABA or glutamate, consistent with a high proportion of amacrine cell targets. These data suggest that regenerating photoreceptors may prefer nonappropriate target cell types, however, the transmitter content of most target cells (GABA, glutamate) is similar to that of cells postsynaptic to photoreceptors in the intact retina.

SYNAPTIC COMPETITION BETWEEN SUPERNORMAL AND NORMAL SENSORY NEURONS IN THE COCKROACH IS MEDITATED THROUGH A CHANGE IN QUANTAL CONTENT AND NOT QUANTAL SIZE. M.A. Song* and J.M. Blagburn, Insitute of Neurobiology, University of Puerto Rico School of Medicine, San Juan, Puerto Rico 00925

The cens of the first instar cockroach (Periplaneta americana) bear two filiform hairs each, one lateral (L) and one medial (M), which are innervated by individual sensory neurons. These sensory neurons project to the CNS, where they synapse with giant interneurons (GIs) that project the perirenal ganglionic. Mutant strains have been previously discovered which have an extra L hair or one on both cens. The sensory neurons that innervates the extra hair, known as Spaces Injector (SN), projects to the same GIs as the normal L hair innervated neurons for these synaptic targets. The size of the GI3-EPSP in GI3 is reduced in the presence of SIN. We wanted to determine whether this reduction in ESPP is a reduction of the postsynaptic current (giant akin). This led us to ask if the ESPP amplitude is the result of pre- or post-synaptic changes. Intracellular recordings from GIs in a modified open bath showed no increased size of L hair, were made in normal cockroach saline (or 5 mM CaCl2/10 mM MgCl2) (low Ca), 

SYNAPTOGENSESIS AND SYNAPTIC PLASTICITY IN DISSOCIATED CHICK CEREBRAL NEURONS. T. Taguchi, K. Kojima, K. Kuroi, A. Ishida, E. Suzuki, O. Fujito, K. Nishikawa, K. Ohishi, T. Kato, and K. Izumi, Dept. of Biology, Kyoto University, Osaka, Japan

We used electrophysiological methods to study the synapse between two cell types: two different types of amacrine cells. We wanted to know whether synapses between two different types of amacrine cells are able to make a functional connection. We found that the synapse between two different types of amacrine cells can make a functional connection.

INTERACTIONS BETWEEN PHOTODAMAGED AND INTACT TERMINALS AT POLYNEURONALLY INNervATED FROG NEUROMUSCULAR JUNCTIONS. J. Thum, I. Tak, and A.A. Horny, Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90009

Our goal is to study how changes induced in one motor nerve terminal can affect another in polyneuronally innervated neuromuscular junctions in frog. This approach is important in understanding the role and nature of competition during synaptic elimination in neuromuscular junctions. Reinnervated sarcolemma of Rana pipiens has a substantial percentage of polyneuronally innervated junctions 8 weeks after nerve crush. Our previous in vivo observations indicated that under normal conditions such junctions are functionally stable over a period of several weeks which makes artificially induced changes easily detectable in this system. To induce changes in a small portion of a terminal in vivo we used the fluorescent dye 4-Di-2-Asp and low-light video microscopy was used for repeat in vivo observations of exposed and intact terminals. In cases where reexposure of the receptors, no changes were detected in intact terminals in the same neuromuscular junction a week after photodamage. We are not yet able to make repeated exposures of identified neuromuscular junctions over longer periods of time after selective photodamage. Our study also includes an electrophysiological examination of changes in postsynaptic potentials of one input in a doubly innervated junction effects the other input.

A HIGH NUMBER OF GABA SYNAPSES TARGETING DISTAL PORTIONS OF CORTICAL NEURONS IS LOST AFTER PERIPHERAL DEPRIVATION. J. Michéa*, K. Crozier and C. Crevier, Dept Pathology and Centre de Recherche en Sciences Neurologiques, Université de Montréal, Montréal, (Qué) CANADA.

The numerical density (N), and proportion (%) of GABA synapses on dendritic spines, shafts, somata, and initial segments of the axon was estimated in the somatosensory barrel fields of 5 rats having their vibrissae from the right face continuously removed from birth. For the cortical dendrites, no significant differences in the N, and % of GABA synapses on these post synaptic elements were found in the barrel field cortex contralateral and ipsilateral to the deprivation. About 19.7 million GABA synapses per mm² of tissue were devoted to spines (representing 3.8% of all contacts) on spines 2.55 million were on dendritic shafts (38.1%), 5.6 million on somata (71.0%) and less than 0.01 million on the initial segments of the axon (100%). In layer IV however, sensory deprivation induced a drop from 55.6 in the ipsi cortex to only 11.9 million/mm² of GABA synapses on spines in the contra cortex (a 4.7 times loss: p<0.0001) and from 82.2 to 33.8 million/mm² on shafts (p<0.005). Only 2.2% and 29.1% of all contacts on spines and shafts respectively, were GABA in the contra cortex as compared to as many as 93.9% and 49.1% in the ipsi layer IV. We conclude that the population of GABA synapses located on distal portions of layer IV neurons is the most plastic of all populations of cortical synapses. (Supported by MRC, FRSQ, and FCAR).

Development of iterated structures in the NMDA receptor deficient mice. Yung Li¹, Reha S. Erurumlu², Chong Chen, Sonal Jhaveri² & Susumu Tonegawa HMMI at the Ctr. for Cancer Res., ¹Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA 02139.

Sensory pathways of the brain generally develop from crudely wired networks to precisely organized system and in some cases to iterated structures such as stellar dendrite columns and barrel fields in the cerebral cortex. Several studies have implicated neural activity-dependent mechanisms including NMDA receptors, in this refinement process. We applied the gene targeting in mouse embryonic stem cells to the NMDAR1 gene and created a mutant mouse which lacks functional NMDA receptors. We analyzed the formation of iterated structures in the mutant mice. The development of glomeruli in the olfactory bulb of mutant mice is compared to that of wild type animals. The number of glomeruli in the mutant mice is the same as their normal littermates, suggesting that the development of glomeruli is not dependent on NMDA receptor activation. In contrast, whisker-related patterns in the trigeminal nuclei (barrellets) failed to develop as judged by both cytochrome oxidase staining and immunohistochemistry, although patterning, initial targeting and crude topographic projection of trigeminal axons in the brainstem are unaffected. In addition, in the absence of functional NMDA receptors, the synaptic transmission from trigeminal ganglion to the second order neurons in the brainstem trigeminal complex is functional in mutant mice. These results suggest that NMDA receptor and/or activity is essential for the development of somatosensory maps in the mammalian brain. HOMONYMOUS NEUROMUSCULAR PREPARATION USING THE CAMPENOT CHAMBER. A. Parfitt, E.A. Neale*, C.C. Fitzgerald and P.G. Nelson: Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

We have shown that mouse ventral horn motor neurons grown on mouse cortical astrocytes, in the side wells of Campenot chambers that have been scaled onto laminin-coated plastic culture dishes, will extend axons underneath the chamber barrier into the center compartment, there to make functional contact with muscle striated muscle fibers. These fibers will contract in response to electrical field stimulation across one or both of the Campenot barriers. Most field-induced contractions could be blocked by rhodaminated- bungarotoxin, which was used to label post synaptic cholinergic receptors, suggesting that they were neurally mediated and not the result of direct electrical stimulation of muscle fibers which had grown into or under the Campenot barrier. Neurites that were immunoreactive for CHAT could also be found in association with muscle fibers that had contracted in response to electric field stimulation. Cells and their processes in the side wells of the Camponot chamber could be stained with Fast DII/DIO. Intracellular diffusion of these dyes along the neurites that passed under the chamber barrier permits visualization, and will facilitate the differential characterization, of the neurite fields in the center compartment. Preliminary experimental data include evidence for activity-dependent synapse elimination.

SELECTIVE DECREASE IN THE NUMBER OF GABA SYNAPSES IN LAYER IV AFTER SENSORY DEPRIVATION. J. Michéa*, K. Crozier and C. Crevier, Dept Pathology and Centre de Recherche en Sciences Neurologiques, Université de Montréal, (Qué) CANADA.

The effects of modified peripheral activity at cortical level were estimated by quantifying the overall and GABA synapatic populations in the somatosensory barrel field cortex of 5 rats whose whiskers on the right face were continuously removed after birth.

The numerical density of GABA synapses was found to decrease more than twice (p<0.005) in layer IV contralateral to the deprivation (63 million/mm²) compared to the ipsilateral layer IV (145 million/mm²). Accordingly, GABA synapses represented only 9.4% of the overall synaptic population in the contralateral versus 18.7% in the ipsilateral layer IV. At the same time, GABA synapses in the deprived layer IV were bigger (0.48 μm in the contralateral layer IV vs. 0.32 μm in the ipsilateral layer IV; p<0.05). No significant changes in the numerical density, proportion or size of GABA synapses were detected in any other cortical layer. No differences in these parameters were found for the total synaptic population either.

As the firing activity and receptive field properties of cortical neurons are under the control of GABA, such a selective reduction in the number of GABA synapses in layer IV, the major recipient of thalamocortical inputs, would undoubtedly lead to profound functional alterations in the entire circuitry of the deprived somatosensory cortex.

The adult pattern of axonal connections from the eye to the brain arises during development by refinement of a roughly ordered pattern of connections in chick. One characteristic of the early pattern of connections is a transient ipsilateral retinotectal projection. Previous studies showed that administration of arginine analogs prevented the loss of this transient ipsilateral projection. The most likely interpretation of this result is that the drug inhibited nitric oxide (NO) synthesis in the visual system, and that NO is somehow involved in the refinement process. The present study examined whether administration of an arginine analog actually reduces NO synthesis and identified the most likely site of action. L-NOARG was applied to the chorioallantoic membrane of embryos. Controls received saline. On E13, the middle of the period of refinement, nitric oxide synthase (NOS) activity was assayed by measuring the conversion of arginine to citrulline in homogenates of retina and tectum. In normal embryos, NO activity was detected in the tectum but not in the retina. This was consistent with the histochemical detection of NOS in these tissues during the period of refinement. NO activity in the tectum was inhibited in the L-NOARG treated group but not in the saline treated group. The effect of L-NOARG was dose-related. There was a correlation between the level of NO synthesis inhibition and the degree of preservation of the ipsilateral projection in the tectum. These results suggest that NO serves as a messenger from the tectal cells back to the retinal axons and that it is involved in the developmental refinement of the visual projection. Thrombin, at nM concentrations, has been implicated in the process of activity-dependent synapse reduction (ADSR) in a mouse neuromuscular junction preparation in vitro (Liu et al., Soc. Neurosci Abs, this volume). This is based on the block of ADSR by nM concentrations of hirudin, a highly specific thrombin inhibitor. Also exogenous thrombin (~10 nM) causes synapse loss which is blocked by hirudin. We have, therefore, investigated the regulation of thrombin release from muscle cells. We compared the levels of thrombin in media conditioned by muscle cells treated with tetrodotoxin (TTX, 1 μM, to block activity) or acetylcholine (ACH, 10 μM, to activate the cells). Significantly more thrombin was released by the ACh treated cells (1056 nM ± 0.03 nM; S.D., n=18 with ACh vs .027 ± 0.02 nM, t=15 with TTX). (The medium with 5% horse serum contained 0.066 nM thrombin). We hypothesize that increased thrombin secretion produced by muscle activation could contribute to ADSR.

OVEREXPRESSION OF NGF IN TRANSGENIC MICE INDUCES NEUROTROPHIC FACTORS AND ALTERS PRIMARY SENSORY NEURONS. B.M. Davis1*, D.M. Katz2*, K.B. Srogovsky and K.M. Albers3. 1Depts. of Anatomy & Neurobiology, and 2Pathology, Univ. of Kentucky College of Medicine, Lexington, KY 40536; *Dept. of Neurosciences, Biomedical Research Unit, University Hospital of Cleveland, Cleveland, OH 44106.

Peripheral nerve crush induces novel projections from sympathetic neurons to skin in transgenic mice that overexpress NGF in the skin. Specifically, a large proportion of primary sensory neurons in NGF transgenic mice were innervated by tyrosine hydroxylase (TH)-positive pericellular (PC) nerve fibers that were seen only rarely in controls. Removal of the superior cervical ganglion abolished TH-immunoreactive arborizations in the ipsilateral trigeminal ganglion confirming the axonic effects. A two-site ELISA revealed that transgenic ganglia contained a ten fold increase in NGF peptide. Reverse transcriptase PCR analysis showed no apparent expression of the transgene in sensory ganglia suggesting that the additional NGF was derived from increased NGF expression in the skin. These results indicate that NGF induces novel sympathetic projections to sensory neurons, and supports the hypothesis that increased NGF expression is a critical link in the development of sympathetic hyperalgiesia. Supported by AR-40873 (KMA), NS-31826 (BMD), HL-42131 (DMK) and IBN-9221136 (KBS).

451.2

Neurotrophins and their high affinity binding proteins (HABP) have been identified as novel neurotrophic factors (BDNF, neurotrophin-3 (NT-3), and neurotrophin-4/5 (NT-4/5), are a family of homologous proteins that affect neuronal cell survival and support neuronal growth and differentiation. During development, neurotrophins are made by neuronal target tissues such as skin and the decline in their expression levels correlates with the onset of naturally occurring neuronal cell death. To examine the role of neurotrophins in the development of the peripheral nervous system, we isolated transgenic mice that express fusion gene constructs containing a human keratin (K14) gene promoter linked to the versant mouse neurotrophin cDNAs. Transgene expression begins in the basal cell layer of epidermis around embryonic day 14 (E14), coinciding with the normal decline in neurotrophin levels. Previously we have isolated and characterized mice containing a K14-NGF transgene. In this study, mice expressing a K14-BDNF transgene have been isolated. BDNF is normally expressed in neuronal tissues of both the central and peripheral nervous system and is lost in neuronal tissues such as heart, lung and skin. By overexpressing BDNF in the epidermis, its role in development and in the adult may be elucidated. Three lines of mice have been isolated that express the K14- BDNF transgene as shown by both Southern and Northern hybridizations. Mice appear normal in size and health. Initial histological examination of the skin and sensory ganglia show no major alterations in these structures. Supported by NS-31826 (BMD) and AR-40873 (KMA).

451.3

Neurotrophins and their high affinity binding proteins (HABP) have been identified as novel neurotrophic factor, (BDNF, neurotrophin-3 (NT-3), and neurotrophin-4/5 (NT-4/5), exhibit wide overlapping effects to skin in sensory ganglia suggesting that the additional NGF was derived from increased NGF expression in the skin. These results indicate that NGF induces novel sympathetic projections to sensory neurons, and supports the hypothesis that increased NGF expression is a critical link in the development of sympathetic hyperalgiesia. Supported by AR-40873 (KMA), NS-31826 (BMD), HL-42131 (DMK) and IBN-9221136 (KBS).

451.4

NGF OVEREXPRESSIN in EPIDERMIS Disrupts SYMpathetic INNERVATION OF SWEAT GLANDS AND DIFFERENTIALLY ALters TRANSPReSSOR Molecules. G. Gudary*, B. M. Davis2, S. C. Landis3 and K. M. Albers4. 2Dept. of Neurosci., Case Western Reserve Univ., Cleveland OH 44106, 3Dept. of Anatomy and Neurobiol. and 4Dept. of Path. Univ. of Kentucky College of Medicine, Lexington KY 40536.

We examined sympathetic innervation in transgenic mice carrying multiple copies of the NGF gene driven by an epidermal keratin promoter. In adult wild-type mice, cholinergic and noradrenergic sympathetic fibers and peptidergic sensory fibers innervate the distal tail. Acetylcholinesterase (ACHE) and vasoactive intestinal peptide (VIP) sympathetic axons were associated with sweat glands while catecholaminergic fibers innervated blood vessels. The NGF overexpression was restricted to tissues in the pad area. Calcitonin gene-related peptide (CGRP) and substance P (SP) sensory fibers traversed the pad and terminated at the interface between the epidermis and dermis. While the timing of innervation in footpads did not appear to be affected in transgenic mice, segregation of sympathetic and sensory innervation was altered. A dense plexus of ACHE and catecholaminergic fibers was found beneath the epidermis and VIP fibers extended into the epidermis. The plexus was absent from footpads of mice treated with the adrenergic neurotoxin 6-OHDA, indicating its sympathetic origin. This same region was hyperinnervated by CGRP and SP sensory fibers. In addition, sweat gland innervation was disrupted. While some ganglia were innervated by ACHE and VIP fibers, most lacked innervation. Despite the sparse gland innervation, sympathetic responsiveness appeared normal. Our findings suggest that over-expression of NGF in skin interfered with the normal segregation of sensory and sympathetic fibers. Further, the ecotopic sympathetic fibers displayed an abnormal neurotransmitter phenotype, expressing both catecholamines and cholinergic properties.

451.5

Brain derived neurotrophic factor is a member of the family of related molecules, which includes NGF, NT-3 and NT-4/5. Neurotrophic effects on neuron survival and differentiation in vivo and in vitro suggest important roles for these molecules on essential developmental processes such as programmed cell death and determination of neuronal phenotype. As part of our efforts to clarify the in vivo role(s) of the neurotrophin genes, using gene targeting methodologies, we have generated mice in which most of the sequence coding for BDNF was deleted and replaced with a neomycin resistance gene. Homozygous mutant mice (+/--) are reduced in size compared to the wild type mice and die within the first three postnatal weeks. Analysis of DRG cell numbers and size indicates that many neurons die in the (-/-) animals. Heterozygous (+/-) were viable but consistently intermediate in size. This problem was examined in the function of three primaryafferents innervating skin in adult (+/+) mice using an in vivo recording technique (Kohlaugeg et al. Soc Neurosci., this meeting). Briefly, single primary afferents were recorded in the saphenous nerve using standard trac- ted fiber techniques. All cutaneous primary afferent types were encountered and characterized in wild type and (+/--) animals (Ai, Al and C-fibers), however, only one type was severely affected in the (-/-) fibers. Slowly adapting, non myelinating fibers, conducting in the A8 fiber range, had very elevated mechanical thresholds. These initial results suggest that BDNF is critically important for the regulation of this afferent type. It will be important to see if total absence of BDNF in (+/--) animals has more widespread effects on the functional properties of sensory neurons.

TRANSGENIC MICE OVEREXpressing BDNF IN NEURAL STEM CELLS. Torkel Falkenberg1,2*, Thomas Ringstedt2,3, Erik Nilsson2, Urban Lendahl2, Ron McKay3, Hakan Persson2 and Carlos F. Bates1. 1Molecular Neurobiology, Medical Biochemistry and Biophysics, 2Department of Women and Child health, 3Department of Bioclinical Science, Bioclinical Biology, Cell and Molecular Biology, Bioclinical Institute of Physiology, Karolinska Institute, Stockholm, Sweden, 4Molecular Biology, NIH, Bethesda, MD, USA.

Neural stem cells in the neuroepithelium of the neural tube are transiently present during embryonic life and later differentiate to form neurons and glial cells. The neural stem cell state is accompanied by expression of the intermediate filament nestin. Regulatory regions controlling the nestin expression in the stem cells have recently been characterized in transgenic mice using lacZ as a reporter gene. We have analyzed the effects of overexpression of the neurotrophic factor BDNF (brain derived neurotrophic factor) using transgenic mice harboring BDNF under the control of regulatory regions of the nestin gene so the coding portion of the BDNF gene. This DNA construct was injected into fertilized mouse eggs with the attempt to generate transgenic mouse lines. With this particular construct we have observed a very low frequency of postnatal transgenic mice (6% of all offspring were transgenic mice). However, one of the founders did not express BDNF from the exogenous gene, while another one did not pass the gene further to its offspring. Thezera suggest that BDNF may be a significant regulator of neural stem cells, which may be critical for the maintenance of the transgenic embryos. Further work is aimed at analyzing phenotypes in transgenic embryos at different developmental stages.

451.10 STRUCTURE AND TRANSGENIC EXPRESSION OF RAT NEUROTYPHON-4 GENE. P. Metsinis, S. Salin, Y. Hurj*** and T. Timmusk. Lab. of Molecular Neurobiology, Karolinska Institute and *Dept of Clinical Neuroscience, Karolinska Hospital, Stockholm, Sweden.

Neuropathic pain and related disorders are a major health problem affecting millions of people. However, the underlying mechanisms of pain due to nerve damage remain largely unclear. Recent studies have revealed that the degeneration of sensory neurons is not only a secondary event in neuropathic pain, but also plays a key role in the initiation and maintenance of pain. In this study, we investigated the structural and transgenic expression of neurontrophin-4 (NT-4) gene in various tissues to understand its role in the development of neuropathic pain.

Neurontrophin-4 (NT-4) expression is very low in the adult organism, while higher levels are present during embryogenesis. Developmentally regulated expression of NT-4 is thought to contribute to the hypothesis of its target derived action on the trigeminal ganglion. To study the regulation of the NT-4 gene and to evaluate the possible roles of this neuropot in developing and an adult system we have characterized rat NT-4 gene. A cDNA library was made from P1 testis, where a high expression level was previously detected. Screening of this library resulted in 10 CDNA clones that were used to screen a rat genomic library. 10 overlapping genomic clones were isolated that covered 45 kb of the NT-4 locus. Mapping of the intron-exon structure revealed two upstream noncoding exons separated by an 800 bp intron. Transient expression analyses with bacterial chloramphenicol acetyl transferase reporter gene suggests an important role of intronic sequences in regulating the promoter activity. Rat NT-4 gene fragment containing upstream exons, promoter region and coding exon was introduced into transgenic mice. The expression pattern of the transgene recapitulates the endogenous gene expression pattern and regulation. Transgenic mice with high level of NT-4 expression have altered levels of other members of neurotrophin family in distinct brain regions.
451.13 EVALUATION OF GROWTH FACTOR EFFECTS ON MESENCEPHALIC DOPAMINERGIC NEURONS USING A FOS-LACZ TRANSGENIC MOUSE LINE J. Engels* and K. Schilling, Dept. Anatomy and Cell Biology, University of Ulm, 89069 Ulm, FRG.

One of the initial effects of many growth factors is the rapid and transient induction of the immediate early gene c-fos in their target cells. In the present study, we have exploited this feature to probe the cellular target(s) of growth factors previously observed to support survival of cultured dopaminergic neurons. Specifically, we used low density cultures established from the dissociated mesencephalon of E14 fos-lacZ transgenic mice (generously provided by J.J. Morgan, Roche Institute, Nutley, N.J.) to monitor c-fos expression in immunocytochemically identified cellular phenotypes. NT-3 (10 ng/ml, 3 hrs), bFGF (25 ng/ml) or a combination of aFGF (50 ng/ml) and heparin (2.5 U/ml) induced transient expression in subpopulations of tyrosine hydroxylase-immunoreactive dopaminergic neurons as well as non-dopaminergic neurons and glial cells. The effects of these growth factors on dopaminergic neurons were not affected by cellular plating density or by eliminating synaptic communication. In contrast, TGFα (50 ng/ml) and PDGF-BB (50 ng/ml) induced transient expression exclusively in glial cells but not in dopaminergic neurons.

These studies identify mesencephalic dopaminergic neurons as the primary target of NT-3 and FGF and further demonstrate that sensitivity for these growth factors is restricted to distinct subsets of dopaminergic neurons. Finally, our results suggest that the known survival-promoting effects of TGFα and PDGF-BB on dopaminergic neurons are mediated through mesencephalic glia.

451.14 NEUROTROPHIC FACTORS AND CEREBRAL VESSELS OF TRANSPLANTED MOTOR NEURONS DERIVED FROM THE E14-FOS-LACZ TRANSGENIC MOUSE.

A number of workers have made use of transplantation and retroviral-mediated gene insertion using a variety of monoclones in order to immortalise neural precursor cells. This study used a conditionally immortalised hippocampal cell population derived from the E14-Fos-LacZ transgenic mouse. The mouse possesses an established integrated copy of the early region of the large tumour antigen from the temperature sensitive gene allowing immortality to be controlled by the permissive temperature of 33°C, the non-permissive temperature being 39.5°C. We examined the effects of several growth factors including basic fibroblast growth factor (bFGF), nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3), the tyrosines were p75-neurotrophin and ciliary neurotrophin factor (CNTF) on E14 transgenic mouse hippocampal progenitor cells.

Initial results showed that NGF produced an elevation in both survival and proliferation in the hippocampal cells with maximal effects produced at a concentration of 10ng/ml. NGF produced minimal increase in cell number, but did however induce differentiation when kept at 36.5°C. The other 2 neurotrophins (BDNF and NT-3) as well as CNTF produced interesting results which will be shown in the poster. Cells treated with FGF in general were lower in number and longevity at the higher concentrations.

451.15 ROLE OF ESTROGEN IN AFFECTING INCREASED ALCOHOL INTAKE IN TRANSGENIC TGα-MICE. Leena Hikmat-Clark*, Lorenzo Hikmat-Clark, Lombardi Cancer Research Center, Georgetown University, Washington, DC 20007.

Results with transgenic CD1 mice that overexpress transforming growth factor α (TGα-M) suggest that this growth factor alters non-reproductive sex-related differences in behavior. Specifically, male TGα-M mice exhibit a feminization of locomotor activity, immobility in the swim test, and sodium preference. These effects may be mediated through an interaction between TGα-M and estrogen. The TGα-M mice exhibit elevated plasma 17β-estradiol (E2) levels. Castration reverses the feminized behavioral patterns in the male TGα-M mice. The present study investigated the effect of orchectomy, E2 and the antiestrogen tamoxifen on voluntary alcohol consumption in transgenic TGα-M mice. Both the male and female transgenics consumed more 5% alcohol (expressed as a percentage of total fluid intake) than the non-transgenic mice (P<1.39=8.8, p<0.005). Orchietomy did not have a significant effect on alcohol intake. In non-transgenic CD1 male mice, treatment with pellets releasing E2 increased and treatment with tamoxifen reduced alcohol intake, when compared with placebo-treated mice (HSD=25.2, p<0.001). In ovariecetomized females, E2 reduced alcohol intake (H4)=12.6, p<0.006). These data suggest that overexpression of TGα increases alcohol consumption in both sexes. Estrogen also increases alcohol intake in non-transgenic male mice, and this is reduced by the antiestrogen tamoxifen. However, since orchietomy at adulthood did not reverse the increased alcohol intake patterns in the transgenic mice, the effects of TGα on alcohol consumption may be mediated through other pathways than elevated E2. Alternatively, the effects of E2 occurred during the critical period of sexual differentiation.

We are interested in examining mechanisms regulating estrogen actions during neuronal differentiation in the central nervous system. Our research has focused on one possible mechanism, the developmental interations of nerve growth factor (NGF) and estrogen receptors. Using a combination of steroid autoradiography, immunohistochemistry and in situ hybridization methodologies, we have shown that estrogen target neurons of the developing forebrain express the NGF receptors, p75NGFR (the pan-neurotrophin receptor) and rn4 (the specific tyrosine kinase receptor). Moreover, NGF and estrogen reciprocally regulate their receptors in P12 cells, a neurotrophin-responsive cell line. In this study, we examined the regulation of estrogen binding by NGF in the developing forebrain using organotypic explant cultures maintained in roller tube assemblies. Explant cultures of the postnatal day 2 rat cerebral cortex and basal forebrain were maintained 8 days in vitro, in the presence or absence of NGF (100 ng/ml). Our data indicate that estrogen receptors and receptor mRNA are expressed in these cultures, in patterns similar to those observed in vivo. Using a modified nuclear exchange assay to measure specific, intr-nuclear estrogen (3H-moxestrol) binding, we found that NGF alters nuclear estrogen binding in a regionally-specific manner. We are currently examining mechanisms underlying regionally-specific NGF regulation of estrogen binding. (Supported by grants from the NIH, NIMH, NSF, AHA and an ADAMHA-RA to C.D.-A.)

451.17 NEUROTROPHIC FACTORS FAIL TO PREVENT CAstration-INDUCED REGRESSIVE CHANGES IN AN ANDROGEN-SENSITIVE RAT SPINAL NUCLeUS. M.C. Clark-Phelps*, T.R. Nett, and D.R. Sengelaub1

Program in Neural Science, Indiana University, Bloomington, IN 47405: Cephalon, Inc., West Chester, PA 19380.

Motoneurons of the rat spinal nucleus of the bulbocavernosus (SNB) are sensitive to androgens. Castration of adults significantly reduces SNB dendritic length, soma size, and target muscle weight, and these changes can be prevented or reversed with androgen treatment. Using compounds demonstrated to have trophic effects on motoneurons in several models, we assessed maintenance of muscle weight and motoneuron morphology of the androgen-sensitive SNB system following castration in adulthood.

Adult male rats (Sprague-Dawley) at approximately 90 days of age were either castrated or left intact. Castrated rats received daily subcutaneous injections over the SNB target muscles of either IGF-I (1 mg/kg), CNTF (1 µg), or vehicle alone for six weeks. Following treatment, SNB target muscles (bulbocavernosus and levator ani; BCLA) were weighed and motoneuron morphology was visualized histochemically after retrograde labeling with a cholera toxin-TRH conjugate. Castration significantly reduced SNB soma size and BCLA muscle weight relative to intact males, and treatment with either IGF-I or CNTF had no effect. Thus, unlike androgen, IGF-I and CNTF failed to prevent castration-induced regressive changes in these aspects of SNB morphology, suggesting that the androgen-dependent trophic effects observed in this system are not mediated by these compounds in adulthood. (Supported by Cephalon)

The hippocampus is a primary site of neurotrophin mRNA expression in both developing and adult rats. Neonatal sympathetic ganglia transplanted into adult rat hippocampus grow into the dentate gyrus and CA3 regions, which display NGF-like staining. The discrete boundaries of this staining suggest the occurrence of NGF, or a related neurotrophin, firmly bound to hippocampal structure, supplemented by a pool of soluble NGF. NGF-like immunoreactive immunostaining in the hippocampus was blocked by the monoclonal antibody directed against NGF (WNI-2), suggesting that NGF is bound to hippocampal structure. In addition, we have developed an immunocytochemical method utilizing a monoclonal antibody directed against NGF immunoreactivity. Our results suggest that NGF is primarily bound to hippocampal structure.

We have used purified, well-characterized granule cell cultures (Gao et al. 1991) for this study. Neurons 6705-715 to examine the possible effects of the neurotrophins on four different stages of cerebellar granule cell neurogenesis. The four stages included neuronal proliferation, maturation, neuronal differentiation, and maintenance. None of the neurotrophins stimulated proliferation of the granule cell precursors or rescued granule cells that were eliminated by neuronal insults. However, neurotrophin-4/5 (NT-4/5) and BDNF, but not neurotrophin-3 (NT-3) and neurotrophin-2 (NT-2), promoted neurite extension and survival of differentiated cerebellar granule cells. Moreover, NT-4/5 and BDNF enhanced neurite extension by unjured granule cells, which were rescued from various types of cell death in the hippocampus. These findings suggest that NT-4/5 and BDNF promote the development and maintenance of differentiated granule cells, which are downstream to the neuron. In addition, the effects of these factors were seen with the combination of NT-4/5 and BDNF. The neuron-promoting and survival effects of NT-4/5 and BDNF could be completely blocked by the specific tyrosine kinase inhibitor K-252a. Thus, these two neurotrophins activate the same receptor tkβ for signal transduction.

INVOVLEMENT OF NEUROTROPHINS IN THE PHENOTYPIC SPECIFICATION OF CHICK CUTANEOUS AFFERENTS: G.R. Lenzi1*, M. Koltenborg, K.V.Troyka, and Y.A. Barde
Dept. Neurochemistry, Max-Planck Institute for Psychiatry, D-81589, Germany.

Neurotrophins may influence the phenotypic fate of sensory neurons during development. Here we have used an electrophysiological recording technique to study the functional properties of sensory neurons whose access to neurotrophins was manipulated in vivo. Monoclonal antibodies (anti-NGF and anti-NT3) were delivered by hybridoma cells placed on the choroidallastic membrane at E1, while NT3 was delivered at E17 and staining with rhodamine was made from cutaneous sensory neurons as described (Koltenborg et al. Soc. Neurosci. this meeting). After anti-NGF treatment fibers conducting in the C-fiber range (<1 m/s) were reduced by 50%, while none of the fibers responded to noxious heat, although all had mechanical thresholds similar to those in normal chicks (i.e., they were C-M fibers). In contrast to untreated controls animals where nearly 50% of the fibers responded to noxious heat (C-MB), the functional properties of presumptive A-fibers appeared normal (conduction velocity >2 m/s). This is consistent with the idea that only C-MB fibers in the chick depend on NGF for survival. After NT3 treatment the conduction velocity range of recorded afferents was indistinguishable from controls. A-fibers also appeared unaffected by the treatment in terms of mechanical threshold. However, amongst the C-fiber population all the fibers studied (n=12) had unusually low mechanical thresholds, and none responded to noxious heat. Comparison of the NT3 treated C-fibers to control A-fibers revealed that their mechanical thresholds were very similar. Anti-NT3 treatment did not appear to affect the physiology of C-fiber afferents. These results indicate that the availability of neurotrophins can selectively affect the functional properties of developing sensory neurons in vivo.

452.8

SINGLE UNIT RECORDINGS OF CHICK CUTANEOUS SENSORY NEURONS IN VITRO AND IN DRUGS: G.R. Lenzi1, K.V. Troyka, and Y.A. Barde

Chick sensory neurons have been commonly used as a model system to study the effects of neurotrophins on neuronal survival in vitro. As these DRG neurons are highly sensitive to NGF deprivation, we have chosen to characterize functionally different types during late embryonic development and early post-hatching. The cutaneous teres majoris mediates pain sensation which was dissected out together with the skin of its innervation territory and placed in an organ bath. Single unit recordings were obtained using conventional techniques and units were analyzed with controlled mechanical, thermal and chemical stimuli. A total of 91 neurons conducting between 0.5-10 m/s were studied. Units displayed no ongoing and mechanical thresholds (von Frey hairs) ranged from 1-64 mN. Of 44 units conducting <1 m/s many had probably non-sense function, as 16/34 were excited by noxious heat (thresholds 35-47°C) and >430 by noxious cold. Application of 10mM bradykinin, 5-HT, histamine, PGE2 activated 14/27 units all of which were also thermosensitive. Following a chemical stimulation 1/14 units displayed lowered heat thresholds and stronger suprathreshold responses indicating sensitization. Heat-insensitive fibers did not respond to chemical stimulation. During the ongoing developmental interval mechanical thresholds tended to increase. At all ages units conducting >2 m/s (presumptive A-fibers) could be classified on the basis of a slowly or rapidly responses to innocuous mechanical stimuli. The results indicate that the cutaneous-nervous in vitro preparation is suitable for the study of functional properties of diverse cutaneous sensory neurons both during embryogenesis and the early post-hatching period.

INFLUENCE OF NEUROTROPHINS ON THE DEVELOPMENT OF PRIMARY AFFERENT PROJECTIONS IN THE CHICK SPINAL CORD: A.L. Edie*, G.B. Lewin and Y.A. Barde
Inst. Basic Medical Sciences, University of Oslo, N-0317 Oslo, Norway. Dept. Neurobiochemistry, Max Planck Institute for Psychiatry, D-81325, Martinsried, Germany.

Primary afferent projections in the chick can be studied using the lipophilic tracer DiI. In the present experiments we have examined the influence of neurotrophin treatment or deprivation with monoclonal antibodies to NT3 and NGF. NT-3 was delivered by NT-3 secretion A-293 cells placed on the choroidallastic membrane at E15, whilst antibodies were delivered by hybridoma cells. At E12 or E14 treated and control embryos were fixed and DiI was injected into the L5 DRG, the L5 spinal nerve or into an identified muscle or skin. All afferent fibers or primary afferents have long ranging projections outside their segment of entry and have collaterals at least 6 segments below their segment of entry (Ekemalm and Comp Neuror, in press). In contrast, L5 fibers in anti-NT3 treated embryos projected primarily to their segment of entry. Furthermore, axons projects ventrally to the motoneuron pool although those labeled only retrogradely were seen innervating all dorsal horn laminae. Interestingly, sensory neurons and their collaterals in the dorsal horn were labeled from muscle nerves, but few collaterals were seen in the ventral horn. After NT-3 application intersegmental projections appeared normal, although there appeared to be fewer collaterals in L2-3 segment of entry. This may be related to a change in the phenotype of sensory neurons treated with NT-3 (Lewin et al. Soc. Neurosci Abs this volume). Finally, animals treated with anti-NGF showed little projection to laminae, which is consistent the idea that C-M fibers are killed by this treatment. The results suggest that primary afferent projections may be modulated by the availability of neurotrophins.

POSTNATAL AUDITORY NEURONES DEPEND UPON BRAIN DELINEATED NEUROTROPHIC FACTOR FOR SURVIVAL: M. LeBleu*, J.E. Boudreau and R. Lefebvre
Dept. of Otolaryngology & Audiology, Alwin P. G. de Lancey, MD. Hospital of Medicine, Bronx, New York 10461; Dept. of Physiological and Pathological University of Liege, Liege, B-4000, Belgium.

Both aR/3 and aR/4 immunolocalized over neurons while aR/2a was associated with the supporting cells of the postnatal spiral ganglion. Using in situ RT-PCR of postnatal cochlea tissue sections, we identified products for NGF, BDNF and the NGF isoform in this tissue. Organotypic explants of postnatal organ of Corti were cultured in the presence of either antisense or sense nucleotides (5mM) for NGF, BDEN or NT3. ELISA testing showed a 90% reduction in NGF protein levels in response to NGF-AS oligo. Evaluation of the effects of neurotrophin antisense treatment in explants was accomplished by confocal microscopy of antiGlut1 immunostained whole mount. BDNF-AS treatment resulted in neuronal cell death. NT-3-AS treatment affected synaptic contacts, and downregulation of NGF destabilized perisome platinic findings demonstrate that the neurotrophins studied play separate, unique but interrelated roles in postnatal organ of Corti explants. (Supported by grants from NIH, DOD0488 to TRV, HS, NSF of Belgium to FPL and GM).

HIGH-AFFINITY NEUROTROPHIN RECEPTOR EXPRESSION IN THE CAT RETINA DURING NORMAL DEVELOPMENT AND FOLLOWING NEONATAL VISUAL CORTEX DAMAGE: V.R. King, J.T. Xue, and P.D. Spear
Dept. of Psychology and Ctr. for Neuroscience, Univ. Wisconsin, Madison WI 53706.

We recently showed that normal 1-4 week-old kittens that displayed pericellular labeling of the high-affinity nerve growth factor receptor (p140NGF) in the retinal ganglion cell layer (GCL). In addition, kittens that receive a visual cortex lesion at E14 show normal 1-4 week-old kittens. Soma and dendrite labeling indicated that many of these cells are ganglion cells. Kitten that received V3 damage on day of birth had greater pericellular labeling in the hemisphere projecting to the damaged hemisphere than in the hemisphere projecting to the intact hemisphere. This difference was seen in kittens that survived from 3 days to 8 weeks, but not for 12 weeks. It also was seen in kittens at 12 weeks of age, but not for 26 weeks. Truncated k1a labeling was light and limited to the nerve fiber layer. The p140NGF receptors may be involved in retinal development and plasticity. In addition, both nerve growth factor, which binds preferentially to k1a, and BDNF may affect the retina via Müller cells.

NORADRENERGIC NEURONS IN THE LUCUS COEULEUS OF BIRDS EXPRESS TRKA AND TRP AND RESPOND TO NGF: G.S. von Bardeleben, A. Schober, Y. Kadonaga, R. Williams, and M. Bothwell
Dept. of Physiology and Biophysics, University of Washington, Seattle, WA 98195 & Dept. of Developmental Biology, Biomedical Center, Uppsala University, Uppsala, Sweden.

The noradrenergic neurons in the chicken locus coeruleus express the neurotrophin receptor p75 (see von Bardeleben et al. Brain Res. 599:320-479, 1992). To determine which neurotrophin may regulate these neurons, expression of trk receptors was examined by in situ hybridization. A subpopulation of neurons in the locus coeruleus expresses trkA receptor at 9 and 18 days of incubation (El and E18). To test if these neurons can bind and internalize NGF, retrograde transport of radio-iodinated NGF was examined. Neurons in the locus coeruleus of E15 chick embryos accumulate 1:125 NGF after injections into the basal forebrain. The retrograde transport of radio-iodinated NGF is restricted to the noradrenergic neuronal population as evidenced by double-labeling with an antibody to dopamine-beta-hydroxylase (DBH). To test if these neurons respond to NGF, explants cultures and dissociated neurons were treated with or without NGF. NGF did not significantly improve neurite outgrowth from E15 explants or the survival and morphology of DBH-labeled coeruleus neurons that were dissociated at E12 and labeled with DBH antibody two days later. In vivo, the site of DBH-labeled coeruleus neurons was visualized by injections of NGF into the telencephalon of E19-20 embryos, but NGF did not rescue these neurons from toxin-induced cell death after injections of 6-hydroxydopamine. These data suggest that noradrenergic neurons may play a role in the development and physiology of the avian locus coeruleus. The data confirm major differences in the occurrence of neurotrophic factors in birds and mammals with regard to trophic regulation of presumptive homologous neuronal populations. Supported by grants from NIH (HD 29717, HS 30305), DFG (F98V-1/1) and the Medical Faculty of Uppsala University.

Several neurotrophic factors enhance motoneuronal survival in vitro and in vivo. The most potent of those reported to date, the neurotrophins BDNF, NT-3 and NT-4/5, act by binding to specific membrane receptors shared by all other neurotrophins. We tested recombinant hGDNF on purified motoneurones from E14 rat spinal cord. After 5 days in culture, GDNF maintained nearly all (>90%) motoneurones that initially developed; similar efficacy was obtained with mouse response curves revealed that GDNF was 20- to 50-fold more potent than the neurotrophins; half-maximal survival was achieved at 0.01-0.1 ng/ml.

Using RT-PCR, GDNF mRNA was detected in E15 rat limb bud, cultured neonatal Schwann cells and embryonic myotubes; levels in skin were considerably lower. In situ hybridization on sections of E14.5 rat embryos showed signal over some muscle masses and some developing nerve tracts; labeling was essentially absent from the spinal cord and skin.

Taken together, these findings suggest that GDNF plays an important role in early motoneuronal development. Its actions may be complementary to those of the neurotrophins (and perhaps other factors) both during development and in therapeutic approaches to human motoneurone disease.

Systemic NGF injections in fetal rats preserve excess ganglionic cells and interspersed TGF-β related patterns in the hindbrain (Henderson et al., J. Neurosci. 14, 94; primary afferents in the hindbrain also lack somatotopic patterns and collaterals and do not have ephaxtor axons. Because these findings suggest mechanisms by which the periphery makes CNS patterns, it is important to understand how NGF alters pattern formation. Oligo NGF preserve (or induce) a transient ephaxtor projection to whisker-like surfaces that lessens disparity in the innervation densities of the whisker follicles and intervening skin, wherein lesioning the "digitized" nature of the resultant CNS map. A related idea is that NGF accelerates development of a late-arriving innervation of inter-whisker-like, leading to the same CNS effect. These hypotheses are tested by systematically injecting rats with NGF on embryonic days 15 and 18, sacrificing at birth, confirming that CNS pattern were absent, and examining the myotaxic pad innervation with PFG 9.5 and RTF7 immunofluorescence. Comparable infraorbital nerve fascicles in NGF- treated neonates were larger and contained more labeled axons than in normal neonates, although the innervation of whisker follicles seemed comparable in both distribution and maturation. However, preliminary observations indicate that the innervation of the inter-digit ephaxtor is more mature in the NGF-treated cases. These data support both of the above hypotheses and suggest that neurotrophins control pattern formation by orchestrating innervation density patterns in the whiskerpad during a critical period in development. NIH DE07374, NS17763, NS24679.
545.2  Evidence for the role of DARP (Dopamine-Releasing Protein) during the development of rat dopaminergic neurons and the adrenal gland.  
D.A. Linnerord, Y.D. Ralphs, Department of Molecular and Integrative Physiology, University of Illinois at Urbana Champaign 61801 
Recent work from this laboratory suggests a role for DARP during development. DARP is a glycoprotein that is secreted from the cortical striatum in vivo (Brain Res. 463: 335) and has been immunocytochemically located in the adrenal gland (Neuroendocrinology 58: 444) and in close association with catecholaminergic neurons in the rat CNS (Neuroendocrinology, in press). In addition, intracranial administration of an anti-DARP monoclonal antibody (DARP mAb) in embryonic day 10 rats failed to alter the pattern in response to a dose-dependent manner (Mol. Cell. Neurosci. 2: 410). In this study, ELISA analysis indicated that normal DARP concentrations were maintained in the brain extracts from E17 brains that were two to three times higher than those reported for P5 rats. These findings add to the evidence that DARP is present in the embryonic and early postnatal rat brain and may play a role in the pre- and postnatal development of dopaminergic neurons of the mesencephalon and the postnatal development of the adrenal gland.

NEUROTROPHIC FACTORS: BIOLOGICAL EFFECTS X

545.1 RECOMBINANT HUMAN INSULIN-LIKE GROWTH FACTOR--I (hIGF-I) PREVENTS CISPLATIN-INDUCED NEUROPATHY  
Injection of the endogenous excitotoxic quinolinic acid into the rat striatum produces a lesion which is neurochemically similar to that seen in Huntingdon's disease. We examined whether neurotrophin-3 (NT-3), a member of the neurotrophin family of growth factors, is capable of reducing the damage caused by quinolinic acid in the rat striatum. NT-3 (0.15 or 0.5 μg/kg) was infused via osmotic pump into the brain hemisphere for 12 days, beginning immediately after injection of quinolinic acid (225 nmol in 1 μl PBS). Control rats received PBS infusions following quinolinic acid injection. Rats were sacrificed on day 12 and both the lesioned and intact striatum dissected for measurement of choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) activities, neurochemical markers for cholinergic and GABAergic neurons, respectively. Quinolinic acid injection depleted GABA activity by 13% in the intact, uninjected side; NT-3 infusion at a dose of 0.15 mg/kg attenuated the effect of quinolinic acid, with ChAT activity on the lesioned side reduced by only 12% (p<0.05), while NT-3 at a dose of 0.5 mg/kg did not have a significant effect on the depletion of GAD activity. These findings suggest a possible therapeutic role for neurotrophic factors in reducing or reversing neuronal damage in Huntingdon's disease.

545.2 NEUROTROPHIN-3 REDUCES DEPLETION OF STRIATAL CHAT AND GAD ACTIVITIES FOLLOWING QUINOLINIC ACID LESION  
Injection of the endogenous excitotoxic quinolinic acid into the rat striatum produces a lesion which is neurochemically similar to that seen in Huntingdon's disease. We examined whether neurotrophin-3 (NT-3), a member of the neurotrophin family of growth factors, is capable of reducing the damage caused by quinolinic acid in the rat striatum. NT-3 (0.15 or 0.5 μg/kg) was infused via osmotic pump into the brain hemisphere for 12 days, beginning immediately after injection of quinolinic acid (225 nmol in 1 μl PBS). Control rats received PBS infusions following quinolinic acid injection. Rats were sacrificed on day 12 and both the lesioned and intact striatum dissected for measurement of choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) activities, neurochemical markers for cholinergic and GABAergic neurons, respectively. Quinolinic acid injection depleted GABA activity by 13% in the intact, uninjected side; NT-3 infusion at a dose of 0.15 mg/kg attenuated the effect of quinolinic acid, with ChAT activity on the lesioned side reduced by only 12% (p<0.05), while NT-3 at a dose of 0.5 mg/kg did not have a significant effect on the depletion of GAD activity. These findings suggest a possible therapeutic role for neurotrophic factors in reducing or reversing neuronal damage in Huntingdon's disease.

545.3 NEUROTROPHIN-4/5 AND TRANSFORMING GROWTH FACTOR--A PARTIALLY PROTECT STRIATAL CALBINDIN-CONTAINING NEURONS AFTER QUINOLINIC ACID LESION  
T. Akef*, V. Usunoff and E. Helft, Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089. 
Lesioning of the parasympathetic preganglionic cholinergic neurons by the excitotoxin quinolinic acid (QA) results in the degeneration of medium spiny neurons that contain γ-aminobutyric acid (GABA). Neurotrophic factors have been shown to rescue degenerating cortical pyramidal neurons in vitro and in vivo. We have tested the efficacy of neurotrophin-4/5 (NT-4/5) and transforming growth factor--α (TGF--α) on the QA lesioned striatum. Conclusions were made for administration to rats lesioned acutely with QA. Caudate rats received a single unilateral intrastriatal injection of QA (150 μg). Treated rats were injected either with NT-4/5 (0.6 μg), TGF--α (0.8 μg) or both (0.6 μg NT-4/5 and 0.8 μg TGF--α) into the QAx-injected side. Control rats received saline injections. The animals were sacrificed 7 days after injection. 

545.4 FAILURE OF CONTINUOUS INTRATHecal NEC INFUSION TO PREVENT TOXIC CHEMICAL-INDUCED DISTAL AXONOPATHY DESPITE REPEATING THE INJURY-INDUCED UPREGULATION OF C-FUN EXPRESSION IN DRG NEURONS  
B.C. Golub*, T. Stenson-Dickerson and D.R. Antin, Center for Research on Occupational & Environmental Toxicology (CROET) and Department of Cell Biology & Anatomy, Oregon Health Sciences University, Portland, OR 97239. 
Clinical trials of NFL for the treatment of peripheral neuropathies have begun. However, direct (morphological) evidence that NFL prevents axonal degeneration is lacking. In the present study, we asked whether supplementing the cell body's supply of neurotrophic factors by intrathecally perfusing NFL prevents the development of distal axonal degeneration in a proangiogenic model of distal axon degeneration. 3,4-Dimethyl-5-2-  
hexanone (DMDH), a potent derivative of the gamma-diketone, was given daily intrathecally to naive rats for 2 weeks. Rats were perfused with 5% paraformaldehyde at 7 days. The axons were etched in 20% ammonium hydroxide to reveal the axons' Neurophilic factors may provide protection for subpopulations of striatal cells. 

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
BNF PROTECTS CULTURED DENTATE GRANULE CELLS AGAINST HYPOGLYCEMIC DAMAGE

Tadatoshi Ito, Akira Ohkawa, Masao Kakita, and Oli L. Lindvall
Respiratory Neurology Unit, Department of Neurology, University Hospital, S-22185 Lund, Sweden

We have previously shown (Lindvall et al., 1991, 1992, 89, 648-652) that and 10 min of insulin-induced hypoglycemic coma led to a marked increase of BNF and NGF mRNA levels in dentate granule cells. The aim of this study was to explore whether brain-derived neurotrophic factor (BNF) in insulin-deprived cultures of rat dentate granule cells subjected to a hypoglycemic insult. Dentate gyrus was dissected from rat pups (P5-6), dissociated and cells were plated on chamber slides at 37°C in 1% CO2 and with 95% humidity. After 24 h the serum-containing medium was switched to serum-free N2 medium. The hypoglycemic insult was induced after 7 days in vitro by glucose deprivation. The duration of hypoglycemia was 3h and cultures were fixed and processed for MAP-2 immuno-cytchemistry immediately thereafter. In control cultures 40% of cells was stained. Glucose deprivation for 15h caused severe neuronal loss (about 70%). BNF added 24h before or 6h after onset of hypoglycemia completely protected granule cells against the insult-induced damage. Nerve growth factor (NGF) had similar effects. These findings support the hypothesis that the rapid up-regulation of BNF and NGF mRNAs in dentate granule cells after brief periods of hypoglycemic coma and other insults is a local protective mechanism.

453.5
A QUANTITATIVE ANALYSIS OF ASTROGLIAL AND MICROGLIAL CELL REACTIONS IN PRIMARY SENSORY SPINAL TRUNK TRANSECTION: FOLLOWING SCARCE NERVE INJURY AND TREATMENT WITH NERVE GROWTH FACTOR IN THE ADULT RAT

Eriksson S., Eriksson K. E., Persson M., Portera-Cailliau C., and Halldin C.*
Dept. of Neuroscience, Karolinska Institutet, S-171 77, Stockholm, Sweden

Previous quantitative immunohistochemical studies have shown that the microglial cell reaction in primary sensory projection areas after peripheral nerve injury follows a very rapid exponential growth phase which is succeeded by a constant exponential growth phase; the peak level is reached after 5-10 days and is sustained for more than 70 days after injury (Eriksson et al., Exp. Brain Res., 1993; 96-127). Further, it has been shown that following peripheral nerve injury, astrocytes are activated via reactive microglial cells (SVV et al., J. Neurosci., 1993; 13: 273-303). Using image analysis we have examined quantitatively the temporal appearance of the astroglial reaction to scarrc nerve injury as revealed by the area of glial fibrillary acidic protein (GFAP) immunoreactivity in the dentate granule nucleus. Concomitantly, the temporal appearance of GFAP-mRNA profiles were observed by in situ hybridization. Astroglial cells in the dorsal horn and the granule nucleus were seen to follow similar growth and decline curves with an increase to two days and a maximum to two-three weeks following scarrc nerve transection with nerve growth factor (NGF) during four weeks following scarrc nerve transection did not result in any different glial response, as investigated with our quantitative methods. These results indicate, that even though promoting dorsal root ganglion (DRG) cell survival, NGF does not seem to have any influence on the glial cell reaction neither directly nor indirectly through the innuited DRG-neurons. The microglial cell reaction therefore does not seem to be triggered by the target loss of the sensory neurons.

CHRONIC NGF TREATMENT RESTORES HIPPOCAMPAL MUSCARINIC, BUT NOT NICOTINIC RECEPTOR FUNCTION FOLLOWING FIMBRIAL TRANSECTION

P. A. Landshø, D.M. Araya and F. Hed, Andersson Neurology Center, University of Southern California, Los Angeles, CA 90089-0191.

The effects of chronic NGF administration (1 mg qod for 21 days) on hippocampal muscarinic and nicotinic receptor densities and functions were determined in adult rats with partial fimbrial transections. The first study, the distribution of cholinergic receptors in the hippocampus was determined using autoradiography. Neither fimbrial transections nor NGF treatment altered the density of muscarinic M1 (H-pirenzepine) or M2 (H-2AF-DX) binding sites in the hippocampus. In addition, neither the lesion nor NGF treatment altered the distribution or density of nicotinic [3H]-diethylaminoethylazabenzimidazole-2(1H)tetrahydroazepine (TPH) uptake in the hippocampus. Second, we determined the effects of NGF treatment on muscarinic receptor-mediated second messenger production in rats with fimbrial transections. In lesioned rats, oxotremorine i.p. increased IP3 synthesis by 81% compared to the contralateral unlesioned side. This lesion-induced supersensitivity of M1 muscarinic receptor function was prevented by chronic NGF treatment. Third, we determined whether nicotine receptor functions using the rat fimbrial transection model and nicotinic-induced uptake of [3H]-tetraphenylphosphonium (TTPP) into hippocampal synaptosomes as a marker. In the unlesioned control hippocampus, nicotine produced a characteristic 35% reduction of [3H]-TTPP uptake into synaptosomes. However, in rats with partial fimbrial transections there was a loss of nicotine-induced alterations of [3H]-TTPP uptake into synaptosomes. Chronic NGF treatment did not affect nicotine-induced [3H]-TTPP uptake, nor did it reverse the lesion induced loss of presynaptic hippocampal cholinergic functions involved in ACh turnover (Lapchak, Exp. Neurol. 124, 16-20, 1993) translate into an enhanced function of postsynaptic muscarinic M1 receptor function. However, chronic NGF treatment does not attenuate the lesion-induced loss of presynaptic nicotinic autoreceptor function.

THE MICROGlia/MACROGliE RESPONSE FOLLOWING NGF INJECTION INTO THE HIPPOCAMPUS

M. Knott, D. Elegua, K. Andrews, M. Sipes, & A. Avendaño, Department of Neurological Surgery, University of Washington School of Medicine & Seattle VA Medical Center, Seattle, WA.

The response of microglia and macrophages during waldrogen degeneration of axons is remarkably different in the peripheral PNS and central CNS. Nervous system of adult mammals (Soffin et al., 1993; Perry et al., 1987). In the PNS, blood monocytes rapidly infiltrate degenerating nerve to clear and neural debris, in contrast, the recruitment of monocytes and response of microglia with clearance of cellular debris is much slower in the CNS. The mechanisms underlying the differential recruitment of microglia and macrophages are unclear. Neurone Growth Factor (NGF) has been shown to be a possible chemotactic factor for leukocyte recruitment (Boyle et al., 1985). The low affinity (NGF) and high affinity (NGF) receptor have been detected in a number of mouse and rat isolates (Lin et al., 1990, and Yan and Johnson, 1990; Morgan et al., 1989). In addition, a linear arrangement of macrophages was found immediately adjacent to NGF treated but not untreated trophic implants injected into rat spinal cords (Houle, 1992). NGF may therefore play a role in modulating the response of microglia and macrophages in the CNS. To test this hypothesis, we performed local needle injections of NGF, vehicle (2% bovine serum albumin), into needle injections into rat spinal cords either with or without an injection of an adjacent dorsal cord (12). We employed the ED1 immuno-microscopy which normally stains peripheral ral macrophages and monocytes but not CNS microglia. Immunohistochemistry was performed upon paraflxed eneved paraffine sections of spinal cords. Following simple transection of a dorsal root, we found ED1 labeled cells infiltrating the PNS portion of the cut dorsal root after a delay of days that stopped abruptly at the PNS/CNS interface and did not extend into the spinal cord for up to 3 weeks. Needle injection into the spinal cord induced the local appearance of ED1 staining cells. The number of cells and volume of tissue staining with ED1 was greater following injections of NGF, significantly less with injections of vehicle alone, and smallest following needle injection alone. Spinal cord injections of NGF combined with an adjacent dorsal root resulted in ED1 labeled cells extending across the PNS/CNS interface of the cut dorsal root towards the injection site. These results suggest that NGF may activate microglia to express ED1 and/or induce the migration of peripheral ED1 monocytes/microphages into the CNS. Supported by NH and VA Funds.

Retinal ganglion cell (RGC) survival can be enhanced by the intracranial administration of BDNF or NT-4 (Mansour-Robay et al., PNAS 91: 1652-1656, 1994. Chau et al., submitted). Is there still a role for NT-3 on RGC survival and regeneration? Intracranial injections of NT-3 (provided by Regeneron Pharmaceuticals Inc.) had only a marginal effect on the overall survival of gap43-expressing RGCs, consistent with the observation that immunocytochemistry for TrkC, the high affinity receptor for NT-3, revealed staining in only 5% of RGCs. However, in comparison to the more neurotrophic, NT-3 increased intraretinal axonal growth, as revealed by staining with RT91, a monoclonal antibody to the heavy neurofilament subunit.

The effect of NT-3 on the expression of GAP43 mRNA was then investigated by in situ hybridization. Two weeks after axotomy, approximately 10% of surviving RGCs expressed high levels of GAP43 mRNA. After NT-3 treatment, the incidence of these GAP43-expressing cells increased to 30% of surviving RGCs. Furthermore, GAP43 mRNA levels within these cells doubled, compared to operated controls. These findings suggest that NT-3 has a significant effect in increasing GAP43 expression and on axonal growth of a discrete population of RGCs.

EFFECT OF NT-4/S IN AXOTOMIZED RAT FACIAL MOTOR NEURONES. Karl Fernandes, Annie Beaudet and Wolfram Teissieg. Dept. of Physiology, University of Ottawa, Ottawa, Canada.

We have previously shown that axotomy of facial motoneurons induces the expression of GAP-43 and Tau-1 tubulin mRNAs while the expression of neurofilament mRNA is decreased. In addition, we report here that the mRNA expression for AChE is reduced by about 35% consistent with the general downregulation of neurotransmitter related mRNAs after axotomy. In the present study we have tested the role of a presumed target derived neurotrophin, NT-4/S, in the regulation of these changes in gene expression. The facial nerve of male adult Sprague Dawley rats was transected at the stylomastoid foramen and the proximal nerve stump attached to the lumen of a silastic tubing. The latter was connected to a chronic minipump which delivered 1 ul with 125 ng (low dose) or 500 ng (high dose) NT-4 per hour over a period of 7 days. The contralateral proximal nerve stump received vehicle only. In situ hybridization revealed that application of NT-4/S sustained the expression of ACNE mRNA at normal levels (202 % of vehicle, n=4) and further stimulated the expression of GAP-43 (211 % of vehicle, n=4) and Tau-1 tubulin (170 % of vehicle, n=4) mRNA. The expression of neurofilament-M (NFM) mRNA was increased to 150% of vehicle (n=4), but was only significantly different from vehicle in 1 of 4 animals. NFM expression was still far below a normal level of expression, thus, not normalized by NT-4 treatment.

These data show that NT-4/S enhances regeneration associated gene (GAP-43, Tau-1 tubulin) expression and might be useful to stimulate peripheral nerve regeneration. Supported by MRC of Canada.

EFFECT OF CNTF DELIVERY METHODS TO RESCUE FACIAL MOTONEURONES FROM INJURY-INDUCED CELL DEATH. E.A. Tarin, V. Pedrun, A. Mercier, J. Hammang, E. Batzios, A.O. Zurn, P. Astrid, Lausanne University Medical School, Switzerland; CytoTherapeutics, Providence, RI.

Ciliary Neurotrophic Factor (CNTF) has been shown to increase the survival of motoneurons in vitro and in vivo. For potential human application, the mode of delivery needs to be investigated. In the present study, local application of CNTF on the transected facial nerve of neonatal rats was compared to systemic delivery through a murine recombinant (rhCNTF) and to transplantation of genetically engineered cells. Baby hamster kidney cells (BHK) were transfected with a pMNJ vector containing either the gene for mouse CNTF (mCNTF) or human CNTF (hCNTF) and were encapsulated in polypropylene fibers to prevent tumor formation and immune rejection. Facial nerves of neonatal (P2) rats were transected and CNTF was delivered by direct application of CNTF on the nerve stump using gelatin impregnated with mCNTF (0.25mg/ml); ii) by repeated subcutaneous injections of rhCNTF (1mg/kg) 3 times a week; or iii) by subcutaneous implantation of 1x10^6 encapsulated BHK cells releasing either mCNTF or hCNTF. Control animals received either bovine serum albumin or the parent BHK cell line. One week post-injury, the number of surviving motoneurons on the lesioned side was compared to the non-lesioned side. All three methods of CNTF application significantly improved motoneuron survival with the encapsulated method appearing to be the most efficient.

ROLE OF NT-3 IN INTACT & INJURED PRIMARY SENSORY NEURONS. K.A. Gratton, P. Friedman & L. Lin. 2 R.N. Lindeman 4 1 Dept. of Anatomy, University of Saskatchewan, Canada; 5700 W. Regeneron Pharmaceuticals Inc., Tarrytown, NY 10951.

The hypothesis that NT-3 plays a role in maintaining the differentiated state of responsive trkC-expressing neurons and may be responsible for reversing changes observed after injury, in vivo was tested. Adult rat right sciatic nerves were proximally cut. 14d after injury NT-3 was intrathecally infused for an additional 7d in half of the rats. Crystal sections of intact and injured DRG with and without NT-3 infusion were processed for in situ hybridization to detect mRNAs encoding trkC and peptides a-CGRP and NPY. Preliminary results indicate that in intact neurons a-CGRP and trkC are abundantly and heterogenously expressed, whereas few if any neurons express detectable NPY mRNA. Two weeks after injury levels of a-CGRP and trkC mRNA are dramatically reduced, while, many neurons now express abundant NPY mRNA. Infusion of NT-3 counteracted injury-induced decreases in trkC mRNA and was also effective in upregulating expression of a-CGRP in many neurons, but the percentage of neurons appeared smaller when compared to injured ganglia infused with NGF. Finally, NT-3 infusion resulted in reduced expression of NPY mRNA in injured neurons, suggesting a role for NT-3 in gene suppression in intact neurons. The ability of exogenous NT-3 to regulate expression of its receptor trkC and differentially regulate peptide expression supports a role for it in maintaining aspects of the differentiated state of adult primary sensory neurons. Canadian MRC supported.

NT-3 AND BDNF PREVENT AXOTOMY INDUCED DEATH OF CORTICOSPINAL NEURONS. Klaus M.G. Giehl* and Wolfram Teissieg. Dept. of Physiology, University of Ottawa, Ottawa, Canada.

A major problem of regeneration in the CNS is atrophy and cell death of injured neurons. We have quantified the death of corticospinal neurons (CSN) induced by axotomy at the level of the internal capsule and tested the effect of survival promoting factors in this system. In vivo hybridization combined with retrograde tracing revealed that CSN express mRNAs for both trkA and trkB but not trkC receptors. This provided the rationale to test the survival effect of Neurotrophins in this model. Again, the CSN were positively identified by spinal cord injection of Fast Blue and a second spinal cord injection of Rhodamine Dextran was applied after internal capsule lesion to control for the area of CSN extended in anterior posterior direction over 5.6mm. A mean of 49.5% (n=4) of the axotomized CSN died within 7 days after injury. Continuous application of saline (0.9% rat serum albumin [vehicle]) via osmotic minipump over 7 days reduced this cell death to 30.4% (n=8). Application of NGF (500ng/ul) resulted in further reduction to 24.2% (n=4), however this was not significantly different from the vehicle. The application of NT-3 (50ng/ul) or BDNF (500ng/ul) prevented the axotomy induced death and only 3.7% (NT-3, n=7) and 10.2% (BDNF, n=4) of the CSN died within the first week after axotomy. These findings are the first demonstration for survival factors for CSN in vivo and may be important for traumatic brain injury and in neurdenerative disorders which involve death of CSN like amyotrophic lateral sclerosis. Supported by MRC and Network of Centres of Excellence for Neural Regeneration and Functional Recovery (Canada).

453.16

Brain-derived neurotrophic factor (BDNF) promotes the survival, differentiation and maintenance of motoneurons. We compared the effects of different BDNF doses on the rescue of axotomized sciatic and facial motoneurons in neonatal rats. Application of BDNF directly to the central nerve stump significantly enhanced motoneuron survival. Additional BDNF supplied with intermittent subcutaneous injections (1 mg/kg, 3 day intervals) yielded a further small survival increase; however, injecting BDNF daily markedly reduced the motoneuron rescue at both 1 week and 2 weeks post-injury. These results, corroborated by findings in motoneuron primary cultures, show that a dose-dependent reversal of BDNF-mediated motoneuron rescue may occur both in vitro and in vivo.
453.17

Conditionally immortalized neural progenitors were infected with a retrovirus coding for mnGfP, and clones were isolated and analyzed for NGF production. Among them, one clonal line of NGF-negative/mnGfP- cells was characterized in vitro for their ability to produce NGF and for the expression of the retroviral vector, finding no differences between the proliferative and growth arrested cultures (permissive and non-permissive temperatures). After grafting to the septum, striatum or nucleus basalis in young animal, the cells survive well and migrate away from the implantation site, and neurite formation is observed. NGF production was studied in dissected pieces of nc basalis tissue 4 and 10 weeks after grafting. RT-PCR revealed moderate but stable expression of the transgene, and a bouquet for NGF demonstrated antigen and NGF-like activity. Immunohistochemical staining for NGF showed high neurotrophic activity on PC12 cells (the hippocampal tissue). Cells grafted to the substantia nigra induced a consistent 40% hypertrophy of the cholinergic cell bodies (1, 4 and 10 weeks post-grafting). When grafted to the septum in rats with fornix lesion, 30% of the cholinergic cells on the lesion side was rescued from acetycholine induced death. Thus, there seems to be a good correlation between cell survival, expression of the transgene, NGF production and cellular effects observed.

We next looked for behavioral effects of the NGF cells in vivo by grafting into the medial septum and/or nc basalis of memory impaired aged animals. In the Morris water maze test, there was a progressive improvement of their performance (2 and 4 weeks post-grafting) up to the point when they were not different from the control, non-impaired animals. Histological analyses revealed surviving grafted cells, as well as a clear hypertrophic effect in the host cholinergic neurons, that showed the same size as in young rats. An increased expression of NGF-like neurotrophic activity from grafted brains will also be presented.

453.19

Subcutaneous injection of acidic fibroblast growth factor (aFGF) into senescence accelerated mice (SAM-R/1) at one per week was started at 3 weeks after birth and continued for 9 months. When tested by passive avoidance and Morris water maze tests, the mice learning and tasking performances were deteriorated in the control group, while those of the aFGF-treated group did not. At the end of the 9 months, brain and striatal tissues were stained immunohistochemically using anti-cholin acetyltransferase (CAT) antibody. The number of cholinergic neurons in the septum was decreased by 15% in the control group and was no change in the aFGF-group treated, as compared to SAM-R/1, a reference strain of SAM-R/8. The activity of CAT in individual cholinergic neurons in the MS also decreased significantly in the control group. Results suggest that aFGF has neurotrophic effects on cholinergic neurons in the MS of SAM-R/8 and ameliorate learning and memory disorder in both tasks tested.

454.1
Effects of BDNF in animal models of parkinson's disease. C.W. Shults, C. Shline, and C.A. Alkon. +VA Med. Ctr., San Diego, CA 92161; Dept. of Neuroscience, Univ. Cal., San Diego; +Regional Research & Ttreatment Center, NY.

Groups of 8 naive rats received 3 unilateral, intrastriatal injections of either BDNF or cytocrome c (22.5 µg/injection) on consecutive days. of the injection or control treatment. On the second day, the animals received an intrastriatal injection of 25 µg of 6-hydroxydopamine hydrobromide (6-OHDA). The animals were then tested weekly for amphetamine and apomorphine-induced rotations in left and right sides. The BDNF treated animals had fewer apomorphine-induced contraversive and amphetamine-induced ipsiversive rotations than did the cytocrome c treated group. At the fourth test week, the BDNF treated group had 0.8 ± 0.4 (mean ± SEM) apomorphine-induced and 0.7 ± 0.8 amphetamine-induced rotations/min, and the cytocrome c treated group had 3.1 ± 1.0 apomorphine-induced and 2.7 ± 0.6 amphetamine-induced rotations/min.

Two groups of rats with partial unilateral lesions of the mesostriatal dopaminergic system, which had been matched for apomorphine-induced rotations, were injected with either BDNF or cytocrome c (22.5 µg/injection) into the partially denervated striatum over 2 weeks. After the sixth injection the BDNF-treated group had significantly fewer apomorphine-induced rotations (2.6 ± 0.4, n=10) than the cytocrome c treated group (5.4 ± 1.0, n=11).

454.2
Effects of BDNF-producing fibroblasts on substantia nigra dopaminergic neurons in vivo. W. B. Galvin, I. K. Tatton, M. F. Peal, D. M. Franl, and H. O. Breckfield, and D. Factor. +Neurogeneregulatory Laboratory, McLean Hospital, Belmont, MA 02178; 2Molecular Neuromeration Unit, Neurosurgery and Neurology Services, Massachusetts General Hospital, Boston, MA 02114; 3School of Medicine, University of Massachusetts, Worcester, MA 01655.

We have previously demonstrated that brain-derived neurotrophic factor (BDNF) is able to protect against dopaminergic (DA) cell loss in the substantia nigra pars compacta (SNc) following striatal infusion of the mitochondrial complex I inhibitor MPTP in rats. To investigate the effects of BDNF on SNc neuronal function in vivo, we performed the following experiments: BDNF was delivered for 4 weeks using microinjection pipettes inserted to the SNc. Half of the implanted rats received unilateral striatal infusion of MPP+ one week after grafting. For the non-lesioned animals, tissue was processed for tyrosine hydroxylase (TH) immunohistochemistry or for biochemical analysis 1-2 weeks following implantation. Lesioned animals were sacrificed 2 weeks after implantation, and the effects of BDNF on the generation of free radicals using salicylic acid-trapping as well as thiobarbituric acid assay were performed. Initial biochemical observations reveal an increase in DA content in SNc neurons associated with BDNF administration. Preliminary assessment of the effects of BDNF on cellular morphology indicate there is no generalized effect on TH+ cell size in the SN. Further experiments aimed at determining the effect of BDNF on the metabolic and oxidative states of DA neurons in intact and MPP+ lesioned rats are in progress.
545.3

Brain-derived neurotrophic factor (BDNF) is a neurotrophic factor for dopaminergic neuronal cells, but the cell type that degenerates in Parkinson's disease(PD) To examine the potential BDNF gene therapy for PD, astrocytes transduced with a BDNF cDNA or alkaline phosphatase (AP) cDNA (control) and prelabeled with Dil were grafted into the right rat striatum 15 days after partial lesioning of the right substantia nigra with 6-hydroxydopamine. Prior to grafting, BDNF mRNA was expressed by BDNF but not AP astrocytes. At 32 days, BDNF astrocytes, but not AP astrocytes, attenuated amphetamine-induced rotation by 45% (p<0.05). Aporphamine-induced rotation was not significantly changed in either group. At 42 days, Dil labeled astrocytes were present in the graft site, however, BDNF mRNA positive cells were not detected with in situ hybridization. Analysis of the density of dopamine transporter (DAT) immunoreactive fibers showed no effect of BDNF astrocytes on the area occupied by TH-positive fibers in the lesioned striatum. These findings suggest that BDNF gene therapy ameliorates Parkinsonian symptoms through a mechanism that does not involve regeneration or sprouting from DA neurons. Furthermore, expression of BDNF from this retroviral construct appears to be down-regulated after a critical period. The efficacy of this method will be addressed before this method can be utilized for long-term delivery of biologically produced BDNF. (Supported by Merck-Kasirsky Trust & AG00926)

545.4

Cholinergic neurons which have been genetically modified to secrete brain-derived neurotrophic factor (BDNF) are effective in enhancing the neuronal survival and neurite extension of embryonic rat dopaminergic neurons in vitro. Rotated mesencephalic tissue transplants containing such embryos were harvested, dissociated, and cultured in a serum-containing medium. Shortly thereafter, three BDNF oligodendrocyte clones (A1, B6, and B12) and the non-BDNF secreting parental line (N1) were individually plated with rMT and rMT and cultured in a 37°C incubator. The coculture medium was changed to a serum-free medium about 24 hours and placed back into the incubator for 4 days. The number of dopaminergic neurons as well as the number of neurite extensions per neuron were then quantified in 7-8 replicates using tyrosine hydroxylase (TH) immunocytochemistry. An mean increase in TH-positive neurons of 5.9%, 41.0%, and 10.5% was observed in cocultures with clones A1, B6, and B12, respectively when compared to rMT alone or rMT cocultured with N201 oligodendrocytes. Thirty-four% of TH-immunoreactive neurons exhibited 3 or more processes when cultured alone or with N201. In contrast, 60%, 80% and 84% of TH-immunoreactive neurons exhibited 3 or more processes when cocultured with the A1, B6, and B12 clones, respectively. BDNF-secreting oligodendrocytes enhance the viability and neuronal differentiation of embryonic dopaminergic ventral mesencephalic neurons suggesting that BDNF oligodendrocytes might enhance the structural and functional consequences of fetal nigral grafts in animal models of Parkinson's Disease.

546.4

The delivery of neurotrophic factors to the CNS poses a major obstacle to the treatment of neurodegenerative disorders such as Parkinson's disease. We have developed a polymer encapsulation technology that provides a means for the delivery of BDNF (generally provided by Regeneron) for a prolonged period of time. Several different types of chitosans, algatanes and co-polymers with various proportions of poly-L-lysine were used. Size distribution profiles were determined by an image analysis system and surface characteristics were assessed by electron microscopy. The mean diameter of microspheres with BDNF was 1.2-1.6 μm whereas spheres with genetically transformed cells secreting BDNF (provided by X.O. Breakefield and M.P. Shotton) were much larger (300-500 μm). The total content of BDNF as well as the amount released per day were determined by dot blot assays. The results from the release kinetics demonstrate that longterm secretion (30-60 days) of BDNF is achieved by chitosan microspheres. Alginate spheres provided only relatively short term release (2-7 days) and the type of macromolecules encapsulated with BDNF significantly influenced the rate of BDNF delivery. Neuron survival and neurite growth in cultures of rat retinal ganglion cells, DRG, and midbrain floor were supported by microencapsulated BDNF indicating biological stability of BDNF. BDNF-secreting cells survived for different periods of times depending on cell density within spheres, sphere sizes, and properties of the semipermeable membranes. These model systems can also be used for delivery of other trophic factors such as CNTF and GDNF. These studies provide a basis for future comparisons of microencapsulated genetically engineered cells and agents used in the treatments of neurodegenerative disorders.

546.5
REGULATION OF PLATELET-DERIVED GROWTH FACTOR (PDGF) AFTER NEURONAL LESIONS AND EFFECTS OF PDGF ON DOPAMINERGIC AND STRIATAL NEURONS IN VITRO. K. Piao 1, K. Fujii 2, Y. Nakajima 1, A. Ichiba 1, T. Tsukamoto 1 and O. Ito 1*, 1Dept. of Pharmacology, graduates School, University of Tokyo, Bunkyo-ku, Tokyo, Japan and 2Dept. of Neuroscience, Kurume Medical School, Kurume, Fukuoka, Japan.

We have previously demonstrated an increased expression of platelet-derived growth factor (PDGF) around intrasplenial implants of fetal dopamine (DA)-rich mesencephalic tissue in a rat model of Parkinson's disease. PDGF-BB but not PDGF-AA promotes survival and neurite outgrowth from rat and human DA neurons in vitro and influences expression of c-fos and tyrosine hydroxylase mRNA in mesencephalic cells. These effects could be directly mediated via PDGF beta receptors expressed on the mesencephalic DA neurons. The objective of the present study was to further characterize the changes of PDGF expression following intrasplenial implants of DA-rich mesencephalic tissue and to analyze the effects of PDGF-AA and -BB on striatal DARPP-32-positive neurons in vitro. Immunohistochemistry, PCR and primary cell culture techniques were used. Following an isotonic acid lesion to the rat striatum (model of Parkinson's disease), a strong increase in the expression of PDGF was observed in astrocytes in the striatal tissue. Also increased PDGF receptor expression was induced in the lesioned area. In cell cultures of fetal striatal PDGF-BB but not PDGF-AA promoted the survival of DARPP-32-positive neurons. Also neurite outgrowth from these striatal cells was significantly more pronounced in the presence of PDGF-BB. These findings indicate that PDGF could be of importance for the survival and function of CNS neurons after lesions and in neurodegenerative processes.

546.8
NEUROTROPHIC FACTORS AND CELL DEATH OF A CELL LINE DERIVED FROM RAT VENTRAL MENENCEPHALON. H. Takashima*, Department of Neurology, Kawata National Hospital, Kawatana, Nagasaki 859-36, Japan.

Basic fibroblast growth factor (bFGF) has neurotrophic effects on dopaminergic neurons. Recently, reduced concentration of bFGF in substantia nigra in the Parkinson's disease brain has been reported. Reduction of this factor might be related to the cell death of dopaminergic neuron in Parkinson's disease. In this study, the effects of neurotrophic factors on the differentiation and cell death of a neuronal cell line derived from rat ventral menencephalon were investigated.

A cell line was established from rat ventral mesencephalon using a retroviral vector containing the temperature-sensitive allele of the SV40T antigen. When cultured with serum-free medium at the permissive temperature, this cell line showed cell death accompanied with DNA laddering in gel electrophoresis and positive in situ staining for DNA 3'-OH end. An addition of bFGF (10 ng/ml) prevented cell death, supported cell proliferation and increased the expression of neoflament in serum-free medium. bFGF (10 ng/ml) and NT3 (10 ng/ml) did not support the survival of the cells in serum-free medium at the permissive temperature.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
454.11 allergic CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) EFFECTS ON NIGROSTRIAL DOPAMINERGIC NEURONS AND BEHAVIOR IN MPTP-TREATED MICE. A. Tomasi,4 E. Lindvist,4 B. Hoffner,4 S. Ogren,5 L. H. Lin,4 and L. Olson.4 1Department of Neuroscience, Karolinska Institute, S-75177 Stockholm, Sweden, and 4Synergon Inc., Boulder, CO 80301.

Allergic glia promotes neuronal growth and survival, but the mechanisms of the trophic effects are still not clear. It has been suggested that trophic substances secreted by astrocytes can modify the sensitivity of neurons to neurotrophins and other trophic factors. In the present study, we have examined whether glial components in MPTP-treated mice, a model of Parkinson's disease, can modify dopaminergic neurons in vitro (Lin et al., Science 260:1130-1132, 1993). We used a novel recombinant GDNF produced in E. coli, which was purified and cloned (Lin et al., Science 260:1130-1132, 1993). We used a novel recombinant GDNF produced in E. coli, which was purified and cloned (Lin et al., Science 260:1130-1132, 1993). We used a novel recombinant GDNF produced in E. coli, which was purified and cloned (Lin et al., Science 260:1130-1132, 1993). We used a novel recombinant GDNF produced in E. coli, which was purified and cloned (Lin et al., Science 260:1130-1132, 1993). We used a novel recombinant GDNF produced in E. coli, which was purified and cloned (Lin et al., Science 260:1130-1132, 1993).

We examined the effects of a single intracerebral injection of recombinant GDNF 24 hours prior to or 7 days after MPTP exposure in C57/BL mice, monitoring neurochemical and behavioral changes. MPTP (50 mg/kg, i.p.) was injected in a volume of 2 ml into the striatum or over the substantia nigra. Animals were monitored for either 5 or 18-20 days postoperatively, and were then sacrificed for HPLC analysis. Behavioral data include significant increases in spontaneous motor activity (freezing, locomotion and motility) in GDNF-treated compared to vehicle-treated animals. HPLC data showed significant increases in dopamine levels in striatum (97%, p<0.001) and substantia nigra (87%, p=0.003) compared to vehicle-treated animals, when GDNF was given in striatum 24 hours prior to MPTP exposure. When GDNF was given into the striatum 7 days after MPTP exposure and sacrifice, increases in dopamine levels were found in striatum (70%, p=0.003) and in substantia nigra (94%, p=0.0001) compared to vehicle-treated mice. Injection over substantia nigra also led to increases in dopamine levels, but only in substantia nigra (64%, p=0.004) compared to vehicle-treated animals. The findings reported here suggest that GDNF may play a crucial role for dopaminergic neurons, reverting effects of MPTP toxicity in this rodent model of Parkinson's disease.

454.12 BEHAVIORAL, NEUROCHEMICAL, AND HISTOLOGICAL CHANGES IN THE NIGROSTRIATAL SYSTEM OF UNILATERALLY 6-OHDA LESIONED RATS FOLLOWING INTRANIGRAL ADMINISTRATION OF GLIAL CELL-LINE-DERIVED NEUROTROPHIC FACTOR. H. T. van der Kolk,5 A. Van der Hagen,5 E. Clark6, and H. J. F. Van den Bergh.5 1Department of Neurosurgery, Karolinska Institute, S-75177 Stockholm, Sweden, and 5Synergen, Inc., Boulder, CO, USA.

Young adult male Fischer 344 rats were unilaterally injected into the medial forebrain bundle with 6-hydroxypoline (10 mg/kg, 4-6 mg/ml), or saline (4 ml). A single injection (7) was used to select animals whose average rotation exceeded 100 degrees/90 min (100% depending to greater than 99% dopamine (DA) depletion in the ipsilateral striatum. Six weeks later, 0.1 to 100 pg of GDNF (Synergen, Inc.) or vehicle was injected intranigral ipsilaterally to the lesion. Amphetamine-induced rotational behavior (Sigma, St. Louis, MO, US) was quantified weekly for up to 5 weeks post-GDNF injection. Rats were sacrificed at 1, 3, and 5 weeks post-GDNF, for tyrosine hydroxylase (TH) immunohistochemistry and HPLC, for the region of the TH immunoneurons. The presence of NE, DA, DOPAC, HVA, 5-HT, and 5-HIAA in the right and left substantia nigra (SN), ventral tegmentum, and striatum. The highest dose of GDNF treated (100 pg) produced a greater than 65% decrease in rotational behavior which persisted for 5 weeks. This dose also produced leave of DA and DOPAC in the ipsilateral SN which were not statistically different from the contralateral, unlesioned side. Vehicle-treated animals showed an marked DA depletion in the ipsilateral SN. In contrast, there was no change in the lesioned side in the ipsilateral striatum. Immunohistochemistry of nigral sections from the 100 pg GDNF dose groups showed vacuoles associated with increased TH-immunoreactivity. These results demonstrate neurochemical and behavioral improvements in unilaterally-lesioned rats following intranigral administration of GDNF, suggesting that GDNF may be a useful therapy for Parkinson's Disease.
454.15
POSTNATAL SPINAL CORD GRABS IN OCULO: EFFECTS OF TREATMENT WITH GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR. K. Troik, B. Hoffner*, D. Russell**, I. Olson, Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden, and **Synergex Inc., Boulder, CO.

Glial cell line-derived neurotrophic factor (GDNF) is postulated to be a trophic factor for developing dopaminergic neurons. However, the distribution of mRNA for GDNF in the prenatally injured spinal cord is unknown. The intracortical transplantation of neural tissue provides a unique approach to study the actions of trophic factors in vivo. In the case of spinal cord, although prenatal tissue matures well in the anterior chamber, grafts from newborn animals showed limited survival and reduce their size. Grafts from two-week-old animals usually do not survive at all. In our studies spinal cord tissue from newborn (P1) rats was transplanted to the anterior eye chamber of hosts rats after incubation in 200 μg/ml, 10 μg/ml GDNF or vehicle. GDNF in doses of 0.5 μg, 0.1 μg or 0.05 μg was then injected into the anterior eye chamber at days 5, 10, 15 and 20. There was a dose-dependent increase in growth of the transplants induced by GDNF. Indeed, grafts treated with 0.5 μg actually grew to larger than their initial size after grafting. We also transplanted P14 spinal cord to the anterior eye chamber and injected 0.5 μg CD3P at days 5, 10, 15, 20, 30 and 35. Grafts treated with GDNF also responded with increased growth compared with controls, but did not exceed their original size at transplantation. We are currently investigating the immunohistochemical properties of these grafts.

454.17

GDNF was known to enhance the survival and development of midbrain dopaminergic neurons with an EC50 of ~40 ng/ml (Lin et al., Science, 260:1130, 1993). To further define the specificity of the neuroprotective activity of GDNF, we determined the EC50 for promoting the survival of several distinct classes of embryonic chick PNS neurons on immunoprecipitated chick (ESC) neurones, parasympathetic ciliary ganglion (CG) neurons and sensory dorsal root ganglion (DRG) neurons. In addition, we also examined GDNF as a neurotrophic factor for neocortical rat superior cervical ganglion (SCG) neurons. GDNF promoted the survival of CG, CRG and DRG neurons with an EC50 of 9, 13 and 325 ng/ml, respectively. However, these values are several order of magnitude greater than that required for GDNF to function as a dopaminergic neurotrophic factor in midbrain cultures. GDNF at all concentrations tested (100 ng/ml to 10 μg/ml) could not support the survival of rat SCG neurons in serum-free defined culture medium whereas NSG at 50 ng/ml promoted neuronal survival and neurite extension. Hence, although GDNF can promote the survival of some PNS neurons, GDNF appears to be most potent with cultured midbrain dopaminergic neurons.

454.19
MODULATION OF NEUROTROPHIN RECEPTOR TYROSINE KINASE (RTK) PATHWAYS IN THE MESOLIMBIC DOPAMINE SYSTEM BY DRUGS OF ABUSE. D.S. Russel*, M.T. Behrow, K.L. Winder, and E.J. Nestler. Laboratory of Molecular Psychiatry, Dept of Neurology and Psychiatry, Yale Univ Sch of Med, New Haven, CT 06510

The AMP system is an important mediator of neuronal changes due to drugs of abuse in the mesolimbic dopamine system (Nestler, 11,955, 1993). Neurotrophic factors may modulate or mitigate these changes (see accompanying abstract, Behrow, et al.) Various methods are being employed to investigate the role of the neurotrophin RTK pathways, and their regulation by the AMP system, in the changes induced by morphine and cocaine. Chronic morphine treatment in rats increases PLC-infranmuneactivity in the VTA by 20-30% as determined by western blotting. Morphine also appears to regulate ERK1 and 2 differentially, while significant changes in the levels of raf, PI-3-kinase, and pax were not observed. Chronic cocaine, however, decreased PLC by 10-20%. Several proteins that are immunogically like insulin receptor substrate-1 (IRS-1) are detected in rat brain and some appear to be associated with raf receptor complexes. Levels of a 100 kDa IRS-1-like protein decrease in the VTA with morphine treatment, while levels of a 130 kDa form increase in the hippocampus. Studies of regulation of the phosphorylation states and activities of these proteins are ongoing. Several recent studies demonstrate interactions between the AMP system and RTK pathways. This abstract will mediate to make this include our, ERK and CREB. Single injections of CREB antisense-S-cis-2-acetoxybenzoic acid into the nucleus accumbens lead to a 50% decrease in CREB levels, and attenuate Fos-like protein expression and result in rotation behavior in response to an acute amphetamine challenge. This approach should help to elucidate the study of CREB and the various other proteins mentioned above, in mediating the converging actions of neurotrophins and drugs of abuse in specific brain regions.

454.16

In the present study, the effects of single injections of GDNF into the substantia nigra or striatum of five monkeys were investigated using immunohistochemical, neurochemical, and behavioral methods. GDNF was injected using MRI-guided sterile stereotactic surgery into 150 μg of dopamine into the right substantia nigra and 450 μg/18 into the right caudate nucleus. A separate group of animals served as controls receiving equal volume injections of phosphate buffered saline. Monkeys were tested for functional behavioral changes in the post-GDNF infusions. GDNF was seen to produce some behavioral changes in the animals for up to three weeks following the injections. Some decrease in body weight, increase in activity and occasional slurry disturbances were seen in the GDNF injected group as compared to controls. In vivo electrophysiological studies involving local application of potassium using NFAT-coated carbon fiber electrodes showed increased DA release in areas containing caudate nucleus and putamen, ipsilateral to the GDNF injections. HPLC-EC studies of tissue perfusion with dopamine and glutamine of GDNF injected animals showed an increase in DA content bilaterally in animals which had received GDNF as compared to controls. Immunohistochemical studies showed a proliferation of TH-positive neurites in the substantia nigra of the animals receiving intranigral GDNF injections. These findings demonstrate increases in the functional properties of DA neurons upon exposure to GDNF in monkeys and support the hypothesis that GDNF may be a useful therapy in Parkinson's disease.

INFLUENCE OF NEUROTROPHIC FACTORS ON BIOCHEMICAL CHANGES IN THE MESPOLLIC DOPAMINE SYSTEM ASSOCIATED WITH DRUGS OF ABUSE. MT Berthou*, DS Russell, DW Self, RM Lindsay*, and EJ Nestler, Laboratory of Molecular Psychiatry, Yale Univ Sch of Med, New Haven, CT.

*Hegeneron Pharmacuticals Inc., Tammy, NY

Chronic morphine and cocaine treatments have been shown to regulate levels of tyrosine hydroxylase (TH) and glial fibrillary acidic protein (GFAP) in the ventral tegmental area (VTA) of the adult rat brain. Previous results demonstrated that the morphine-induced changes could be prevented by direct injection of BDNF or NT4 on TH (2.5μg/ml) into the VTA. In contrast, NT1 (5.1ug/day) intuions mimicked these biochemical changes that are characteristic of chronic morphine treatment (Baltiner-Johnson et al, Neurosci Ab 1953). In the present study, all intracerebral paradigms were utilized. The first tested the ability of neurotrophins to reverse the biochemical changes in rats already pretreated with chronic morphine pellets. NT-4 infusion reversed the characteristic increases in TH and GFAP without any effect on these proteins when given alone. NTFT mimicked the morphine induced increase, but was not additive with morphine. The second paradigm tested the effect of concurrent cocaine (15mg/kg twice daily for 10 days) and growth factor treatment. As with morphine, BDNF abolished the cocaine-induced increases in TH levels.

A possible site of convergence for the intracranial actions of neurotrophins and drugs of abuse is the ERK's (extracellular-signal regulated kinases). We are infusing ERK1 and 2 antisense oligonucleotides into the VTA by osmotic micropumps. Initial studies suggest that these interventions can reduce ERK levels detected via immunoblots. These studies, and related studies of other intracranial targets (Russell et al. Neurosci Abs, this volume), will help elucidate the molecular actions that may be common to the neurotrophins and drugs of abuse.

454.20
CONDITIONED MEDIUM DERIVED FROM MESENCEPHALIC TYPE-I ASTROCYTES EXERTS DIFFERENT EFFECTS ON DOPAMINERGIC NEURONS AND PC12 PHEOCHROMOCYTOMA CELLS. J.M. Johnston*, T. Takahashi*, K. Blakely* and J. W. Commission

Previously, we have developed a primary neuronal culture of the ventral mesencephalic region of the E14 rat in which the ventral mesencephalic dopaminergic cells are enzymatically purified and the percentage of dopaminergic neurons is reduced to ~2% at days in vitro (DIV 5). These cultures are thus good models for the biochemical and specific dopaminergic neurotrophic factors. In this study we use our model culture and a PC12 differentiation bioassay to demonstrate specific effects of conditioned medium derived from type-I astrocytes (A-CM) on dopaminergic neuronal survival and function. When cultured in defined medium, 3.8±1x10⁶ neurons/dm² dopaminergic neurons were present at DIV 5. The addition of 10% serum, A-CM or conditioned medium derived from B49 glial cells (B49-CM) increased the survival of dopaminergic neurons present to 42.4±15.9 x10⁶ (p<0.0001) and 36.6±26.7 x10⁶ (p<0.0001) and 8.3±1.9 x10⁶, respectively. Further, B49-CM increases the survival of dopaminergic neurons and promotes the differentiation of PC12 cells, however, the effects of A-CM are specific to the survival of dopaminergic neurons. We are currently investigating the active glycoproteins that we have identified. The true significance of these factors remains to be elucidated.
455.1 A BIOSYSSAY METHOD FOR DOPAMINERGIC NEUROTROPHIC FACTORS BASED ON THE USE OF MICROCULTURES AND IMAGING METHOD: T. Takeda*, G. Ishida, K. Takahashi, J.M. Johnston*, J.W. Commission* Division of Neuroscience, Rush University Medical Center, Chicago, IL 60612. Japan. NTU, 60th, NINDS, NIH, Bldg. 10, Rm S218, Bethesda, MD 20892.

BDNF, GDNF, IL-1β, MGF, POFG-β3, EGF, TGF-α, type-1 α-tropo, type-2 α-tropo, α-2A predominant, microglia, and ischemic insults all promote the survival of dopaminergic neurons in cultures directly or indirectly. Experimental conditions used to test the survival of dopaminergic neurons differ widely among investigators; 1) cell density, 2) fetal age, 3) dissection techniques, 4) type of serum, 5) the age of the cultures when stained and 6) the methods selecting fields for analysis are among the most important. We have developed a method, if used widely, could bring a degree of objectivity to the field, and allow for a comparison of data from different laboratories. In this method, the E14 fetus is used. Only 1.0 mm of ventral mesencephalic tissue, which contains 90% of dopaminergic neurons, is dissected. The growth medium contains 0% of serum throughout. The cells are suspended at a density of 5 x 10⁶/ml. Only 25 μl of the cell suspension is plated per chamber (area covered ~6.25 mm²), as a 90% confluent growth medium. This method is in use for the study of basal ganglia neurotoxicity and the role of NGF, a survival factor for dopaminergic neurons.

The physiologic factors that regulate survival of midbrain dopaminergic neurons have not yet been identified with certainty. Here we show that, transforming growth factors (TGF)-β2 and TGF-β3, at picomolar concentrations, prevent the death of embryonic dopaminergic neurons in culture, and that both factors are expressed in the environment of dopaminergic neurons. The TGF-β2 & 3 could therefore be physiologic trophic factors for midbrain dopaminergic neurons and may be useful as therapeutic agents for Parkinson’s disease.

It is known that while the cholinergic innervation of the rat striatum express the low-affinity NGF receptor (LNGF) during development, the immunoreactivity of these neurons is increased bilaterally following injury to this region. We demonstrate that the LNGF of the adult striatum were increased in response to striatal damage and that this phenomenon is apparently modulated by endogenous NGF. Because immunoreactivity of the LNGF following tissue damage may provide fundamental information on the modulation and function of this receptor, we studied various parameters which might affect immunoreactivity. Injury was administered in one group by implantation of a cannula unilaterally into the striatum (AP=-5.7, L=-2.5, 3.5 mm) and injected and attached to an Alzet 2002 osmotic pump. In addition to injury, this group also received a 14 day continuous infusion of either NGF (300 ng/day) or ACP. Injury was administered in a second group via intra-striatal infusions of acetylcholinesterase (90 or 120 nm) into the striatum. In both cases animals were sacrificed and the tissue was processed for p75 and ChAT immunohistochemistry. Results indicate that contrary to expectations, in neither group was p75 immunoreactivity of striatal cholinergic neurons observed, despite clear immunoreactivity of septal-dorsal band cholinergic neurons in the same sections. Additionally, pronounced hyperactivity of ChAT immuno-reactive striatal cholinergic neurons was seen in the NGF infusion group, demonstrating a biologically effective NGF response in these neurons.

In summary, the lack of striatal p75 immunoreactivity in either the damaged or NGF infected animals, in the face of clear p75 immunoreactivity in the septum, as well as NGF-induced ChAT(+)/acetylcholinesterase, raises more questions than answers. While regulation and function of the LNGF remains an area of interest and intrigue, the new experimental design and biologic activity seen in the present study suggest that an NGF response is more complex than previously suggested.

To date, two key pieces of evidence are lacking to substantiate the hypothesis that NGF may provide an effective means to treat neurodegenerative diseases: (1) better evidence for NGF-enhancement of survival, function or fate of basal forebrain cholinergic neurons under conditions of neurodegeneration (as opposed to atrophy); and (2) a convincing demonstration of direct delivery of NGF to the target cells in vivo. The present studies were intended to address these issues. The neurotrophin AFS64a (referred to as AFS64a) was used to induce degeneration of the basal forebrain cholinergic system. In this first study NGF was continuously infused into the lateral ventricle via an Alzet pump. The results demonstrated a reliable decrease in high affinity choline uptake (HACU) due to AFS64a neurotoxicity and slowly complexing via NGF secretion. These data demonstrate that NGF is able to provide a protective and/or a compensatory response against neurotoxic-induced degeneration of the basal forebrain cholinergic system.

In a second study, we attempted to determine whether similar effects could be achieved through direct delivery of NGF. We studied the effect of a NGF conjugate targeted to the transferrin receptor antibody, OX26. This conjugate has been shown to transport NGF across the BBB. As in the first study, substantial degeneration of basal forebrain neurons was observed in the AFS64a group. In the NGF/OX26 conjugate group was increased by 90% compared to AFS64a vehicle-treated rats. However, immunocytochemistry directed against ChAT and the low affinity NGF (p75) indicated that no increase in p75 immunoreactivity. Thus, we made the following conclusions: 1) the conjugate apparently increased HACU by enhancing the activity (and presumably the viability and function) of surviving neurons while not necessarily protecting against the AFS64a cytotoxicity, per se.

455.5 NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
455.7

The regulation and function of the low-affinity NGF receptor (p75) is an issue of current interest and controversy. To better understand the role of this receptor in basal forebrain cholinergic neurons, we analyzed tissue for changes in immunoreactivity to the p75 in two different rodent models of NGF expression and function: AP54A toxicity and fibroblastng- (FKN) interactions. In the first model, 10 days following the bilateral administration of AP54A to young adult rats, there was a significant reduction in the levels of hippocampal high-affinity choline uptake, as expected. Additionally, the number of septal choline acetyltransferase (ChAT)-immunoreactive neurons was reduced; however, enlarged fibers intensely immunoreactive for p75 were observed in the septum. These fibers were most prevalent in the area dorsal to the anterior commissure, were organized in a dorsoventral orientation and were never associated with an obvious cell body.

Brain sections from animals subjected to FKN lesions were characterized by a loss of acetylcholinesterase activity in the target tissue and both ChAT and p75-immunoreactive neurons in the septum. In contrast to the AP54A lesion, there was no evidence of thick p75 fibers as a result of the FKN lesion. While it remains unclear whether the presence of these p75-positive fibers represents a regenerative response (i.e. sprouting) or evidence of a degenerative response (i.e. tombstone marker), it is likely that an understanding of this phenomenon may provide insight into the regulation and/or function of the p75 low affinity NGF receptor.

455.10

**EXPRESSION OF BIOLOGICALLY ACTIVE NERVE GROWTH FACTOR (NGF) MEDIATED BY RECOMBINANT HERPES SIMPLEX VIRUS TYPE 1 (HSV-1) GENE TRANSFER VECTORS.** K.A. Led*, S.E. Lipton, D.J. Kozak, and J.C. Glorian*. Department of Molecular Genetics & Biochemistry, and Western Psychiatric Institute & Clinic, University of Pittsburgh School of Medicine, Pittsburgh, PA; and Department of Neurology, University of Michigan Medical School, Ann Arbor.

In order to study the effects of neurotrophic factors in chronic neurodegenerative conditions such as Alzheimer's and Parkinson's diseases, we have constructed replication compromised and replication defective (mutant d102) Delucia et al. (1987, J. Viral. 6;558) Herpes simplex virus (HSV-1) gene transfer vectors that express the herpes g B-gene product (v-110) as a supporting factor for human cytomegalovirus immediate early promoter (HCMV-IEP) driving transcription of the murine B-NGF DNA was incorporated into the HSV-1 thymidine kinase (tk) gene region of the recombinant viral vector. The NGF vectors resulted in NGF specific transcription and expression as detected by Northern bio analysis. In vivo expression of the NGF transgene was observed by in situ hybridization two days following stereotactic injection of the expression vector into the hippocampus of rat brains. These results suggest that the NGF vectors are transcriptionally active in vivo. For the length and level of bioactive b-NGF expression in the CNS is in vivo. Thus, we are poised to use these vectors in studies of recovery from fibromyalgia syndromes and excitoisential lesioning of striatum in rat brain as models of chronic neurodegenerative conditions.

455.12

**ASPHYXIA DURING BIRTH MAY PRIME THE CNS. Induction of a long-lasting increase in bFGF gene expression coincidentally with increased mitotic activity in neuronal cell bodies in the substantia nigra.** F. Anderson*, A. Blum, Y. Chen, P. Grenoth, B. Bijlsma, B. Diaz, and M. Herrera-Marschitz. Dept. Internal Medicine, Karolinska Institutet, Huddinge Hospital, 141 86 Huddinge, Sweden; Dept. Neuroscience and Dept. Physiology & Pharmacology, Karolinska Institutet, 6Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, U.S.A.

Asphyxia was induced during birth to male Sprague-Dawley rat pups. A quantitative analysis of the number of tyrosine hydroxylase-immunoreactive (TH-IR) and thrombin-stained nerve cell bodies as well as measurement of basic Fibroblast Growth Factor (bFGF) mRNA levels was carried out in the substantia nigra and the hippocampus on male rats at 3-4 weeks of age. Immunocytochemical analysis of the hippocampus of the control and the bFGF mRNA levels and a concomitant increase in the number of dopamine nerve cell bodies of the substantia nigra. Asphyxia reduced the number of cell bodies in the C/A region of the hippocampus while bFGF mRNA levels remained unchanged.

In conclusion, the asphyxia-induced long-lasting increase in bFGF gene expression may cause the increase in dopamine cell body number in the substantia nigra. The present results indicate that asphyxia during birth can prime the development of the central nervous system in a long-term perspective and may be important in the development of neurodegenerative disorders later in life.
455.13
EVIDENCE FOR NOVEL NERVE GROWTH FACTOR (NGF)-
RESPONDING NEURONAL POPULATIONS IN THE MAMMALIAN
Kodatos**. Departments of Pathology, Neurology, and Neuroscience,
Neuropathology Laboratory, The Johns Hopkins University School of
Medicine, Baltimore MD 21205; Neurogeniatric Research Institute,
University of California, Santa Barbara, CA 93106.
In the CNS, only striatal and basal forebrain cholinergic neurons have been
shown to respond to NGF. Both of these populations are also known
to express the high-affinity NGF receptor, TrkA. This study was
designed to delineate novel NGF-responsive neuronal populations in the
rat brain. Using a hybridization histochemical and RT-PCR, TrkA mRNA
was found in the nucleus prepositus hypoglossi and ventral
torticollis nucleus. TrkA protein was also detected by
immunocytochemistry in the nucleus prepositus and in the dorsal and
ventral torticollis nucleus. In addition, trkA immunoreactivity was seen in the
spinal ventral nucleus, neurons within the medial longitudinal fasciculus, and the
gigantocellular nucleus of the reticular formation. NGF mRNA was present throughout the vestibular and auditory systems with high levels of expression in the cerebellum. These results suggested that NGF might play a role in cerebellar afferent systems. Radiolabeled NGF injected into various sites within the cerebellar cortex was retrogradely transported to the nucleus prepositus and spinal ventral nucleus. The trkA and NGF expression patterns and retrograde transport data together identify novel trophic targets for NGF in the brain and raise the possibility that NGF may be used as a therapeutic agent for diseases of the vestibular and auditory systems.

455.15
COORDINATE EXPRESSION OF NEUROTROPHIN-3 AND TRK C LINKED TO A MORE FAVORABLE PROGNOSIS IN
Children's Hospital, Dept. Cell. and Mol. Biol., Dana-Farber Cancer
Inst., Harvard Medical School, Boston, MA 02115.
We have examined the expression of neurotrophins in medulloblastoma, a malignant brain tumor believed to be derived from the external germinal layer of the cerebellum. Northern and western analyses were performed on tumor samples (n = 11) which were snap frozen in the operating room to preserve RNA and protein integrity. All of the tumors were found to express mRNAs encoding neurotrophin-3 (NT-3) and its cognate receptor, trk C. Due to limited tissue, 3 tumor samples were tested and found to have NT-3 protein and TrkC immunoreactivity. Patients with tumors expressing high levels of trkC mRNA had significantly longer intervals without disease progression than those with low levels (Kaplan-Meier, P = 0.02). Expression of trkA, trk B, or p75 was not associated with favorable disease outcome.

Coordinate expression of ligand and receptor implies the constitutive activation of Trk C receptors in patients with a more favorable outcome. Conceivably, this activation promotes the differentiation of medulloblastoma and may be relevant to the development of new therapeutic strategies for the tumor. At minimum, our findings indicate that trk C expression is a marker of prognostic value.

455.17
NT-3 ATTENUATES REDUCTION IN H-REFLEX PRODUCED BY PYRIDOXINE TOXICITY TO LARGE PRIMARY AFFERENT NEURONS IN
Tarrytown, NY 10591.
High doses of pyridoxine (vitamin B6) are toxic to large primary afferent neurons, producing a peripheral neuropathy in experimental animals that can serve as a model for toxic large-fiber neuropathies in humans. Affected neurons are part of the circuitry that mediates the monosynaptic stretch reflex and a neurophysiologically correlate, the H-reflex. Sprague-
Dawley rats were treated with pyridoxine (400 mg/kg), with or without
additional NT-3 treatment. When half the animals receiving either of these two treatments developed severe deficits on a precise locomotor task, all were tested electromyographically. Animals receiving NT-3 without pyridoxine and non-injected control animals were also tested. We recorded electromyographic activity in the plantar muscles, evoked by stimulation of the tibial nerve. Amplitudes of directly evoked motor (M-)
and reflex-evoked (H+) waves were recorded. M-wave amplitudes did not differ among groups of pyridoxine treated rats (magnitudes normalized to the M-wave amplitude as H/M ratio) were absent or greatly diminished in nearly all animals receiving pyridoxine without NT-3. The reduction was significantly attenuated in anesthetized rats receiving NT-3, resulting in substantial H-reflexes in nearly all animals so treated. H-reflex amplitudes were correlated with performance on the locomotor task. The results are consistent with protection by NT-3 of large sensory fibers from neurotoxic damage, potentially including damage caused by chemotherapeutic agents.

455.18
THE UPERPULATION OF NGF DURING INFLAMMATION PRODUCES PAIN HYPERSENSITIVITY AND AN
INCREASED GROWTH CAPACITY IN PRIMARY SENSORY NEURONS. C.J. Woolf, B. Safihi-Garbadian, T. Leslie, J. Winter.
SPIN: Brain Research Association. Dept. of Anatomy, University
College London, London WC1E 6BT, Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN
The inflammation produced by an intraplantar injection of complete Freund's adjuvant results in a significant elevation in NGF levels, first in the inflamed tissues, then in the innervating nerves. This is accompanied by the development of substantial thermal and mechanical hyperalgesia, and an upregulation in DRG neurons of the mRNA neurotrophine substance P, and CGRP and the growth associated protein GAP-43. Neuronal pretreatment with a neutralizing anti-NGF antibody which does not recognize BDNF or NT3, prevents the development of the abnormal sensitivity and the changes in chemical phenotype, without reducing local edema or erythema. The production of increased levels of NGF in the periphery during inflammation may play a key role in generating inflammatory pain hypersensitivity by increasing transduction sensitivity, amplifying the input to the dorsal horn, sensitizing dorsal horn neurons and promoting a hyperinnervation of the inflamed area by inducing collateral sprouting. Supported by Sandoz and the Sir Jules Thorn Trust.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
455.19 BRAIN DERIVED NEUROTROPHIC FACTOR (BDNF) PRODUCES AN ANTI-DEPRESSANT LIKE EFFECT IN TWO ANIMAL MODELS OF DEPRESSION. P. A. Mason, A. Jin, D. N. Green, and S. J. Wiegand. Ronald M. Lindsay. Regeneron Pharmaceuticals, Tarrytown, NY. 10591

We have previously reported that midbrain infusion of the BDNF, a member of the neurotrophin family, produces behavioral and neurochemical evidence of antidepressant-like effects in two animal models of depression, the forced swim test and the learned helplessness paradigm. Adult rats were infused with BDNF (24 ug/day) or PBS vehicle into the midbrain, near the PAG and dorsal raphe, as previously described (Olney et al., 1994). In the learned helplessness paradigm, rats pre-exposed to inescapable shocked showed severe impairments in escape behavior during subsequent conditioned avoidance trials (61% decrease). With the y numbers of escapes, 5 fold increase in escape latency). Midbrain BDNF infusion reversed this escape deficit to levels similar to that obtained from non-shot control rats. No changes in locomotor activity as measured by the total number of 629 partial rotations or grid activity, was seen. These data demonstrate an antidepressant-like action of midbrain-infused BDNF. Furthermore, these results support a role for neurotrophins in the etiology and treatment of neuropsychiatric disorders.

456.1 DEVELOPMENT OF SOMATOSTATIN AND LEU-KNEKPEPHALIN IN THE AUDITORY BRAINSTEM OF THE RAT. M. Koga* and E. Pippin. Univ. Tubingen, Animal Physiology, Auf der Morgenstelle 28, 72076 Tubingen, Germany.

During early ontogeny, the neuropeptides somatostatin and leu-enkephalin are prominent in several brain areas and are therefore thought to be involved in developmental events. This study was focused on the developmentally related expression of these neuropeptides in the auditory brainstem of the rat by means of PAP-immunocytochemistry between the ages of embryonic day 17 and adulthood. During fetal development somatostatin immunoreactive (SOM) neurones appeared in the nuclei of the cochlear nucleus complex (CN), the inferior colliculus (IC), whereas SIR fibres were predominantly found in the superior olivary complex (SOC) and in the IC. In all auditory brainstem nuclei, the immunoreactivity increased developmentally until postnatal day 7. At this age the immunoreactivity in the brainstem was nearly restricted to auditory nuclei, which showed a heavy labeling. The most dense SIR fibre network was found in the SOC, which most probably originated from neurons of the CN, thus providing a system-immanent innervation. Subsequently SIR decreased dramatically until adulthood. In contrast to the transient expression of somatostatin, the number and labeling intensity of leu-enkephalin (LKR) structures increased progressively with age. LKR fibres in the fetal brain appeared in the SOC, NLL, CN and IC. LKR somata were found only after P12 in the CN and in the IC. Our results demonstrate a strong and transient expression of somatostatin and a progressive increase of the leu-enkephalin expression during development. Both neuropeptides are expressed during a period when synaptic stabilization occurs in the rat auditory brainstem, suggesting that they may play a role in synaptic refinement. Supported by the DFG (Pi 727/1-3) and the GKN Tubingen.

456.3 POSTNATAL DEVELOPMENT OF THREE ISOFORMS OF PROTEIN KINASE C IN CENTRAL VESTIBULAR PATHWAYS AND CEREBELLUM OF THE RAT. M. Garcia* and R. E. Haltas. Dept. of Otolaryngology and Anatomy and Neurosurgery Training Program, Tulane University School of Medicine, New Orleans, LA 70112.

Although various protein kinases (PKC) isoforms are highly expressed in brain, little is known about patterns of expression of PKC during development of the CNS. We used immunocytochemistry to study the ontogeny of PKC-β1, β2 and β3 in central auditory pathways of the rat brain, at postnatal (P) days 5, 11, 15, 20, and adult. With the β1 antibody, labeled fibers were found in primary afferents of the VIIIth nerve in all ages.Weakly stained cells in the inferior colliculus nuclei (VCN) at P5 only; no terminals were found in the dorsal cochlear nucleus (DCN), suggesting that the labeled afferents are primarily vestibular. Labeled cells were observed at all ages, with a few labeled cells in the DCN in adults only. Labeled terminals were found in the superior olive (SO) beginning at P15. Cell body labeling was found in the SO and trapezoid body (TB) at P30 and in the lateral lemniscus at P15. In the lateral lemniscus (LL) at all ages, with labeled terminals on neurones of the nucleus of the LL (NLL) beginning at P30. Labeled terminals and a few labeled cells in the DCN were found in the inferior colliculus (IC) at all ages, and in the medial geniculate (MG) at P20 and adult. With the β2 antibody, a few labeled fibers were found in the VIIIth nerve as early as P11, but labeling was strongest at P30. Labeled terminals in the DCN beginning at P11 were present at the same age. Labeled cells were found consistently in the VCN beginning at P15. Cells decorated with labeled terminals were found in the SO beginning at P1. Cytosplastic staining of SO and TB was observed beginning at P11. In the IC beginning at P15. Decorated cells were first observed in the VCN and DCN at P15. Labeled terminals were found in the SO beginning at P11. Labeled terminals were found in the central core of the LA beginning at P15. These results suggest that these isoforms of protein kinase C may play roles in the development and function of central auditory pathways. (Supported by the National Institute of Neurological Disorders and Stroke.)

456.4 POSTNATAL DEVELOPMENT OF THREE ISOFORMS OF PROTEIN KINASE C IN CENTRAL VESTIBULAR PATHWAYS AND CEREBELLUM OF THE RAT. R. E. Haltas* and M.M. Garcia. Dept. of Anatomy and Otolaryngology and Neuroscience Training Program, Tulane Medical School, New Orleans, LA 70112.

The protein kinases C are a family of enzymes which are enriched in brain, yet little is known about their abundance during development of the CNS. We used immunocytochemistry to study the ontogeny of the β1, β2 and β3 isoforms of protein kinase C in the vestibular system and cerebellum of the rat brain, at postnatal (P) days 5, 11, 15, 20, and adult. With the β1 antibody, labeled cells were found in primary afferents of the VIIIth nerve at all ages. Most of these cells were in the cochlear nucleus (VCN) at P5 only; no terminals were found in the dorsal cochlear nucleus (DCN), suggesting that the labeled afferents are primarily vestibular. Labeled cells were observed at all ages, with a few labeled cells in the DCN in adults only. Labeled terminals were found in the superior olive (SO) beginning at P15. Cell body labeling was found in the SO and trapezoid body (TB), beginning at P11. In the lateral lemniscus (LL) at all ages, with labeled terminals on neurones of the nucleus of the LL (NLL) beginning at P30. Labeled terminals and a few labeled cells in the DCN were found in the inferior colliculus (IC) at all ages, and in the medial geniculate (MG) at P20 and adult. With the β2 antibody, a few labeled fibers were found in the VIIIth nerve as early as P11, but labeling was strongest at P30. Labeled terminals in the DCN beginning at P11 were present at the same age. Labeled cells were found consistently in the VCN beginning at P15. Cells decorated with labeled terminals were found in the SO beginning at P1. Cytosplastic staining of SO and TB was observed beginning at P11. In the IC beginning at P15. Decorated cells were first observed in the VCN and DCN at P15. Labeled terminals were found in the SO beginning at P11. Labeled terminals were found in the central core of the LA beginning at P15. These results suggest that these isoforms of protein kinase C may play roles in the development and function of central auditory pathways. SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

456.2 DEVELOPMENT OF PRIMARY VESTIBULAR AFFERENTS AND VESTIBULOSPINAL PROJECTIONS IN THE OPOSSUM, MONADELPHIS DOMESTICA, J. F. Piétreger* and T. Cabana. Sciences Biologiques, Université de Montréal, C.P. 6128, Succ. centreville, Montréal, Canada, H3C 3J7.

The opossum Monodelphis domestica is born after only 17 gestational days. It is then very immature (eyes and ears closed, budlike hindlimbs, etc.) but has the capacity to locomote on the mother’s belly with its forelimbs, hand the genital aperture to a nipple for sucking until postnatal day 28. This behavior of the newborn suggests that some sense systems must be present to guide it. One such system may be the vestibular system, which is known to mediate sensory clues about head movement and which has a strong influence on posture and balance during locomotion in adult mammals. We have looked at the development of the primary afferents to the vestibular nuclei and the vestibulospinal projections to the spinal cord using the neuroanatomical tracing of BI and LET-DH. We found that VIIIth nerve fibers have attained the vestibular nuclear complex at birth and that some of the fibers project to the contractral vestibular ganglion, a projection which was not found in the adult opossum. Projections from the lateral vestibular nucleus, and, to a much lesser extent, parts of the median and the inferior vestibular nucleus, to the brachial and lumbar sacral enlargements of the spinal cord are also present on the day of birth. Without excluding the possibility of olfactory and/or tactile guidance for directing the “climbing” behavior of the newborn opossum, the vestibular system is likely involved.

The trapezoid body decussation carries information that is essential to the localization of sound by the mammalian auditory system. The trapezoid body decussation consists of fibers from the ventral cochlear nucleus that terminate in the contralateral superior olivary complex. The purpose of this study was to establish the developmental decussation and to examine the relationship of the fibers and their growth cones to potential cues during pathfinding. The carboxyamine dye DL was placed in the area of the presumptive olivary nuclei of P8-12 mice, in order to label the different fibers and their growth cones. At E13, although cochlear nucleus neurons were just beginning to migrate away from the rhombic lip ventricular zone, they were already sending axons along the marginal edge of the hindbrain towards the midline. By E15, many fibers had entered the midline region and some appeared to contact glial cells at the midline. In addition, by this time some of the fibers had crossed the midline and had reached the vicinity of the presumptive superior olivary complex on the contralateral side. At E17, the presumptive cochlear nucleus could be clearly distinguished on the lateral surface of the hindbrain and there was a noticeable increase in the number of fibers in the trapezoid body decussation. Based on growth cone morphology and axon anatomy, it does not appear that all trapezoid body fibers depend on the basal lamina for guidance during pathfinding. In addition, growth cone complexity did not show any consistent increase in the floorplate region. Growth cone contact of glial cells at the midline is an important role in directing fibers across the midline to their targets. Supported by NIH DC003155.

5.6.6 A TRANSIENT DEVELOPMENTAL GRADIENT OF GLYCINERGIC ENDINGS IN THE FERRET SUPERIOR OLIVARY NUCLEI. C. K. Hitt, J. K. Brunso-Bechtold, and C. K. Hitt, Dept. of Neurobiology and Anatomy, Neuroscience Program, Wake Forest University, Bowman Gray School of Medicine, Winston-Salem, North Carolina 27157.

The development of inhibitory connections from the medial nucleus of the trapezoid body (MNTB) to the lateral (LSO) and medial (MSO) superior olivary nuclei was investigated in ferrets using immunocytochemistry with antibody for glycine (courtesy of D. R. Westphal). We were particularly interested in whether or not the glycergic gradient was established by a tonotopic gradient. Videograms of LSO and MSO in selected innervated sections at 7 postnatal ages were digitized. Samples of the neuropil were analyzed and averaged to determine the relative density of glycine immunostaining. Only a diffuse background staining is immunohistochemically observed in the neuropil at postnatal day 7, but by the end of the second postnatal week immunostaining in the neuropil is more granular. Between the third and fourth postnatal weeks, the neuropil has the characteristic puncta of immunostained endings in the adult. A gradient is present across the tonotopic axis of both nuclei during the earliest period of diffuse immunostaining. At this time, there is a near two-fold increase in density of immunostaining from low to high frequency regions. By postnatal day 28 when puncta are evident, glycine immunostaining is homogeneous all along the tonotopic axis. Glycine-immunopositive cells in the MNTB appear progressively along a spatial gradient during the first postnatal month as this maturation of glycnergic terminals in LSO and MSO is taking place.

Supported in part by NIH grant DC003155.

5.6.7 FREQUENCY-DEPENDENT ADJUSTMENT OF BINURAL TUNING PROPERTIES IN THE FERRET ON OWLS OPTIC TERRITORY: A RESULT OF ALTERED AUDITORY EXPERIENCE. J. T. Gold, and E. J. Knudsen, Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

Barn owls localize sounds by combining auditory cues, including interaural differences in timing (ITD) and level (ILD), which are computed across a broad range of frequencies. The auditory space map in the optic tectum (OT) contains neurons sensitive to external sound stimuli from external sources and from external receptive fields. Previous studies have shown that, in the OT, neuronal tuning to ITD and ILD for narrowly frequency-limited sound stimuli in the region corresponding to the unit's receptive field. We examined the extent to which each frequency-dependent tuning is shaped by experience by testing the ability of neurons in the OT to respond to ITD and ILD levels under novel, frequency-dependent localization cues. An ear plug-like device ("twisted tube") was developed and shown via auditory microprobes microinjected in the optic tectum to affect the timing and level of sounds in a frequency-dependent manner. Juvenile owls were trained on 60 dB with a twisted tube in one ear. The results showed that neuronal tuning to ITD and ILD levels was significantly changed. First, neurons that were tonotopically-predicted, broadband stimuli were characterized at a variety of sites. The frequency-dependence of both ITD and ILD tuning was shown to reflect the frequency-dependence of the sound stimuli caused by the twisted tube. Second, with the twisted tube removed, the auditory receptive fields measured with broadband stimuli of different frequencies were shown to be misaligned in both azimuth and elevation, corresponding to the frequency-dependent changes in ITD and ILD tuning, respectively. Re-insertion of the device realigned the receptive fields, thereby demonstrating the compensatory nature of the adaptive adjustments. Thus, experience-dependent plasticity shapes the frequency-dependence of unit tuning to ITD and ILD of neurons in the barn owl's optic tectum. Supported by NIH: 3752 MH11074 and R01 DC001515-14.

5.6.8 TOPOGRAPHY OF THE PROJECTION FROM THE CENTRAL TO THE EXTERNAL NUCLUSES OF THE INFERN COCCULUS IN NORMAL AND PREMATURE-BORN BARN OWLS. E. H. Klionsky, Dept. of Neurobiology, Stanford University, Stanford, CA 94305-5401.

The central nucleus of the inferior colliculus (ICc) contains neurons sensitive to interaural timing difference (ITD), the primary cue used by the barn owl to localize sounds in azimuth. ICc neurons are organized into a map of ITD where the most central region of ICc is most sensitive to ITD and the peripheral regions are more sensitive to ILD. ITD neurons project to ICc via a topographic projection from ICc to ICc. Rearing owls with laterally displacing prismatic spectacles in adult life did not show the same pattern in ICc as in the normal owls, but not in the ICc, suggesting that the projection from ICc to ICc is altered by prism-rearing. This hypothesis was tested by making small injections of biotinylated dextran amine (BDA) at a variety of locations in ICc and frontal and prismatic-reared owls. R departed labeled ICc neurons were visualized by avidin-biotin-peroxidase histochemistry. The positions made in ICc were measured along the rostrocaudal axis of the ICc (the axis of varying ITD), relative to the calbindin immunostaining of the ICc complex.

Injections (n=10) were made at the level of 0 μsec ITD in the ICc of normal normal labeled ICc neurons (n=149) in the rostral one-third of the lateral shell of the ICc, consistent with the known projection from the ICc to the ICc. Injections (n=13) made in the ICc of prism-reared owls at the same anatomical location, which in these birds was tuned to 40-50 μsec contra-ear leading ITD, labeled ICc neurons (n=245) in a significantly different distribution. About half of the labeled neurons were situated caudally in the lateral shell at locations representing ITDs corresponding to the prismatically induced shift in tonal auditory map. The remaining neurons were situated in the rostral third of the lateral shell, as in normal birds. These preliminary data suggest that the adaptive alteration in ITD tuning observed in the ICc of prism-reared owls results at least in part in an alternation in the projection from ICc to ICc.

Retinal axons can be induced to innervate the auditory thalami followin neonatal lesions in ferrets. We have now shown that induction of retinal projections into the medial geniculate nucleus (MGN) critically depends on extensive afibrillar axonal arborizations extending from both dorsal and ventral retina, as well as from other auditory brainstem nuclei.

To examine the pattern of retinal innervation of the MGN, adult "treated" ferrets received binocular injections of cholera toxin B subunit (CTB). The procedure stains axons and terminals in detail, thus allowing reconstruction of single axons. Retinal fibers can invade all the subnuclei of the MGN, but consistently avoid its caudal part. The ventral and the medial divisions are the most densely innervated. In general, axons innervating the ventral division enter the MGN directly from the optic tract. These axons have an average 6 - 8 μm diameter, are more highly branched, and have large clumperted boutons. Retinal axons innervating the medial division enter the MGN through the lateral posterior nucleus (LP), the precocious nuclei (PF) and the lateral terminal nuclei. They are the most prominent in the MGN, with boutons and sparsely terminal arborizations. Arteries entering the MGN through the LP and PF can also arborize in the dorsal division and in the posterior nucleus (Po).

By injecting WGA-HRP into one eye and CTB into the other, we find that both eye projection to the same areas of MGN and the LP, the ipsilateral projection being less dense. The patterns of projections formed by one eye are adjacent to each other, but closely segregated, from those formed by the other eye. In LP, the projection from each eye appears band-like. These data suggest that while the site of retinal innervation into the MGN, these results reflect the existence of functional and anatomic zone differences. 5.6.10 CHANGES OF AUDITORY EVOKED POTENTIALS IN RESPONSE TO BEHAVIORALLY MEANINGFUL TONES INDUCED BY ACUTE ETHANOL INTAKE IN ALTRICIAL NESTLINGS AT THE STAGE OF FORMATION OF NATURAL BEHAVIOR: L. I. Alexandrov, Y. T. Alexandrov Inst. of Higher Nervous Activity & Neurophysiology and Inst. of Psychology, Russian Acad. of Sci. Moscow, Russia.

Acute ethanol's influence on f i l d auditory evoked potentials (AEP) was studied in 6-7-day-old altricial nestlings of the field flycatcher. Nestlings were presented with bi-temporal, non-tonal stimuli, at a frequency index (MI) of the AEP in response to "behavioral" but not to control frequencies. This effect was first observed on day 0, when the nestlings' behavior became more complex: their eyes opened and defense behavior appeared, and when previ-ously formed feeding behavior was undergoing modifications. The MI increase during the early postembryonic ontogeny was probably due to the selective involvement of neurons with newly formed behavioral specializations into the subserving of new behavioral patterns while the decrease of MI under alcohol was due to the depression of activity in these neurons.
SYNAPTOSPHERE EXPRESSION IN THE DEVELOPING INNER EAR OF THE CHICK. A.M. Cunningham* and B.A. Kondoh. Garvan Institute of Medical Research, Sydney, NSW 2010, Australia and University of South Florida, Tampa, FL 33612.

Development of the auditory and vestibular systems is closely associated with early morphological and physiological changes in the inner ear. Studies of synaptosome expression have been used to identify specific neurotransmitter release sites. In this study, we investigated the expression of synaptosomal proteins in the developing chick inner ear to determine their role in the development of the auditory and vestibular systems. We found that the expression of synaptosomal proteins in the inner ear is dependent on the stage of development and that the proteins are required for the normal development of the auditory and vestibular systems.

SYNAPTOSPHERE EXPRESSION IN THE DEVELOPING INNER EAR OF THE CHICK. A.M. Cunningham* and B.A. Kondoh. Garvan Institute of Medical Research, Sydney, NSW 2010, Australia and University of South Florida, Tampa, FL 33612.

Syntapsphere is the major integral membrane protein of presynaptic vesicles and is useful as a marker for synaptic terminals. The glycoprotein may be involved in presynaptic functions such as vesicle fusion. In this study, syntapsphere has been implicated as having a specific role in neurotransmitter release (Adler et al., 1992). The expression of syntapsphere was examined during development using monoclonal antibodies (mAb 20.11) which recognize the avian homologue of syntapsphere (Cunningham & Jeffrey, 1990, Soc. Neurosci. Abstr. 16, 1296).

We examined the expression of syntapsphere in the chick embryonic day 6 (ED 6) to posthatch using an immunoperoxidase technique. In the cochlea, syntapsphere immunoreactivity was demonstrated as an ED 8 in the proximal region of the sensory epithelium. In the organ of Corti, immunoreactivity was observed on the regions containing the tectorial and intermediate hair cells. As development progressed, ED 10, immunoreactivity also appeared in the distal regions of the cochlea, consistent with later maturation of this region. In the vestibular endorgans, the saccule, utricle and cristae ampullaris, immunoreactivity was observed at ED 14, the earliest age studied.

Previous studies in mammals have suggested that syntapsphere is expressed primarily in the nerve fibres innervating the cochlea as well as the afferents of the peripheral vestibular system (Gil-Lozoya & Pujo, 1988; Scarfone et al., 1991; Nadol et al., 1993). In the present studies, we demonstrate a pattern of syntapsphere immunoreactivity in areas which primarily receiveafferent innervation and would be consistent with localization to the base of the hair cells. Immunofluorescence studies are needed to verify these findings and to determine the relationship between the expression of syntapsphere immunoreactivity and the events of synaptogenesis and maturation. Supported by grants from The Medical Foundation, Univ. of Syd. to AMC & NIH/NIDCD NS 529 DC01923-01 to BMB.

456.13

Visual signals appear to play an instructive role in the development of the map of auditory space. In the superior colliculus (SC), identified by the site at which this visual auditory interaction occurs has yet to be determined. We have examined the contribution to the development of the auditory space map of the visual representation in the corresponding superficial layers of the SC in the ferret.

The causal region of the superficial layers of the right SC was removed by aspiration at PND 17. Recordings were made bilaterally when the animals were fully grown. On the left, unoperated side, both the visual representation in the superficial layers and the auditory representation in the deeper layers appeared to be normal. On the right side, the visual responses recorded from the superficial layers in normal SC had normal receptive field locations that covered a restricted region of anterior visual space. Auditory units recorded in the deeper layers of the same electrode were much smaller and had corresponding locations, suggesting that the auditory representation in this part of the SC was unaltered. However, the preferred sound directions of auditory units recorded in more caudal regions of the SC, where the superficial layers were missing, were much more scattered, even though many of these units were also visually responsive.

These data suggest that visual responses in the superficial layers of the SC may contribute to the development of the auditory topography in the deeper layers.

DEVELOPMENT OF VISUAL CORTEX III

457.1

We are interested in factors that control the formation of visual corticocortical connections from area 17 to area 18 and the reciprocal projections to area 17. We examined the role of layer 1 in these processes. From the earliest postnatal ages, apical dendrites of pyramidal cortical cells project to layer 1, where they connect with long horizontal fibers that cross several cortical areas.

We lesioned layer 1 in area 18 in newborn kittens, let them develop to 1 month of age and examined cortical projections after labelling them with horseradish peroxidase (HRP) and Fast Blue. In normal kittens, by the end of the first postnatal month, fibers projecting from area 17 to area 18 terminate in patches in the cortex that project back from area 18 and cells projecting back from area 18 are grouped in clusters, mainly in superficial layers with a few in deep layers. In lesioned animals, very few projections into areas 17 and 18 in Nissl-stained sections or cytochrome oxidase-stained cortical sections were observed.

Thus, the lesions produced a disproportionate loss of corticocortical connections that is not easily explained on the basis of generalised cortical damage. Furthermore, the results indicate that intercellular signaling via layer 1 is important for the development of corticocortical connections in the visual cortex.

457.2

DEVELOPMENT OF LONG-RANGE HORIZONTAL CONNECTIONS IN FERRET PRIMARY VISUAL CORTEX. Edward S. Ruthazer* and Michael P. Strzyz. W.M. Keck Center for Integrative Neuroscience and Neurorehabilitation Program, UCSF, San Francisco, CA 94143-2444.

The specificity of long-range tangential connections emerges during development from initially diffuse connections. In the cat, manipulation of visual experience influences only the late portion of this refinement. To examine the activitydependence of the early component we have studied the ferret.

Focal injections of biocytin into the subiculum of collateral (CTB) or CTB-gold conjugate were made into area 17 of ferrets ranging in age from PND 20 to adulthood. Following two to four days post-injection survival, animals were perfused and their occipital cortex flattened for sectioning parallel to the pial surface. In all but the youngest ferrets studied (PND 14 and older), small injections of CTB into superficial cortex resulted in clusters of retrogradely labeled neurons, the axons of which can be traced back to the injection site, and also in many cases to nearby sites of dense axonal arbors labeled in the same injection site. In the adult ferrets, the clusters of labeled neurons appeared coincidently, but not always, with clusters of labeled cells. All at ages studied, several clusters of labeled cells were also found in areas 19, 10, and suprasylvian cortex.

In adult animals, the clusters in area 17 were most prominent in layer III where they formed discrete groups of cells, generally within 3 mm of the injection site, separated by regions of relatively sparse labeling. In the young ferret, the clusters were larger, and more frequently included both the injected sites, and were spread in a more scattered pattern. In the adult ferrets, the clusters of labeled neurons were observed following injection on PND 29. The degree of clustering of labeled neurons was similar to that observed in the young ferrets, with the largest clusters observed in the case of injections on PND 29.

Activity blocked by intracortical TTX injection from PND 23 until sacrifice two weeks later appeared to disrupt normal cluster formation in area 17. Supported by NSF Training Grant EY01710 and NIH Grant EY09760.

456.12

In one set of experiments, we examined the development of projection from the superior olive (MSO) to the inferior colliculus (IC) by examining Fluoro-Gold into the IC unilaterally at postnatal days 0 (P0), 3 (P3), 7 (P7) and adult. They were killed 1 day after injection. Retrogradely labeled neurons in the MSO appeared on the ipsilateral side only in any cases. The labeled frequency of MSO neurons was increased stepwise (from 35% to 50%) with postnatal steps, suggesting differential growth of early- and late-developing axons.

In another set of experiments, we found that the MSO was performed in rats, of which IC had been unilaterally ablated between P0 and maturity. Upon reaching adulthood, rats received injections of Fluoro-Ruby into the contralateral IC and that the labeled axons crossed the midline to the intact IC could be examined. These rats were euthanized 2 days after injection.

1) No exuberant projections to the contralateral IC are found in the normal development. 2) When the IC is ablated unilaterally, many neurons die in the ipsilateral MSO as a result of axotomy. 3) An abberant crossed projection occurs in a few of the survived MSO neurons only in the P3 ablation cases. 4) Growth of late-developing axons is a major factor of plasticity in this system.
DEVELOPMENT OF CLUSTERED LATERAL CONNECTIVITY IN MACAQUE VISUAL CORTEX. K. Takeishi.1, K. Tsumoto.1, J. K. Durack.2,3, S. J. Durack.2,3, C. A. J. Durack.2,3. 1Koganei Mind/Brain Institute, Johns Hopkins University, Baltimore, MD 21211. 2The Brain Research Institute, University of California, Los Angeles. 3Department of Neurology, University of California, Los Angeles.

The clustered lateral connection network in the visual cortex is thought to be a substrate for the parallel information processing underlying visual perception, and is mainly present in layers 2-3 and 5. To examine this hook circuitry, and to identify whether the visual experience influences cluster formation, the anatomical organization of striate cortex (area V1) in the infant and adult macaque was investigated using DI as a tracer. Following the placement of DI crystals at various depths of gray matter, lateral spread of axons and densely branched dendrites of pyramidal neurons was observed in both superficial and in infragranular layers at 140 days, approximately 3 weeks before birth. In the supragranular layer, labeled axonal terminals and somata formed clusters, whereas, in the infragranular layer, a continuous lateral spread of labeled axons was visible without noticeable clusters. These data suggest that the patches seen in layer 5 of adult V1 develop by elimination of axonal branches in later stage. Cytochrome oxidase (CO) histochemistry revealed no evidence of stained dots despite the presence of clustered terminal patches in supragranular layers. From these observations, it was concluded that the visual experience is not necessary to form clustered horizontal connections in macaque V1, and that CO does not guide axons to the proper termination site of intrinsic neurons, but rather blocks are expressed after the time of the formation of patchy connection system. (Supported by NIH grant EY06432).

5.6

We have previously shown that, following neonatal monocular enucleation (ME), the adult rabbit visual (V1) CC distribution is exuberant, extending into areas of cortical regions which do not normally contain callosal cells, similar to the CC distribution in the neonate. We have also shown that levels of noradrenaline (NA) increase in the normal development of the CC distribution. There is a decreased tangential extent of the CC distribution in the adult rabbit visual cortex following administration of an alpha-2 receptor antagonist, yohimbine, during the critical period of ontogeny. We presently examine the effects of yohimbine administration on the CC distribution following neonatal ME. Rabbits (N=4) were deeply anesthetized and had ME on the day of birth. Each animal received injections of yohimbine HCl (2.5 mg/kg, IP) every day from postnatal day 5 through 12. A control group (N=3) had ME and received equal volumes of IP injections of saline. Rabbits were reared until adult, at which time multiple injections of HRP (Boehringer, 20% in H2O) were made (total volume injected: 7 μl) throughout one entire visual cortex. Animals were perfused 24 hours later and the brains were cut and reacted with TMB. ME plus saline animals had a significantly increased tangential extent of the CC distribution, similar to previous reports. ME plus yohimbine animals had a restricted tangential extent of the CC distribution in area 17 similar to the normal adult pattern. Yohimbine administration during the critical period prevents ME induced CC exuberance. Results indicate that NA influences developmental plasticity of visual callosal cells. Supported by NIH NS25689 and DA06681.
CHANGES IN CYTOCHROME OXIDASE-RICH PATCHES IN STRIATE CORTEX OF HUMANS WITH RETINAL LESIONS.

ICBF/ UFRJ, Rio de Janeiro, RJ, 21941-900, Brazil.

We studied the tangential distribution of cytochrome oxidase (Cyto)rich patches in striate cortex of two humans with retinal lesions. Patch spatial density and patch cross-sectional area were analyzed in Cyto-rich tangential sections of flat-mounted preparations of V1. Rows of patches are more conspicuous in the cortical representation of the retinal lesions than in normal areas. The spatial density of patches remains constant in the binocular field representation in V1, although patch size changes drastically in the region of representation of the retinal lesion. In this region, patches are larger and darker above and below the ocular dominance stripes of the normal eye than in the alternate stripes. After long-term lesions, the patches corresponding to the normal eye columns appeared larger than in normal controls. In contrast, patches corresponding to the columns in the retinal lesion representation appeared smaller than in normal controls. These results suggest the existence of competitive interactions which modify the cortical intrinsic organization in adult humans.

TRANSPLANT- AND PROSTHESIS-ASSISTED REGENERATION

458.1 ELECTROPHYSIOLOGICAL RECOVERY AFTER SPINAL CORD INJURY USING CARBOXYL GROUP ENRICHED FILAMENT IMPLANTS AND TENDON 2746 S SUPPORT.

T. Kamada, M. Dauvard, A. Liu, and C. Tausch.

Rehabilitation R&D Center, Hines VA Hospital, Hines, IL 60141.

Our previous studies have shown that carbon fibers are capable of supporting neurite growth by providing a favorable attachment surface and directionality to regrowing axons. Axons have been found to exert a trophic influence on both the central and peripheral nervous systems. The purpose of this study was to determine whether the implantation of carbon fibers and/or the administration of CMAP (a sub-stimulated ACTH 4-9 analog) would have any beneficial effect after spinal cord injury.

Rats were anesthetized and a total transection of the spinal cord was performed at the T8-T9 level. For animals receiving carbon filament implants, a bundle of approximately 10,000 carbon fibers of 5 μm diameter (AMOCO Themed™) were placed into the transection site. For animals receiving CMAP (50 μg/kg) or CMAP and ACTH (10 μg/kg), the solution was injected into the central canal of the spinal cord at the level of the transection site. All of the five spinal cord transected animals, which received carbon filament implants and CMAP and ACTH, showed significant behavioral recovery (grade 5) at 5 months post-injury. All of the five spinal cord transected animals without CMAP and ACTH showed significant behavioral recovery (grade 5) at 3 months post-injury.

All the reported results were statistically significant (P<0.05) compared to the control group. These findings are consistent with our previous studies on the role of a trophic factor, NGF, in the regeneration of nerve fibers. This study supports the hypothesis that carbon fibers and/or CMAP and ACTH are capable of promoting the regeneration of nerve fibers following spinal cord injury.

458.2 CARBON FILAMENT IMPLANTS ENHANCED WITH GROWTH FACTORS SECRETING FIBROBLASTS PROMOTE REGENERATION OF INJURED SPINAL CORD FIBERS.

Rehabilitation R&D Center, VA Hines Hospital, Hines, IL 60141.

Neurotrophins are proteins which are essential for the survival and maintenance of a variety of different populations of neurons. Among the neurotrophins, nerve growth factor (NGF) is the best characterized. NGF infusion into certain types of neural tissue results in a dramatic outgrowth of nerve fibers. Recent studies have shown that NGF has an effect on a broader spectrum of neuronal populations than was originally believed. Carbon fibers have been shown to provide a substrate for the outgrowth of injured spinal axons. The goal of this study was to determine the effect of NGF-secreting fibroblasts on the regeneration of injured spinal cord fibers.

Fibroblasts which were genetically modified to secrete NGF were cultured on carbon fibers attached to the bottom of petri dishes. After 24 hrs, the fibroblast-coated carbon fibers were implanted into the lesion site of spinal cord contused Fischer 344 rats. All animals were cared for according to IACUC guidelines. Animals were killed 4 weeks post-injury. The results of this study indicate that the implantation of NGF-secreting fibroblasts, grown on carbon fibers and implanted into the contused spinal cord, would promote transition growth of injured spinal cord fibers.

458.4 DISSOCIATED, CULTURED SCHWANN CELLS SUPPORT AXONAL GROWTH WHEN IMPLANTED INTO THE SPINAL CORD OF ADULT RATS.

Dept. of Surgery, Tulane University, New Orleans, LA 70112; Dept. of Neuroscience, Tulane University, New Orleans, LA 70112.

The ability of cultured Schwann cells to support axonal growth in the spinal cord has been investigated using adult rats. Schwann cells were cultured from the sciatic nerves of newborn rat pups. They were then harvested and injected into small tubes (1-mm diameter; 5-7 mm long) made of polycarbonate film. After a laminectomy, a lesion was made in the dorsal half of the thoracic spinal cord (total length 5-7 mm) and a tube was implanted. In other animals empty tubes were implanted as controls. 1-5 weeks after the animals were perfused and longitudinal sections were cut from the tube and the adjacent spinal cord. Sections were then immunolabeled with antibodies specific for axons, astrocytes and basement membranes. After implantation of 11 days or longer the tubes are filled with cells, many of which have a spindle shape typical of cultured Schwann cells. Neovascularization is evident. Axons can be seen streaming into both ends of the tubes. With short survival times (<2 weeks) these axons extend 2-3 mm toward the center. With longer survivals axons are seen throughout the full length of the tubes. Many are grouped in fascicles while others appear as single fibers. Astrocyte labeling reveals a sharp border between the host tissue and the ends of the tubes. These results provide additional evidence that cultured Schwann cells can support axonal growth in the adult central nervous system.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

Experiments in female Long-Evans rats tested the suitability of a mixed tissue of CNS and PNS components to support axon elongation. A transected optic nerve was cut and inserted into the end of a silicone tube and a peripheral nerve graft (PNG) was tutured in the opposite end forming a 3-mm chamber gap. The chambers were resected after various time periods post-implantation and the contents of the chambers were studied in serial cross sections to assay the growth across the gap. Early events in these chambers are similar to the analogous PNS chambers with the chamber within one day macrophages, erythrocytes and other vascular components exude from the stumps. A fibrin matrix forms a suspended, coaxial spindle-shaped bridge across the gap. During the second week, although growing axons grew retrogradely through the PNG but advanced further than the end of the graft inserted into the tube, suggesting that mixed PNS and CNS tissue does not support axon regeneration. Supported by the Canadian Spinal Research Organization.

AXONAL OUTGROWTH FROM AN INTRASPINAL PERIPHERAL NERVE (PN) GRAFT PROMOTED BY SUBSTRATE-BOUND NEUROTROPHIC FACTORS (NTFs) [J.H. Ye and J. Houle*]. Dept. of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

One month following spinal cord injury, PN grafts to repair injured central nervous system (CNS) pathways has been the reluctance of regenerating axons to extend beyond the distal end of the graft. Substrate bound NTFs (BDNF, NT-3, NT-4, basic FGF, Regeneration Promoting Factor, RPF) were used to clarify whether the CNS environment adjacent to a PN graft insertion site could be made more favorable for the growth of axons. Following hiruection of a mid-cervical spinal cord of adult rats, a segment of autologous PN was apposed to the rostral cavity surface. The distal end was ligated and left unapposed for 2 weeks, then apposed to a strip of NTF-treated nitrocellulose membrane implanted into the spinal cord 5 mm caudal to the lesion. Untreated nitrocellulose served as a control. Five weeks later the PN graft was cut at midpoint and the caudal end exposed to HRP and the rostral end exposed to True Blue to label neurons contributing to the graft. NTF-treated bundles of labeled axons that had grown down to the ventral edge of the implant, with some fibers extending into the adjacent immediate gray matter. Outgrowth associated with BDNF or NT-3-treated implants was less robust in terms of length and number of regrowing axons than with CNFT, yet was greater than with untreated nitrocellulose implants where very few axons extended beyond the PN graft. True Blue-labeled neurons were prominent in the spinal cord, raphe area, reticular formation and vestibular nuclei, the distribution of which was the same with the different NTFs used. These results indicate that regenerating axons of supraspinal neurons can be induced to extend beyond a PN graft, back into the spinal cord, by a variety of substrate bound NTFs, thereby increasing the potential for establishing contact with host neurons. Supported by NIH grant NS 26380.

HUMAN SCHWANN CELLS CAN ENHANCE AXONAL REGENERATION AND MYELINATION IN THE NUDE RAT SPINAL CORD. J.D. Guest & R.P. Bunge. The Miami Project and Dept. of Neurological Surgery, Univ. of Miami School of Medicine, Miami, FL 33136

Human Schwann cells (HSC) can be purified from donor peripheral nerves; such HSC have been shown to enhance regeneration and to provide myelination for regenerating axons when seeded into semipermeable guidance channels in combination with Matrigel and then placed into gaps spanning sciatic nerve lesions in immunocompromised rodents (Levi et al., J. Neurosci. 14:1309-1319, 1994). Furthermore it is known that syngeneic Schwann cells transplanted within semipermeable guidance channels spanning a thoracic spinal cord lesion promote axonal regeneration from locally implanted axons with cells bodies up to 9 segments rostral and provide myelination for many regenerating axons (X.M Xu et al. Soc.Neurosci.Annual Meet. 1995). We have now evaluated whether human Schwann cells can have similar effects on the regeneration and myelination of CNS axons. In this series of experiments we have placed closed ended (caudal) guidance channels filled with HSC and capped with Matrigel (30:70 vol/vol) contact with the T8 spinal segment of adult female Nude rats. We provide evidence that the HSC survive in contact with the T8 nude rat spinal cord and promote regeneration of axons from various neuronal populations (including brainstem DBH positive neurons) into the channel and provide myelination to large numbers of regenerating axons within the closed ends 4 days after surgery. Because numbers of HSC obtained from human donors are limited methods to expand HSCs to large numbers at high purity have been developed (Levi et al. see abstract this meeting). After 3 passages with mitogens the HSC used within guidance channels appear as competent to recruit regenerating fibres and provide myelination as non-expanded HSC. Dr. Guest is a Fellow of the

SCs support regeneration of axons from spinal cord neurons into guidance channels grafted into transected adult rat spinal cord (Xu et al, '92, '93). We investigated if axonal regeneration is improved in SCI and in SCI treated with methylprednisolone (MP), is administered when SC grafts are implanted. SCI were perfused in culture from adult rat spinal cords, survived in Matrigel/DMEM (30:70), and were seeded into semipermeable PAC/PVC channels at a density of 120 X 10^6 cell/ml. MP (30 mg/kg) or vehicle (control) was injected i.v. at 5m, 2h, and 4h after transection at T8 and removal of 1-3 caudal cord segments. Either the rostral stump was inserted 1.5mm into a channel capped at the caudal end, or both stumps were inserted into an open-ended channel. One mo later, the MP + SCI-chopped channel group, compared with controls, had larger tissue cables, improved blending of host cord and graft tissue, more myelinated axons (n=6; x=1159 vs. 500) in the graft, and labelling of more spinal cord neurons (n=1128 vs. 280) after injection of Fast Blue into the graft (n=4). Also, in contrast to the control, 5-HT+ and DBH+ axons were detected in the graft, and brainstem neurons (n=34) extended axons into the graft as determined by Fast Blue tracing. When the channel was open at both ends, 45-60 d later the mean of myelinated axons in the graft was 3237 (n=5; control, 1217). Retrograde tracing showed labelled cord (both rostrally to C4 and caudally to S4) and brainstem neurons. Additional tracing is underway to assess axonal growth from graft into caudal host cord. In sum, MP improves axonal regeneration from both cord and brainstem neurons into SC grafts, possibly by reducing secondary injury of cord adjacent to graft. (NIH NS09923, NS28059 and The Miami Project; XMM is Heumann Int. Scholar.)

We previously demonstrated that Schwann cells (SCs) in semipermeable guidance channels promote regeneration of propriospinal but not supraspinal axons in adult rat spinal cord transected at T8. Here, we tested whether known brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) could stimulate supraspinal axonal regeneration in this model. SCs were purified in culture from adult rat lumbar, caudally suspended with Matrigel and seeded into PAN/PVC channels (Soc. Neurosci. Abstr. 18:1479, 1992). BDNF and NT-3 were delivered together into the capped caudal end of the channel by a miniature mini-pump (18 ml/min) for the first 14 of 30 days tested. Controls received vehicle solution. The spinal cord was transected at T8 and T9-11 segments were removed. The rostral cord stump was inserted 1 mm into the channel. One month after grafting, a mean of 1523 myelinated axons was present in SC/BDNF grafts, twice as many as in SC/vehicle grafts. Brainstem serotonergic axons regenerated into the SC/NT-3 grafts for at least 5 mm, but not in control grafts. When Fast Blue was injected at the channel midpoint, on average, 92 retrogradely labeled neurons were found in 10 specific regions of the brainstem with the highest labeling (67%) in vestibular nuclei. Labeled cells were also present throughout the rostral cord. Thus, regeneration of some neural populations was promoted in a spinal cord transection can be recruited by combinations of trophic factors and a favorable cellular substrate. [Regeneron Pharmaceuticals generously provided neurotrophins and Dr. F. Aeberscher (Lausanne), channels; supported by NIH NS 28059 and NS 09923 and The Miami Project. XMM is the Heumann Int. Scholar.]

EMBRYONIC CNS TRANSPLANTS ASSIST ADULT DORSAL ROOTS TO FORM SYNAPSES IN HOST SPINAL CORD. Y. Itoh*, F. Morii*, T. Supawara*, M. Kowada* and A. Teissier†

Adult dorsal root axons regenerate into embryonic spinal cord transplants and form contacts with transplant endfeet. Stimulating properties of the endfeet are due to electrical stimulation of regenerated dorsal root axons. It is unknown whether embryonic CNS transplants also assist synapse formation by adult dorsal roots regenerated into host spinal cord. Adult Sprague-Dawley rats received intraspinal transplants of E14 spinal cord into left dorsal quadrant cavities in the lumbar enlargement. The severed L4 or L5 dorsal root was sandwiched between the transplant and host spinal cord. Three to 12 months later sagittal sections were processed for calculations of gene-related peptide (CRGP) immunohistochemistry. CRGPeptide immunoreactivity was observed in both cells and endfeet of the E14 M CGRP-labeled axons regenerated into host spinal cord and some extended into the motoneuron pool. The area fraction occupied by regenerating axons in C4 CRGP-labeled transplant was statistically larger than in control rats without transplants. CCRGP-labeled axons formed synaptic terminals within host spinal cord; most were axo-dendritic. Embryonic CNS transplants therefore mediate permanent synapse formation by adult dorsal root axons in host spinal cord and may provide a milieu that promotes reconstruction of interrupted spinal reflex arcs.

INTERSPINAL WIRING OF THE TRANSCANTED RAT SPINAL COLUMN. Hinchin Cheng, Feng-Lee Huang* and Lara Olson. Department of Neurosciences, Karolinska Institute, Stockholm, Sweden, and Institute of Neuroscience, National Yang-Ming Medical College, Taipei, Taiwan.

Shortening of the spinal column has been regarded as one possible method to obtain cord-to-cord apposition after total transection of the spinal column. However, to further improve regenerative possibilities, the problems of inconsistent bony fusion and cyst formations within the junctions must be resolved. To modify the method of de Medinaceli on the rat thoracic spine, we attempted several strategies to achieve better interspinal fixation after spondylectomy and transsection, including transpedicular miniwires, wiring of the transverse processes, and wiring of the posterior spinal processes. A dynamic model into single fibers was created and compared with the cut ends of the spinal cord by means of adjustable fixation devices to permit swelling and shrinkage of the stumps. The data were also obtained following suppressive wiring of partial spinal processes. Preliminary results support that the best regeneration, as indicated by regrowth of 5-HT fibers below the level of transection, was obtained following suppressive wiring of partial spinal processes. In this group, the distance between two spinal cord stump approximations to spinal levels was inconsistent. To solve the problem of this situation, the MSO spicule was loaded with the hypothermic suspension, and we attempted to use the spinal cord stump approximations to spinal levels. These observations suggest that gap junctions between Schwann cells may be important for both normal function of peripheral nerves and their responses to injury.

458.13

Partial nerve defects are a challenging clinical problem. In this study we examined the regeneration process in partially transected rat sciatic nerve repaired with the previously established silicone chamber model. The tibial nerve fascicle was transected and a 10 mm segment was removed. The tibial proximal and distal stumps together with the intact peroneal fascicle were enwrapped into a silicone tube leaving a 10 mm defect between the two tibial stumps. The regenerated nerve was examined by immunocytochemistry and light microscopy after 7, 16, 28 or 42 days. A cellular fibrin matrix, spanning the proximal and distal stumps of the tibial fascicle and surrounding the intact peroneal fascicle, was formed within one week. This cellular matrix was then invaded by non-neuronal cells and regenerating axons. Regeneration in nerves with a partial defect was more advanced with respect to ingrowth vasculature, Schwann cells, axons and myelination as compared to a totally transected nerve with a 10 mm gap repaired with a silicone chamber. The results suggest that a partial nerve defect could be repaired using the silicone chamber technique. It opens a perspective to solve the clinical problem of repairing a partial nerve defect when neither direct suture nor nerve grafting is applicable.

458.14

The silicone tube technique was used to repair transected median (two cases) or ulnar nerves (one case) at the distal forearm level in three patients. In all three cases the nerve stumps were approximated with a silicone tube of such a dimension that would not cause compression of the nerve and leaving a gap of 3-5 mm between the two nerve ends. Three years after nerve repair the patients were examined including sensory evaluation and assessment of muscle contraction force. In two cases the tubes had to be removed two years (median nerve) or three years (ulnar nerve) after surgery. The case with the shortest type of minor local discomfort. At the time of exploration the former gap was bridged by a smooth continuous nerve structure of the same diameter as the adjacent nerve trunk. There were no signs of neuraoma formation. In the median nerve case there were excellent motor recovery of the thenar muscles. Two point discrimination (2PD) was < 6 mm (12 year old patient) and 8-10 mm (21 year old patient) respectively. In the ulnar nerve case (21 year old patient) the first dorsal interosseus muscle was almost normal in size and the strength remarkably good. 2PD was 6 mm. These three cases have demonstrated that the principle of using the tube technique in humans is feasible. The results have inspired us to conduct a randomized, prospective clinical study of the tube technique versus the conventional technique for repair of median or ulnar nerves at the distal forearm level.

Glutamine synthetase localized in astrocytes utilizes glutamate and ammonia. We tested the hypothesis that astrocyte enlargement associated with hyperammonemia can be reduced by inhibition of glutamine synthetase with methionine sulfoximine (MSO). Pentobarbital-anesthetized rats were pretreated with either vehicle, MSO (150 mg/kg, i.p.), or buthionine sulfoximine (BSO; 88 mg/kg, i.p.), an analogue of MSO that does not inhibit glutamine synthetase. Infusion of ammonia acetate for 6 hours increased plasma ammonia levels from 5.8 to 533 μM. Control astrocytes had marked enlargement of all cytoplasmic areas with increased numbers of mitochondria, rough and smooth endoplasmic reticulum, and glycogen. Enlargement of small astrocytic processes in neuropil and perverscular endfoot was reduced by MSO but not BSO pretreatment despite elevated ammonia levels. Nuclear diameter in hyperammonemic rats treated with vehicle (7.9±0.73 μm; ±SD) was greater than in those pretreated with MSO (7.34±0.94 μm) or in controls receiving sodium acetate (6.79±0.9 μm). These data are consistent with the hypothesis that ammonia-induced astrocyte hypertrophy that occurs during acute hyperammonemia is related to glutamine accumulation and synthesis localized in astrocytes. (Supported by NS22757).

NITRATE EXCHANGE CHARACTERIZED AS NHE-1 IN RAT HIPPOCAMPAK ASTROCYTES. John P. Panagopoulos1 and Christopher A. Pappas2. Departments of Internal Medicine1 and Neurology2, Yale University School of Medicine, New Haven, CT 06510.

Precise regulation of intracellular pH (pH(i)) in astrocytes is essential for proper function and modulation of the surrounding environment. The Na+/H+ exchange (NHE) is an integral membrane protein which mediates 1:1 electroneutral countertransport of Na+ for H+. Four distinct isoforms (NHE's 1-4) have been reported with differing localizations and physiological properties. NHE-1, an amiloride-sensitive (50μM-10μM) isoform mediating various cell functions such as growth and proliferation, has been found to be expressed in all mammalian cell types examined. NHE-1's 2-4 are less well characterized with a more restricted pattern of localization, which includes brain for NHE-2 and 3, and is known to be amiloride resistant (IC50 > 50μM). We examined NHE-1 expression in primary cultures of rat hippocampal astrocytes. pH(i) recovery from an acid load in the absence of CoCl2 was assessed using BCECF. Rate of recovery from an acid load measured at a pH(i) of 6.7 was 0.193 ± 0.03 pH units/min. and was completely inhibited by 50μM of amiloride (IC50 = 3.18 ± 0.47μM). Northern blot performed under low stringency, using full-length NHE-1 showed expression of a single isoform (~4.8 kb) consistent with NHE-1. Interestingly, application 50μM EIPA, a highly potent amiloride analog, did not inhibit recovery from an acid load and caused a reversible alkalization when applied to resting cells. (Supported by NS 15589 and CT Heart Association).

RAT HIPOPCAMPAL ASTROCYTES EXHIBIT ELECTROGENIC SODIUM-BICARBONATE COTRANSPORT.
Edward R. O'Connor*, Harald Sontheimer and Bruce R. Ransom.
Dept. of Neurology, Yale School of Medicine, New Haven, CT 06510
Using whole-cell patch-clamp recordings we studied expression of electrogenic Na+/H+ antiport in primary cultures of hippocampal astrocytes derived from newborn rats were studied after 10 days in culture. Application of 25 mM HC03- at a constant pH7,4 to astrocytes bathed in nominally HC03- free solution, produced a reversible change in membrane potentials ranging from +5 to +31 mV (Avc ± s. D. = +11.8±34 mV). The size of the HC03- induced hyperpolarization was strongly related to the cell's initial resting membrane potential; cells with more negative resting potentials had smaller responses. The HC03- induced change in membrane potential was dependent on extracellular Na+, blocked by the dibutyl cyclic dihydro and, of extracellular calcium. Voltage-clamp recording demonstrated that HC03- induced hyperpolarization was caused by outward currents averaging 35±10 pA (holding potential = -90 mV). The reversal potential of the HC03- induced current was between -80 to -90 mV. Based on the reversal potential of the HC03- induced response, and knowledge of the transmembrane gradients for HC03- and Na+, it was calculated that the transporter has an apparent HC03-/Na+ stoichiometry of 2:1. These findings indicate that hippocampal astrocytes express electrogenic Na+/HC03- cotransport. This transporter may play an important role in regulation of intracellular pH, depolarization-induced alkalization and intracellular Na+ homoeostasis. (Supported by NIH grants NS 09542 to ERO and 15599 to BRR).

ION CHANNELS AND GLIAL PROLIFERATION: II. Role of K+ channels, [Ca2+]i and [pH].
Harald Sontheimer
Interdepartmental Neuroscience Program and Dept. Neurology, Yale University School of Medicine, New Haven CT 06510.

Unlike neurons, glial cells retain the ability to proliferate postnatally and can divide rapidly to form astrocytomas under neoplastic conditions. The precise control of factors involved in proliferation is poorly understood. We studied possible role of K+ channels in regulating proliferation by comparing properties of spinal cord astrocytes, rat C6 glioma cells, and human astrocytoma cells in culture. To determine whether chronic exposure to ion channel blockers alters proliferation, control and sister cultures were grown in the presence or absence of channel-blocking agents, and cell proliferation determined using [3H]-thymidine incorporation as a quantitative measure of DNA synthesis. Application of 4-aminopyridine (2mM), Ba2+ (1mM), Ca2+ (5mM), and TEA (5mM), in concentrations to block glial K+ channels, significantly reduced [3H]-thymidine incorporation in astrocytes, but failed to alter proliferation of neoplastic cells. The phorbol ester PMA (100mM), a known mitogen, increased proliferation in normal astrocytes by 33%, but reduced proliferation in neoplastic cells by up to 50%. As K+ channel block should result in depolarization, we examined the potential interdependence of resting potential and proliferation. Astrocytes in which proliferation was inhibited by cyanide arsenite (ARA-C) exhibited 20-30% more hyperpolarized resting potentials than untreated, proliferating, sister cultures. Similar treatment of neoplastic cells resulted in changes in Vm of the same magnitude, but towards more depolarized potentials. These differences suggest that proliferation is regulated differently in normal and neoplastic glial cells. We are presently investigating the possibility that differences in steadystate pH between control and growth-inhibited cells play a role in limiting ion channel expression, membrane potential, and glial proliferation.

Division of Neurosurgery and Dept. of Pharmacology/Toxicology, Albany Medical College, Albany, New York 12208
In pathological conditions astrocytes are known to swell markedly and one of the effectors thought to be responsible is an increase in [K+]. Astrocytes are well-known, both in culture and in vivo, to take up the excitatory amino acid glutamate and to release it in a specific manner. Mechanisms of release involving K+-dependent reversal of this transporter and/or cell swelling were studied. Primary astrocyte cultures, from P1 rat cerebral cortex, were exposed to high K+ and the release of [3H]-D-Aspartate was measured. A twenty minute exposure to 100mM K+ resulted in a biphasic release of [3H]-D-Aspartate, an initial transient release response followed by a slower sustained release. L-644,711, an anion transport blocker, blocked the slower release component but had no effect on the initial release component. The initial release component can be enhanced by increasing [Na+] by treating cells with ouabain; which had no effect on the second release component. The initial component seemed more sensitive to increased [K+], while the second component required >100mM K+.
We propose that the initial release is caused by reversal of the uptake transporter and the second caused by a Na+-insensitive swelling induced anion transport process. (Supported by NS 30303)
GLUTAMATE MEDIATES ASTROCYTE-NEURON SIGNALING IN CORTICAL CULTURES. V. Pappas, S. T. Berger, F. Lui, J. Keifer.
459.11 RESPONSE OF ASTROCYTIC GAP JUNCTIONS FOLLOWING NEURONAL DAMAGE IN RAT BRAIN. J. Nagy, M.Z. Houssa, P.A.Y. O'Doherty, L. Murphy, E.L. Hertberg and M.A. Seshwall. Department of Pharmacology, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, CANADA R3E 0W3

The presence of multiple pathways for increasing [Ca2+]j within a single astrocyte suggests the possibility of integration of multiple stimuli.
NEUROGLIA

646.1

Neurotransmitters, growth factors and cytokines have been shown to mediate neuronal-cytochrome communication. Astrocytes are shown to exhibit receptors for most of these mediators. Activation of receptors by agonists results in a cascade of intracellular events, including the stimulation of calcium influx and subsequent phosphorylation of substrate proteins. To study the regulation of astrocytic functions, we analyzed intracellular target phosphophosphoryts of extracellular signals, in cultured astrocytes using 2-dimensional polyacrylamide gel electrophoresis. Previously, we described a novel substrate of protein kinase C (PKC) enriched in astrocytes, PEA-15 (J. Biol. Chem. 268:5911-5920). Recent RFLP studies performed both in vivo and in vitro, followed by microsequencing, suggested that PEA-15 is also a substrate for calcium-calmodulin-dependent protein kinase II (CaMkII) at a seril residue different from the PKC site. Indirect immunofluorescent studies using antibodies raised against synthetic peptides corresponding to the two phosphorylated sites, demonstrated that PEA-15 is colocalized with microtubules in cultured astrocytes. To determine which form(s) of the protein associate preferentially with tubulins, polymerized tubulin was separated from unpolymerized tubulin by using solubilizing triton-X 100. Analysis of the microtubule-associated fraction suggests that both PKC and CaMKII phosphorylation of PEA-15 may be involved in regulating the binding of the protein to microtubules.

REGIONAL AND FOCAL ALTERATIONS IN NEUROFILAMENT AND TUBULIN IMMUNOREACTIVITY IN INJURED RAT BRAIN. K. E. Saatman and T. K. McIntosh*. Dept. of Neurosurgery, Univ. of Pennsylvania, Philadelphia, PA 19104.

Axonal injury resulting from rapid deformation of the brain is often characterized by the presence of notochordal axonal swellings (club-like endings) (terminal clubs) and axons with regions of enlarged diameter. These pathological changes in axonal morphology have been described clinically, in cases of diffuse axonal injury, and in animal models of acceleration and fluid percussion brain injury. We have used antibodies to tubulin, tyrosinated tubulin, and both 68 kD and 160 kD neuron-specific (NF) subunits to examine axonal swelling and terminal clubbing in the rat brain following fluid percussion brain injury. In addition, regional alterations in the immunoreactivity (IR) of these cytoskeletal proteins were investigated. Adult male Sprague-Dawley rats were anesthetized (sodium pentobarbital, 50 mg/kg) and subjected to lateral fluid percussion brain injury of moderate severity (2-4 atm). Animals were sacrificed at 2, 3, or 7 days post-injury. Cortical neurons surrounding the injury site showed decreased tubulin and NF IR and disruption of their normal radial alignment when compared to the contralateral cortex and to sham-injured animals. Decreased tubulin IR was also seen in the CA3 region at all time points. At 3 days, typical axonal swellings and terminal clubs were readily visible in injured rats, using NF antibody labeling. Populations of these damaged axons were seen in the ipsilateral subcortical white matter, cortex, and thalamus. While these focal axonal swellings could be easily located due to their intense NF IR, neither tubulin antibody used in this study showed intense labelling at the regions of axonal damage. (Supported, in part, by NS26818 and NS08803.)

646.4

A MICROTRIT TER PLATE FORMAT FOR THE MEASUREMENT OF TAxOId-INDUCED POLYMERIZATION OF TUBULIN. F. E. Macdonald, S. Blumenthal-Z, F. Gu, K. Nyberg and B. S. Glasser*, PHYTOPharmaceuticals, Inc., San Carlos, CA 94070 and S. Mudumba, Department of Pharmacology, University of the Pacific, Stockton, CA 95211.

We describe a 96-well plate assay for the measurement of tubulin polymerization based on the method described by Gaskin et al. (1994). Tubulin was purified from fresh bovine brain by two cycles of assembly and disassembly induced by heat, glycerol and OTP, followed by a third cycle with assembly induced by DMSO. For the assay (200ul), tubulin is diluted (0.1 M PIPES, 1Mm EGTA, 1Mm MgSO4). Prior to tubulin addition, each microtiter well receives 100ul of sample or reference compound in 10%DMSO for 30 min. Optimization concentration is 0.75mg/ml. Polymerization is monitored kinetically at 540nm and at 374nm. Thermomax plate reader (Molecular Devices Corp., Menlo Park, CA). The OD340 correlates with compound concentration until saturation of binding sites. Compound potency is expressed as the concentration of compound causing a response equal to 50% of that observed at saturation (IC50). Results in the Table show good reproducibility. Compounds promoting the dissociation of tubulin/NGI, a scaffold-like protein that prevents GTP off, inhibit taxol-induced polymerization in a dose-dependent manner. This assay may be useful for the characterization of compounds that affect tubulin assembly and disassembly such as specific microtubule modulators.

460.5 PHOSPHORYLATION AND CONFORMATIONAL CHANGES OF MAP2 DURING CAT BRAIN DEVELOPMENT
B.M. Riederer, E. Dibrovsky, P. Dibrov, V. Viliksci.
Institute of Anatomy, University of Lausanne, Lausanne, Switzerland; Institute of Molecular Genetics, Prague, Czech Republic.
Molecule-associated protein 2 (MAP2) is essential for the stability of microtubules and for dendritic growth. In this study five monoclonal antibodies were used to analyze MAP2 during brain development. Antibody AP18 was the only one directed against a phosphorylation-dependent epitope on MAP2b and c. Dephosphorylation with alkaline phosphatase abolished most immunoreactivity with AP18 and indicated that MAP2 is phosphorylated throughout postnatal development, possibly by a calcium-dependent kinase. The AP16 epitope was less susceptible to dephosphorylation in larger apical dendrites of cortical pyramidal cells and in some neurons of the upper layers of visual cortex. It is suggested that the AP18 epitope is less accessible to alkaline phosphatase, and that MAP2 conformation changes may differ within parts of neurons. Three antibodies, AP14, MT01, MT02, were directed against the central region of MAP2b. An immunocytochemical comparison revealed differences in the cellular distribution during early postnatal development of cat cerebellum, while at later ages, most antibodies stained similar neuronal elements. Antibody MT02 stained at early stages cell bodies and dendrites in cerebellar cortex and cerebellum. Within the first postnatal month immunoreactivity became restricted to the distal parts of apical dendrites of pyramidal cells but staining was absent from perikarya and finer basal dendrites, and no immunostaining was found in cerebellum. MT02 immunoreactivity is independent of phosphorylation. It is suggested that immunocytochemical detection of MAP2 depends on its conformation, posttranslational modifications such as phosphorylation, or masking of sites by other proteins. Supported by grants of the Swiss National Science Foundation 31-3447.92 and 37TPRJO38808.

460.6 REGULATION OF NEURONAL CYTOSKELETAL PHOSPHORYLATION BY CATION FLUX
M. Mars**, and D.J. Firek, Department of Neurology and ORED, University of Michigan, Ann Arbor, MI 48105 and University of Lausanne, Lausanne, Switzerland.
We studied the state of cytoskeletal terminal phosphorylation of neurofilament (NF) proteins, and of the microtubule-associated proteins in rat brain aggregates in culture. Cultures containing rat telencephalic neurons and glia in defined medium were grown for 4 weeks until myelination occurred. The cultures were then treated with 300 μM veratridine or calcium ions in order to trigger Na+ influx. We used Western blot with antibodies BS1-31 (Sterneberg Meyer) and N-14 (Boehringer Mannheim) to detect phosphorylated NFs, and AB 1991 (Chemicon) to detect MAP tau-1 independent of phosphorylation. Antibody tau-1 (Boehringer-Mannheim) was used to detect tau.
Beginning at 2 hrs of veratridine treatment, there was a marked decrease in phosphorylated NFs, with no change in total NF content, although a shift in mobility of total NFs detected by AB1991, consistent with dephosphorylation of NF-H. Veratridine treatment also resulted in multiple bands with more rapid electrophoretic mobility detected with the tau-1 antibody, consistent with dephosphorylation of tau.
Prolonged treatment with veratridine led to a decrease in total content of a variety of calpain substrates (NF, tau, GAP-43 and calcium) without affecting the level of other proteins that are not calpain substrates (membrane Na-K-ATPase al subunit).
These results suggest that sodium entry through voltage gated channels may regulate the dephosphorylation of cytoskeletal proteins while prolonged treatment may result in Ca2+ entry and activation of calpains.
Supported by grants from the Zyma Foundation and the NIH.

460.7 PROPOFOL INDUCES NO CHANGES IN ACTIN IN THE CYTOSKELETON WHEN INTRACELLULAR CALCIUM IS DEPLETED
By MARTA A. VLAP and PIETER A. G. J. Joosse and A. R. Sengers, Departments of Anaesthesiology and Cell Biology, Faculty of Health Sciences, University Hospital, S-581 85 Linkoping, Sweden.
The site of action of the intravenous anesthetic drug propofol (Diprivan®) is still uncertain. The intracellular action of propofol is studied on primary cultures of neurons from rat. Cytosolic free calcium changes in neurons were studied using Fura2 and a single-cell microfluorometric method. Fluorescence microscopic analysis enabled the body of the organism of activity. An increase in the cytosolic free calcium concentration (Ca2+free) amounting to 24±3E3M was seen shortly after addition of 3μg m.l-1 of propofol. When neurons were depleted in intracellular calcium by the presence of MAPTMA and stimulated by 3μg propofol no changes were seen in the actin organisation of cytoskeleton, as revealed by a fluorescence microscopy. Only 18 of 306 cells exposed to 3μg m.l-1 of propofol exhibited changes in the morphology. Of 250 untreated cells that served as controls, 21 showed morphological changes.
Propofol in concentration exceeding or equivalent clinical relevant concentration induces changes in the morphology of cultured neurons from the rat. These changes are a consequence of the increase in cytosolic free calcium concentration seen after stimulation with propofol. Evidence of this is that no change in actin organisation were observed when intracellular calcium was depleted.

460.9 Vilip 22 kD neuronal EF-hand Ca2+-binding protein from chick brain: regulation of its interaction with intracellular target molecules. K.H. Braunsteiner, R. E. Lent and E. D. Gundelfinger*, Federal Institute for Neurobiology (IFN), Dept. of Neurochem./Mol. biology, P.O. Box 1860, D-39008 Magdeburg, F.R.G.
Vilip (Vilip: Vila-lipin) (Lent et al., 1992, Mol. Brain Res., 15, 133-140) is a member of a new family of neuronal Ca2+-binding proteins, such as vila, recoverina-modal or frequenin. The function of these proteins remains unclear.
Vilip is expressed by a subset of neurons in the brain and retina. The molecule is localized in the cell body, dendrites and axons, and seems to be associated with the cortical cytoskeleton. At least one of the four EF-hand structures of Vilip is able to bind Ca2+-ions, as revealed by mobility shift analysis. The molecule is able to interact with membrane- and cytoskeletal cellular fractions in a Ca2+-dependent manner. In overlay assays several EF-hand containing binding partners for Vilip have been identified. One of them is actin, a main component of the cortical cytoskeleton. Several potential phosphorylation sites exist in the EF-hand structures of Vilip. This raises the possibility that the ability of Vilip to bind Ca2+-ions and to interact with intracellular target molecules in a Ca2+-dependent manner might be regulated. These results suggest that Vilip may act as a Ca2+-effectomolecule. It may transmit Ca2+-signals to the cytoskeleton, thereby affecting processes, such as neurotransmitter release, cell outgrowth or synaptic plasticity, which are dependent on the dynamics of the cytoskeleton. This work is supported by DFG.

460.8 CORTICAL INTERNEURONS EXPRESSING CALCIUM BINDING PROTEINS HAVE AN ERYTHROCYTE-RELATED MEMBRANE CYTOSKELETON. M. R. Celesia1, R. M. Riederer, S. Langer,2 1Department of Histology and general Embryology, University of Fribourg, CH-1705 Fribourg; 2Institute of Anatomy, University of Lausanne, Lausanne; Howard Hughes Medical Institute and Dept. of Biochemistry, Duke University, North Carolina USA.
Cortical interneurons have a non-pyramidal shape, receive their inputs mainly on the cell body and proximal dendrites, express a calcium-binding protein of the EF-hand family and are often surrounded by the "perineuronal net", a specialized extracellular matrix containing e.g. restrictin/janusin. We have found by immunohistochemistry that cortical interneurons immunoreactive for the calcium-binding protein parvalbumin, calcium-dependent 28k and calrein express the red blood cell isofrom of spectrin and ankyrin (βg spectrin brain spectrin 240/235 B or β5 Splb and ankyrin). The immunolabelling for the two calcium associated proteins in each nerve cell is restricted to the cortical portion of the cytoplasm, whereas the calcium-binding proteins occur dispersed in the whole cytoplasm. Ankyrin and βg spectrin immunolabelling is reticulated, whereas the ankyrin staining is punctuated. The study of the distribution of ankyrin and βg spectrin in relationship to restrictin/janusin reveals that the membrane cytoskeletal proteins are in register with the extracellular matrix protein. We suspect that calcium-binding proteins interact with the proteins of the membrane cytoskeleton, thus modulating the lateral mobility of integral membrane proteins and the adhesion of interneurons to the extracellular matrix.

460.10 SORTING SIGNALS FOR TRANSFERRIN RECEPTOR AND RETROVIRUS PROTEINS IN AXONAL AND DENDRITIC TRANSPORT. K. Kristensson*, E. Weeluccius and W. Carolff, Karolinska Institutet, Dept. of Neuroscience; S-17177 Stockholm, Sweden, Dept. of molecular Biology, Karolinska Institutet, Riddings, Sweden.
Rat embryonic dorsal root ganglia, spinal cord and hippocampal neurons in culture were infected with recombinant Semliki forest virus (SFV) containing the genes for the human transferrin receptor, the envelope or macrophage-activating proteins of human immunodeficiency virus type 1 (HIV-1) or Kolesney murine leukemia (Mo-MLV) virus. All nerve cell lines expressed the human transferrin receptor in all cell bodies, but not in their axons. In spinal cord and hippocampal neurons the receptor also occurred in the dendrites. A mutant form of the receptor, in which the amino acids 6-53 in the cytoplasmic tail had been deleted, appeared both in axons and dendrites. HIV-1 envelope protein was also exclusively localized to the dendrites, while the gag protein appeared both in axons and dendrites. Co-expression of the envelope and the gag proteins resulted in a dendritic localisation of the latter, indicating that the envelope protein can interact with and determine the intracellular sorting of the gag protein. Similarly, the Mo-MLV gag appeared in both axons and dendrites, but only in dendrites when co-expressed with the envelope protein. Heterologous co-expression of HIV-1 envelope and Mo-MLV gag proteins and vice versa did not influence the distribution of the gag proteins.
DENDRITE TRANSPORT OF NEURAL BCI RNA IN SYMPATHETIC NEURONS IN CULTURE. L. Mastromatteo, S. Pernini, D. Higgins. H. Tiedge. 1Fishberg, 2Neurobiology, Mount Sinai School of Medicine, New York, NY 10029. 2Department of Pharmacology, SUNY at Buffalo, Buffalo, NY 14214.

Extrastratal protein synthesis in postsynaptic dendritic domains may contribute significantly to long-term synaptic plasticity of nerve cells [see Steward and Banker (1992), Trends Neurosci. 15, 180-186, for review]. In this model, selected RNAs would have to be preferentially targeted to dendritic microdomains. Here, the mechanism of dendritic RNA targeting and transport has remained elusive.

We have analyzed the dendritic targeting competence of neural BCI RNA. This short, non-translatable RNA has been identified in somatomedendritic domains of neurons (Tiedge et al. 1991), Proc. Natl. Acad. Sci. USA 88, 2093-2097; where it may participate in transport- and/or translation-related processes. We have generated various radiolabeled BCI sequences, including full length BCI RNA as well as 5’ and 3’ segments, and microinjected them into somata of rat sympathetic primary culture. We observed a significant and specific accumulation of full length BCI RNA in dendrites. In contrast, injected small nuclear RNAs, such as U4 and U6 RNAs, distributed to somata and muscles. Even when antibodies to any significant extent. Transport of BCI RNA was rapid: distal dendritic tips were reached in less than 2 h. The various structural subdomains in BCI RNA showed significant differences in their dendritic targeting potentials. These results support the notion that BCI RNA contains specific signaling elements that direct its sorting and targeting to dendritic domains.

SYNAPTIC STRUCTURE AND FUNCTION III

PSD-95 is a prominent, highly-enriched protein in postsynaptic density fractions prepared from rat brain. PSD-95 has an apparent molecular weight of 95,000 and is enriched in the PSD fraction where it comprises about 1% of total protein. It was purified from the postsynaptic density fraction, and tyrosine phosphorylated and dually labeled with a combination of the membrane-impermeable dyes di-4-ANEPPS and FM1-43. The detergent solubilized protein was purified by precipitation with ammonium sulfate and by ammonium acetate. We have purified a recombinant protein expressing a C-terminal 6X-His tag. We present a preliminary characterization of purified recombinant PSD-95.

We have identified a novel protein, termed PSD-UP180, from the postsynaptic density (PSD) fraction of rat brain. PSD-UP180 has an apparent molecular weight of 180 kDa, and is enriched in the PSD fraction where it comprises about 1% of total protein. It was purified from the postsynaptic density fraction, and tyrosine phosphorylated and dually labeled with a combination of the membrane-impermeable dyes di-4-ANEPPS and FM1-43. The detergent solubilized protein was purified by precipitation with ammonium sulfate and by ammonium acetate. We have purified a recombinant protein expressing a C-terminal 6X-His tag. We present a preliminary characterization of purified recombinant PSD-95.

Recent evidence showing high levels of protein tyrosine kinase (PTK) activity in adult rat brain was shown. Evidence shows that protein tyrosine kinase (PTK) activity is crucial for synaptic function, we examined this activity in the postsynaptic density fraction of rat brain. Our results suggest that there were 2 PTKs (M.W = 166, 90, 66, 50 kDa) present in the cortical PSD of adult rat brain. Results of phosphorylation analysis and confidence PTNs of these kinase. Recently, Csk, designated as Csk-like type, was found to be predominantly expressed in the brain. Similarity in molecular weight and unique localization in the brain suggest that Csk and the 50 kDa PTK in the PSD may be similar or identical. Indeed, we found that 50 kDa PTK co-precipitated with anti-Csk antibodies in brains sections as well as PTNs. Consequently, we observed the 50 kDa PTK in the PSD Csk-like PTK, and have employed the antisera to Csk to begin characterizing the enzyme in synaptosomes. Our results, obtained by Western blot analysis, suggest that the Csk-like PTK was selectively localized to the PSD. Further, the protein was differentially expressed in the PSD isolated from hippocampus, cerebral cortex, cerebellum and olfactory bulb, implying region-specific function. Among the 4 brain regions examined, the PTK was expressed most abundantly in the hippocampus, an area of crucial importance for learning and memory. The identity of the Csk-like PTK remains to be determined. Nonetheless, our present findings suggest that the enzyme may play important roles in synaptic function at the postsynaptic site.

461.8 A MULTITUDE OF SYNAPTOSOMAL PROTEINS POSSESS O-LINKED NACETYLGALACOSAMINE. N. Cole* and G.W. Hart. Dept. of Biochem. and Molecular Genetics, Univ. of Alabama, Birmingham, AL 35294.

Glycosylation of Src/Thr tyrosine kinase substrates N-linked glycoprotein 0-N-acetylgalactosamine (O-GlcNAc) is a dynamic post-translational modification on a variety of nuclear and cytoplasmic proteins. This abundant form of glycosylation often occurs at sites of protein-directed protein kinases and appears to have a reciprocal relationship with protein phosphorylation. A current hypothesis views O-GlcNAc glycosylation as a mediator of reversible association/disassociation of multi-protein complexes.

Recent studies have demonstrated that the neuron-specific phosphoproteins, synapsins, neurofilaments, and now, tau proteins (Arnold et al., 1994, Soc. Neurosci. Abst.), also possess the O-GlcNAc modification. As a first step towards elucidating a role of O-GlcNAc glycosylation in the nervous system, we assessed for the presence of O-GlcNAc in synaptosomes. Galactosyltransferase, a highly specific probe for terminal GlcNAc residues, labeled numerous synaptosomes, ranging from 30-200 kD. More than 60% of the label associated with synaptosomal proteins was associated to PAGase F (removes terminal sugars), but sensitive to alkaline β-elimination (removes O-linked sugars). Analysis of these β-elimination products by gel filtration and Dionex HPLC confirmed that the O-linked sugars originate from single GlcNAc modifications. Taken together these data indicate that O-GlcNAc is abundantly present on synaptosomal proteins.

We also detected O-GlcNAc transferase activity in synaptosomal preparations. This, the dynamic form of glycosylation could play a role in the association/disassociation of multi-protein complexes regulating neurotransmitter release.

461.9 LIPASES AND PHOSPHOLIPASES IN SYNAPTOENEURONOS FROM RAT, MOUSE, AND PIG BRAIN. L.A. Horrocks, H.-C. Yang, and A.A. Farcougl. Dept. Med. Biochem., The Ohio State Univ., Columbus, Ohio 43210.

Lipases (EC 3.1.1.34) and phospholipases (EC 3.1.1.4) are involved in signal transduction and neurodegeneration. Compared to homogenates, synaptosomes from cerebral cortex of rat, mouse, and pig brain exhibit significantly higher activities of triacylglycerol and monoacylglycerol lipase activities and 15 to 20% of the Ca2+-independent phospholipases A2 activities of lipases are higher in pig and mouse brain synaptosomes than in rat brain synaptosome homogenates. Lipase and phospholipase A2 activities of synaptosomal fractions from various animal species were similar. However, the specific Ca2+-independent phospholipase A2 activity, acting on 1-alk-1-enyl-2-acyl-sn-glycerol-3-phosphoethanolamine was higher than that of the Ca2+-independent phospholipase A2 activity, acting on 1-alk-1-enyl-2-acyl-sn-glycerol-3-phosphoethanolamine. The occurrence of lipases and phospholipases in synaptosomes from rat, mouse, and pig brain suggests that these organelles provide a useful model for studying signal transduction systems. Supported by NIH grants NS10165 and NS29441.

461.10 A NOVEL INTERACTION BETWEEN SYNAPTOBREVIN AND SYNAPTOPHYSIN. L. Edelman*, E. Chapman and R. Jahn, Howard Hughes Medical Institute, Yale University School of Medicine, New Haven, CT 06510.

Synaptobrevin and synaptophysin are integral membrane proteins of synaptic vesicles. It has recently been established that synaptobrevin is a key component of the exocytotic fusion complex. In contrast, the function of synaptophysin is still undefined. It has been proposed to form a channel which may play a role in transmitter release.

Here we report about a specific interaction between synaptobrevin and synaptophysin. Using a novel monoclonal antibody for synaptobrevin II, we performed immunoprecipitation experiments with synaptic acetylcholine extracts. With this antibody, synaptobrevin co-immunoprecipitated with syntaxin and SNAP-25, the members of the putative fusion complex. When a monoclonal antibody for synaptophysin was used, synaptophysin but none of the other proteins co-immunoprecipitated. The interaction between synaptobrevin and synaptophysin was further investigated using recombinant synaptobrevin GST fusion proteins immobilized to glutathione beads. Synaptobrevin bound to all isoforms of synaptophysin including phalloidin. Our findings indicate that synaptobrevin participates in at least two independent sets of protein-protein interactions. Thus it is possible that the availability of the v-SNARE synaptobrevin for membrane fusion may be regulated by synaptophysin or synaptophysin-like proteins indicating that synaptophysin may function as an important regulator of exocytosis.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
461.11 PROTEIN-PROTEIN INTERACTIONS BETWEEN ACTIN AND ACONITASE-LIKE PROTEINS IN THE PHOTORECEPTOR TERMINAL. 
E.A. Zastawny*, G.W. Balakrishna*, Department of Biology, Boston College, Chestnut Hill, MA 02167.

Actin binding proteins are important in the dynamic role the actin molecule plays in the architecture of the cellular cytoskeleton. It is thought that many of these actin binding proteins interact with actin by mimicking certain amino acid sequences within the actin molecule. Certain actin binding proteins are found concentrated at the presynaptic terminal of neurons. These proteins function in the regulation of synaptic vesicle exocytosis. We have generated a monoclonal antibody, B16, that labels the presynaptic structure of photoreceptors. Biochemical analysis of tissue homogenates shows that B16 also recognizes four proteins. By use of the recombinant protein, the RBK protein, we have demonstrated binding to homologous actin. Aconitase is found in two forms, mitochondrial, and cytoplasmic. The latter enzyme is capable of being released for translational regulation. Both forms of the enzyme have the citrate to isocitrate activity.

We decided to investigate the relationship between aconitase and actin. Amino acid sequence comparison of aconitase, actin and other actin binding proteins showed that aconitase contains two motifs implicated in the molecular memory of other actin binding proteins. We found that the positive actin binding sites were active by probing western blots of aconitase and aconitase containing homologues with bovine actin (rat-actin). Next to determine if this actin-aconitase interaction was functional we found that aconitase contributes to the polymerisation of actin into a filamentous network in low Ca2+. Aconitase is also recognized by rat-actin and is a monoclonal antibody. These results suggest there may be a functional role as well in physiological processes such as aconitase and other actin binding proteins. (Supported by Boston College REU)

461.12 NEUROCHEMICAL CHARACTERISTICS OF A POSTSYNAPTIC DENSITY (PSD) FRACTION ISOLATED FROM BOVINE RETINA. 

Considerable evidence suggests that the PSD, a disc-shaped proteinaceous structure attached to the inner surface of postsynaptic membrane, play a crucial role in synaptic function. We have previously demonstrated that the molecular characteristics of the PSD differ among different regions of the cerebellum (CTX, cerebellum (CBL), hippocampus (HI) and olfactory bulb (OB)). To further characterize the regional differences of PSD characteristic throughout the brain, we examined the adult bovine retina, a structure richly innervated by both peripheral and central afferents. Bovine CTX-PSD was studied in parallel for comparison. Morphologically, both the CTX-PSD and retina-PSD exhibited a typical disc-like structure. On average, the retina-PSD was shorter in length than the CTX-PSD and appeared to be more sensitive to Triton X-100. A monoamine degergent employed for isolation of the PSD. SDS-PAGE profiles of the CTX-PSD and CTX-PSD were similar qualitatively, but were different quantitatively. Both bovine retina- and CTX-PSD contained several intrinsic protein kinase activities, similar to those found in rodent and canine PSDs. We conclude that bovine retinal PSD may provide a useful model to study the regulation of synaptic molecular architecture in the visual system in response to environmental stimuli.

PRESYNAPTIC MECHANISMS III

462.1 DIRECT RECORDING FROM IDENTIFIED SYNAPTIC TERMINALS IN THE RAT AUDITORY PATHWAY: EXAMINATION OF A GLUTAMATE AUTORECEPTOR. 
J.D. Forster*, M. Barnes-Davies. Department of Cell Physiology & Pharmacology, Leicester University, LE1 9HN, U.K.

We are interested in the mechanism by which presynaptic glutamate receptors mediate transmission at excitatory synapses. A spatial analysis can give indirect information on the spatial probability of transmitter release, but to address the mechanism of such phenomena, direct presynaptic recording is desirable. The small size of most synaptic terminals in the mammalian CNS makes direct recording impossible, so we have developed a slice preparation of the rat brainstem, containing the superior olivary complex, within which a large synaptic terminal called the calyx of Held is localized.

Transverse slices were prepared from 6-12 day-old Lister Hooded rats. Whole-cell single channel recordings were made from the principal neurons in the medial nucleus of the trapezoid body (MNTB). Dual component monomeric EPSCs were evoked by stimulation of the presynaptic axon. A fast component is mediated by AMPA receptors and has an EPSC probability of transmission nearly equal to unity. In the presence of NMDA-receptor antagonists, perfusion of 10-500 nM ACPD or L-AP4 depressed the EPSC by up to 80 % as has been observed in the hippocampus (Forster & Clements, J. Physiol. 429: 1-16, 1990). Analysis of the coefficient of variance for the evoked EPSCs showed that both drugs act at a presynaptic site to depress transmitter release. The putative mGluR antagonist to-methyl-4-carboxyphenylglycine (1 mM) had no effect on the presynaptic depression.

Direct patch recordings from these presynaptic terminals have been achieved, using Lucifer yellow to confirm the identity of the recording site. Under current clamp, the action potential possessed a profound after-hyperpolarization and responded to depolarizing current injection with a train of APs at up to 200 Hz. (25°C). In voltage-clamp a tetradotoxin-sensitive inward current was followed by a rapidly activating outward current which was sensitive to micromolar concentrations of 4-aminopyridine. (Supported by the Wellcome Trust.)

462.2 GABA_A AND METABotropic RECEPTOR AGONISTS ATTENUATE EVOKED EXCITATORY POSTSYNAPTIC CURRENTS IN LATERAL PARABRACHIAL NUCLEUS (LBPN) NEURONS IN VITRO. 
J.A. Zidovitch*, J.E. Essaye & J.J. Marder*. Department of Medicine (Neurology), University of Alberta, Edmonton, Canada.

The LBPN is a major recipient of autonomic information from more caudal regions of the brainstem. Previously, we have reported that postsynaptic excitatory (NMDA & non-NMDA) and inhibitory (GABA_A) type receptors mediate neurotransmission within the LBPN. The present study shows that excitatory postsynaptic currents observed in the LBPN are attenuated by GABA_A and metabotropic receptor agonists. These actions are independent of any apical postsynaptic effect and suggest that the principal transmitters released in the LBPN can negatively influence transmitter liberation via a presynaptic mechanism of action.

LBPN neurons were recorded from 400 μm thick coronal brainstem slices using the whole-cell patch clamp technique. Monosynaptic excitatory postsynaptic currents (EPSCs) were evoked via bipolar electrodes (6.0 Hz; 100 μA; 10-50% placed across the dorsal medial aspect of the LBPN. Bath application of the metabotropic receptor agonist, trans-1-amino-cyclopentane-1,3-dicarboxylate (t-ACPD; 10 μM) reduced EPSC amplitude by 45.9 ± 6.9% (n=9). No concomitant change to the resting current (V_rest >60 mV) or the current observed during voltage ramp (-120 to +20 mV) was observed. The GABA_A agonist, baclofen (BAC; 1 μM), similarly reduced the amplitude of the EPSC by 61.3 ± 5.3% (n=2). Bath application of BAC at this dose did not activate postsynaptic GABA_A receptors as no change was observed in resting current or voltage ramp-generated currents. These results provide evidence for the existence of two receptor-mediated inhibitory intrinsic mechanisms that reduce evoked transmitter release from terminals and thereby influence the excitability of LBPN neurons.

Supported by the MRC Canada (HU, JCB, & IA2) and Ciba-Geigy Canada Ltd. (OAZ)

462.3 PREGNANIC METABOTROPIC GLUTAMATE RECEPTOR REDUCE SYNAPTIC TRANSMISSION IN THE NEONATAL RAT HIPPOCAMPUS. 
T.G. Dunst* and T.C. Foster, Dept. of Psychology, Univ. of Virginia, Charlottesville, VA 22903.

Prenatal modification of synaptic transmission occurs in the developing rat hippocampus. Developmental increases in population and unitary EPSPs are accompanied by decreased paired-pulse facilitation suggesting an increase in the probability of transmitter release. This increase may reflect developmental regulation of autoreceptors. Previous research has shown that the metabotropic glutamate receptor (mGluR) antagonist, trans-ACPD, depresses CA3-CA1 EPSPs in voltage-clamped CA1 neurons in neonatal rats. This experiment investigates possible presynaptic effects of mGluR antagonists on CA1 cells. Whole-cell recordings of CA1 mGluR agonists were recorded from CA1 neurons of 10-15 day-old rats. mGluR agonists were recorded from area CA1 in hippocampal slices taken from male or female rats after the fifth week of gestation. Agonists applied at a concentration of 10 μM were found to reduce AMPA EPSPs by 40% on average. These effects were reduced by 20% after the second week of gestation. These effects were significantly increased in males as compared to females. These results suggest that glutaetatic synaptic transmission, which may mediate physiologically important inputs to the NMDA, can be modulated presynaptically by GABA_A and metabotropic receptors. (Supported by the MRC Canada and the AHFMRI)

462.4 PREGNANIC MODULATIONS OF GLUTAMAMIC NEUROTTRANSMISSION BY GABA_A AND METABotropic RECEPTORS IN THE HORIZONTAL LIMITS OF THE DIAGONAL BAND OF BROCA (hBB) IN VITRO. 

The D8B, a basal forebrain cholinergic nucleus, participates in central autonomic regulation, theta rhythm generation, and memory mechanisms. Previously, we reported that GABA_A and metabotropic receptors mediate excitatory transmission in hBB neurons. In the present study, we examined the mechanism whereby GABA_A and metabotropic receptors modulate glutaetatic neuronal transmission. Whole cell patch clamp recordings were obtained from coronal slices (400μm) of the rat forebrain containing the hBB. Bipolar stimulation electrodes (200 μA duration; 2Hz; range 10-100 Hz) were used to determine voltage ramps (-140 to +40 mV; 20 sec) (n=12). NBOX (10 μM), an AMPA receptor-selective antagonist, also attenuated the EPSP. The metabotropic receptor antagonist trans-ACPD (10 μM) also reversed the changes in resting current or input resistance (n=13). Furthermore, both baclofen and trans-ACPD did not alter postsynaptic AMPA-mediated inward current, thereby confirming their presynaptic locus of action. These results suggest that glutamamatic synaptic transmission, which may mediate physiologically important inputs to the hBB, can be modulated presynaptically by GABA_A and metabotropic receptors.

Supported by the MRC of Canada and the AHFMRI.
A new technique for comparing evoked and spontaneous synaptic transmission at corticostriatal synapses. We have found that spontaneous EPSCs (sEPSCs) in striatal slices are very small and infrequent. Thus, we have developed a new preparation in which we grow cortical explants in dissociated striatal neurons. The cortical explants (250 x 500 μm) extend processes and form synapses with the neighboring striatal cells. In this preparation we can record sEPSCs using whole-cell recordings in the striatal cells. In the presence of TTX, sEPSCs reconstitute EPSCs (meEPSCs). To record evoked EPSCs in the same striatal cells a bipolar electrode placed on the cortical explant is used to stimulate the tissue. 5 μM dNQX blocks meEPSCs, sEPSCs and EPSCs indicating that synaptic transmission in this system is glutamatergic.

The amplitude of evoked EPSCs is inhibited by GABA-A receptor and by adenosine. 5 μM T-ACPD produces a 9.8 ± 3.6% (n=9) potentiation, 50 μM T-ACPD produces a 31.3 ± 5.2% (n=7) inhibition, 75 μM T-ACPD, 46.9 ± 5.2% (n=8) inhibition, and 50 μM adenosine. 43.8 ± 8.6% (n=5) inhibition. Spontaneous transmission is also affected by GABA-A receptor with T-ACPD. 5 μM T-ACPD has no effect on the mean amplitude of meEPSCs and decreases the time between events by 21.8% (n=2), 50 μM T-ACPD produces a 12.3 ± 10.0% (n=7) inhibition of the mean amplitude and increases the time between events by 100 ± 84.9%. 50 μM T-ACPD appears to have no effect on the mean amplitude of meEPSCs (n=3) and increases the time between events by 0 - 35%. We have successfully used this preparation to look at evoked and spontaneous transmission at the same synapse and have shown that GABA-A activation affects both. (Supported by NS 30470)

**PRESYNAPTIC CHARACTERISTICS OF TWO GABA_A IPSCS IN RAT HIPPOCAMPAL CA1 NEURONS. R.A. Peper* & S.D. Gustafson. Departments of Anesthesiology, Madison, WI 53792.**

Acting via a GABA_A autoreceptor, GABA limits its own release during trains of synaptic excitation, thus permitting induction of LTD and imparting a filter characteristic to the hippocampal circuit. It is not known to what extent these characteristics reflect modulation of the fast somatic or the slow dendritic GABA_A components, nor whether these two components are modulated similarly. In the present study we have characterized use-dependent and GABA_A-mediated depression of the two components of GABA_A-mediated inhibition.

Monosynaptic IPSCs were recorded from adult rat hippocampal CA1 cells in the presence of APV (40 μM) and CNQX (20 μM). Sharp electrodes filled with CaAcetate (3M) or CaCl_2 (3M) and 4X-114 were used to record GABA_A fast and GABA_A slow in response to electrical stimulation of stratum pyramidale and stratum lacunosum-moleculare. As described previously (Neuron 10:189-200, 1993) it was found that paired-pulse depression of GABA_A slow follows the time course described previously for stratum radiatum responses, with a slow onset and maximal depression of 60% at approximately 160 ms. In contrast, GABA_A fast was depressed maximally by 40% at 5 ms, and declined at later time points, so that only 10% depression remained at 160 ms. This suggests that GABA_A fast was also relatively resistant to the action of CaAcetate, being maximally depressed by only 50% at 10-20ms, with no effect at 1 μM, whereas GABA_A slow was depressed by 50% at 0.3 μM and completely eliminated at 1 μM. CDP 15348 only partially reversed the paired-pulse depression of GABA_Afast but eliminated paired-pulse depression of GABA_A slow.

These experiments demonstrate significant differences between the presynaptic characteristics of the two components of GABA_A inhibition, suggesting that different mechanisms may underlie use-dependent depression, and further supporting distinct functional roles for the two systems.

**CHARACTERIZATION OF AN ATRP RECEPTOR ON A CHOLINERGIC PRESYNAPTIC NERVE TERMINAL. X.P. Sun and J.F. Stanley. Synaptic Mechanisms Section, NINDS, Bldg 36, Rm 5A27, NIH Bethesda, MD 20892.**

ATP activates a cation channel on the presynaptic nerve terminal of the cholinergic calyx-type synapse in chick ciliary ganglion (Sci. N.S. Abst. 1991). We have examined the pharmacology of this receptor using purinergic agonists and antagonists. Calyx nerve terminals and their postsynaptic ciliary neurons were isolated and patch clamped (J Neurosci, 11:985). ATP induced fast-activating currents in the nerve terminal and neuron with reversal potentials of about 0 mV. The nerve terminal ATP current inactivated slowly whereas the neuron exhibited both fast and slow inactivating current components. The P_2 agonist, ATPs and 2MeS-ATP mimicked ATP while the P_2a and P_2a agonists, adenosine and β,γ-methylene ATP were ineffective. The P_2 blockers, reactive blue and suramin, were ineffective on the nerve terminal and eliminated only the fast-inactivating current.

Our results suggest that the slowly inactivating ATP conductance on this presynaptic nerve terminal is mediated by neither P_2a nor P_2b-type receptors but by an as yet unidentified receptor type. Since ATP is stored with ACh in secretory vesicles, this presynaptic ATP receptor may play a role in the feed-back modulation of transmitter release.

**RECEPTOR-EFFECTOR COUPLING MECHANISM UNDERLYING THE DESENSITIZING PRESYNAPTIC GABA_A RECEPTOR-MEDIATED INHIBITION OF EXCITATORY TRANSYNAPTIC SYNAPSES. J.L. Plaut.**

We previously proposed the existence of a desensitizing presynaptic GABA receptor (DS-GABA) mechanism as a functional unit in a system in which the postsynaptic membrane only expresses N-methyl-D-aspartate (NMDA) receptors (Plaut et al., Soc. Neurosci. Abstr. 18:792). In the present study, whole-cell patch-clamp recordings from hippocampal neurons in CA1 revealed two distinct synaptic components, an excitatory component driven by DS-GABA receptor and the non-desensitizing (NDS-GABA) receptor. Both receptors display distinct excitatory transynaptic synapses which express postynaptic NMDA and non-NMDA receptors. Superfusion of Ba^2+ (1mM) failed to block baclofen-induced activation of DS-GABA or NDS-GABA inhibition of spontaneous NMDA or non-NMDA receptor-mediated synaptic currents, respectively, indicating that neither receptor is coupled to a K^+ channel. Pretreatment of cell cultures with pertussis toxin (1.0 μg/ml, 24-48 hr) selectively blocked DS-GABA but not NDS-GABA inhibition in some cultures suggesting receptor coupling to separate G-proteins. Pretreatment and co-superfusion of pertussis toxin (1.0 μM) blocked both DS-GABA and NDS-GABA receptor-mediated inhibition. Pretreatment with dicyclohexylcarbodiimide 1 μM) blocked NDS-GABA inhibition, whereas DS-GABA inhibition remained blocked. These results suggest that preyective DS-GABA and NDS-GABA receptors may regulate the synaptic release of glutamate through distinct receptor-effector coupling mechanisms. This raises the possibility for selective modulation of transmission at functionally distinct glutamatergic synapses.

**DOES MUSCARINE ACTIVATE K^+ CHANNELS AT PRESYNAPTIC TERMINALS IN HIPPOCAMPAL AREA CA1. M.G. Rapistain* & S. Wachtler and W.F. Coinger. Dept of Pharmacology, Univ. of Alberta, Edmonton, Alberta, Canada, T6G 2H7.**

Prejunctional inhibition of glutamate release from hippocampal area CA1 can be activated by the activation of several different receptors, including GABA_A, Adenosine_A, Neuropeptide_Y, and a muscarinic acetylcholine receptor. The mechanism whereby these receptors act at presynaptic terminals cannot be recorded directly. Nevertheless, if they all act via an identical mechanism, their actions should be equally affected by manipulations that affect transmitter release. 4-Aminopyridine (30 μM) reduces inhibition mediated by the Y, and GABA_A receptors, but not that caused by muscarine. We found that NMDA (1 mM) reduced the inhibition caused by muscarine. Here, we tested the hypothesis that muscarinic receptors activate presynaptic K^+ channels, by examining its actions when either the blocking Ba^2+ is removed.

Extracellular recordings were made of population EPSP's evoked area CA1 by stimulation of stratum radiatum with 500 μA. We examined the effect of 200 μM muscarine on the EPSP recorded from the stratum radiatum with the same stimulation, and 0.36 mM Ba^2+ reduced the effects of Ba^2+ on the EPSP. These observations are not consistent with muscarinic receptors inhibiting glutamate release by the same mechanisms as ACh or GABA_A receptors, respectively. The observed response is consistent with the activation of muscarine on a presynaptic K^+ channel. If this were the case, the block of presynaptic K^+ current by Ba^2+ would reduce the resistance of the terminal, and activation of another K^+ channel by muscarine would bring the membrane potential closer to E_K, thus further from threshold than under control conditions.

**NICOTINE FACILITATES AND DEPRESSES GLUTAMATERGIC SYNAPTIC TRANSMISSION AT A CNS SYNAPSE IN VITRO. D.S. Mckeeber* & L.W. Role. Dept of Anatomy & Cell Biology in the Center for Neurobiology and Behavior, Columbia University, 722 W 168 St, NY, NY 10032.**

Although habenular neurons from both chick and rat express nicotinic ACh receptors (nAChRs). Physiological studies demonstrate that these receptors are not involved in synaptic transmission. Autoradiographic studies localise many CNS nAChRs to terminal fields, including that of the habenula-IPN projection. We tested whether habenular nAChRs could play a role in modifying glutamatergic transmission in vitro.

Embryonic habenular cultures were cultured in dissociated IPN neurons, a principle target of habenular neurons in vivo. Whole cell recording from IPN neurons located near habenular explants revealed potentials of about 10 mV. Embryonic habenular explants revealed synaptic activity that is blocked by a mixture of the glutamatergic antagonists, CNQX and APV, and not by the nicotinic antagonist, mecamylamine, demonstrating glutamatergic synapses at these habenular-IPN synapses. Stimulation of the habenular neurons by an extracellular stimulating electrode evokes post synaptic currents (EPSCs). Application of a low concentration of nicotine (0.5 μM) increases the amplitude of EPSCs, returning to baseline within 30-60sec, in the continued presence of the nicotine.

This concentration regimen caused an increase in the frequency of spontaneous miniature IPSCs recorded in the presence of 4μM TTX, without affecting the amplitude of these currents. This supports the idea that the receptors responsible for nicotine-induced synaptic facilitation are located on the preysynaptic cell.

In contrast, application of nicotine at 10-20μM increases the percent failure of the evoked EPSCs, possibly due to shunting of theulking action potential. The mechanisms and nAChR subtypes responsible for these nAChR-mediated modifications in synaptic transmission are not yet known. α-LATROTOXIN ENHANCES SYNAPTIC TRANSMISSION BUT DOES NOT PREVENT PRESYNAPTIC INHIBITION INDUCED BY ADENOSINE, BACLOFEN AND OPIOID PEPTIDES IN HIPPOCAMPUS, M. Capuano*, B.H. Gähwiler and S.M. Thompson. Research Institute, University of Zurich, CH-8029 Zurich Switzerland

The black widow spider venom component α-latrotoxin (α-LTX) binds to the α-LTX receptor that is associated with presynaptic proteins, synapticcaptoprin, syntaxin, and Ca**2+** channels. These proteins control the docking of synaptic vesicles at the active zones and regulate exocytosis. Spontaneous mEPSCs (in the presence of TTX and bicuculline) and mIPSCs (in the presence of TTX, CNQX, and AP5) were recorded by means of whole-cell patch clamp in CA1 pyramidal cells of rat hippocampal slice cultures. Focal application of α-LTX (< 1nM) produced a 10-100 fold increase in the frequency of both basal mEPSCs and mIPSCs which persisted for at least 1 h. The α-LTX-induced activity was characterized by intermittent high-frequency bursts, and was only slightly affected by 100 μM Cd**2+**. Furthermore, α-LTX (with or without Cd**2+**) did not occlude the reduction in the frequency of miniature currents induced by 50 μM adenosine, 10 μM baclofen, and by 1 μM of the μ-opioid agonist FK 33-824. Therefore, these agents inhibit transmitter release by a mechanism that does not involve the modulation of the proposed α-latrotoxin/synaptotagmin syntaxin/Ca**2+** channel complex.

ACETYLCHOLINE RELEASE EVOKED BY ACTION POTENTIALS IN THE ABSENCE OF CALCIUM ENTRY IN FROG MOTOR NERVE: ANTAGONISM BY ADENOSINE. M. Watanabe, E.M. Silinsky*, R.S. Redman, J.K. Hirsh, B. Ouy, J.M. Hunt, S. Alfred and R.C. MacDonald, Dept. of Physiol., Pharmacol. and Biolog. Chem., Northwestern U., Chicago, IL 60611 and Evans, U. (39±9% of stimulated EPSC) was observed when AcCh was applied in Ca**2+**/syntaxin/Ca**2+** release experiments. This indicated that a voltage-sensitive Ca binding protein promotes phasic acetylcholine (ACh) release and ii) that the action of adenosine might be impaired by the functioning of Ca binding proteins associated with the synaptosomal apparatus. We delivered Ca via Ca-containing lipid vesicles (Ca liposomes) to motor nerve terminals in frog cutaneous pectoris muscle under conditions in which Ca entry cannot occur. Neurally-evoked AcCh release (recorded as multiquantal end-plate potentials) was generated by Ca liposomes suspended in solutions with no added Ca and containing either a) Mg (1-3 mM), b) Mg (1-3 mM) + Co(1 mM) or c) Mg (1 mM) + EGTA (1 mM). Adenosine (10-100 μM) inhibited AcCh release generated by nerve impulses in the absence of Ca entry. Both electrophysiological and morphological studies using confocal laser microscopy suggest that the liposomes are interacting with the nerve terminal membranes and delivering their entrapped contents to the cytoplasmic milieu without leakage to the exterior of the cell. The results suggest that action potentials in vertebrate motor nerve endings can promote the synchronous, physiologically-functional form of AcCh release in the absence of Ca entry provided the cytoplasmic Ca is elevated by Ca liposomes. Such evoked AcCh release in the absence of Ca entry is antagonized by adenosine. (Supported by NIH Grants NS12782 and NS30795).

GENETIC EVIDENCE THAT MODULATION OF BOTH K AND CA CURRENTS CONTRIBUTE TO α2-ADRENERGIC-RECEPTOR-MEDIATED INHIBITION OF HORMONE SECRETION. P.P. Lakhiani, D.M. Levinger and L.E. Liberti*. Department of Endocrinology and Department of Molecular Physiology and Biophysics, Vanderbilt University, Nashville, TN 37232.

The α2-adrenoceptor (α2-AR), a member of the G-protein-coupled receptor family, inhibits neurotransmitter and hormone release in nearly every system. Point mutation of the highly conserved aspartate residue in the putative second transmembrane segment of the receptor to asparagine (D79N/α2-AR) results in loss of coupling of the receptor to G-protein (Gα2) without any profound effect on the receptor-mediated inhibition of adenylate cyclase (AC) and calcium (Ca) current (Science, 257:971, 1992). We have utilized this unique α2-AR as a tool to examine the precise involvement of these effector systems in the inhibitory action of the α2-AR. The effect of activation of stably transfected wild-type (D97 WT) and D79N α2-AR-expressing aortalorticortic hormone (ACTH) secretion from mouse anterior pituitary cells (A1720) was examined. The basal ACTH secretion was not significantly different in A1720 cells expressing D97 WT and D79N α2-AR. Treatment with the β-adrenoceptor agonist isoprenaline resulted in concentration-dependent stimulation of ACTH secretion which, again, was not significantly different in the two cell lines. However, activation of D79N α2-AR by the maximal concentration of the α2-AR agonist UK 14,304 resulted in significantly less inhibition of isoprenaline-stimulated ACTH secretion compared to that observed with D97 WT (395% vs 771% release). Next the possible involvement of AC in the α2-AR-mediated inhibition was examined. When ACTH secretion was stimulated by the cAMP analogue 8-bromo-cAMP, D97 WT and D79N α2-AR activation was still able to suppress the stimulated secretion. These results suggest that (i) only a part of the α2-AR-induced inhibition is mediated by cAMP current activation, and (ii) modulation of AC plays a minor role in the α2-AR-induced inhibition, implying that suppression of the remaining α2-AR inhibitory component. PRESYNAPTIC ENHANCEMENT OF EXCITATORY SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS BY β-ADRENERGIC RECEPTOR ACTIVATION. P.J. Conn* and R.W. Greiss* IV. Department of Pharmacology and Program in Neuroscience. Emory Univ. Sch. of Med. Atlanta, GA 30322.

β-adrenergic receptor activation has effects in the hippocampus that might influence synaptic transmission as a result of activation of voltage-gated calcium channels and phosphorylation of synaptotagmin I. Direct stimulation of adenylyl cyclase with forskolin has been shown to potentiate transmission in area CA1, but it is not known if the β-adrenergic receptor-activated adenylate cyclase is similar effects. We now report that application of isoproterenol to hippocampal slices potentiated evoked excitatory postsynaptic currents (EPSCs) in CA1 pyramidal cells, and this response was potentiated in the presence of a phosphodiesterase inhibitor. Isoproterenol also resulted in the appearance of a late inward current that likely represents polyynaptic EPSCs. The potentiation of EPSC in response to isoproterenol was blocked by 889, an inhibitor of cAMP-dependent protein kinase. In addition, isoproterenol induced an increase in the frequency of spontaneous miniature EPSCs, but did not affect the amplitude of mEPSCs or currents elicited by direct application of AMPA. These results suggest that presynaptic β-adrenergic receptor mediated responses may act to enhance synaptic transmission in area CA1 via activation of cAMP-dependent protein kinase.

NOREADRENALINE PRESYNAPTICALLY INHIBITS THE EPSCS OF SYNAPTIC TRANSMISSION TO NEURONS. T. Miyazaki, H. Kobayashi, S. Mochida and T. Tosaka Dept. of Physiol., Tokyo Medical College, Tokyo 160, Japan

Excitatory postsynaptic currents in spinal cord thin slices from P7 to P12 rats were identified by DiI preinjection to the superior cervical ganglion. Under the whole-cell configuration of slice-patch method, we recorded a mono-synaptic EPSC in the SPMs evoked by stimulation at the nerve intercalate, containing strychnine (5μM) and bicuculline (10μM). The EPSCs were abolished by kynurenam (2μM) or CNQX (10μM) and were inhibited reversibly by the EPSCs in about 80% neurons tested. The inhibitory effect was dose-dependent, reaching maximal inhibition (50-100%) at a higher dose of NA (500μM), about 50 % of EPSC was remaining. NA did not induce any appreciable shift of the reversal potential of the EPSC which was around zero mV. Glutamate current generated by pressure application to the soma was not affected by NA, though the simultaneously recorded EPSC was not inhibited. NA effect completely disappeared in the photolamine (10μM) solution. The results suggest that noradrenergic nerves inhibit the release of glutamate through activation of the α1-adrenergic receptors.

Previous studies have shown that dopamine (DA) receptor agonists and antagonists may induce dopamine release and receptor effects. We have recently shown that endogenous DA. We used a model of intrastriatal microdialysis in freely moving rats to study the effect of pergolide, a D1 and D2 DA receptor agonist, on the biotransformation of endogenous and exogenous L-DOPA. Levels of L-DOPA, DA, DOPAC and HVA were measured by high-performance liquid chromatography. Pergolide (2 mg/kg, i.p.) caused a 47 % decrease in basal striatal extracellular (EC) levels of DOPAC and a 65 % decrease in basal striatal EC levels of HVA, 60 minutes and 120 minutes after injection, respectively. EC DA became undetectable 60 minutes after injection of pergolide. L-DOPA (100 mg/kg, i.p.) was detected in 5 minutes after pergolide, produced significant increase in EC levels of L-DOPA, DOPAC, HVA and DA in rats with and without perfusion of 104 M pergolide. The DOPAC peak value was lower and was reached 60 minutes later in the group with pergolide.

This study demonstrates inhibitory effects of pergolide on release and metabolism of endogenous DA and on biotransformation of exogenous L-DOPA. These effects, probably mediated by DA autoreceptors, might have important pharmacological implications.
463.1 Cloning and expression of the P2X receptor reveals a new class of ligand-gated ion channel
Glaxo IMB, CP 674, 1228 Geneva, Switzerland
A cDNA encoding an ion channel gated by extracellular ATP (P2X receptor) was isolated from the rat vas deferens by expression cloning in Xenopus oocytes. When expressed in oocytes or in the HEK-293 cell line, this clone produces a receptor activated by nM concentrations of ATP, which shows strong desensitization. It is non-selective for cations and highly permeable to Ca2+2. It exhibits a P2X-type pharmacology, being activated by 2-methyl-5-ATP > ATP > d3-methyl-ATP, and inhibited by suramin and pyridoxalphosphate-6-azophenyl-2,4-dimethyl-3-phenylhydantoic acid (PDAPS). In outside-out patches excised from oocytes expressing the P2X clone, single channels of about 11 pS are activated by ATP. The cDNA consists of 1837 bp with an open reading frame predicting a protein of 206 amino acids. The protein sequence bears no homology to other ligand-gated ion channels and appears to have only two hydrophobic segments long enough to span the membrane. This receptor with novel structure probably represents the first member of a new class of ligand-gated ionotropic receptors.

463.2 Zn2+ POTENTIATES STEADY-STATE ATP ACTIVATED CURRENTS IN RAT NODOSO GANGLION NEURONS. A WHOLE-CELL AND SINGLE-CHANNEL STUDY. Jerry M. Wright* and Chao-Li Li. LMCC, National Institute on Alcohol Abuse and Alcoholism, NIH, Bethesda, MD 20892
Zn2+ and ATP are normally present in serum at low levels and are released from some neurons during synaptic activity. In whole-cell recordings, 10 μM Zn2+ potentiated steady-state currents in rat nodosus ganglion neuron cells by 18% in 0.5 μM ATP and 120% in 2 μM ATP. Fluctuation analysis of whole-cell currents suggested that the mechanism was increased burst-duration. Single channel recordings indicated the presence of several channel conductances. There was a primary conductance of 25-35 pS plus other low conductances present in the baseline noise. 10 μM Zn2+ did not alter the conductance of the 25-35 pS ATP-activated channel but did increase the probability of opening. Kinetics of the 25-35 pS channel were complex with fast openings and closings in addition to substate transitions and bursting. The response of the low conductance channels to Zn2+ was highly variable, suggesting multiple types of low conductance ATP-activated channels.

463.3 BIPHASIC MODULATION OF THE GLYCINE RECEPTOR BY Zn2+. A.R. Blomesthal, E. Goldwater, D.R. Frritch* and N.L. Harrison*. Deps. of Anesthesia and Pharm./Phys. Sciences, Univ. of Chicago, Chicago, IL, and *Dep of Pharm, Univ. of Pennsylvania, Philadelphia, PA. Zn2+ exerts a subunit-dependent inhibitory action on the GABA receptor (Drugaul et al., Neuron, 5: 781-8). We have studied the effects of Zn2+ on the structurally related glycine receptor (GLY-R). In whole-cell patch clamp experiments on cultured rat spinal neurons, Zn2+ potentiated GLY-activated CI- currents at a concentration of 500μM, but blocked the current at a concentration of 50μM. The native GLY-R is an αβ heteropentamer (Langosch et al., PNAS, 85:7394-4). Further experiments were conducted by transient expression of receptor in HEK 293 cells by transfection with cDNAs encoding the α2 and β subunits of the human GLY-R. When the α2 subunit alone was expressed, GLY-activated CI- currents were blocked by strychnine (10μM) and inhibited by picotoxin (PTX) concentrations as low as 1μM, potentiated by Zn2+ concentrations between 0.2 and 2μM, and blocked by concentrations > 5μM. When the α2 and β subunits were expressed together, PTX sensitivity was abolished, as in spinal neurons. However, the addition of the β subunit had little effect on Zn2+ sensitivity. It seems likely that Zn2+ acts on the α subunit, while the β subunit has little effect on the Zn2+ interaction. The dual action of Zn2+ in modulating GLY-Rs suggests that two distinct binding sites may be present. The biphasic action of Zn2+ on the GLY-R is interesting in view of other reports of dual Zn2+ modulation of ligand-gated ion channels (Hollmann et al., Neuron, 1994-95). The possible conservation of Zn2+ modulatory sites may prove significant in the case of the NMDA receptor, which also carries a binding site for glycine as an essential co-agonist. We thank Heinrich Betz for the β subunit cDNA.

463.4 EFFECTS OF NICOTINIC ANTAGONISTS ON GLYCINE RECEPTORS. V.E. Wotring and K.W. Yoon. Department of Pharmacology and Physiological Science and Division of Neurosurgery, Saint Louis University Health Sciences Center, St. Louis, MO 63104.
Since certain nicotinic antagonists can inhibit GABA induced currents (Wotring and Yoon, Soc. Neurosci. Abs., 52:93), we pursued the possibility that these same agents might also inhibit glycine induced currents. Measurements of glycine evoked currents were made using the whole cell patch clamp technique with rat hippocampal cells grown in culture for 10 - 15 days; drug applications were made with a U-tube. In these experiments, GABA currents and glycine currents could be distinguished using the w/cusculine and strychnine. Strychnine (1μM) blocked 63% (p<0.001, n=4) of the control glycine (100μM) current while it did not alter a 30 μM GABA current (p=0.02, n=4). Correspondingly, baclofen (1μM) decreased the current but did not affect the glycine current. Application of the nicotinic antagonist, d-tubocurarine at a concentration of 100 μM reduced glycine currents by 37% (p<0.001, n=5). 100 μM trimethaphan camylate diminished glycine currents by 63% (p<0.001, n=8). Nicotinic antagonists that we have previously found to not significantly affect GABA currents had unexpected effects on glycine currents. 100 μM d-tubocurarine blocked 51% (p<0.001, n=5) of the glycine current. Application of 1 μM mecamylamine resulted in a nearly complete blockade (89%, p<0.001, n=6) of glycine current. However, 1 μM hexamethonium did not alter the control glycine current (p>0.2, n=6).
The ability of these nicotinic antagonists to block glycine and GABA currents forebodes structural similarity among these ligand-gated channels. However, the differential effect of mecamylamine on GABA and glycine currents suggests common variances in the mechanisms of antagonism.

Four proteins isolated from rat brain synaptic membrane have molecular weights of 67-70, 53-58, 41-46, and 31-36 kDa and contain binding sites for NMDA, glutamate, 2-AAP, TCP, and glycine (Kamin et al., Nature, 354, 70, 1991). A 40-42 kDa glycine-binding protein has been isolated by affinity chromatography on 7,5-dichlorokynurenamine (7,5-DCKA) column (Babcock et al., Neurosci. Abs., 1994). Polyclonal antibodies raised against the 40-42 kDa proteins purified from 41-43 kDa protein in synaptic membranes. These antibodies were used to screen a rat hippocampus cDNA library in ZAP vector and an ~1.9 kbp clone expressing the antigenic protein was identified. The open reading frame of this clone describes a unique protein of 470 amino acids (52.8 kDa). Northern blot analysis of brain RNA revealed hybridization of the cDNA probes to transcripts of ~2.0 kb. RNA levels were expressed approximately equal in hippocampus, cerebral cortex, and cerebellum. Lane 1 corresponded with the pIII vector carrying the 1.9 kbp insert expressed a fusion protein that was recognized by the anti-glycine binding protein antibodies. The fusion protein was purified by IPTG induced E. coli extract using 5, 7-DCKA-derived column. Two defined proteins identified two binding sites for [3H]glycine with estimated K2 of 124 nM and 8.1 μM. The binding of glycine was displaceable by D-serine, 7,5-DCKA and HA-966. These results suggest that there are two classes of protein that may belong to a different subset of brain NMDA receptors (Supported by grants AA 04732 and DA003-91-G-0167 and an unrestricted grant from Parkinson's Disease).

An 40-42 kDa protein that has binding sites for glycine, D-serine, HA-966, and 7,5-dichlorokynurenamine was purified from rat brain synaptic membranes (Babcock et al., Neuroscience Abstr., 20, 1994). Polyclonal antibodies were developed against proteins of 41-43 kDa. These antibodies reacted specifically with an 60 kDa protein in synaptic membranes (Western blot analyses). Immunohistochemical studies in rat brain were performed using the antigen to the 41-43 kDa proteins. The results of these studies indicate that in detergent-permeabilized brain sections, the pyramidal neurons of the cerebral cortex and the hippocampus exhibit strong immunoreactivity with the anti-glycine-binding protein antiserum. Most heavily labeled were the pyramidal neurons, including their proximal dendrites, in the CA2 region of the hippocampus. The granule cells of the cerebellum and the dentate gyrus were also strongly labeled. A comparison between the labelling observed with the antiserum to the 63-70 kDa glutamate-binding protein, the 53-58 KDa CPP-binding protein, and the glycine binding protein indicates that all three antibodies label some of the same populations of neurons with only small differences observed in the pattern of labelling. The antibodies raised against these three proteins may be useful probes for the determination of the distribution of a subpopulation of glutamate and NMDA-like receptors in brain. (Supported by grants AA 04732, DA003-91-G-0167 and HD 05258.)

A group of synaptic membrane proteins with sizes of 67-70, 53-58, 41-46, and 31-36 kDa has recognition sites for NMDA receptor ligands, such as a glutamate receptor subtype, a Ca²⁺ channel, and a GABA receptor. It is possible that these proteins are breakdown products of the NMDAR1/G2 proteins or that they are distinct entities. An ~40 kDa protein that has binding sites for glycine was purified from a rat synaptic membrane preparation. Affinity chromatography first through a matrix derivatized with 5,7-dichlorokynurenam (5,7-DCKA), then through a derivatized with O-OH-quinolone. An 40-42 kDa protein was isolated and this protein bound [3H]glycine in a symmetric-symmetric-intensive manner and with a stoichiometry of 1 mol glycine/mol protein. The glycine binding sites of the protein had a low affinity (3-8 μM) for glycine. D-, Serine, 5,7-DCKA, and HA-966 inhibited glycine binding to the protein. Polyclonal antibodies developed against proteins of 41-43 kDa electroeluted from SDS-polyacrylamide, which were recognized with an 60 kDa protein in synaptic membranes (Western blots). Treatment of solubilized synaptic membrane proteins with these antibodies led to the immunoreaction of approximately 60% of the [3H]Gly 2863-binding proteins. These observations indicate that a synaptic membrane protein of ~60 kDa size may be a symmetric-symmetric-intensive glycine receptor and that this protein is a component of a form of NMDA receptors. [Supported by grants AA 04732, DA00319-01A6, and a grant from Parke-Davis].

643.9 AGONIST-INDUCED CURRENTS IN IDENTIFIED NEURONS OF THE RAT DORSAL HORN. H. U. Zelhafer, T. Liebel, K. Brunner* and D. Swindulla, Institute of Experimental and Clinical Pharmacology and Toxicology, University of Erlangen-Nuremberg, D-91054 Erlangen, Germany.

Neurons within the dorsal horn of the spinal cord play a critical role in sensory information processing. In the present study, we have investigated ionic currents elicited by external application of the excitatory aminoacid neurotransmitter glutamate and of the noncompetitive neurotransmitters glycine and GABA. 250 μM thick transverse slices were cut from the spinal cord of 7 to 14 day old rats. Agonist currents were recorded from visually identified neurons in the dorsal horn of the rat spinal cord (lamin III to V) using the tight seal whole cell configuration of the patch clamp technique. Currents elicited by application of 100 μM L-glutamate showed a strong outward rectification in the presence of 1 mM Mg²⁺, indicating that a large portion of the current was through NMDA receptor channels. Currents induced by 100 μM glycine showed a transient and a maintained component. Both components reversed at the chloridie equilibrium potential. Neither run down nor wash out of the current could be observed with recordings that lasted up to 90 minutes. This indicates that the current was through chloride channels that are directly gated by glycine. GABA (10 μM) at a holding potential of -80 mV elicited inward currents which showed only a steady state component. Currents elicited by GABA displayed a rapid run down within 10 minutes of whole cell recording and were blocked by the GABReceptor antagonist CGP 36348 (200 μM) These findings indicate that GABA induced currents depends on the activation of GABAB receptors and on a rapidly diffusible intracellular molecule. Supported in part by a grant from the Hildgck Doerenkamp-Gerhard Zbinden Foundation to HUZ and DS.

The GABA receptor is a pentameric protein composed of various combinations of α, β, and γ subunits. At least one α, one β, and one γ are necessary for a fully functional GABA receptor expressing α (benzodiazepine) pharmacology. In the present report we describe the development of a recombinant cell line expressing a βγ α3 subunit of the GABA receptor. Following transfection and selection in G418 several clonal cell lines were isolated and tested for [3H]-muscimol binding and [3H]-flumazenil binding activity. Among the cell lines one exhibited 200 fmol of [3H]-flumazenil binding sites per mg membrane protein and was selected for further characterization. Equilibrium saturation analysis revealed a Kᵰ value of 0.39 nM for [3H]-flumazenil in good agreement with the Kᵰ values of 1.4 μM for [3H]-flumazenil using transiently-transfected α3βγ GABA receptor constructs and rat cerebellar membrane preparations. The Kᵰ values of diapace, CL 218872 and zolpidem to inhibit [3H]-flumazenil binding to this cell-line were 18 nM, 210 nM and 40 nM, respectively. The concentration-dependency of GABA-induced chloride current in this cell-line gave an EC₅₀ value of 6.3 μM as determined by the whole cell patch-clamp technique. GABA (1 μM)-induced chloride current was poteniated by diazepam and zolpidem with EC₅₀ values of 36 and 160 nM, respectively. In conclusion, these properties indicate that a functional GABA receptor subtype with α3 pharmacology has been stably expressed in this transfected cell-line.

The symmetrical compound bis (2,6,6-tetramethyl-4-piperidinyl) sebacate (BTMPS) is a use-dependent inhibitor of nicotinic AChR. The active portions of BTMPS are the tetramethylpiperidine (TMP) rings. However, inhibition of neuronal nAChR by TMP is much more rapidly reversible than inhibition by BTMPS, suggesting prolonged inhibition of neuronal nAChR may result from binding of the conjugated compound to multiple sites within the receptor. A compound related to BTMPS, but differing by four carbons in the piperidine rings, showed a dramatic loss of inhibitory activity.

The inhibition of neuronal nAChR by BTMPS is rapidly reversible unless a neuronal beta subunit is substituted for the muscle beta subunit. This suggests that normal muscle-type receptors may contain a single site for BTMPS inhibition and that the expression of a neuronal beta subunit provides an additional site. The sequences of the neuronal beta subunits differ from the muscle beta subunits in regions that are extracellular vestibule forming domains. The muscle delta subunits are similar in sequence to the neuronal beta subunits in these regions, while the muscle gamma subunit more closely resembles the muscle alpha subunits. Over-expression of the delta subunit (omitting gamma subunit RNA) has the same effect on the reversibility of BTMPS inhibition as a neuronal beta subunit for the muscle beta subunit. Compared with muscle-type and delta-less, recombinant C. elegans a subunit, the neuronal gamma subunit is sensitive to mecamylamine (p<0.01), 2 showed a significant increase in divalent ion permeability (p<0.05), and 3 had greater inward rectification (measured by chord conductance). Our data suggest that the domains which control noncompetitive inhibition may also regulate ion permeation properties.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

Cholinergic nicotinic receptor desensitization was studied in cultured rat myoblasts using the whole cell configuration of the patch clamp technique. Whole cell currents were recorded following treatment of desensitized applications (40s-2min) of ACh. The current reached a peak in sec and declined to a steady state level during agonist application. The rate of onset of desensitization was voltage dependent and accelerated by an increase in extracellular [Ca\textsuperscript{2+}]. Simultaneous measurement of [Ca\textsuperscript{2+}]\textsuperscript{i}, using dual excitation microspectrofluorometry with fura-2 loaded myoblasts indicated a significant permeability of activated ACh receptor channels to calcium. Agonist-induced currents as well as increases in [Ca\textsuperscript{2+}]\textsuperscript{i}, were blocked by prior exposure of myoblasts to α-bungarotoxin. Acceleration of the onset of desensitization by calcium required external calcium during receptor activation. The [Ca\textsuperscript{2+}]\textsuperscript{i} reached a peak following ACh application and declined slowly to basal levels. An increase in [Ca\textsuperscript{2+}]\textsuperscript{i} produced by photolysis of cytosolic DMS-Nitrophen-Ca\textsuperscript{2+} complexes also accelerated desensitization onset in the absence of external calcium. These results suggest that Ca\textsuperscript{2+} entry through ACh-activated channels is an important pathway for the regulation of the ACh receptor-channel by providing Ca\textsuperscript{2+} required for intracellular modulatory mechanisms. The technique of photolesere calcium will be used to determine the minimum amplitude and duration parameters of the [Ca\textsuperscript{2+}]\textsuperscript{i}, required for the modulation of the ACh receptor and desensitization kinetics (Supported by MDA).

ASTROGLIAL AND NEURONAL ADRENERGIC RECEPTORS LINKED TO CHANGES IN [K\textsuperscript{+}] AND [Ca\textsuperscript{2+}]\textsuperscript{i}: EXHIBIT DIFFERENT CHARACTERISTICS. M. Nilsson, T. M. Marderman, P. S. Eriksson, L. Hansson and L. R. Petrussevs, 1, 2, 3.

Institute of Neurobiology 1, Departments of Neurology 2, University of Gottingen and Department of Cell Biology, Faculty of Health Sciences, University of Linköping, Sweden.

Various adrenergic agonists were investigated for their effects on intracellular concentrations of calcium ([Ca\textsuperscript{2+}]\textsuperscript{i}) and potassium ([K\textsuperscript{+}]\textsuperscript{i}). The calcium sensitive dye fura-2 and the potassium sensitive dye PBF were used in mixed astroglial/neuronal primary cultures from newborn rat cerebral cortex.

We found considerable differences in the adrenergic-evoked changes in [Ca\textsuperscript{2+}]\textsuperscript{i} and [K\textsuperscript{+}]\textsuperscript{i} between the two celltypes. Norepinephalin (NA), phenylephrin (phe; α1-agonists), clonidine (clon; α2-agonist) and isoproterenol (iso; β-agonists) were all able to increase calcium and decrease potassium concentrations with one exception; clonidine could not induce potassium responses. In neurons, NA and phe evoked calcium transients while clon and iso did not. NA and clon were able to elicit potassium reductions but no responses were seen with phe and iso stimulation. The astrocytes responded in general with up to 4 different types of calcium response patterns while the neurons only exhibited 2 types. After adrenergic stimulation, no oscillations in intracellular calcium were seen in the neurons, but could on the other hand, in the astrocytes, the agonist-induced reductions in [K\textsuperscript{+}]\textsuperscript{i} always persisted at the lower level in the presence of the agonists. The results point out the astroglial cellpopulation as potentially important receivers of adrenergic input. The results also show that astroglial and neuronal changes in [Ca\textsuperscript{2+}]\textsuperscript{i} and [K\textsuperscript{+}]\textsuperscript{i} exhibit different characteristics which might be of great importance for the understanding of the basic principles involved in the homeostasis of extracellular calcium and potassium concentrations.
LIGAND-GATED ION CHANNELS I

663.19 POINT MUTANTS OF THE INHIBITORY GLYCINE RECEPTOR α1 SUBUNIT ASSOCIATED WITH HEREDITARY HYPEREKPLEXIA DISPLAY REDUCED AGONIST AFFINITY AND EFFECT IN SINGLE CHANNEL CONDUCTANCE.
B. Labs*, N. Rundum*, U. Emsberger*, H. Betz* and D. Langanke. Department of Neurochemistry, Max-Planck-Institute for Brain Research, D-60021 Frankfurt (Main), Germany.

Native adult inhibitory glycine receptor (GlyR) is a pentameric ligand-gated ion channel protein composed of two different subunits (α1 and β) in a stoichiometry of 2:2. Hyperkplexia (STHE) is a human autosomal dominant neurological disorder associated with point mutations in the gene encoding the α1 subunit of the GlyCl receptor (Ann. Neurol. 35:135-138, 1994). According to an arginine residue bordering the channel forming transmembrane region M2 at position 271 is substituted to either tyrosine or glutamine.

We have determined the functional properties of these GlyR mutants on heterologous expression in Xenopus oocytes and kidney 293 cells. When analysing homomeric channels, glycine concentrations eliciting half-maximal responses (EC50) were approximately 100-fold increased in comparison with wild-type α1 GlyR. Further, we observed drastic decreases in maximal whole-cell currents (up to 90%) and a reduction in single channel main conductances. In addition, the glycine agonists β-alanine and taunine did not elicit detectable currents but no significant change in affinity for the competitive antagonist strychnine could be observed. Coexpression of the mutants with wild-type α1 subunits in different ratios resulted in mixed channels with intermediate glycine affinities and maximal currents depending on the ratio of the expressed subunits. Interestingly, coexpression of the mutants with both α1 and β diminished the effects of the mutations in comparison to coexpression with α1 alone.

Our results imply that the phenotype of STHE patients is the consequence of diminished agonist affinity and efficacy of the mutant GlyRs.

663.20 ISOLATION AND CHARACTERISATION OF THE MOUSE GLYCINE RECEPTOR β SUBUNIT GENE M.Fischer, H.Betz* and J.Kuhse. Max-Planck-Institute for Brain Research, D-60021 Frankfurt (Main), Germany.

The structure of the mouse glycine receptor β subunit gene was deduced from overlapping genomic lambda clones. Subcloning and sequencing of the identified ten exons which are spread over a distance of more than 50 kb. Comparison of the β gene with the previously characterized glycine receptor α subunit genes revealed high structural homology. However, there are some notable differences. Whereas the 5' non-coding region of the α gene is encoded by the first exon, the respective region of the β gene is separated by one intron. Also, the transmembrane region 2 is encoded by two exons, a finding similar to the GABA<sub>B</sub> receptor β gene structure.

The different glycine receptor subunit genes exhibit developmental and spatial specific expression in spinal cord. These expression patterns should reflect complex regulation at the level of transcription. Therefore, we are interested in a detailed characterization of the promoter and upstream regions of the glycine receptor β gene. Trancription start points were mapped 1.5 kb upstream of the start codon. To identify regulatory elements, transient expression studies with reporter gene constructs in neuroblastoma and control cell lines are being pursued.

LIGAND-GATED ION CHANNELS: ALCOHOL MODULATION

664.1 STUDY OF ETHANOL EFFECTS ON TM II DOMAIN MUTANTS OF THE NMDA RECEPTOR CHANNEL.
K. Masood*, C. Wu and F. F. White, Lab. Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

The N-methyl-D-aspartate (NMDA) receptor is one of the key neurotransmitter-gated ion channels, as it is involved in important physiological and pathophysiological aspects of nervous system function. NMDA receptors have been found to be affected by psychoactive drugs such as ketamine, phencyclidine and ethanol, possibly contributing to the behavioral effects of these drugs. Earlier we reported differential ethanol sensitivity of NMDA receptor subunit combinations (Mol. Pharmacol. 49:524, 1996). However, the mechanism by which ethanol exerts its effect on NMDA receptors is unknown. The transmembrane II (TM II) domain of NMDA receptor subunits is thought to constitute the pore of the channel. Single amino acid mutants in and around the TM II domain of NR1 were coexpressed with NR2A in Xenopus oocytes and the effect of ethanol on NMDA activated ion current was tested using the two-electrode voltage-clamp method. The NMDA activated-current of the native subunit combination was inhibited 41% by 100 mM ethanol. The ethanol inhibition for charged mutants was 43% for E598Q and 42% for D599N. The inhibition for polar mutants was 39% for T602G and 38% for S605G. The observations suggest that these charged and polar amino acid mutations did not significantly change ethanol inhibition of NMDA-activated current flow through the mutated channels.

664.2 ETHANOL SENSITIVITY OF RECOMBINANT GLUTAMATE RECEPTOR EXPRESSED IN XENOPUS OCYTES IS SIMILAR TO THAT OF NEURONS.
B.E. Akinbola* and F.F. White. Lab. of Molecular and Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

The Ethanol(ETOH) sensitive neuronal AMPA(α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid) type glutamate receptors(GluR), have multiple subunits designated as GluR1-4(Cai, Science,249:556-560,1990), which exist in two distinct "splice variant" versions known as the FLIP and FLOP (Science,249:1580-1585,1990). We have examined the ETOH sensitivity of recombinant GluR1-3 FLOP receptor combinations expressed in Xenopus oocytes, using the two electrode voltage clamp technique. ETOH concentrations of 10-500 mM caused 50% inhibition of currents activated by 200mM kainate. The GluR1+2+3 heteromeric combination current exhibited the highest sensitivity to ETOH, with an IC50 value of 176mM. The response of GluR3 homomer receptor subunit to ETOH had an IC50 value of 212mM. The sensitivity of GluR3 and GluR1+2+3 subunits to inhibition by ETOH is similar to the reported sensitivity of non-NMDA glutamate-activated current in hippocampal neurons(Ann. Med.,22:247-252,1990). By contrast, the FLIP forms of GluR expressed in human embryonic kidney (HEK) 293 cells are reported to be more sensitive to ETOH(Neurosci. Letters,159:83-87,1993) than non NMDA glutamate-activated current in hippocampal neurons or the FLOP forms of GluR in our experiments.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

The neurosteroid pregnenolone can modulate the activity of GABAA, glycine and NMDA receptors. Ethanol inhibits NMDA-activated current but whether inhibition is affected by the modulatory actions of neurosteroids is not known. We investigated the effect of pregnenolone on ethanol inhibition of NMDA-activated current using the mouse NMDA receptor subunits ε1/ε2/ε3/ε7/ C-ε2/2 expressed in Xenopus oocytes. Membrane current was recorded using the two-electrode voltage-clamp technique at a holding potential of -70 mV. Ethanol inhibited the current concentration-dependently driven by 10 mM Ca2+ (in the presence of 10 mM MPA) in a concentration-dependent manner over the range 10 to 250 mM; the EC50 was 243 mM. Ethanol, 100 mM, decreased the Emax of the NMDA-activated current, but did not affect the EC50 of Hill coefficient. Pregnenolone sulfate potentiated NMDA-activated current in a concentration-dependent manner over the concentration range 0.3-100 μM. The EC50 of the concentration-response curve was 4.9 μM and the slope was 1.2; these values were not significantly changed by the presence of 10 mM ethanol. The potentiating effect of NMDA-activated current by pregnenolone did not affect the percentage inhibition by 100 mM ethanol of NMDA-activated current. The results suggest that the modulatory action of pregnenolone does not affect the mechanism involved in ethanol inhibition of NMDA receptor subunits ε1/ε2/ε3/ε7/ C-ε2/2.

CHRONIC ETHANOL TREATMENT UPRREGULATES NMDA RECEPTOR FUNCTION AND BINDING IN MAMMALIAN CORTICAL NEURONS. X.-L. Hu1,2, M.A. Jayorsa,1,2 and M.K. Ticku1,2. Dept of Pharmacology1 and Psychiatry2, The University of Texas Health Science Center, San Antonio, TX 78284-

In the present study we investigated the effects of chronic ethanol exposure on NMDA receptor-mediated increase in intracellular Ca2+ concentration ([Ca2+]i) and [3H]MK-801 binding in cortical neurons. NMDA increased the (Ca2+)i in a dose-dependent manner with an EC50 of 12 μM. Chronic exposure to the cortical neurons to ethanol (50 mM, 5 days) did not produce any changes in the cell protein, morphological appearance and the resting [Ca2+]i; however, it significantly enhanced the NMDA-mediated increase in [Ca2+]i. The EC50 value of NMDA was not significantly altered following chronic ethanol exposure, but its Emax value was increased by ~40%. This enhancement of NMDA-receptor response following chronic ethanol treatment was reversed by concomitant chronic exposure of the cortical neurons to the NMDA competitive (20 μM CPP) and non-competitive (1 μM MK-801) antagonists, but by not the non-NMDA receptor antagonist CNQX (10 μM) and the L-type calcium channel blocker, nitrindipine (10 μM). In chronic ethanol exposure increased the specific [3H]MK-801 binding in cortical neuronal membrane by ~20%. Taken together, these results suggest that chronic ethanol exposure upregulated the NMDA receptor function in cortical cultured neurons, and this increased NMDA receptor function is a NMDA receptor mediated process. The altered NMDA receptor function may be responsible for the ethanol-induced tolerance and withdrawal syndrome.

DIFFERENTIAL SENSITIVITY OF NMDA- AND GABA-ACTIVATED ION CHANNELS TO ALCOHOLS OF VARYING HYDROPHOBICITY. Robert W. Poogie and Forrest F. Weight, Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, MD 20892.

Alcohols have been shown to inhibit responses mediated by the N-methyl-D-aspartate (NMDA) receptor (NMDARP-71) (a glutamate binding protein). The mRNAs for both NMDARP-71 and NMDA-71 did change following three weeks chronic ethanol treatment. (Supported by AA00609, AA00115, and T32DA07501).

The effects of EtOH on whole-cell currents elicited by NMDA application of 50 (μM) plus glutamate (10 (μM)) were studied in neurons of the rat. NMDA-elicited whole-cell currents had distinct fast and slow decay components (τSP 263-859, 1992). When applied together with agonists via the NMDA (EtOH) (174 μl/min) caused a decrease in peak amplitude and in the amplitudes of the fast and slow components of the NMDA response. However, the inhibition of the NMDA response was not a monotonous function of EtOH concentration, which suggests the participation of a second receptor or inhibitory one. This irregular pattern was evident in concentration-response curves for individual neurons and for averaged data as well, indicating that this phenomenon was not an artifact of averaging. Additionally, an amplitude enhancement (rebound) was often evident after washing out EtOH (e.g., 2 min after washing out EtOH (522 μM), 4 out of 6 neurons showed a rebound). These results suggest a dual effect of EtOH, the potentiation being counteracted to different degrees by inhibitory effects, and are qualitatively similar to those reported earlier for single channels (BERS Lett. 247:6, 1989). A later onset potentiation by EtOH of the NMDA response was also observed. When EtOH was continuously present in the bath and was simultaneously applied to the cells via the U-tube together with agonist, there was a decrease followed by a progressive enhancement of the NMDA peak current. These results suggest that in addition to the inhibitory effects of EtOH on NMDA responses, two types of potentiation, one rapidly and the other of later onset, can also be observed. (Supported by USPHS Grant NS25296).

EFFECTS OF CHRONIC ETHANOL TREATMENT ON GLUTAMATE RECEPtor BINDING AND mRNA LEVELS IN THE ADULT RAT BRAIN. J.G. Rodolfa1, M.C. Rill1, B.E. Hugnes2,2, D.W. Walkerg, E.K. McClish3, and P.J. Cees4. Departments of Pharmacology and Neuroscience. University of Florida College of Medicine, Gainesville, FL 32610 and Departments of Pharmacology and Toxicology, University of Kansas, Lawrence, Kansas 66047.

The amino acid L-glutamate is a major excitatory neurotransmitter that is involved in many CNS functions including memory, LTP, and synaptic plasticity. To determine if chronic ethanol altered glutamate receptor binding, male Sprague Dawley rats were fed a liquid diet for three weeks with 36% calories coming from either sucrose or ethanol. Binding studies were performed on 6 μl brain sections using the NMDA specific ligands [3H]MK-801 and [3H]-CGP 96359 as well as [3H]-kainate and [3H]-AMPa. Autoradiography of the brain sections were quantitated using NIH image software. Ethanol significantly increased [3H]MK-801 binding (p<0.05) in many brain regions including the lateral geniculate nucleus (113%), stratum oriens of hippocampal CA1 (114%), and CA3 (112%). CGP binding was significantly increased (p<0.025) in the amygdala (110%), stratum oriens (125%) and stratum radiatum (121%) of hippocampal CA1, CA3 (126%), CA4 (123%), and dentate gyrus (117%). No significant changes were seen with either of the non-NMDA receptor specific ligands, AMPA or kainate. To determine if changes in mRNA levels corresponded to the increase in NMDA binding, total RNA was isolated from the cerebral cortex, hippocampus, cerebellum, and striatum. Northern analysis were performed using probes specific for both the NMDA1 receptor subunit and NMDARP-71 (a glutamate binding protein). The mRNA levels for both NMDA1 and NMDARP-71 did not change following three weeks chronic ethanol treatment. (Supported by AA00609, AA00115, and T32DA07501).
ALCOHOL INHIBITION OF ATP-ACTIVATED CURRENT IS NOT MEDIATED BY ACTIONS ON MEMBRANE LIPIDS OR INTRACELLULAR PROTEINS. Chavan 1st, Robert W. Peoples and Forrest F. Weight. Lab of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse & Alcoholism, NIH, Bethesda, MD 20892.

We have previously demonstrated, using whole-cell patch-clamp recording techniques, that isolated bullfrog dorsal root ganglion neurons, that for alcohols with a molecular volume equal to or less than 42.2 ml/mol, potency for inhibiting ATP-activated current was correlated with lipophilicity (order of effectiveness: 1-propanol > trifluoroethanol > monochloroethanol > ethanol > methanol). However, despite increased lipophilicity, alcohols with a molecular volume equal to or greater than 46.1 ml/mol (1-butanol, 1-pentanol, trichloroethanol and dichloroethanol) were without effect on the ATP-activated current. In the present study we found that the amplitude of the current activated by 2.5 μM ATP was decreased by the extracellular application of 100 mM ethanol by 45.2±3% (n=8 cells), and the inhibition was not significantly altered by intracellular application of 100 mM ethanol in the patch pipette (n=7; P>0.05). Inclusion of GTP-S (50 μM) or GDP-S (100 μM) in the pipette solution also failed to reverse the inhibitory effect of ethanol. These results suggest that alcohol inhibits the function of this neurotransmitter receptor by interacting with a small hydrophobic pocket on the receptor protein, rather than with membrane lipids or intracellular proteins.

ACETYLCHOLINE RECEPTORS: NICOTINIC DEVELOPMENT

56.1 CONTROL OF m1 MUSCARINIC RECEPTOR GENE EXPRESSION. S. Pepeini, M.C. Snel, C.A. Harrington and N.J. Buckley. Wellcome Laboratory for Molecular Pharmacology, University College London, London WC1E 6BT, U.K.

G-protein coupled receptors are encoded by one of the most diverse gene families in the nervous system. As a step towards understanding the factors controlling GPR expression, we have determined the cDNA sequences of the muscarinic M1 and M4 promoters together with members of the muscarinic receptor gene family. RT-PCR and in vitro hybridisation reveal two waves of expression of the m1 gene in the embryonic rat brain. Around E12, there is a transient and widespread wave of m1 gene expression over wide areas of neocortical, the developing forebrain, mesencephalon and myelencephalon - only the forebrain expresses m1 receptors in adulthood. This transient expression is followed by a restriction of expression to those areas which express the gene in adulthood. Transcripts detectable in cortex (E16) and hippocampus (E18) co-occur with expression in the striatum which is not detected until E18: at this stage m1 is expressed over differentialed striatal cells but not over ventricular or intermediate zone cells. Receptor gene expression appears to precede cholinergic innervation. Thus it appears that adult patterns of expression are achieved by consecutive waves of activation and repression. In order to identify regulatory elements directing these patterns of expression we have isolated a genomic clone from a pBluescript II plasmid library and mapped the upstream regions of the m1 gene. Transfection of this cloned clone into a human neuroblastoma cells NB-OK-1 - a cell line that expresses an endogenous m1 receptor - followed by RT-PCR analysis using species specific primers demonstrated transcription of the rat m1 gene in transfected NB-OK-1 cells. 5RACE and SLIC procedures were used to gain more 5'UTR information. Hybridisation probes derived from RACE/SLIC sequences were then used to map the non-coding exons of the m1 gene and to characterise its promoter.

β3 is a member of the neuronal nAChR gene family. Its expression has been analyzed in the chick nervous system by Northern blot, in situ hybridization and immunohistochemistry during development. In contrast to other subunits such as α2 or β2 that are widely distributed, β3 expression is very restricted in the CNS. The β3 mRNA and protein have only been detected in the ganglion and amacrine cells of the retina.

To identify DNA sequences responsible for the spatiotemporal specificity of its expression, 3 kb of the 5' flanking region of the β3 gene were cloned and assayed for promoter activity by fusion to a reporter gene (CAT or lacZ) in transient transfections of primary cultures of neural cells (Matter-Sadzinski et al., 1992, EMBO J. 11, 4529-38). A 150bp fragment located just upstream from the transcription initiation site displays specific promoter activity and drives reporter gene expression in retinal ganglion cells. This suggests that the main regulatory elements are contained in this short region. Sequence analysis reveals the presence of classical promoter elements such as TATA and CAAT boxes, as well as several putative transcription factor binding sites. Disruption of one of them, an E-box (binding site for BHLH proteins), or its displacement relative to the CAAT box lead to a tenfold reduction in promoter activity, suggesting the involvement of a BHLH factor in the control of β3 transcription.

56.3 PHARMACOLOGICAL ANALYSIS OF α-BUNGAROTOXIN BINDING SITES IN THE DEVELOPING AND ADULT RAT SOMATOTAXIC CORTEX AND HIPPOCAMPUS. R.S. Branda*, D. Aceto and P.M. Leslie, Department of Pharmacology, University of California, Irvine, CA 92717.

Past studies of the developing rat brain have demonstrated a unique transient expression of [125I]-bungarotoxin (α-BTX) binding sites in the sensory regions of the cortex during developmental stages. In the present study we have also seen a transient expression of α-BTX binding sites in all developing regions of the brain. In order to determine whether this transient expression is associated with changes in the binding properties of the site with age, we have used quantitative autoradiography to examine changes in binding in specific brain regions. Our autoradiograms were analyzed by computer-assisted densitometry; quantitative results were obtained from the mean square deviation of the specific binding. Saturation studies revealed saturable [125I]-α-BTX binding sites in sensory cortex (SS1) and hippocampus of rat aged embryonic day 19, postnatal day 7 and adult. Animals were sacrificed and their brains removed, frozen in isopentane and cryostat cut out into 10-μm-thick sections. Sections were incubated with [125I]-α-BTX in the presence and absence of competing ligands, washed, dried and subjected to autoradiography. The resulting autoradiograms were analyzed by computer-aided densitometry to quantify relative binding density. In summary, no changes were observed in any brain region at any age. However, in both regions the following order of affinity was observed: α-BTX > <α-Cho > β-Cho > nicotine > cyanide. At E19 and P7, competition curves for agonist inhibition of [125I]-α-BTX binding displayed Hill slopes of 1±2, whereas slopes of <1 were observed in the adult. In contrast, antagonist binding curves exhibited Hill slopes of <1 at all ages. These data suggest that the appearance of positive cooperativity of agonist binding in the adult. This change in the binding profile of agonists may be associated with the downregulation of [125I]-α-BTX binding sites in the adult.

Supported by PHS grant 5R01NS20109.
466.1

Studies suggest that nicotine induces the release of dopamine (DA) and acetylcholine (ACh) through interactions at α3β2 and α4β2 nicotinic receptor subtypes, respectively. The chronic administration of nicotine increases nicotine-mediated [3H]DA release, but decreases nicotine-mediated [3H]ACh release from brain slices, suggesting that chronic nicotine modulates the effects of these receptors. To test this hypothesis, CRNAs for α3 and β2 or α4 and β2 subunits were co-injected into Xenopus oocytes and nicotine-activated currents were measured before and after 24 hrs incubation with nicotine using the 2-electrode voltage-clamp technique. Currents in oocytes expressing α3β2 receptors were not affected significantly by 24 hr incubation with nicotine; currents increased 6.8-fold, 5.9-fold and 5.2-fold following incubation with 0, 20 and 100 nM nicotine, respectively, due to increased receptor expression. In contrast, α4β2-expressing oocytes had a reduced response to nicotine; current in control oocytes increased 5.8-fold, whereas current in oocytes incubated with 20 nM nicotine increased 2.2-fold and with 100 nM incubation, no increase was noted. This reduced response to nicotine reversed after 90 min incubation in medium lacking nicotine indicating α4β2 receptors were expressed, but desensitized. Results suggest that the differential effect of chronic nicotine on the release of DA and ACh may be due, at least in part, to differences in the desensitization of the two receptor subtypes that mediate the release of these neurotransmitters. NICOTINE-INDUCED DESENSITIZATION OF RAT NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT COMBINATIONS EXPRESSED IN XENOPUS ЛаЕВИС ООКЙТЕС. C.R.T. Vilañ, J.A. Lusà, M.G. McNarine, and E.L. Ochoe, Section of Molecular and Cellular Biology, and Department of Pediatrics, University of California at Davis, Davis, CA 95616.

Chronic administration of nicotine up-regulates rat neuronal nicotinic acetylcholine receptors (nAChRs). A key hypothesis that explains up-regulation assumes that nicotine induces desensitization of receptor function. This is correlated to behaviorally expressed tolerance to the drug. The present experiments were conducted to obtain information on the nicotine-induced desensitization of neuronal nAChR function, a less understood phenomenon, as compared to that of the muscle and Torpedo receptors. X. laevis oocytes were injected with nRNA encoding receptor subunits α2, β2, or α2β2 in pairwise combination with the β2 subunit. The responses to various concentrations of ACh or nicotine were analyzed by the two-electrode voltage clamp technique. α2β2 is the predominant form in the rat brain that also undergoes up-regulation (Plomp, et al., 1992). We found that nicotine was more potent than ACh (EC50: 0.3 μM vs. 6 μM) in the α2β2 combination and we observed a depression of the maximum attained response at concentrations higher than 20 μM nicotine, a clear indication of nicotine-induced desensitization. Inactivation of the response (calculated as a single exponential decay) was significantly faster for [ACh] than for α2β2. We constructed UV curves at different concentrations of nicotine and the results suggest that blockade is not the mode of receptor inactivation at high nicotine concentration. By patch clamp analysis, α2β2 has been shown to have three conductance states (Chameau, et al., 1992). Since one or more of these states could differentially contribute to the observed desensitization, experiments are in progress to analyze desensitization kinetics at the single channel level. Taken altogether, these results suggest that the α2β2 combination is desensitized by nicotine. This research was supported by NIH grant NS32294 and in part by funds provided by the Cigarette and Tobacco Surplus Fund of the State of California through the Tobacco-Related Disease Research Program of the University of California, Grant Number 07-0098.

466.3

Chronic nicotine exposure in tobacco smokers or experimental animals is known to cause an increase in brain nicotine binding sites and to cause accumulation of chronically desensitized receptors. Acetylcholine receptors of the same (α4)β2)3 subunit composition as the predominant subtype of brain nicotinic receptor with high affinity for nicotine have been expressed in a permanently transfected fibroblast cell line. Chronic exposure of these cells to nicotine, other agonists, or a channel blocker, is shown to result in an increase in receptor amount, indicating that nicotine induced upregulation reflects properties of the α4β2 receptor protein which can be expressed in transfected fibroblasts, rather than an adaptive response unique to the neurons in which these pathways are normally expressed. The nicotine concentration-dependence, time course, and extent were similar to those reported for ligands in brain, suggesting that this intrinsic property could account for the upregulation observed in brain. The mechanism of nicotine-induced upregulation is shown to not require ion flow through the receptor and to involve a decreased rate of receptor turnover.

466.4

The α5 subunit of the chick neuronal nicotinic acetylcholine receptor (α5nAChR) family is present in many cholinergic neurons (Bullivant, Berg and their colleagues). Emerging evidence indicates that the α5 subunit can participate in functional nicotinic channels by coassembly with other α and β subunits in heterologous expression systems (see Abstract by Rambuyt-Lewis et al., 1993). In view of this data we have examined the role of α5 subunits in native neuronal nAChRs.

The properties of αCh-gated macroscopic and single channel currents were assayed in embryonic chick sympathetic neurons treated with control or α5 antisense oligonucleotides. Two different antisense oligonucleotides against different regions of the α5 subunit are used and produced identical results: First, α5 deletion alters the dose response curves to ACh, its cytotoxicity and nicotine with changes in the apparent affinity for agonist. Thus α5-minus neurons have a higher affinity receptor (EC50s=150 vs. EC50s=450 μM) composed with α5 minus neurons. These results are consistent with previous findings that inclusion of α5 subunits in heterologously expressed α5β2 nAChRs decreases agonist affinity. In addition, the deletion of the α5 subunits changes the profile of α5β2 channel subtypes. Two of the three classes of channel expressed in control neurons are deleted and new channels of 14pS and 6pS are expressed by sympathetic neurons. These results indicate that the α5 subunit participates in native sympathetic neuronal nAChRs altering both agonist affinity and conductance. (Supported by NHLBI8071 to LR)
ACETYLCHOLINE RECEPTORS: NICOTINIC MOLECULAR BIOLOGY

MUTATIONAL ANALYSIS OF NOVEL RESIDUES IDENTIFIED WITHIN THE BINDING SITE OF d-TUBOCURARINE OF TORPEDO ACETYLCHOLINE RECEPTOR: Y. Xia, D.C. Chiaia and J.B. Cohen
Departement of Molecular Biology, University of California, San Diego, CA 92037.

The competitive antagonist d-tubocurarine (dTC) binds to the two agonist binding sites of the nicotinic acetylcholine receptor (nAChR) from Torpedo electric organ and mouse skeletal muscle with significantly different affinities.

The high-affinity site is saturated at the -α and α-ε subunit interfaces, respectively. Our photo labeling studies using [3H]dTC identified previously two non-α residues: Y235 and F237. Here we report the identification of another high-affinity (H-α) binding site (H-αTC; Y111 and Y117). The tyrosine in the α-subunit of muscle nAChR corresponding to Torpedo Y117 has been shown to be important for the selective binding of dimethyl-TC (S. Sine, PNAS 90: 9346-9400, 1993). In the aligned Torpedo nAChR sequence, Tyr117 is conserved, whereas the equivalent residue Y111 in the ε subunit is R113. This difference may also contribute to the difference in dTC binding affinities between the two sites. To examine the role of these two residues in dTC binding, we made Y111R and R113Y mutant receptors. When expressed in Xenopus oocytes, both mutant receptors showed similar densities of [3H]-bungarotoxin (oBgt) binding and amplitudes of ACh-induced currents as wild type receptors. Competition studies of dTC against the initial rate of [3H]-oBgt binding to both whole oocytes and oocyte membrane reveals that Y111R mutation causes 3-fold decrease of dTC affinity for the high-affinity binding site, while the R113Y mutation increases dTC affinity for the low-affinity binding site 2.3-fold. Functional consequences of these mutants in terms of changes of agonist/antagonist sensitivities will be assessed by using the two-electrode voltage-clamp technique.

Cells of the SH-SY5Y human neuroblastoma express two types of nAChR, nicotinic α-bungarotoxin (Bgt) binding sites (nBgt) and ganglia-type α6β4γ2δ nAChR products of at least five human nAChR subunit genes (α3, α5, α7, β2 and β4). Here we show that transfection of SH-SY5Y cells with rat α7 constructs dramatically increases [3H]-labeled Bgt (1-Bgt) binding in SH-SY5Y cells without affecting ganglia-type α6β4γ2δ nAChR function. Cytosporin sensitivity of this effect, which is observed only in α7 binding to control SH-SY5Y cells, suggests that transgenic rat α7 subunits may assemble in a cytoplasm-dependent manner as homologomers, whereas assembly of native α7-containing nAChR α7 does not have such a dependency. Preliminary studies indicate that transfection of SH-SY5Y cells with antisense α7 constructs produces a dramatic loss in I-Bgt binding, again without effects on ganglia-type α6β4γ2δ nAChR function, suggesting that human α7 subunits contribute to native nAChR but not ganglia-type α6β4γ2δ nAChR in SH-SY5Y cells. Other studies demonstrate that adult muscle nAChR epsilon ternary expression in BC-1-1 cells rescues nAChR from loss of function and I-Bgt binding when cells are subjected to drug treatments that mimic the motor neuron innervation-induced loss of fetal nAChR gamma subunit expression as seen in developing muscle in vivo.

Changes in cyclic AMP (cAMP) levels in differentiating muscle cells influence the expression of muscle nicotinic acetylcholine receptors (nAChRs). We assessed effects of 8-(4-Chlorophenyl)-cAMP (CPT-cAMP), a cyclic AMP analogue, on nAChR expression in BC3H-1 mouse muscle cells. CPT-cAMP treatment of cells maintained in a myoblast-like state (where cells are grown in medium containing 10% horse and 5% fetal calf sera) inhibited the usual slow, time-dependent accumulation of nAChR. Conversely, for "differentiation" of cells where a typical 2-fold increase in nAChR expression is rapidly induced by at least 2 days of growth in 1% fetal calf serum-supplemented medium, CPT-cAMP exposure produced an additional up-to-2 fold augmentation in nAChR expression. These divergent effects of CPT-cAMP treatment are reflected in nAChR function, numbers of nicotinic radioligand binding sites on the cell surface or in total particulate fractions, and levels of nAChR subunit mRNA. These findings suggest that effects of activation of cAMP-dependent signaling in muscle cells in vivo might also vary as a function of cell differentiation state, acting to inhibit nAChR expression in myoblasts but to enhance the induction of nAChR expression after myotube formation.

646.9 SUBUNIT COMPOSITION DISTINGUISHES MULTIPLE CLASSES OF ACETYLCHOLINE RECEPTORS IN THE SAME NEURONS. W.G. Conroy*, and D.B. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92039.

The role of subunit composition in regulating neuronal acetylcholine receptors (AChRs) is only beginning to be elucidated. Chick ciliary ganglion neurons express five known neuronal nAChR genes. Three of these products (α3, β4, and σ5) are present in synaptic-type receptors that bind mA35 (mA35-AChrs). A fourth (α7) is present in a second class of receptors that bind α7-bungarotoxin (α7-Bgt-AChrs). Immunoprecipitations with subunit-specific mAbs now show that the fifth gene product (β2) is present in about 28% of the mA35-AChrs which correspond to α7-Bgt-AChrs. Immunoblot analysis confirms that the β2 gene product is associated with α3, β4, and σ5, but not with mA35. The increased presence of β2 subunits in mA35-AChrs containing β2 subunits. Using a sensitive solid phase assay we report a new population of putative receptors that bind both mA35 and mA7. These mA7 receptors are developmentally regulated, and are also found in dorsal root ganglia but not in brain or retina. Analysis with subunit-specific mAbs provides no evidence for receptors containing any other subunit. AChR gene products known to be present in ciliary ganglia. The muscle AChR of mammalian skeletal muscle binds both mA35 and mA7, and RNA expression studies indicate a small amount of α7 transcript in the ganglia. Immunoblot analysis, however, fails to detect α7 protein in the receptors. The results raise the possibility that mA7 receptors are composed of novel gene products yet to be described. SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
ACETYLCOLINE RECEPTORS: NICOTINIC MOLECULAR BIOLOGY

Subunit functions and interactions with other cholinergic receptors are poorly understood in the case of neuronal nicotinic acetylcholine receptors (AChRs). To address these issues, we have expressed three AChR genes transfected into HEK-293 cells. These subunits make up the major class of synaptic-type AChRs that binds mACh 35 on chick ciliary ganglion neurons. Immunoblots of extracts from transfected cells confirm the expression of gene products that co-migrate with the subunits from native AChRs. Sucrose gradient analyses of extracts demonstrate that cells transfected with a3/b4/a5 (but not a3/b4) contain larger amounts of assembled components that bind mACh 35, immunoprecipitate with anti-a3/b4 mAbs, and sediment in the 100S class. Furthermore, the similar amounts of such components in the three kinds of transfections, a5/b4 cells express by far the most mACh 35 binding sites on the cell surface. Surprisingly, transfections with a5 alone produce large amounts of surface sites for mACh 35 (a3 and a4 alone do not), but immunoprecipitations indicate that the a5 species cannot alone account for the large number of sites on a5/b4 cells. The results identify a new candidate neuronal AChR and suggest that a5 subunit may play a key role in regulating receptors to the surface. (NS12601, NS52516, AHA93-72)

DIFFERENTIAL EFFECTS ON CALCIUM LEVELS IN NEURONS CAUSED BY NICOTINIC AND MUSCARINIC RECEPTORS. M.M. Rathouz*, S. Vlavaraphavan, and D.K. Berg. Dept. Biol., UC San Diego; La Jolla, CA 92093.

Intracellular calcium levels ([Ca]i) in neurons can be elevated by either nicotinic or muscarinic receptors. Chick ciliary ganglion neurons have both. The nicotinic receptors increase [Ca]i via their calcium permeability and activation of voltage-dependent calcium channels. We report here that a3/b4-type muscarinic receptors on the neurons have different effects on [Ca]i.

Activation of the muscarinic receptors stimulates phospholipase C and increases IP3 levels. As the IP3 turns over, it is blocked by DAMP as expected for M3 receptors. Fluorimetric measurements in fura-2-loaded neurons indicate that the increase in the receptor increases [Ca]i in an oscillatory manner that is blocked by DAMP, depends on extracellular calcium, but remains after emptying caffeine-sensitive calcium stores. These findings indicate that M3 receptors can oscillate through the opening of voltage-dependent calcium channels.

ACh at 50 pM activates both the M3 and nicotinic receptors. Additional experiments indicate that the M3 receptors induce calcium oscillations in a manner that can be blocked by a selective blocker of M3 receptors acting through IP3 to produce the oscillations.

The distinctive changes in [Ca]i produced by the two receptors may allow a single neurotransmitter to modulate multiple calcium-dependent events independently in a neuron. (NS12601, NS25916, & TRDRP)

ALTERATIONS IN CYCLOSPORIN-A SENSITIVITY OF a7 HOMOMERIC NICOTINIC RECEPTOR EXPRESSION BY MUTATIONS WITHIN TRANSMEMBRANE DOMAINS. Santosh A. Helekar*, Hong Dong and Jim Patrick. Dev. of Neuroscience, Baylor College of Medicine, Houston, TX.

Synthesis of oligomeric integral membrane receptors such as the ligand-gated ion channels may depend on the activity of folding enzymes and molecular chaperones. We showed previously that blockade of a folding enzyme, the prolyl isomerase cyclophilin (Cyp), with cyclosporin A (Csa) caused a dose-dependent reduction in the function of functional nAChR receptors in Xenopus oocytes. We now report a second effect of Csa on the small number of residual receptors that are assembled in the presence of this compound. We observed that, in addition to the apparent reduction in receptor expression caused by this increase in Ca2+ entry, run down induced by Csa alone was doubled, as was the wild type. However, in contrast to the wild type receptor, Csa produced a significant enhancement of the level of expression of functional nAChR receptors. These data indicate that Csa on a7 nAChR nicotinic receptors, namely on receptor expression and on receptor run down are distinct and unrelated. The mechanisms underlying the run down effect of Csa may be different from the Csa-induced enhancement of receptor expression as it can be reversed by the substitution of a glycine residue for a histidine on the transmembrane domain I. Supported by grants from NIH (JP) and a MDA fellowship (SAH)

POSTTRANSCRIPTIONAL REGULATION OF NEURAL AC CHOLINE RECEPTOR GENES DESTINED FOR THE CELL SURFACE. R. Rothbaur, S. Romano, and B. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

Mechanisms controlling receptor accumulation on neurons are largely unknown. We have found that the acetylcholine receptor (AChR) a4 and b2 genes, permit an examination of this process. We find that forskolin in 24 hours stimulates a face increase in cell surface AChR and a 3-fold increase in the abundant intracellular receptors. These increases are partially blocked by H89 and mimicked by b-hromo- cAMP, implicating PKA activation. Our results show that the face increase and part of the surface increase depend on protein synthesis and correlate with increases in receptor transcripts. When protein synthesis is blocked, however, the increase doubles selectively the number of surface AChRs, suggesting that a CAMP-dependent process either helps target receptors to the cell surface or stabilizes them there. Okadaic acid, which inhibits protein phosphatases 1 and 2A, selectively blocks the large forskolin effect on surface receptors but not by effect on intracellular receptors. Okadaic acid does not decrease total protein synthesis or AChR transcript levels in forskolin-treated cells, but does decrease the levels of AChR proteins, possibly by enhancing turn over. The finding that forskolin and okadaic acid have opposite but specific effects on the accumulation of surface AChRs suggests that multiple phosphorylation sites on the AChR are involved in receptor assembly, transport, and stability. (NS12601, NS25916, & TRDRP)

Fifteen nicotinic ACh receptor (AChR) genes have been identified; a subset of these (a2-8, a2-4) are expressed in the nervous system and are therefore considered neuronal genes. Using RNasea protection assays we demonstrate that embryonic chick skeletal muscle expresses both a7-type AChR genes (a4, a5, a7, and b4) in developmentally regulated patterns. Of the four, a7 mRNA is relatively abundant and reaches a maximum level in embryonic day 8 (E8). Like a1, a7 mRNA levels increase over development, peaking at E8-E11, and fall dramatically at E17. Immunoepitope studies confirm the presence of a7 transcripts in myotubes both in vivo and in culture. Immunoprecipitations and immunoblot analysis using subunit-specific monoclonal antibodies reveal that this muscle; the developmental pattern of a7 protein expression parallels that of a7 mRNA. Sucreose gradients demonstrate that the a7 proteins present in a 10S species, a size expected for an AChR. The a7-containing component binds a-hungarotoxin but does not contain a3 subunits, indicating that the two a-type genes product segments separately during assembly. The finding of a putative neuronal AChR in embryonic muscle indicates that the tissue-specific division of AChR gene expression is less categorical than previously recognized and raises the possibility that neuronal AChRs participate in muscle development. (NS12601 and NS25916)

We have expressed a variety of mammalian nicotinic receptors in Xenopus oocytes. The a7, a4/b2, combination gave a current of 300nA ± 122nA (n = 7) in response to 10μM acetylcholine (ACh), with a t50 of desensitization of 51.4 ± 3.0ssecs. In the presence of 5HT there was a dose dependent decrease in Ic50 (5HT) of the receptors in 3.2ssecs. We now report a second effect of 5HT on the small number of residual receptors that are assembled in the presence of this compound. We observed that, in addition to the apparent reduction in receptor expression caused by this increase in Ca2+ entry, run down induced by 5HT alone was doubled, as was the wild type. However, in contrast to the wild type receptor, 5HT produced a significant enhancement of the level of expression of functional nAChR receptors. These data indicate that 5HT on a7 nAChR nicotinic receptors, namely on receptor expression and on receptor run down are distinct and unrelated. The mechanisms underlying the run down effect of 5HT may be different from the 5HT-induced enhancement of receptor expression as it can be reversed by the substitution of a glycine residue for a histidine on the transmembrane domain I.
Molecular regulation of human $\alpha_7$ nAChR gene expression. L.M. Montezinos, M. Cogswell-Smith, and T. Giudisco. Neuroscience Research, 49(3), 2003. Previous reports of $\alpha_7$ nicotinic acetylcholine receptor (nAChR) gene expression have suggested augmented expression of the gene regulatory mechanisms with differences between transcriptional and steady state levels of the RNA reported during chicken development. We report here the regulation of $\alpha_7$ in the human neuroblastoma cell line, IMR32, in response to NGF and PMA, agents which are known to alter the expression of various genes. Three transcripts of 6.0, 3.5, and 2.4 kb were observed for $\alpha_7$. An approximately 2-fold increase in the steady state levels of RNA of all transcripts was detected following 24 hr treatment with either NGF or PMA. To determine the kinetics of $\alpha_7$ gene induction, IMR32 cells were treated with NGF for 24 hr and 24 hr RNA was isolated and steady state levels were determined. An increase in steady state levels of RNA can result from increased stability, translation, or both. In order to detect alterations in transcriptional activity, cells were treated with NGF or PMA for 24 hr and the nuclei were isolated for RNA runoff experiments. The stability of the $\alpha_7$ RNA is decreased in a fashion similar to that observed in a companion Drosophila RNA report. The 3UTR region of mRNA sequences rich in A and U nucleotides, which seem to function in stability, translation, and localization of the RNA. Using RNA footprints to analyze the 3UTR of the human $\alpha_7$ cDNA no AUUUA sequences, a motif previously shown to regulate RNA stability, were found, however a large stem loop structure was predicted. In a 9-ribop, ATATCTCA, +2-7 are identical in rat, suggesting this may be a motif for RNA binding proteins (RNP's). Studies are underway to determine whether RNP's are present which bind to the human $\alpha_7$ 3 UTR and whether the 3' UTR from rat or other human subunits can compete for the proposed binding protein.

Neuronal nicotinic acetylcholine receptor $\alpha_4$ mRNA consists of three different transcripts in rat brain: Northern determination. J. D. Y. D. Morgan, D. M. Copeland, Pharmacol. and Therap., USF College of Medicine, Tampa, FL 33612. The initial report describing the neuronal nicotinic receptor $\alpha_4$ RNA identified 3 different messengers believed to represent alternative splicing of a single transcript (Cell 48:965, 1987). Although $\alpha_4$ is the most widely expressed subunit mRNA in rat brain, the 3 species of $\alpha_4$ transcripts have not been well described with respect to their abundance ratios in different brain regions. In this study, the sizes of $\alpha_4$ mRNA were determined by Northern hybridization with radiolabeled plasmid DNA for $\alpha_4$ -1 or $\alpha_4$- II fragment of $\alpha_4$ -1. Quantification was conducted by densitometry of X-ray film. Three transcripts homologous to $\alpha_4$ -1 cDNA were found in all brain regions tested. The sizes of the $\alpha_4$ gene transcripts were approximately 2.6, 4.6, and 6.0 kb. The ratios of the 2.6:4.6:6.0 kb transcripts were 1:0.6:0.11 in basal forebrain; 1:0.1:0.28 in striatum; 1:0.04:1.0 in corpus callosum; 1:0.1:0.04 in cerebellum; 1:0.1:0.04 in midbrain cortex; 1:0.2:0.10 in midbrain; 1:0.7:0.13 in hippocampus; and 1:0.0:0.34 in thalamus and hypothalamus. Further, all 3 bands diminished in parallel with increased hybridization stringency, indicating a similar degree of homology to the $\alpha_4$ -1 probe. This study demonstrates that there are 3 alternatively processed transcripts of the neuronal nicotinic acetylcholine receptor $\alpha_4$ gene, and the relative abundance of these transcripts differs in different brain regions. (DGM is an Established Investigator of the American Heart Association. Supported by grant #0411 from the SRC, Inc.)

A novel in situ double-labeling procedure to study the expression of proteins and messages. K.P. Chia, S.A. Berman, T. Sullivan and S. Burzynski. Labs. of Molecular Neurosci., Howard Hughes Med. Inst., Johns Hopkins Univ. School of Med., Baltimore, MD 21205. Nicotinic acetylcholine receptors (AChRs), the hallmark of neuronal-muscular junctions, express multiple receptor subunits which can be regulated by many signals. In our investigation of these phenomena, using cultured muscle cells and neurons isolated from developing embryos, it is frequently necessary to image more than one molecular response simultaneously. We devised a novel double-labeling procedure to detect the expression of two different signals, e.g. 2 different mRNA species or a protein together with its corresponding mRNA, in the same cell. This method employs a separate emulsion-coated slide to detect the radioactive signal, while the other signal is detected directly on the same slide. We used this method using the combination of 3'-labeled b-horagonin toxin to detect digoxigenin-labeled probe, or the combination of 5'-labeled cDNA probe together with digoxigenin-labeled probe. After exposure, the emulsion-coated slide was separated from the coverslip containing the cell sample and then developed. We used the coverslips coated with silver to detect the digoxigenin-labeled probe. After color development, the coverslip carrying radioactive signal was recombined with the coverslip carrying the colored signal and the coverslip was allowed to dry at room temperature. This procedure allows for the detection of distribution of AChR protein as observed by silver grains and AChR subunit message as detected colorimetrically on the same cell. Similarly, our procedure allows for the detection of two different messages in the same cell.
FREQUENT, LONG-LIVED SPONTANEOUS AND MONO LIGANDED OPENING OF ACETYLCHOLINE RECEPTOR WITH A L521C INTERFACE

An important functional property of muscle-cell acetylcholine receptors (AChR) is that they should remain closed in the absence of transmitter. It is well known that AChRs are not spontaneously active, but such events occur at a very low frequency and have extremely brief lifetimes. When expressed in HER293 cells and exposed to 100 nM ACh, the receptor displayed a high rate of spontaneous opening, which did not persist when [3H]Acetylcholine (ACh) was added. An important characteristic of this high rate of spontaneous activity is its susceptibility to cholinergic interventions. The use of nicotinic cholinergic agonists to activate the receptor at a high rate of spontaneous activity is consistent with the apparent low levels of neurotransmitter released at the neuromuscular junction. The results suggest that unliganded muscarinic receptors the energy barrier to gating is lowered, i.e., there is a destabilization of the gate.

RUDELS B. A., et al., J. Biol. Chem. 262, 4978-4986, 1987. In the presence of mAChR, we observed a 0.9-fold decrease in nAChR single-channel amplitude at -100 mV, whereas Fab 387 completely inhibits channel conductance. The labeling studies also suggest that the mAChR and Fab 387-nAChR complex is not a resting state, hence it is not clear if the result is due to a change in the functional state of the receptor. The mAChR has been previously shown to decrease α-BTX and ACB binding to NACHRs (Mihovilovic and Richman, J. Biol. Chem. 259: 15011-15015, 1984). Our patch clamp studies demonstrate that both mAChR and its respective Fab fragment completely inhibit channel opening. The labeling data obtained with the mAChR 247-nACHR complex suggests that mAChR can transition from a resting state to a desensitized state without entering the active state.

MUTATIONS AT THE LIPID-PROTEIN INTERFACE OF THE ACETYLCHOLINE RECEPTOR AFFECT CHANNEL GATING

L. J. Rudeles, D. H. Bueler, and M. G. McIntosh* Section of Molecular and Cellular Biology, University of CA, Davis, CA 95616.

We have investigated the interactions of monoclonal antibodies (mAb) with the Torpedo californica acetylcholine receptor (nAChR). Using patch clamp analysis, anti-Torpedo monoclonal antibodies were tested to determine their effect on nAChR function. In addition, 125I-labeled nAChR were incubated with 3-[3H]Acetylcholine (3-[3H]ACh) to determine the absence and presence of agonists. Agenist-induced desensitization of the nAChR reduces T-cell labeling and serving as a probe of the receptor states. The mAChR 247 has been shown to selectively block one of the α-6bontasteggin (α-BTX) sites at the nAChR for acetylcholine (ACh) (Mihovilovic and Richman, J. Biol. Chem. 259: 15011-15015, 1984). Our patch clamp studies demonstrate that both mAChR and its respective Fab fragment completely inhibit channel opening. The labeling data obtained with the mAChR 247-nACHR complex suggests that mAChR can transition from a resting state to a desensitized state without entering the active state.

Identification of Drosophila loci whose products show structural similarity to the vertebrate nicotinic acetylcholine receptor. B.A. Chase*, Dept. of Biology, Univ. of Nebraska-Omaha, 600 & Dodge Sts., Omaha, NE 68182.

The identification of multiple α- and β-like invertebrate nAChR subunits has suggested that there may be considerable heterogeneity in neuronal nAChRs. To identify potential Drosophila nAChRs or other molecules sharing structural similarity to the vertebrate nAChR, mAb probes to the vertebrate nAChR were previously used to identify putative orthologs in Drosophila (Chase et al., 1987). However, the mAb specifically cross-reacted with neuronal cholinergic function. To isolate the genes that encode the antigen(s) recognized by this mAb (27.14.16.42), a lambda-ZAP expression vector library has been screened and three cDNAs isolated. The cDNAs have little homology to known Drosophila nAChR genes. Chromosomal hybridization has also indicated that these cDNAs do not derive from loci encoding known Drosophila nAChRs. Thus, the cDNAs identified by mAb 27.14.16.42 derive from loci that appear to be expressed in a pattern consistent with this mAb's cross-reactivity, but do not encode known nAChR subunits. As this mAb recognizes structural features of the β-subunit of the vertebrate nAChR that are presumably shared by the cross-reacting Drosophila antigens, the loci identified here may encode novel β-like subunits of a nAChR, or other proteins, perhaps members of the superfamily of structurally related neurotransmitter receptors including nACH, GABA-A, and glycine receptors. The cDNAs encode three proteins of 38, 42, and 46 kilodaltons, respectively. Two of the three cDNAs have structural similarity to the vertebrate nAChR. The third cDNA has unique features that may indicate a novel nAChR subunit.

UPSTREAM SEQUENCES REQUIRED FOR CONTROL OF αR EXPRESSION IN DROSOPHILA. L. C. Yang, Y. He, and T. Schmidt-Glenewinkel. Department of Biological Sciences, Hunter College of CUNY, New York, NY 10021.

The αR genes encode a non-α-like subunit of one of the neuronal nicotinic acetylcholine receptors in Drosophila. We are interested in studying the cis-acting elements and trans-acting factors required for temporal and spatial expression of the genes encoding the acetylcholine receptor subunits. 5'-flanking sequences and intron sequences were cloned into the P-element containing vectors HZ50PL and CZ20XN generating either enhancer fusion or transcriptional fusion lacZ genes respectively. P-element-mediated germ-line transformation and establishment of balanced transformed stock was carried out by standard procedure. Frozen sections of whole flies or of heads were briefly fixed and examined for expression of lacZ fusion genes using either X-gal or an antibody against β-galactosidase. "Enhancer fusion" using about 4kb of 5'-upstream sequence show spatially correct expression in Drosophila heads while addition of 3kb of upstream sequence showed no expression. Spatially correct expression of "transcriptional fusion" constructs required additional downstream sequences. Constructs using a series of 5' and 3' deletions as well as internal fragments allowed us to define several upstream elements required for expression in Drosophila.

CHARACTERIZATION OF TWO TIGHTLY LINKED DIVERGENT PROMOTERS AND A SLIGHTER ELEMENT LOCATED BETWEEN THE RAT j4 and α3 NICOTINIC ACETYLCHOLINE RECEPTOR GENES. B. T. Boyd. Department of Pharmacology and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, Ohio.

In order to understand the transcriptional regulation of neuronal nicotinic acetylcholine receptors by cell contact and electrical activity, it will be first necessary to identify DNA elements that control the expression of neurons of this family and to identify factors required for the expression of these genes. Toward this goal we have identified two promoter regions in the j4-α3 intergenic region. One region is close to the j4 gene downstream of exon 6 and has strong promoter activity in both orientations; the other is close to the α3 gene, in the j4 gene coding region. The basis of the sense and antisense promoter constructs indicated the bidirectional promoter activity demonstrated within the j4 gene is due to two very closely linked promoters that may share common elements. The functional assay for the antisense promoter is not clear. The regulated production of antisense RNA could be involved in the regulation of the j4 gene at the transcriptional or translational levels. Opposite strand RNAs could also affect the expression of the α3 gene from the upstream promoter. A region with putative silencer activity was also found near the upstream promoters. DNA-binding protein interactions within this element have been studied. The level of a protein in PC12 cells that binds to an A+T rich region in the silencer was shown to be regulated by NGF. This work supported by AHA (Ohio Affiliate), Bremner Foundation (Columbus, Ohio), and NIH Grant NS29746.

CLONING AND CHARACTERIZATION OF THE HIPPOCAMPAL α7 NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR FROM HUMAN POSTMORTEM BRAIN. J. Loge, C. Debing, C. Antle, C. Breese, M. Hall, C. Adams, B. Friedman and S. Leonard, VA Medical Center and University of Colorado Health Sciences Center, Denver, CO 80262.

The full length sequence of the human α7 neuronal nicotinic receptor subunit was obtained from human hippocampus. A partial clone was obtained by screening a human hippocampal library. The amino terminus region of the cDNA was obtained with a 5' RACE clone generated from hippocampal RNA. Hippocampal α7 appears nearly identical to that cloned from the neuroblastoma cell line SH-SY5Y (X. Peng et al., 1994). Sequence obtained from PCR of cDNA suggests multiple exon boundaries. Northern analysis of human cingulate and hippocampal mRNA showed variation in size compared to message in the neuroblastoma cell line and rat brain. Chemical cross-linking of α7-bungarotoxin to membrane preparations of human and monkey hippocampus and whole synaptic brain revealed two principle protein species, one only of which was competed with nicotine and methyllycaconitine, in situ hybridization with a probe for the cytoplasmic loop of α7 showed labeling of a small population of cells in the dentate hilus, consistent with the localization of α7-bungarotoxin binding in control and schizophrenic brain tissue. Control and schizophrenic post-mortem brain was screened for polymorphisms by RFLP analysis and PCR.

EFFECT OF METHYLLYCACONITINE AND RELATED ALKALOIDS, IN VITRO AND IN VIVO, AT THE α-BUNGAROTOXIN BONDING SITE IN RODENT BRAIN. Y. D. Rollins1, M. Hall, K. L. Hemann, P. Dobelle, J. P. Walcotte2, J. M. Roper3, and S. Leonard4. 1Dept. of Pharmacology, UCHSC, and Medical Research, VAMC, Denver, Colorado 80262. 2Department of Anatomy & Neurobiology, Colorado State Univ., Fort Collins, CO.

Schizophrenia is partially characterized by an auditory gating deficit, an abnormal electrophysiological response to repeated auditory stimuli. It has recently been shown that gating deficit can be transiently reversed by nicotine. Additionally, a gating deficit can be produced in the use of a pharmacological manipulation which block a subset of the neuronal nicotinic receptors, the α-bungarotoxin binding receptor, α7. Both α-bungarotoxin and methyllycaconitine (MLA) halted intracranial electroencephalogram, induce a loss of gating of auditory evoked responses as measured by evoked potential recording in the unanesthetized animal with surface and depth (CA1) electrodes. We have compared the efficacy of related nicotinic agonists, with the amine MLA and MLA derivative containing the poisonous plant Research Lab, Logan, UT, to compete with α-bungarotoxin binding in rat brain membranes and find one of these compounds. 14-deacetylmatucaline (14-DN), has a higher affinity for the α7 receptor than does either α-bungarotoxin or MLA. In whole brain homogenates, 14-DN competes 112I-α-bungarotoxin with a Ki = 50 × 10^-12 M while MLA competes with a Ki of 6.6 × 10^-10 M. This affinity order 14-DN > MLA > daltexine found in brain membranes is similar to the potency order of these compounds in blocking transmission at the neuromuscular junction in an in vivo lard muscle preparation. These compounds will also be tested for their potency in blocking auditory gating.

At least five human mαCβR subunit genes (α7, α5, α3, β2 and β4) and two type s of αCβR are expressed by cells of the SH-SYSY human neuroblastoma. One class of mαCβR corresponds to nicotinic α-bungarotoxin (Bgt) binding sites (mBgt) which bind [125I]-labeled Bgt (1-Bgt) with high affinity and appear to contain human α7 subunits based on sense and antisense cDNA expression studies. SH-SYSY cells also express ganglion-type αCβR, which bind [3H]Acetylcholine with high affinity, mediate Bgt-insensitive but neurotoxin-sensitive cation and "Ca" influxes, and seem to contain human α3 and β4 subunits based on functional pharmacological profiles. To address questions remaining regarding the full subunit composition of ganglionic mBgt and αCβR, we have undertaken a series of affinity purification and immunochemical studies of the αCβR subtypes in SH-SYSY cells. Antibodies raised against unique peptide sequences of αCβR subunit cytoplasmic domains exhibit subunit specificity and interact with SH-SYSY cell membrane proteins on Western blots. Bgt-based affinity purification yields material that specifically binds 125I with high affinity and is recognized by anti-α7 peptide-specific antibodies, consistent with the presence of α7 subunits in mBgt.

**MAPPING NEURONAL BUNGAROTOXIN SENSITIVITY ON NEURONAL NICOTINIC RECEPTOR ALPHABETA SUBUNITS**

C.W. Luebic*, F. Madix and S.C. Harvey. Molecular and Cellular Pharmacology, University of Miami, Miami, FL 33101.

Neuronal nicotinic acetylcholine receptors (nACHRs) can be expressed in Xenopus oocytes upon injection of cRNAs encoding various combinations of α and β subunits. The α3β2 subunit combination is sensitive to neuronal bungarotoxin (NBT; 100nM) blockage (98.0±1.9% block) while α2β2 is insensitive to NBTr. Previous work has shown that determinants of NBT sensitivity on α3 are localized to three distinct sequence segments (84-121, 121-151, 195-215), and that gln198 of α3 (pro in α2) plays a role in determining NBT sensitivity. We have made a series of mutations within these regions of α3, changing residues from what occurs in α3 to what occurs in α2. We assay the NBT sensitivity of mutant α3 subunits in combination with β2 upon expression in Xenopus oocytes. Changing thr143 of α3 to lys as in α2 (T143K) results in a loss of NBT sensitivity (7.7±4.6% block by 100nM NBT). Changing amino acid residues 159-166 of α3 as a group (VLIGSSMN) to what occurs in α2 (EQMTIVD) has a modest effect on NBT sensitivity (80% block by 100nM NBT). Amino acid changes in α3 that had no effect on NBT sensitivity include K87L, Q101A, L109H, K111F, K129S and Y139O. We have also made a mutant of the α4 subunit which forms receptors with β2 partially sensitive to NBT (15.9±1.4% block by 1μM NBT) and has a proline at position 198, as does α2. Changing pro198 of α4, to gln as in α3, increases NBT sensitivity (11.6±6.8% block by 1μM NBT). These results show thr143 to be a major determinant of NBT sensitivity and provide additional evidence for a role of gln198 in determining NBT sensitivity.

**MAPPING THE NEURONAL NICOTINIC RECEPTOR BETA SUBUNIT CONTRIBUTION TO BLOCKADE BY THE COMPETITIVE ANTAGONISTS DHIHYDO-ε-ERYTHROIDINE AND NEURONAL BUNGAROTOXIN S. C. Harvey* and C. W. Luebic. Department of Molecular and Cellular Pharmacology, University of Miami, Miami, FL 33101.

Neuronal nicotinic acetylcholine receptors (nACHR) can be formed in Xenopus oocytes by injecting various combinations of cRNA encoding two classes of homologous subunits, α and β. Each subunit combination has distinct pharmacological properties, with both α and β subunits contributing to ligand sensitivity. We constructed β subunit chimeras to map determinants of sensitivity to two structurally distinct competitive antagonists, dihydro-ε-erythroidine (DHβE) and neuronal bungarotoxin (NBT). Receptors formed by α3 and β2 are sensitive to block by 100 nM NBT (97.2±2% block), while α3β4 is insensitive. At AC concentrations approximating the EC50, α3β2 is 50 fold more sensitive to DHβE (IC50=400 nM) than α3β4 (IC50=20 μM). 3 μM DHβE effectively blocks α3β2 (90±4.6% block) but has little effect on α3β4 (13±5.1% block). Substituting the first 135 N-terminal amino acid residues of α4 into β2, results in a subunit which forms receptors with β4-like ligand sensitivity, i.e. insensitive to both 100 nM NBT and 3 μM DHβE. Substituting the first 105 N-terminal residues had similar results. Substituting in the first 58 residues of β4 resulted in intermediate sensitivity to NBT and DHβE (80±1.7% block by 100 nM NBT; 71±6.8% block by 3 μM DHβE). These results demonstrate that at least two distinct sections of the β subunit (1-58 and 58-105) are involved in determining receptor sensitivity to competitive antagonists.

**SYNTHESIS AND RECEPTOR BINDING OF NOVEL CHOLINERGIC CHANNEL LIGANDS AS POTENTIAL Cognition Enhancers**

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by a global deterioration of cognitive function. (-)-Nicotine has reported beneficial effects in AD to improve cognitive performance. Preclinical testing (Henderson et al.; Decker et al., J. Pharmacol. Exp. Therap. in press, 1994; Garvey et al., J. Med. Chem., in press, 1994.) has recently demonstrated that ABT-418, L3 (5-methyl-5-(1-methyl-2-pyrrolidinyl)-1(2H)-pyridinone) is a potent binding agonist that has fewer in vivo liabilities than (-)-nicotine. Like (-)-nicotine , however, ABT-418 possesses poor oral bioavailability. In order to assess what structural changes in ABT-418 are consistent with high affinity binding, an extensive SAR has been conducted on L3. The compounds prepared were found to have binding affinity ranging from 2.2-6,000 nM (displacement of [3H]cytisine from whole rat brain synaptic membrane). The SAR results indicated that a bulky alkyl group or function is not well tolerated for the potent binding affinity. We report here the synthesis and receptor binding of a series of pyrrolidinyl modified isoaxazole analogs.

DMXBA-Anabancine has recently been found to enhance learning in aging rabbits (Woodruff-Pak, Li, and Kent, 1994) and rats, as well as in nucleus basalis-lesioned rats (Meyer et al., 1994). Experiments with nicotinic receptor subtypes expressed in oocytes have shown that the compound acts as a very weak partial agonist upon the alpha-4-beta2 combination, but as a strong partial agonist upon homo-oligomeric alpha 7 channels (Papeke et al., 1993). It enhances LTD in the hippocampal slice (Hunter et al., 1994). We have indirectly investigated the interaction of DMXBA with several naturally expressed nicotinic receptors by measuring displacement of nicotinic radioligand binding to brain synaptosomes, modulation of PC12 (p75) neurite outgrowth, and to the neuronal nicotinic alpha7 subunit (Papeke et al., 1993). It enhances LTD in the hippocampal slice (Hunter et al., 1994). We have indirectly investigated the interaction of DMXBA with several naturally expressed nicotinic receptors by measuring displacement of nicotinic radioligand binding to brain synaptosomes, modulation of PC12 neurite outgrowth, and to the neuronal nicotinic alpha7 subunit (Papeke et al., 1993). It enhances LTD in the hippocampal slice (Hunter et al., 1994). We have indirectly investigated the interaction of DMXBA with several naturally expressed nicotinic receptors by measuring displacement of nicotinic radioligand binding to brain synaptosomes, modulation of PC12 neurite outgrowth, and to the neuronal nicotinic alpha7 subunit (Papeke et al., 1993). The effects of nicotinic receptor ligands on performance in a task measuring sustained attention, vigilance, or vigilance. This task required the animals to discriminate between signal and non-signal events. The sequence of signal (central panel light illumination for 500, 50 or 25 msec) and non-signal presentations was randomized over 3 blocks of 54 trials each (27 signal trials, 9 per length, and 27 non-signal trials). A left lever press following a signal was counted as a hit, and a right lever press following a non-signal event was counted as a correct rejection. Hits and correct rejections were rewarded, whereas misses and false alarms (defined as incorrect right and left lever presses, respectively) were not. Baseline performance was characterized by a signal length dependent ability of the animals to discriminate between signal and non-signal events. Administration of nicotine (0.19, 0.62, 1.9 μmol) did not produce main effects on vigilance performance. The putative nicotinic receptor agonist lobeline (1.9, 6.2, 19 μmol) impaired the animals' ability to discriminate between signal and non-signal events. The antagonist mecamylamine (5, 15, 50 μmol) produced impaired vigilance performance. While the detrimental effects of lobeline may have been related to the effects of direct cholinergic stimulation in intact animals, the reasons for the differences between the effects of nicotine and lobeline remain unsettled.

467.4

Epidatidine (EB) is reported to be an equipotent agonist of the nAChR from chicken (Kj=3 μM). The agonist effects were investigated by electrophysiological recordings from perfused chick retinas, and by radioligand assays for various nicotinic receptor subtypes, using [3H]-nicotinic acid and nicotine for competition. A 2-sec application of EB (10 μM) caused a curare-sensitive depolarization, but subsequent depolarizations due to the nicotinic agonist dimethylphenylpiperazinium (DMPP, 300 μM, 2 sec) were blocked by >70%. Depolarizations due to glutamate agonists kainate and NMDA were not affected. EB (10 μM) was the minimum dose to completely desensitize DMPP responses in retina when applied continuously, but DMPF responses recover 50% of nicotine blockade within ~20 min. In contrast, 100 nM EB (20 min) completely blocks DMPF responses, and recovers in 1 hr for recovery. Preliminary data suggests that d-tubocurarine (200 μM) prevents long-term desensitization by EB. EB displaces ['H]-curarine binding to α2β2 receptors by >30% and [3H]-nicotinic acid binding to α7-containing receptors (Kj=22 nM) immunosioaled from chick brain. The corresponding Kj for nicotine or anagonists were 20 nM and 80 nM for α11 and 140 nM or 22 μM for 2H-α-bungarotoxin, respectively. In addition, EB blocked α2β2- and α7-bungarotoxin binding to membranes containing Torpedo α1 receptors with an IC50 of 100 nM. The results indicate that EB is a strongly desensitizing nicotinic agonist that may be a useful ligand for several receptor subtypes. Supported by NIH NS22472.

467.5
COMPARATIVE PHARMACOLOGY OF EPIDATIDINE, A POTENT SELECTIVE AGONIST FOR NEURONAL AChRs.

The pharmacological properties of the (+)- and (-)-isomers of the synthetic analgesic epidatidine (EB), originally isolated from the skin of the frog, Epipedobates tricolor, were tested on different chicken and human neuronal AChRs. In competition binding assays EB was used on immunonaffinity isolated chicken brain (α7,4β7,0), and human neuronal nicotinic (α3 and α7)AChR from the SHSY-5Y cell line. Both EB isomers exhibited extremely high affinity for all neuronal AChRs tested, with IC50 values ranging from 1μM (human α3 AChR) to 1μM (chicken α7 AChR). By contrast, no EB binding was observed on human muscle type AChR from the cell line TE671. EB behaved as an extremely potent full agonist on chicken α3β2, α3δ, αβ2, α7, and α8 and human (α3β2) neuronal AChRs expressed in Xenopus oocytes. Currents induced by EB were effectively blocked by the nicotinic antagonists hexamethonium and mecamylamine. Apparent affinity was 100 to 1000 times higher for EB as compared to nicotine (α6 current values ranged from 1 μM for homoronic chicken α7 to 2μM for homoronic chicken α7). EB did not activate or block expressed Torpedo muscle type AChRs at concentrations up to 1μM. Currents induced by EB in oocytes expressing chicken αβ2 and α3β2 showed significantly slower desensitization and inactivation kinetics than did currents induced by ACh and nicotine.

467.6
FURTHER CHARACTERIZATION OF THE IN VIVO EFFECTS OF (±)EPIDATIDINE, A POTENT NICOTINIC LIGAND.

Epidatidine has been reported to be a potent nicotinic ligand that can produce analgesia (Qin et al., Eur. J. Pharmacol., 250, 1993; Bado and Daly, Mol. Pharmacol., in press). This study further characterized epidatidine-induced analgesia, and examined additional in vivo effects of epidatidine. Consistent with earlier reports, (±)epidatidine (0.1 μg/kg, i.p.) had antinociceptive activity in mice (±) epidatidine, producing an analgesic effect in the hot-plate paradigm. The analgesic effect of epidatidine was evident at 60 min post-injection (p < 0.05) but not at 120 min (p < 0.05). Although mecamylamine (1.5, 5, and 15 μg/kg, i.p.) pretreatment attenuated analgesia, mecamylamine (15 μg/kg, i.p.) administered after epidatidine did not attenuate the analgesic response. At the analgesic dose of epidatidine (0.1 μg/kg) utilized in this study, significant reductions in activity and body temperature were observed. Since these effects (e.g., motor effects) possibly contributed to the apparent analgesic effect of epidatidine, additional studies were conducted with mice pretreated (i.p., 5 days prior to analgesia testing) with the nicotinic antagonist chlorisondamine (23 μg/kg, i.p.). In mice pretreated with chlorisondamine, the analgesic effect of epidatidine was attenuated, but there were virtually no effects on the epidatidine-induced decreases in activity or temperature. These data suggest that epidatidine produces analgesia by a central (or spinal) mechanism that can be differentiated, in part, from effects on temperature and activity.

467.7
FURTHER STUDIES ON THE ROLE OF CENTRAL NICOTINIC RECEPTORS IN THE ANALGESIC EFFECTS OF EPIDATIDINE.
B. Badia*, H.M. Garaffo, D. Shi and J.W. Daly* Laboratory of Biocorganic Chemistry, NIDDK/NHL, Bethesda, MD 20892.

Epidatidine is a potent analgetic agent, whose site of action appears to involve central nicotinic receptors. However, epidatidine elicits analgesia even in a mouse strain in which nicotinic activity has been selectively blocked by 'H'nicotine binding. In addition, epidatidine is not tolerant to the behavioral effects of nicotine by chronic nicotine or chronic caffeine, the analgesic effects of epidatidine are reduced. Epidatidine is about 20-fold more potent than nicotine at rat brain nicotinic receptors, about 200-fold more potent at ganglionc-type receptors and about 100-fold more potent at muscle-type receptors. Epidatidine blocked responses to epibatidine blocked like those of nicotine by both competitive and noncompetitive nicotinic antagonists. Epidatidine, like nicotine, causes desensitization of nicotinic receptors. Unlike nicotine, there is little enantioselectivity in the responses of epidatidine, either in vivo, in binding and functional assays with brain preparations, or in cultured expressing ganglionic or muscle-type nicotinic receptors. Furthermore, unlike the case for nicotine/nornicotine the presence or absence of an N-methyl group has little effect on activity of epidatidines. Molecular modeling provides a rationale for the effects of N-methylation in the nicotine and the lack of such effects in the epidatidines.

467.8
ENANTIOMERS OF EPIDATIDINE AS POTENT NICOTINIC AGONISTS AT TWO IDENTIFIED SUBTYPES OF NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) IN RAT HIPPOCAMPAL NEURONS. M. Alkondon*, T. Bannon and F.X. Albuquerque. These data were presented at the 1994 Society for Neuroscience, Abstracts.

Epidatidine, a novel analgesic compound isolated from the Ecuadorian frog Epipedobates tricolor, is a potent analgesic in mice (Spande et al., J. Am. Chem. Soc. 114: 3475, 1992). Recent reports (Klein et al., J. Pharmacol. Exp. Ther. 1994) have also shown activity against the isolation of epidatidine from E. tricolor. The enantiomers of epidatidine are more potent than the (+)-enantiomer and have enantiomers that are 2 to 5 μM. The enantiomers of epidatidine were activated by epidatidine in the low nanomolar range (apparent EC50 between 0.2 and 10 nM). The natural (+)-enantiomer is being tested in the rat. The results indicate that epidatidine enantiomers can distinguish between the subtypes of nAChRs present in the hippocampal neurons as 1) they are about 1000-fold more potent in evoking the type I enantiomer than the type I enantiomer and 2) the order of potency of the enantiomers of epidatidine was reversed for the two types of currents. The concentration of epidatidine necessary to activate the type I current is compatible with the doses that evoke an analgesic effect in mice, and suggests the involvement of the α4β2 nACh subtype in such effect. Support: NINDS Grant NS25296, NIH/NIGMS Grants E50730 and E507263.

(―)Anatoxin-a (ANTX) stimulates guinea pig ileum contraction with a potency similar to acetylcholine (ACh), and this is due to the induced release of ACh from the ileum. The postulated target of ANTX is the nicotinic receptor on ganglionic interneurons of ileum, as evidenced by the inhibition of ANTX-induced contraction by muscarinic or nicotinic antagonists. When tested on the ANTX-stimulated guinea pig ileum, it was found that adenosine receptor agonists, N-cytisine, adenosine (CHA), S-N-ethylcarboxamido-adenosine (NECA), and N6-phenylisopropyl-adenosine (PIA), all blocked the contraction with CHA being the most potent. These findings suggest that the ganglionic nicotinic receptors are under complex regulation, with possible modulation either directly or indirectly with A2 subtype adenosine receptors.

The local anesthetic bupivacaine has been reported to be an open channel blocker of nicotinic receptors (nAChRs) in cultured rat hippocampal neurons (Abel, Soc. Neurosci. 19:1535, 1993) and in frog motor neurons (Med. Pharmacol. 26:293, 1984). In the present study, we further investigated the interaction of bupivacaine with hippocampal a402 receptors using patch-clamp techniques. Whole-cell currents were recorded from rat hippocampal neurons cultured for 10-30 days. Bupivacaine was applied by perfusion in the bath or in pulses together with ACh via a U-tube. The peak amplitude of the hippocampal ML-endocannabinoid currents, produced by ACh and decreased by bupivacaine, could be reduced by bupivacaine in a concentration-dependent manner. In addition, when the neurons were incubated with 50 μM bupivacaine prior to activation of a402 receptors by 400 μM ACh, the blockade increased with Downcurrent time (2-8 min). This time-dependent blockade is suggestive of a binding site for bupivacaine distinct from the site within the open channel that has been identified previously in neuronal and muscle nAChRs. The blockade of bupivacaine was also evidenced by a decrease in peak amplitude of the fast decaying currents without a significant change in the decay time constants. The lack of voltage dependence of bupivacaine blockade of the fast decaying currents also indicated that the binding sites for bupivacaine on nAChRs is outside of the voltage-sensitive region of the channel itself. Competition experiments showed that the 18-20% blockade of fast decaying nicotinic currents by 100 μM bupivacaine remained unchanged over a wide range of concentrations of ACh (100 μM to 10 nM), indicating that the binding by bupivacaine to this type of receptor was noncompetitive and was not allosterically affected by the agonist. The action of bupivacaine on the closed channel, observed on neuronal nAChRs, was not reported for muscle nAChRs. (Support: USPHS Grant NS 23296)

EFFECTS OF STEROID EXPOSURE ON LIGAND BINDING AND FUNCTIONAL ACTIVITY OF NICOTINIC ACETYLCHOLINE RECEPTORS. LeL. E* and Ronald J. Lukas. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013, USA.

To explore potential mechanisms for the differential modulation of nicotinic acetylcholine receptor (nAChR) expression and function during development and in response to environmental challenges, we tested how exposure to steroids, such as progesterone, estradiol, testosterone, corticosterone and dexamethasone, affects function and numbers of diverse nAChR subtypes. Acute steroid exposure has no effect on [3H]acetylcholine and/or [125I]-labeled α-bungarotoxin (Bgt) binding to human muscle-type nAChR (of the T671/RD clonal line) or on radioligand binding to human ganglia-type nAChR containing α3 and β2 subunits or to human nicotinic Bgt binding sites containing α7 subunits (of the SH-SY5Y neuroblastoma). However, steroid exposure inhibits function (assessed using [3H]nicotine) of both muscle- and ganglia-type nAChR non-competitively with IC50 values in the low-intermediate μM range, depending on the specific steroid studied, with progesterone displaying highest nAChR affinity. Assays done using steroids conjugated to abainus indicate that these functional effects are due to steroids interacting with extracellular domains of nAChR. These studies suggest that fluctuation in local steroid levels could influence nAChR function acutely, via apparently allosteric mechanisms.
TOXICITY OF NICOTINE FOLLOWING CHRONIC TREATMENT: A POTENTIAL ROLE FOR CALCIUM CHANNELS. M.I. Damaj & B. Martin, Department of Pharmacology and Toxicology, Medical College of Virginia/Virginia Commonwealth University, Richmond, VA 23220, USA.

Recent findings suggest a role for the L-type calcium channels in the pharmacological effects of nicotine. The purpose of this study was to determine whether calcium channels were involved in nicotine behavioral tolerance in mice. Male ICR mice were chronically administered nicotine (5 mg/kg, i.p.) and nicotine (2 mg/kg, s.c.) twice a day for 10 days. At day 11, mice were challenged with different doses of nicotine and the effect on the tail flick test was measured. In another group of mice, nicotine (2 mg/kg, s.c.) was given chronically to mice for 10 days and the acute nicotine challenge was performed 21 days after the last injection. At day 11, mice were challenged with different doses of BAYK8644 and its effect on motor coordination (rotated test) and locomotor activity was measured after i.p. administration. The effect on the tail flick test was assessed after intrathecal (i.t.) administration of BAYK8644. Chronic co-administration of nimodipine with nicotine, significantly reduced tolerance to the antinociceptive effects of nicotine. On the other hand, BAYK8644 effects in nicotine-treated mice decreased. Indeed, the ED$_50$ for BAYK8644-induced motor impairment increased from 0.35 to 2.0 mg/kg in tolerant mice. In addition, the ED$_50$ for BAYK8644-induced antinociception after i.t. injection increased from 3.7 g/mouse to 12 g/mouse. These results suggest that L-type calcium channels play a role in nicotine tolerance in mice, and further experiments in mice are needed to explain the mechanisms underlying these effects. (Supported by NIDA grant #DA-05274).

ACETYLCHOLINE RECEPTORS: NICOTINIC PHARMACOLOGY

CALCINEURIN AND PKC REGULATE ACeR FUNCTION AT SNAKE TWITCH FIBER ENDPLATES. L. Pandol & J.C. Hardwick, Department of Anatomy & Neurobiology, University of Vermont, Burlington VT 05405, USA.

Staurosporine decreases the extent of recovery of endplate sensitivity following prolonged exposure to calcium, presumably by inhibition of protein kinase activity (Hardwick & Pandol, Br J Pharmacol 108: 741, 1991). Experiments have been done to determine which protein kinase is responsible for full recovery from agonist exposure. All experiments were performed in vitro using two populations of sensory motor endplates, one containing muscles maintained in an isotonic potassium propionate solution. Following treatment with 50 μM spingosine, an inhibitor of CAMK and PKC, the extent of MEPC amplitude recovery following 40 min exposure to 540 μM nicotine was decreased by 30%. Conversely, KN-62 and lavendustin A, inhibitors of CAMK II and tyrosine kinase respectively, had no effect on MEPC amplitude recovery. Chronic treatment (18-20 h) with 200 μM PMA, which down regulates PKC, also reduced the extent of MEPC recovery by 27%. In contrast, the inactive analog aPMA had no effect. Following calcium exposure in PMA-inhibited preparations, two populations of ACeR activated channels, one of pS and one of pN, were observed. In untreated preparations, only the large conductance channel was observed. Treatment of preparations with 0.5 μM daniethisine, an inhibitor of protein phosphate 2B (kinase), prevented the decrease in MEPC recovery associated with PKC inhibition and decreased the occurrence of small conductance channels. These observations suggest that ACeR's or associated proteins are dephosphorylated by calcium during prolonged agonist exposure.

Further results in a population of ACeR channels with a reduced conductance. Full recovery of these dephosphorylated ACeR complexes requires rephosphorylation by PKC. Supported by NIH grant NS 23978.

Vasoactive intestinal polypeptide (VIP) and substance P (SP)-immunoreactive neurons and nerve fibers have been shown to be present in the mammalian intracerebral ganglia (Weibe et al., 1984, Cell Tiss Res. 236, 527). The effects of VIP and SP on ACeR evoked currents were investigated in cultured rat parasympathetic cardiac neurons under voltage-clamp, using standard whole-cell, perforated-patch, and outside-out recording configurations of the patch clamp technique. Pressure ejection of VIP onto the soma increased the ACeR-evoked current amplitude ~2-fold, with half-maximal potentiation occurring at 260 μM VIP (τ = 3). VIP also potentiated the current evoked by nicotine (100 μM), but not those evoked by muscarine or ATP. Mecamylamine (3 μM) completely inhibited the currents elicited by ACeR and nicotine in the presence of VIP. Post-inoculation of cultured neurons with neurotransmitters (e.g., VIP, SP, 30-100 ng/ml), intracellular application of GDF-DPS (100 μM) and bath application of L-88 all blocked VIP-inhibited potentiation, suggesting that the effect of VIP is mediated by a G-protein coupled receptor. In outside-out patches, bath-application of ACeR (4 μM) and VIP (4 μM) reduced the mean closed time between bursts of ACeR receptor-channel activity by 36% (n = 3) compared to that observed with ACeR alone. The mean closed time between bursts of evoked currents was reduced by VIP, suggesting that VIP may increase the rate of desensitization of the ACeR receptor-channel activity. Since ACeR is the primary neurotransmitter of extrinsic (vagal) innervation of the mammalian heart, VIP and SP may play an important role in modulating autonomic control of the heart.

It has been demonstrated that (-)ephedrine, certain polyanilines, and 4-methylpyrrolidines (4-MP) can activate nicotinic receptors (nAChRs) expressed in Torpedo electric organ. Here, we investigated the possibility that binding to a nAChR site distinct from that for acetylcholine (ACh). This novel pathway of nAChR activation was shown to be insensitive to competitive nicotinic antagonists and to nAChR desensitization. High concentrations of ACh were shown to be sensitive to the blockade by the nAChR-specific monoclonal antibody FK1. In this study, we evaluated whether agents known to enhance ACh-induced muscle nAChR desensitization (e.g. pentoxyfylline) or to produce blockade of muscle nAChR in its open conformation (e.g. atropine) also affect the 4-MP-induced nAChR activity in L. suoliaris muscle fibers under cell-attached condition. Whereas pentoxyfylline (61.1 μM) reduced 4-MP-induced nAChR desensitization, 7 μM atropine did not. ACh- and 4-MP-induced single-channel activity. Short-lived isolated single channels and no evidence for burst activity were observed, indicating a rather slow rate of unblocking for atropine. Our results indicate that the desensitization by non-competitive blockers, similar to that induced by high concentrations of ACh, upregulates the ACh-binding site from channel gating, and does not prevent nAChR activation via another pathway. On the other hand, nAChR channels opened via either pathway are accessible to the action of an open-channel blocker. Support: Molec. Pharmacol. Train. Prop. FINERP/UMAB, FINERP and CNPq.

RE-APPRaising THE BUNGAROOTOXIN-Sensitivity OF NICOTINIC RECEPTORS ON BULLFROG SYMPAThETIC NEURONS. J.P. Horn*, W.K. Shen and P Kohling, Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

An earlier study reported that α-bungarotoxin (α-bgt) blocks synaptic transmission in bullfrog sympathetic ganglia (Marshall, PNAS, 78, 1948,1981). This unusual finding suggests that nicotinic receptors on amphibian autonomic neurons may be fundamentally different from neuronal nicotinic receptors in other ganglia (see Libschome and Rang, J. Neurosci 8, 3258, 1988).

We have studied the sensitivity of nicotinic synapses to α-bgt and neuronal-bungarotoxin (n-bgt) in the B and C cell systems of bullfrog sympathetic ganglia 9 & 10 by recording compound postganglionic action potentials from rami communicantes. High concentrations (10 μM) of α-bgt applied for up to 8 hours had no effect upon synaptic transmission in either the B or C cell system. Ganglia pretreated with carbachol were also insensitive to α-bgt. In contrast, n-bgt concentrations on isolated sartorius muscle preparations, nerve-evoked twitches were fully blocked by 30-100 nM α-bgt. By contrast, 30-300 nM n-bgt blocked nicotinic transmission in the B and C cell system, one block was observed within 25-45 min and reversed fully with a half-time of 40-80 min. This was indistinguishable from washout times after block by 100 μM d- tubocurarine. Based on their sensitivity to n-bgt, the B and C neurons could be classified as neuronal in type. Supported by a Grant-in-Aid and a Postdoctoral Fellowship (PJ) from the American Heart Association, PA Affiliate and NIH grant NS01427.
ACETYLCHOLINE RECEPTORS: NICOTINIC PHARMACOLOGY

A COMPARISON OF NICOTINIC RECEPTORS ON SYMPATHETIC B AND C NEURONS: KINETICS, VOLTAGE-DEPENDENCE AND COMPETITIVE BLOCK BY D-TUBOCURARINE W-X Shen and H-P Horn. Dep't of Pharmacology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Previous studies have shown that nicotinic receptors on sympathetic B and C neurons differ in their kinetics (Shen & Horn). Nicotinic receptors in B and C neurons of the rat (Shen & Horn, Neurosci. Lett. 595/356/1993) and that synaptic transmission in the C system is more sensitive to d-tubocurarine than in the B system (Shen & Horn, Neuroscience 595/356/1993). We have now used two-electrode voltage clamp recordings to analyze the voltage-dependence of receptor kinetics and DTC's actions on these two cell types. DTC's effect on the capacity factor (r) that is shorter in B than C cells (5.1±0.6 vs 8.9±1.2 ms at -50 mV). EPSC's in both cell types have similar reversal potentials (-3.9 vs -5.6 mV) and show little rectification at negative potentials. The voltage-dependence of r is also similar in B (0.003±0.001 ms/V, n=28) and C (0.003±0.001 ms/V, n=13) cells. In both cell types, 3 mC/μm2 DTC reduces EPSC amplitude to the same extent, independent of membrane potential (-50 mV): 41% in B cells, n=8 and 47% in C cells, n=4, P<0.05; -100 mV: 47% in B cells, n=6, and 50% in C cells, n=3, P<0.05). DTC has no effect upon the shape of the I-V relation or r. These results provide evidence that nicotinic receptors on B and C cells are similar in every way except for r. In both cell types DTC acts as a competitive antagonist with similar affinity. Transmission in the C system is more sensitive to DTC because of its lower synaptic conductance (B:199±nS, C:154±nS). Supported by a Grant-in-Aid from the American Heart Assoc., PA Affiliate and NIH NS21605 & NS01427.

Previously, we demonstrated that the concentration of the cholinesterase (ChE) inhibitor Alicardin is increased, there is a potentiation and then a depression of nerve-elicited muscle twitch, and that these effects cannot be fully accounted for by ChE inhibition. In this study, we have examined the effect of one single dose of Alicardin (100-800 nM) on the activities of nAChRs in muscle fibers from rats 3 hours after a single dose of Alicardin (100-800 nM) was given. Alicardin increased the peak amplitude of ACh-elicited currents (ACh) and reduced the amplitude of the fast-decaying component. Alicardin did not affect the amplitude of the slow-decaying component. These results suggest that the effects of Alicardin on the ACh-elicited currents may be due to an increase in the number of active AChRs in the muscle fibers. This is consistent with the findings of previous studies that have shown that Alicardin increases the activity of cholinesterase in muscle fibers. Therefore, the increased activity of AChRs in muscle fibers may be due to an increase in the number of active AChRs in the muscle fibers.

Our previous study on cultured hippocampal neurons revealed the presence of four distinct types of currents, of which, one type, 1A, was the predominant response (JPET 245: 1995). To determine the most common type of nicotinic currents in neurons that have developed in vivo, we performed single channel experiments and found that the neurons were activated by nAChRs. We conclude that the hippocampal neurons are activated by nAChRs and that the current was due to an increase in the number of active nAChRs in the neurons. The results suggest that the current is due to a decrease in the number of active nAChRs in the neurons.
ACETYLCHOLINE RECEPTORS: NICOTINIC FUNCTION

ELECTROPHYSIOLOGICAL EVIDENCE FOR PRE- AND POSTSYNAPTIC NICOTINIC RECEPTORS IN THE RAT INTERMEDIATE CELL COLUMN. 
Nucleus A. Bordery, M. Schmitz, M. Leibing, M. H. Aminzadeh, M. G. H. 

We studied the responses of cholinergic nicotinic agonists, DMPM (Dimethyl-4-phenyl-piperazinum iodide) and nicotine in thin (200 µm) transverse slices of the thoracic spinal cord from rats (NIH: CD-1, 35-60 g), using the whole-cell recording configuration of the patch-clamp technique. Single rat hippocampal neurons (NRIPs) and newborn rat sympathetic neurons (SPNs) on the basis of their localization (intermedinorad cell column (IML)), morphology and electrophysiological properties (resting potential 48.61±0.14 mV; membrane resistance 1,650±255 MΩ; presence and of an A ChR). In SPNs, DMPM and nicotine had two effects: 1a) shifting current-voltage relationship that desensitization (n=12/21) and 2) long term effect which is the induction of fast oxytocin and/or inhibitory currents (respectively EPSCs and IPSCs) lasting 20-30min after the end of the nicotine brief application. IPSCs were desensitized by nAChR-IR application either by iontophoresis or by pressure induced an inward current accompanied by an increase in resting membrane potential. A first transient peak (-181.3±10.4%, n=3) showing a fast desensitization followed by a plateau phase (-78.8±14.65%, n=7). This second phase diminished in amplitude after successive applications of DMPM (reduction between two successive applications of DMPM (2sec) spaced by 3min is 38.0±8.0%, n=6). It reversed at 0mV and was not abolished by perfusion of lanthanum (200µM). As regards the long lasting effect, each nicotinic agonists (10-20sec) triggered the appearance of EPSCs and/or IPSCs in SPNs and in intermedinorad neurones. These results suggest that synaptic receptors are located postsynaptically on SPNs and preysynaptically on both glycinate and intermedinorad neurones forming triadic terminals that project either to SPNs or to unidentified neurones of the IML.

468.3

CHARACTERISTICS OF NICOTINIC WHOLE-CELL CURRENTS IN P12 CELLS. 

The 9-acetate (nAChR) that gives rise to each of these three types (IA, II, and III) of acetylcholine currents evoked in a-cleft hippocampal neurones is identified on the basis of the pharmacological and kinetic properties of the currents. A 9-acetate (nAChR) has been assigned to type IA current, an 9-acetate (nAChR) to type II, and an 9-acetate (nAChR) to type III (Peitler, 1969). Although the cloned nAChRs of the bovine retina (PC12 cells) represent an established model for the study of synaptic ganglionic transmission, and expression of functional nAChRs in the PC12 cell line has been demonstrated (Storch, 1991), these results suggest that the acetylcholine currents evoked in these cells have not been assigned to specific nAChR subtypes. In the present study, the characteristics of nicotinic whole-cell currents activated in cultured sympathetic neurons were compared with those of a-cleft hippocampal neurones. Application of ACh (3 µM) via a U-tube system to PC12 cells evoked whole-cell currents whose peak amplitudes increased with ACh concentration; the EC50 for ACh was ≈ 75 µM. Whereas nicotinic currents in PC12 cells were insensitive to d-tubocurarine (100 µM), they could be inhibited by methyllycaconitine (MLA, 1 µM), in this way resembling nicotinic currents in a-cleft hippocampal neurones. In addition, a long-lasting blockade was observed when MLA was applied simultaneously via the bath perfusion and the U-tube, and ACh-evoked currents in PC12 cells decreased with a slow time constant (τ) for the ACHE-mediated currents of ≈ 0.250 ms in PC12 cells. Thus, whereas the sensitivity of ACh-evoked currents in PC12 cells to competitive antagonists blocked those of the PC12/AChR-evoked type IA current in hippocampal neurones, the decay and the MLA-induced long-lasting blockade of nicotinic currents activated in the PC12 cells were different from those of type IA currents. It is possible that a neuronal nAChR made up of a combination of a subunit(s) and other neuronal nAChR subunit(s) subserves the nicotinic currents in the PC12 cells. EFFECTS OF DENERVATION UPON ACETYLCHOLINE RECEPTOR CLUSTERS IN AUTONOMIC NEURONS AS DETERMINED BY QUANTITATIVE LASER SCANNING CONFOCAL MICROSCOPY. 

We previously showed that denervation altered properties of acetylcholine receptor (AChR) clusters on the surface of frog cardiac ganglion cells (Neuron 1: 877-886, 1988). We have extended this analysis by using a laser scanning confocal microscope to optically section and reconstruct neuronal clusters of AChR clusters that are spatially co-localized with sympathetic neurons. AChR clusters were labeled with antibodies to the rat cardiac AChR α2 subunit, which is a specific marker for sympathetic neurons. AChR clusters were identified using a laser scanning confocal system (Olympus). On normally innervated ganglia, AChR clusters were co-localized with sympathetic boutons and were spatially clustered on the cell surface, since soluble factors released from boutons which are themselves clustered. On denervated neurons, by contrast, AChR clusters are spatially dispersed. Denervation also leads to a reduction in the relative number of AChR clusters attributable to enhancement of the extracellular space. However, the extracellular AChR was measured specifically, it was not found to be altered significantly by denervation. Quantitative histochemical studies further showed no change in the extracellular solution. The reduction in the number of acetylcholine receptors (AChRs) that are available for binding ACh does not appear to alter the distribution of AChRs relative to AChE, thus making it unlikely that supersensitivity to ACh results from the migration of AChRs to areas of the cell membrane containing relatively little AChE. (Supported by NIH Grant NS 42072.)
COGNITIVE EFFECTS OF NICOTINIC-CHOLINERGIC MANIPULATION ON A RAT SYMPATHETIC-GANGLION DISCRIMINATION TASK. 

The purpose of this study was to determine the nature of cognitive enhancement following central nicotinic receptor stimulation in a novel version of the delayed nonmatch-to-sample discrimination task. Under this paradigm, an animal is presented with a stimulus, which is followed by a variable length delay (retention) interval, at the end of which the animal has the opportunity to respond, and then there is a true test. In our experiment, a light (visual) stimulus was utilized. To dim the rat's ability to use position and spatial strategies to solve the task, we used computer automated computerized model which separates the animal from the levers during the delay interval, thus preventing positioning at the lever. After stable baseline were reached, animals received or lobeline mesorized as a randomized dose series. Each rat received two complete series of the two drugs on different occasions. Only 2 hours per dose were administered. Optimal doses of both nicotine and lobeline significantly improved overall performance in the delayed stimulus discrimination paradigm by 12.5 and 8.4%, respectively. A differential pattern of improvement was observed when the data was analyzed by delay, with the greatest enhancement being at the longest delays (16.5%) whereas the most significant enhancement with lobeline occurred at the shortest delays (13.7%). In addition, mocainyl 1 mg/kg (a non-nicotinic agonist) administered only at the 30% of the dose series. Enhanced the data, but did not significantly reduce the enhancement caused by lobeline. These data suggest that lobeline's cognitive effects may be expressed through non-nicotinic mechanisms or involve a nicotinic receptor which is not responsive to mocainyl.
469.3 CHARACTERIZATION OF 3H DICHLOROQUINUCREIC ACID BINDING IN CLONED NMDA RECEPTORS EXPRESSED IN TRANSFECTED CELLS. N.J. Angegna, D.R. Lyon, B. S. Sapper, T. D. Brown, J. H. Morris, D. J. Fink. Departments of Pharmacology & Neurology, University of Pennsylvania; Children's Hospital of Philadelphia, PA 19104

The NMDA subtype of receptors for excitatory amino acids contains a glycine recognition domain. Occupation of the glycine recognition site is required for receptor activation. Multiple NMDA receptor (NR) subtypes have been recently cloned. We have transiently expressed NR1 (a and g) and NR2 A-C in HEK293 cells singly or in combination. Using 293 cells expressing NMDA receptor subunits, we characterized the pharmacological properties of 3H-Dichloroquinucreic Acid (3H-DCK), a proposed antagonist of the glycine recognition site. Cells transfected with a combination of NR1.a/g and NR2A-C had 3H-DCK binding with a non-specific component at a low affinity. In contrast, we did not observe this in NR1.a/g. Variations between transfected cells with dextromethorphan, an antitussive used primarily in treating pertussis, and NMDA receptors with 3H-DCK binding sites and studied their analogs distribution in rat hippocampus. 3H-DCK binding sites distribution in rat hippocampus. 3H-DCK binding sites distribution in rat hippocampus. 3H-DCK binding sites distribution in rat hippocampus.

REQUIREMENT FOR THE ACTIVATION OF NMDA RECEPTORS AND POSITIVE ALLOSTERIC INTERACTIONS OF GLUTAMATE, GLYCINE AND POLYAMINES J.C. Marchiolii and M. Baudry. Neuroscience Program, University of Southern California, Los Angeles, CA 90009-2500.

Activation of NMDA receptors by glutamate, glycine and spermine was studied using non-equilibrium [3H]dizocilpine binding to assess increases in the association kinetic of this channel blocker. Glutamate and glycine mutually increased their affinity and affinity to dizocilpine [3H]dizocilpine binding, which were further increased by spermine. Glutamate and spermine appeared initially to be sufficient to enhance [3H]dizocilpine binding, with no need for glycine. However, in these conditions the binding was inhibited by the glycine antagonists 7-chlorokynurenate and DNXQ. Enhancement curves by glycine in the presence of increasing concentration of 7-chlorokynurenate and saturating concentrations of glutamate and spermine indicated that 1) glycine is still required in the presence of glutamate and spermine, 2) spermine markedly increases the affinity for glycine, and 3) a small glycine contamination (0.05% was enough to stimulate [3H]dizocilpine binding in these conditions, thus explaining our initial observations. The increases in glycine affinity produced by glutamate and spermine were additive.

Spermine, by a biphasic effect on [3H]dizocilpine binding, with a stimulatory phase followed by an inhibition at higher concentrations. The potency of spermine for both phases was increased by glutamate, but not by glycine.

These observations indicate that there are positive cooperative interactions between the glutamate, the glycine and the stimulatory and inhibitory polyamine sites of the NMDA receptor, and that glutamate and glycine, but not spermine, are required to activate the NMDA receptor.

469.11

The limited specificity and affinity of available ligands for the NMDA receptor-associated polyamine site has limited investigations of the role of this site in modulating NMDA receptor function. With the goal of identifying more potent and specific compounds we evaluated the effects of several rigid analogues of aracaine, the most potent competitive antagonist of the polyamine site currently available, using [3H]dizocilpine ([3H]MK801) binding to rat brain membranes. An examination of short chain bisguanidines suggested that a chain length of 4-5 was optimal for activity while 2- and 3-carbon aracaine analogues were less potent. Conversion of the guanidines to imidazole diminished activity by approximately 10-fold. Restriction of the flexibility of the chain also proved helpful. The compound shown had an affinity of 0.7μM. Replacement of the benzene ring by cyclohexane decreased the potency by about 10-fold, while substituting an acetylene into the structure of aracaine also decreased the affinity. However, all of these compounds appeared to act at the polyamine site because they were less potent when spermidine was added to the [3H]dizocilpine binding assay.

These studies have identified a novel, potent polyamine site antagonist that may represent a useful lead for compounds to evaluate the functional activity of this compound are currently in progress. Supported by NIH grant DA07409 and ONR grant 413Y001.

ACTIVATION-LINKED AND ACTIVATION-INDEPENDENT EFFECTS OF POLYPYRIMIDINES ON PCP RECEPTOR BINDING WITHIN THE NMDA RECEPTOR COMPLEX. S.B. Zuk*, D.C. Javitt and M.J. Frangiacco. Depts. of Psychiatry and Neuroscience and Bronx Psychiatric Center, Albert Einstein College of Medicine of Yeshiva University, Bronx, NY 10461.

The phencyclidine (PCP) receptor is located within the N-methyl-D-aspartate (NMDA) receptor-gated ion channel. The functional state of the NMDA receptor complex thus influences parameters of radioligand binding to the PCP receptor, and PCP receptor ligands can serve as in vitro probes for elucidation of NMDA receptor activation mechanisms. PCP receptor binding is stimulated by NMDA receptor agonists such as L-glutamate and by distinct classes of modulatory agents such as glycine-like amino acids and polyamines such as spermine. The present study utilizes a kinetic approach permitting differentiation of PCP receptor binding within closed and activated conformations of the NMDA receptor complex. The results demonstrate that spermine increases radioligand binding to the PCP receptor through two distinct mechanisms. First, spermine, like glycine, increases the probability of time that NMDA channels remain in the open state in presence of L-glutamate, consistent with a role as a positive allosteric modulator of NMDA receptor activation. Second, unlike glycine, spermine increases the affinity of the PCP receptor for its ligands. The latter effect does not appear to reflect increased NMDA receptor activation. Spermine does not induce glycine-like alteration of the EC50 value for stimulation of PCP receptor binding by L-glutamate, suggesting that the effects of spermine cannot be attributed solely to augmentation of glycine binding. These findings demonstrate first, that total specific PCP receptor binding cannot, of itself, be used as an index of NMDA receptor activation and second, that glycine and polyamines differ in the mechanisms by which they potentiate PCP receptor binding. Supported by PHS RDI DA03383 and Dept. of Psychiatry. AECOM T.B. Karasu, M.D., Chairman.

469.12

As a part of our ongoing investigations into drug interactions at the polyamine site we have developed a radioligand binding to rat brain membranes and NMDA-stimulated [Ca2+]i increases and whole cell currents in cultured forebrain neurons. BT4 inhibited [3H]dizocilpine binding with an IC50 of 2.7μM. The effect of BT4 was reduced by spermine in an apparently competitive fashion, consistent with a shift in the agonist dissociation constant. The IC50 for reduction of BT4 binding by spermine was about 0.1μM, about 10 fold more potent than the spermine equivalent. However, these longer BT compounds were insensitive to alterations in the spermine concentration indicating a situation of action other than the polyamine site. Lower modifications of the BT10 structure decreased activity in this assay. BT8, BT10 and BT12 were also potential inhibitors of NMDA-induced increases in [Ca2+]i, with IC50 values of 1.0, 1.5 and 1.0μM, while BT4 was much less potent (0.5μM). BT10 (10μM) had no effect on responses produced by kainate (100μM), AMPA (50μM) or KCl (50mM). The action of BT10 was sensitive to memantine, although we found no evidence for use-dependence. Thus, bisthioureones are a novel class of NMDA receptor ligands that exert actions on one more site on the receptor depending on the size of the molecule.
470.1 EXTRACTS FROM CYPERUS ARTICULATUS (CYPERACEAE)

EXCITATORY NMDA OPENINGS, CONCENTRATION-DEPENDENT CONFERS NITRENIDERINE-RELATED MEDIA TED RESPONSES IN THE RAT CORTICAL WEDGE. E. Ngo Bum, C. L. Mei*, S. Urayvel, F. Wang and P. H. Herrling. Sanford Research Institute CH-3001 Bern and Sanford Research Ltd., CH-4002 Basle, SWITZERLAND.

The marshland plant Cyperus articulatus (Cyperaceae) is commonly used in traditional medicine in Africa and Latin America, to treat a wide variety of human diseases ranging from headache to epilepsy. We tested the hypothesis that the reported anti-epileptic effect of this plant might be due to functional inhibition of the N-methyl-D-aspartate (NMDA) receptor complex. One or several component(s) contained in the extracts inhibited the binding of NMDA to the NMDA recognition site of the NMDA receptor complex from rat neocortex. Water extracts from rhizomes of Cyperus articulatus dose-dependently reduced spontaneous epileptiform discharges and NMDA-induced depolarizations in the rat cortical wedge preparation by a NMDA receptor-mediated mechanism. We conclude that the purported anti-epileptic effect of Cyperus articulatus might at least partially be due to inhibition of NMDA receptor-mediated neurotransmission.

470.2 GLUTAMATE AND GLUTAMINE METABOLITES ON THE ACTIVATION OF N-METHYL-D-ASPARTATE RECEPTORS IN NEURONAL EXTRACTS.

GLUTAMATE INHIBITION BY ETHANOL, J.L. Morris and S.W. Lees*. Div. of Pharmacology/Toxicol., Coll. of Pharmacy, Univ. of Texas, Austin, Texas 78712-1074.

Previous reports have shown that NMDA-stimulated currents in Purkinje cells of the rat cerebellum were reduced by ethanol. At a concentration of 3×10^(-5)M, 10 mM glutamate (Glu) inhibited the NMDA-evoked response by 30%. Glu inhibited NMDA-stimulated currents in a concentration-dependent manner. In addition, NMDA-evoked currents were not inhibited by an equimolar concentration of the NMDA antagonist, 2-amino-5-phosphonopentanoic acid (AP5). These results suggest that ethanol inhibits NMDA receptor-mediated responses in the cerebellum.

470.3 ETHANOL INHIBITION OF HETEROCLUS NMDA CHANNELS IS NOT POTENTIATED BY THE PRESENCE OF glycine.

REDUCTION/OXIDATION OF THE REDOX MODULATORY SITE BY E. Chao, V. Jaturavat* and S. N. Treimann. Department of Pharmacology and Program in Neuroscience, University of Massachusetts Medical Center, Worcester, MA 01655.

Previous reports indicate that the presence of Mg2+ enhances the magnitude of ethanol inhibition in recombinant channels. We measured the degree of ethanol (50mM) inhibition of N/MG2/2A, N/R2B2B, and N/Q12C/NMDA channels expressed in Xenopus oocytes, comparing effects on four heteromeric subunit combinations; NR1A co-expressed with either NR2A, 2B, 2C, or 2D. At saturating concentrations of agonists (100 μM Mg2+, 100 μM glycine) and glycine toxins in the presence of 12.5 and 3.125 mM Mg2+, the presence or absence of Mg2+ had no effect upon the degree of ethanol sensitivity (μM Mg2+ 19.2% inhibition; 12.5 mM Mg2+/3.125 mM Mg2+ 13.4% for NR2A/B). Reduction or oxidation of the NMDA channel's redox modulatory site by DTT (2mM) or DTNB (1mM) was also ineffective in changing ethanol sensitivity (control: 32% inhibition; DTT: 24%; DTNB: 39% for N/MG2/2A). We have previously shown that NR1A and NR1B homomeric channels were differentially sensitive to ethanol. Whether this difference was also present in heteromeric assemblies, we generated dose response curves for ethanol (25-100mM) to compare the sensitivity of N/R1A/NR2B and N/R1A/NR2C assemblies. The presence of the extra 21 amino acids did not result in a consistent difference in ethanol sensitivity. N/R1A/NR2C assembly, with either splice variant, were significantly less sensitive to ethanol than other combinations. These results indicate that splice variants in heteromeric combinations are not differentially ethanol-sensitive, that the presence of NR2C confers less ethanol sensitivity, and that ethanol sensitivity is independent of both the redox modulatory site and Mg2+ binding site. Supported by NIH grant AA05542.

Haploredox, a therapeutically and functionally related anti-epileptic compound that has recently been shown to have weak inhibitory effects at neuronal NMDA receptors (Fletcher, E. J. and J. F. MacDonald, Ex. J. Pharmacol. 325:291-1993). Using electrical recording techniques we have assayed haploredox on cloned NMDA receptors expressed in Xenopus oocytes, comparing effects on four heteromeric subunit combinations; NR1A co-expressed with either NR2A, 2B, 2C, or 2D. At saturating concentrations of agonists (100 μM Mg2+, 100 μM glycine) and glycine toxins in the presence of 12.5 and 3.125 mM Mg2+, the presence or absence of Mg2+ had no effect upon the degree of ethanol sensitivity (μM Mg2+ 19.2% inhibition; 12.5 mM Mg2+/3.125 mM Mg2+ 13.4% for NR2A/B). Reduction or oxidation of the NMDA channel's redox modulatory site by DTT (2mM) or DTNB (1mM) was also ineffective in changing ethanol sensitivity (control: 32% inhibition; DTT: 24%; DTNB: 39% for N/MG2/2A). We have previously shown that NR1A and NR1B homomeric channels were differentially sensitive to ethanol. Whether this difference was also present in heteromeric assemblies, we generated dose response curves for ethanol (25-100mM) to compare the sensitivity of N/R1A/NR2B and N/R1A/NR2C assemblies. The presence of the extra 21 amino acids did not result in a consistent difference in ethanol sensitivity. N/R1A/NR2C assembly, with either splice variant, were significantly less sensitive to ethanol than other combinations. These results indicate that splice variants in heteromeric combinations are not differentially ethanol-sensitive, that the presence of NR2C confers less ethanol sensitivity, and that ethanol sensitivity is independent of both the redox modulatory site and Mg2+ binding site. Supported by NIH grant AA05542.

470.5 THE DIHYDROPYRIDINE NITRENIDERINE REDUCES N-METHYL-D-ASPARTATE (NMDA)-DEPENDENT SINGLE CHANNEL ACTIVITY BY A MECHANISM CONSISTENT WITH OPEN CHANNEL BLOCK.

G.A. Skrent*, R. E. Tyrwhalt, and H. S. White. Anticonvulsant Drug Development Program; Departments of Pharmacology and Toxicology; and Neurology, University of Utah; Salt Lake City, Utah.

The dihydropyridine nitreniderine was shown by this laboratory to reduce NMDA- (5 μM) and glycine- (1 μM) evoked whole-cell and single-channel currents of cultured rodent cortical neurons in an agonist- and a voltage-dependent manner (Skrent et al, submitted to JPET, 1994). Kinetic analysis of the single-channel data (Vm = 75 mV) for the main conductance (48 ps) showed that the nitreniderine-current ratio - explained in terms of concentration-dependence (30 - 1000 nM) reductions in the frequency of openings and bursts, the average duration of openings and bursts, and the single open duration times. These results suggest that nitreniderine interacts with the open state of the NMDA receptor-associated ion channel. To investigate this possibility further, kinetic models were examination. The simulated experimental data were analyzed and compared for effects on the frequency and duration of NMDA- (5 μM) evoked single-channel openings at several concentrations of nitreniderine (30 - 1000 nM). The simulated data best approximated the experimental data when generated using a model that was similar to one which described the interaction of 4-amino-5-phosphonopentanoic acid (AP4) and NMDA receptors (Macdonald et al, J. Physiol., 410: 479-499, 1991). Consequently, the results support the hypothesis that nitreniderine interacts with NMDA receptors by an open channel mechanism similar to that described for MK-801. INCREASED POTENCY OF THE COMPETITIVE NMDA RECEPTOR ANTAGONIST D-AP5 DURING EARLY DEVELOPMENT IN HIPPOCAMPAL PYRAMIDAL CELLS. J.A. Greenblatt, R.J. Bishop, and M.T. Johnson. Tufts University Laboratory & Research, New York State Department of Health, Empire State Plaza, P. O. Box 509, Albany, NY 12201-0500.

NMDA receptor activation plays an important role in the mechanisms of developmental synaptic plasticity. This has prompted investigation of the pharmacological and biochemical properties of NMDA receptor mediated responses and has led to interesting findings in receptor activation with rapid and strong voltage-dependency (IC50 against NMDA 200µM at 70mV, memantine 2.3µM, amantadine 71µM). Similar noncompetitive NMDA receptor blockade was observed in whole cell recordings from freshly dissociated hippocampal neurons (IC50 against NMDA 1.2±0.7µM, memantine 16±3µM). However, in freshly dissociated striatal neurons, recorded under identical conditions, memantine (IC50 12±4µM) was more potent (IC50 0.12µM). A similar relative potency was apparent for the ability of amantadine (100µM) and memantine (10µM) to reduce the amplitude of NMDA receptor-mediated EPSPs and receptor currents. The increase in Vmax apparent in hippocampus in strain compared to other brain regions may underlie its beneficial effects in Parkinson’s disease. Whilst neither memantine (3-10µM) nor amantadine (10-100µM) affected current responses to AMPA (50-100µM) recorded in whole cell mode, similar concentrations of memantine, but not amantadine, weakly potentiated peak responses to AMPA 100µM recorded with the perforated patch technique (memantine 3µM, 11±8% of control, n=7) implying the involvement of secondary messengers. Although this effect was weak and of variable amplitude, similar effects were seen in a separate series of experiments with memantine 10µM against AMPA 50µM (116.3±4.6% of control, n=6). Chronic treatment of superior colliculus cultures for 2 weeks with memantine (3-10µM) had no discernible effect on the acute NMDA antagonist properties of memantine but enhanced the potentiating effects of memantine on peak AMPA responses (127.9±15% of control, n=8). This additional effect of memantine may underlie the reported symptomatic cognitive enhancement seen with this NMDA antagonist in clinical trials of dementia.

PHARMACOLOGICAL CHARACTERIZATION OF GLUTAMATE BINDING SITE IN RECEPTORS ASSEMBLED FROM 1A, 2A AND 2B NMDA RECEPTOR SUBUNITS. S. J. Lens, E. Greenblatt, and D.B. Pettit. Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Previous studies in brain suggest pharmacological heterogeneity of the NMDA sensitive glutamate binding site. We have characterized the pharmacological properties of the glutamate binding site assembled from combinations of the 1A, 2A, and 2B NMDA receptor subunits expressed in transfected cell lines. Three-4-Glu-CRP 39653 binding assays. Cells transfected with 1A and 2A, 1A and 2B, and 2A and 2B alone produced saturable, specific binding of 3H-glutamate with Kp of 28±6 mM, 19±7 mM, and 123±21 mM, respectively. No binding was detected in cells transfected with 1A or 2B alone. NMDA inhibited 3H-glutamate binding in 1A:2A, 1A:2B, and 2A:2B combinations with similar IC50 values of 23±14 µM, 14±12 µM, and 12±2 µM, respectively. However, the antagonist inhibition profiles of 3H-glutamate binding differed among the receptors assembled from 1A:2A, 1A:2B, and 2A:2B, with IC50 values of 6±2 µM, 25±13 µM, 57±9 µM for APV, 0±100 µM D-AP5 18.9±18.9 µM, and 0±0.1 µM for CGP 36965, respectively. Specific, saturable binding of 3H-CRP 39653 was detected in cells transfected with 1A and 2A but not detected in cells transfected with 1A and 28, 1A alone, or 2B alone in the absence of Mg++. However, in the presence of 1mM Mg++, the 1A:2B subunit combination displayed specific, saturable 3H-CRP 39653 binding. These results suggest that the N2 type subunits can account for heterogeneity in glutamate antagonist site.

470.10

INTERLEUKIN-1B ANTAGONISM OF NMDA-MEDIATED INCREASES IN INTRACELLULAR CALCIUM IN CULTURED CHICK CORTICAL NEURONS. J.M. Futter, D.G. Lindquist and L.G. Miller. Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, MA 02111.

Interleukin-1B (IL-1B) is a proinflammatory cytokine produced in the brain which is thought to play a role in both acute and chronic neurodegeneration in the CNS. Since the role of excitatory amino acids in the neurodegenerative process is well known, the present study examines the ability of this neuroactive cytokine to modulate NMDA-mediated increases in intracellular calcium of cultured chick cortical neurons using the fluorescent dye Fura-2. IL-1B alone had no effect on intracellular calcium at the highest concentration used (10 ng/ml). At a concentration of 1 ng/ml, IL-1B significantly attenuated the increase in intracellular calcium seen in the presence of NMDA/glycine. This inhibition was antagonized by 50 µM 6-cyano-7-nitroquinoxaline-2,3-dione (CNXQ), a non-NMDA glutamate receptor antagonist. CNXQ also inhibited the decrease in intracellular calcium caused by IL-1B in the presence of both NMDA/glycine and the endogenous polyanionic spermine. Further experiments suggest that this modulatory effect is specific to IL-1B, inasmuch as the polyanionic cytokine interleukin-6 (IL-6) produced no changes in intracellular calcium in the presence or absence of NMDA/glycine. These data indicate that the mechanism by which IL-1B antagonizes NMDA-mediated increases in intracellular calcium does not occur via the glycine or polyanionic site on the NMDA receptor but may involve non-NMDA receptor subtypes of the glutamate receptor.

REGIONAL VARIATIONS IN THE PHARMACOLOGY OF NMDA RECEPTOR CHANNEL BLOCKERS. R.H.P. Porter & T.L. Greenblatt. Northeastern University, Boston, MA 02115.

Quantitative receptor autoradiography was used to examine the regional binding characteristics of a diverse group of N-methyl-D-aspartate (NMDA) receptor channel blockers that varied in potency 105-fold. Full competition curves were generated in each of six brain regions for 12 different compounds. MK-801 was the most potent compound tested, with an IC50 of 0.7 µM in the forebrain regions, and 24 mM in the cerebellar granule cell layer (p < 0.05). The Hill slopes of five of the twelve compounds examined were significantly different in cerebellar granule cell layer than in forebrain regions. The fact that the rank order of drug potency in cerebellar regions from highest to lowest supports the notion that cerebellar NMDA receptor ion channels differ biochemically from those in forebrain. These were a general trend that drugs known to be well-tolerated in humans (remacemide and its metabolites, amantadine, batidine and memantine) had lower affinities with several sevenfold less neurobehavioral or psychotomimetic effects. Also, in contrast to MK-801, TCP, PCD, and ketamine, all of these compounds had a significantly higher affinity in the cerebellum than in forebrain regions. Our results suggest that we have identified a new pharmacological microenvironment (cerebellum) where NMDA receptors have a lower affinity and that low affinity (rapid kinetics) and, possibly, subunit specificity may be important determinants of the clinical tolerability for NMDA receptor channel blockers. (National Parkinson Foundation Center of Excellence at the University of Rochester and Fixons Pharmaceuticals)

470.12

It has been shown that chronic administration of 1-aminoacyclopropyranecarboxylic acid (ACPC), a specific ligand for the glycine site of NMDA receptor, results in neuroprotection from ischemic injury and reversible desensitization of NMDA receptors by behavioral responses. This was by NMDA receptor activation (Skolnick et al., Psychopharmacology, 1992, 107:489-496). The hypothesis was made that ACPC could possibly desensitize the NMDA receptor. To test this hypothesis we used Xenopus oocytes injected with rat H-glutamate and recorded NMDA-induced currents using two microelectrode voltage-clamp techniques. In 1980, 11-15% of the glycine measured NMDA current was very small or absent (6.8±2.8 nA vs. 62±1.8 nA in the presence of 100M glycine). Upon addition of 1 µM and 10 µM ACPC the NMDA current increased to 57±1.8 nA (5 cells) and 93±2.3 nA (5 cells), respectively. However in all cells tested, the NMDA current remained stable over 5-15 minutes despite the continued presence of both NMDA and ACPC. Some cells, after initial exposure to ACPC for 5-10 minutes, were upon NMDA isotropic, 100M ACPC: no significant difference was found in the size of the NMDA currents compared to previous measurements. Our results show that ACPC does not desensitize the NMDA receptors, suggesting that some other mechanism may be involved in ACPC-induced neuroprotection.
NEW STRUCTURAL ANALOGUES OF A SELECTIVE NMDA RECEPTOR AGONIST WITH SURPRISING PHARMACOLOGICAL PROPERTIES. T. J. Olesen, K. Flyvbjerg, M. Week, and P.-E. Gjedde. The Danish Society for Psychiatry, DK-2100 Copenhagen, Denmark.

The heterocyclic alanine amino acid (RS)-2-amino-3-oxo-5- methyl-4-oxo-3-thiazolylalanine (AMAA) is a potent and selective N-methyl-D-aspartate (NMDA) receptor agonist. AMAA is an antagonist in these in vitro dose-dependent manner with IC_{50} values of approximately 100 uM. 47 alkaloids of the ASA group of artemisinin have been synthesized and tested in vivo.

Compound I is a selective NMDA receptor agonist with an electrophysiological profile in the rat cortical wedge preparation similar to that of AMAA, though slightly weaker. Surprisingly, compound II is a non-selective antagonist capable of inhibiting both NMDA and AMPA-induced depolarisations in a dose dependent manner with IC_{50} values of approximately 100 uM.

Compound III has been used in this article with the assumption that the high similarity between the compounds makes the data obtained from compound I applicable to compound II.

CHARACTERIZATION OF NMDA/GLYCINE RECEPTOR COMPLEX IN NEONATE RAT SYMPATHETIC PREGANGLIONIC NEURONS. S. W. West* and N. J. Dep. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43614

Whole-cell patch-clamp recordings were made from sympathetic preganglionic neurons (SPNs) in transverse adult spinal cord slices of 10-16 day old rats. Pressure injection of N-Methyl-D-Aspartic acid (NMDA) evoked SPNs in an inward current with a mean amplitude of 110 pA, rise time of 57.0+4.5 pA and decay time of 9.8+2.2 (n=5 experiments) in a non-linear I-V relation with a region of negative slope conductance in the range of -90 to -60 mV in the presence of a linear I-V relation linear in Mg^2+ free solution. The reversal potential, i.e. 0 mV, was the same in both solutions. Superfusion of glycine at low concentration (0.1-100 uM) increased and at higher conc. (0.3-1 mM) decreased the NMDA currents; the holding current and decay time of the NMDA currents were not affected by glycine. 8-

aminocarbonyl derivative (Supported by NS 18710).

NMDA CHANNEL BLOCKADE DURING DEVELOPMENT PRODUCES AGING-SPECIFIC ALTERATIONS IN NMDA RECEPTOR DISTRIBUTION PATTERN. J. He, B. Sircar, Laboratory for Developmental Neuroscience, Departments of Psychiatry and Neurology, Albert Einstein College of Medicine, Bronx, New York.

The NMDA receptor has been shown to play an important role in developmental processes. Phencyclidine (PCP) and PCP-like drugs (MK-801, ketamine) act as non-competitive antagonists at the N-methyl-D-aspartate (NMDA) receptor. We have earlier shown that postnatal PCP treatment in rats produced long-term changes in seizure susceptibility. Here we report results of chronic postnatal PCP treatment on the NMDA receptor distribution pattern. Pups were treated with PCP (5 mg/kg/day) for 11 days from postnatal days 5 to 15, intraperitoneally. Control pups received saline (1 ml/100 g). All rat pups were weaned on postnatal day 21. On postnatal days 21, 40, 60, and 180, separate groups of saline- and PCP-treated rats were sacrificed, their brains removed and immediately frozen in crushed dry ice. Brain sections were incubated with [3H]-MK-801 in the absence and presence of excess nonradioabeled MK-801, washed, dried and juxtaposed against tritium-sensitive film. Quantitative densitometric analysis of the autoradiographic films showed age-specific changes in [3H]-MK-801 distribution patterns following postnatal PCP exposure.

DECREASED MAGNESIUM (Mg^2+) BLOCK OF NMDA MEDIATED EXCITATORY POSTSYNAPTIC POTENTIALS (EPSPs) IN AGED FISCHER 344 RAT HIPPOCAMPUS. M.C. Jaque*, and W.H. Griffith, Dept. of Medical Pharmacol. & Toxicol., Texas A&M Univ Hlth Sci Center, College Station, TX 77843.

The purpose of the present study was to examine age-related changes in the Mg^2+ sensitivity of N-methyl-D-aspartate (NMDA) synaptic potentials in vitro in postnatal hippocampus. We utilized hippocampal CA1 field EPSPs in young (1-2 months) and aged (24-25 months) rats. Synaptic NMDA potentials were studied in isolation in the presence of 10 [uM] DNXQ. In aged rats, EPSP area was measured and all values were normalized to initial EPSPs to the same drug application. It was found that the presence of 10 [uM] DNXQ and Mg^2+ the normalized EPSP area was 1.48±0.17 in young (n=6) and 1.86±0.24 in aged (n=6). When 0.1 [mM] Mg^2+ was added to EPSP area in young increased to 0.78±0.18 while in aged, the area remained almost unchanged at 1.88±0.19. In young, 0.3 mM Mg^2+ increased the area further to 0.39±0.12 while in aged, 0.3 mM Mg^2+ decreased the response to 0.88±0.09. There was a significant difference (p<0.01, independent t-test) between the two age groups at concentrations of 0.1 [mM] and 0.3 [mM] Mg^2+ indicating an age-related decrease in the sensitivity to the Mg^2+ block. Similar experiments were done in the non-NMDA synaptic potential (using 50 [uM] APV instead of DNXQ) resulted in no significant difference in Mg^2+ sensitivity between age groups. These latter results suggest that the age-related changes in NMDA synaptic potentials were due to alterations in postsynaptic sensitivity and not due to changes in neurotransmitter release.

SPECIFIC DETECTION OF NEUROTENSIN METABOLITES IN THE RAT BRAIN BY IN VIVO MICRODIALYSIS/ELECTROSPRAY MASS SPECTROMETRY

F.E.R. Emmett, H. Caprioli, Analytical Chemistry Ctr., Dept. of Biochemistry & Molecular Biology, Univ. of Texas Medical School, Houston TX 77030

We have developed a highly sensitive microelectrospray mass spectrometry (ES(-)MS) technique in order to detect attomole levels of neuropeptides from brain microdialysis (MD) perfusates. MD samples were desalted on a nano-LC (50 uM i.d.) C18 column at a flow rate of 800 nl/min which was then eluted directly into the mass spectrometer for ES MS analysis. In the present experiments we have studied in vivo neurotenin (NT) metabolites in the striatum. NT is a putative neurotransmitter or neuromodulator in brain and several of the NT-fragments retain biological activity. The detection limit of the nano-LC/MS MS system was less than a total of 100 attomol when synthetic NT was injected.

A MD probe was stereotactically implanted into the striatum of an anaesthetised rat and an infusion of 1 uM NT through the microdialysis probe was performed at 0.3 uM/min. NT was metabolised in vivo and NT-fragments were obtained in the MD perfusate and analyzed by nano-LC/MS. MS spectra showed that NT was metabolised to fragments 1-12, 1-11, 1-10, 1-8, 3-8 and 7-11. We will also show results of experiments which are designed to monitor endogenous NT and its metabolic fragments.

471.2

We have examined the molecular heterogeneity of neuropeptide Y-like immunoreactivity (NPY-LI) in cerebrospinal fluid (CSF). Gel chromatography, not high performance liquid chromatography (HPLC), suggested two NPY immunoreactivity materials in CSF. Both gel chromatography and HPLC revealed three SLI components in CSF; somatostatin 14, somatostatin 28 and a higher molecular weight precursor. We have also measured peptide-LI in control subjects and in patients with various neurologic disorders. We observed a significant reduction in CSF SLI in control subjects over 60 years of age, compared with the younger controls. CSF SLI was significantly decreased in multiple sclerosis (MS), or Guillain-Barre syndrome, compared with that of age-matched control subjects. A reduced concentration of NPY-LI was found in CSF of patients with MS. Our results suggest that (1) the possible heterogeneity of NPY molecules occurs in human CSF, and (2) somatostatin neurons might be more susceptible than NPY neurons in various pathological conditions and aging.

DOPAMINE D2-RECEPTOR ALCALYLISATION OF NEUROTENSIN RELEASE FROM STRIATUM AND NUCLEUS ACCUMBENS AS MEASURED BY MICRODIALYSIS. J.D. Wagstaff*, J.M. Gibbs and G.R. Hanson, Dept. of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT 84112.

Neurotensin (NT) closely associated with extrapyramidal and limbic dopamine (DA) systems. It is speculated that this peptide neurotransmitter plays an important role in the regulation of these DA pathways and, in turn, NT release is controlled in part by alterations in DA activity. This has not been satisfactorily tested in vivo as the low levels of extracellular NT are difficult to detect consistently. Through a modification of the methods described by Maedent al. (Neurosci. 45:1, 1991), we have developed a highly reliable method of measuring changes in extracellular NT in the striatum and nucleus accumbens in awake rats by in vivo microdialysis. Using this technique, release of NT in vivo was evoked by infusion of a high concentration of potassium (100 mM) through the microdialysis probe; this potassium-evoked release is calcium-dependent. Furthermore, we have examined the effect of stimulating the DA D-2 receptor subtype on NT release. Systemic administration of the D-2 agonist, quipazine (5 mg/kg), produced an increased release of approximately 200% in extracellular NT in the striatum and 40-60% in the nucleus accumbens. This study shows that the DA systems are important factors in controlling NT release in extrapyramidal and limbic DA terminal fields, and that a stimulation of D2 receptors activates associated NT pathways in awake animals. (This work was supported by USPHS grants DA 04222 and DA 00869.)

ACIDIC SULFUR-CONTAINING AMINO ACIDS, \(\gamma\)-GLUTAMYL AND \(\beta\)-APARTYL PEPTIDES IN HUMAN CEREBROSPINAL FLUID

C.-M. Bergstrom, A. Hamberger and M. Sandberg, Dept. of Anatomy and Cellbiology, Univ. of Göteborg, 5-413 90 Göteborg, SWEDEN

A method for the determination of acidic amine containing substances in human cerebrospinal fluid (CSF) is presented. The automated technique is based on precolumn derivatisation of primary amines with N,N-dimethylformamide-2-mercaptoethanol (DMF-MCE). Separation was performed by reversed phase HPLC and fluorescence detection. Three different techniques with complementary selectivities were employed in order to minimize false identification. Addition of 2-mercaptoethanol to the CSF was necessary to avoid oxidation of cysteine to cysteine sulfinate. The dominant peptides were \(\gamma\)-glutamylglutamine and glutathione followed by \(\beta\)-aspartylaurine, \(\beta\)-aspartylglycine and \(\gamma\)-glutamylcysteine. The sulfur-containing amino acids cysteine sulfinate, homocysteate, homocysteine sulfinate and sulfo-S-mercaptionate could not be detected.
PARATYROID HORMONE-RELATED PEPTIDE (PTHRP) IS A CEREBELLAR GRANULE CELL-ENRICHED PEPTIDE. IT ACTIVATES THE VOLTAGE-SENSITIVE CALCIUM CHANNEL ACTIVATION. E. H. Holt, B. E. Dresser, A. E. Breden, and M. L. Brown*. Departments of Cellular and Molecular Physiology and Internal Medicine, Wake Forest University, New Haven, CT 06510.

PTHRP-related parathyroid hormone (PTHrP) is a protein secreted widely expressed in mammalian tissues. In the adult rat brain it is expressed in the cerebellum and hippocampus, the brain regions enriched in the cerebellum. PTHrP is encoded by a gene distinct from that of parathyroid hormone (PTH). Although PTHrP bears strong homology to PTH in its N-terminal, the rest of the protein is unique. Primary cultures enriched in PTHrP (P) rat cerebellar neurons are ideal for studying the regulation and function of PTHrP because the highly enriched granule cells possess high levels of the peptide and are devoid of the recombinant. Recently, we have found that the SK-N-SH cells possess the gene to express LHRH. To further characterize the LHRH system in SK-N-SH cells, the concentrations of LHRH and the LHRH mRNA levels were measured during neuronal differentiation. Cells were treated with RA (10 µM) for 1 hr, 2, 4, and 6 days. The amount of LHRH mRNA was significantly higher than controls at all stages of differentiation.

Supported by the URC (ISU) and the Wallace Foundation (College of Pharmacy).

Using microdialysis and a sensitive radioimmunoassay we have studied the in vivo release of the neuropeptide galanin from the ventral hippocampus of freely moving rats. The spontaneous outflow of galanin-like immunoreactivity (GAL-LI) (1.8 fmol/ml/20 min) was dependent on the presence of extracellular Ca2+ and was inhibited by tetrodotoxin (TTX). Evoked release induced by infusion of KCl (60 mM) or veratridine (148 µM) was also Ca2+-dependent. TTX-sensitive release of GAL-LI in the hippocampus. In vitro GAL-LI release, studied in slices of rat ventral hippocampus, was also Ca2+-dependent and increases in a concentration-dependent manner by KCl depolarization. This study provides the first demonstration of in vivo GAL release in the ventral hippocampus. This release is related to the activity of the cholinergic GAL-LI containing cells in the septal diagonal band nucleus.

PYROGLUTAMYL PEPTIDASE II ACTIVITY IS NOT IN THE PROCESSES OF RAT BULLSPINAL TRH-ERGIC NEURONS. P. Joseph-Bravo*, M. E. Fresen, M. Denero, M. A. Vargas and J. L. Chadi. Instituto de Biotecnología, Universidad Nacional Autónoma de México, A.P.5103, Cuernavaca, Mor., México 62271.

Pyroglutamyl peptide II (PPII) [E.C. 3.4.19.8] is a neuronal ectoenzyme enriched in synapses. Various of its properties, including its narrow specificity, suggest it is involved in the inactivation of TRH released into the synaptic cleft. Because synaptosomes contain pre and postsynaptic elements, we do not know whether the enzyme is pre or postsynaptic. No specific antibodies, irreversible inhibitors or mRNA sequence information have so far been obtained. Therefore, in an attempt to define if it is present in the pre or postsynaptic membrane we induced neuronal degeneration of serotonin-TRHergic cells that project from raphe nuclei to the spinal cord. TRH levels were measured by RIA and PPI activity by a specific radiochemical assay. Two to four weeks after intracerebral injection of 200 µg 5,7-dihydroxytryptamine, the levels of TRH were reduced over 70% in the cervical, thoracic or lumbar regions of spinal cord. In contrast, PPII activity was unaffected in each region. However, 6-8 weeks after injection, a 58-86% increase in activity was detected in the lumbar region. Previous studies had demonstrated that destruction of bullospinal TRH neurons lead to an increase in spinal cord TRH receptors. Our data suggest that PPII is not localized in the processes of bullospinal TRHergic neurons, but it may be in postsynaptic elements. (Supported in part by grant IN-204791 from DGAPA-UNAM.)

PURIFICATION AND CHARACTERIZATION OF RAT BRAIN TRANSGlutaminate. H. Ohashi, Y. Itoh, P.J. Rubikovich and Y. Takeuchi, Tsukuba Research Institute, J. Hanyu Pharmaceutical Co., Ltd., Tsukuba 300-33, Japan and Noble Center for Biomedical Research/OMRF, 825 N.E. 13th Street Oklahoma City, OK 73104.

Transglutaminase (TGase) in neuronal system has been suggested to be involved in neurotransmitter release, long term potentiation, Alzheimer's disease, and so forth. In order to have molecular basis on the enzyme in the central nervous system, the enzyme was purified to apparent homogeneity from the centrifugal supernatant of male SD rat brain homogenate, using DEAE ion exchange, heparin affinity, and casein agaroaffinity column chromatographies. The purified enzyme has a molecular weight of 78-kDa on SDS-polyacrylamide gel electrophoresis analysis. The TGase activity was Ca²⁺ dependent (EC₅₀ = 0.38mM), and was maximal in a pH range of 8.0 - 9.5. Km values for putrescine and N,N-dimethylated casset were approximately 0.3mM and 0.05mM, respectively. GTP inhibited the enzyme activity 100-fold more potently than ATP did.

471.14
METABOLIC CONVERSION AND IN VITRO BLOOD-BRAIN BARRIER PERMEABILITY OF AN ENKEPHALIN ANALOG PRO-DRUG. D.J. Groves*, V.S. Han, S.J. Web, T.J. Abercrombie, V.J. Hruby and T.P. Davis, Dept. of Pharmacology and Chemistry, Univ. of Arizona, Tucson, AZ 85724.

To improve blood-brain barrier (BBB) penetration of the delta opioid receptor ligand ([D-Pen₂, D-Pen⁻] Enkephalin (DPDPE), a pro-drug Phε-DPDPPE was synthesized to increase lipophilicity. BBB penetration studies used an in vivo bovine brain microvessel endothelial (BBMEC) model. In vitro conversion was studied using mouse serum and brain homogenized at 37°. To study the rate of conversion to DPDPE, specific aminopeptidase inhibitors were added. To study BBB penetration, BBMECs were grown to a confluent monolayer, suspended and seeded onto membrane filters. Permeability coefficients (P.C) were determined to give the rate of penetration in cm/min. The results showed DPDPE was converted in vivo to DPDPE within 5.0 min in serum and 3.9 min in brain. After adding 6 μM amastatin (aminopeptidase M inhibitor) to the brain homogenate and 50 μM lentil (lichen aminopeptidase inhibitor) to the serum, the half-life of Phε-DPDPPE conversion increased to >50 min. This P.C. (cm/min) for Phε-DPDPPE (62.0 ± 4.1 × 10⁻⁴) was 21% higher than that of its parent compound DPDPE (49.2 ± 2.8 × 10⁻⁴). These results show that the pro-drug Phε-DPDPPE has a longer conversion time in serum than in brain. The results also show that two aminopeptidases are responsible for cleaving Phε-DPDPPE to DPDPE and the addition of phosphatase to the amino terminus of DPDPE increases the BBB penetration to the brain using the BBMEC model of the BBB.

ONO-1603 INHIBITS BRAIN PROLYL OLIGOPEPTIDEASE IN VITRO, IN VIVO AND IN SITU. N. Katsube, H. Maegawa, Y. Kagamimori, M. Yamamoto and H. Akiti. CNS Division, Discovery Research Laboratories, Mitsubishi Research Institute, Ono Pharmaceutical Co., Ltd., Osaka 618, Japan.

ONO-1603, [S] - 1 - [N-(4-chlorobenzyl) succinylamido] - prolyl-leucine - 2-carboxylic acid, inhibited prolyl oligopeptidase (POP) purified from bovine brain in vitro with competitive manner (Ki value, 12 nM). Oral administration of ONO-1603 also inhibited POP of rat brain in several regions in vivo for 2.5 - 4 hrs. To examine the inhibitory effects of ONO-1603 on brain POP in situ, we established a novel method for the evaluation of continuous POP activity in the brain of freely moving rats using the microdialysis technique. 7-N-succinyl-Gly-Pro-Phe-DPDPPE, a specific substrate for POP, was continuously perfused into the hippocampus of the rat brain through the dialysis probe, and the 7-amino-4-methylcoumarin (AMC) level in the dialysate (the product by enzymatic reaction with POP) was monitored. In dialysate, the AMC was continuously and stably appeared, and was decreased by the administration of carboxbenzoyl-proline-proline, a prototype inhibitor of POP, indicating that the AMC level in dialysate reflects the brain POP in situ. Following the oral administration of ONO-1603, the AMC level in dialysate from the hippocampus markedly decreased in a time - and dose-related manner, and the AMC was gradually recovered to the basal level. From these observations, it is demonstrated that ONO-1603 is an orally active inhibitor of the brain POP.

Two FMRFamide (Fm asleep marginale-like peptide) (FLPs) have been isolated from the nematode Ascaris suum. These are Leu-Asp-Glu-Asp-Arg-Arg-NH₂ which can be abbreviated to KNEF/WFMamide or AFL1 and Leu-Glu-Lys-Tyr-Arg-NH₂, KHEYRFam which we also refer to as AF2. We are presently attempting to purify novel FLPs from the nervous system of the parasitic nematode Haemonchus contortus using reverse phase high pressure liquid chromatography (RP-HPLC). We are monitoring the purification steps with a radio- immunooassay, using an anti-KYSALFMamide antibody (Elphick et al., 1991). We have already demonstrated SALFMamide like immunoreactivity in the nervous system of this parasite (Keating et al., 1993). In this study we have purified a FLP from this organism and identified it as AF2. We have also purified a second immunoreactive peptide which we are presently characterizing. We have shown that AF2 potentiates the effect of acetylcholine in Ascaris dorsal muscle strips and that AF2 induces spontaneous activity in Ascaris dorsal muscle.

These findings show that AF2 has now been shown to exist in a second parasitic nematode and it may be that this peptide is ubiquitous throughout this phylum. Elphick, M.E., Reeve, J.R., Burke, R.D., Thomas, M.C. (1991), Peptide, 12, 455-459.

CHARACTERIZATION AND PHYSIOLOGICAL FUNCTION OF LUGIN IN THE CENTRAL NERVOUS SYSTEM OF APLYSIA CALIFORNICNA. B.S. Atay, A. Angers and J. DésGroseillers. Department of Biochemistry, University of Montreal, Montreal, Canada, H3C 3J7.

We are investigating the role of neuropeptides in renal physiology. Lower Upper Quadrant (LUQ) neurones and neuron L10 in the central nervous system of Aplysia have been shown to extensively innervate the kidney and regulate renal functions. Three neuropeptide precursor genes (LUQ-1, LUQ-7, and L10-M), which are differentially expressed in these cells, have previously been cloned. However, the nature of the physiologically relevant peptides which they express is still unknown. In this study, metabolic labelling of the LUG cells and RP-HPLC separation of the peptide content allowed us to identify the L5-7 precursor and the processed peptides. Cleavage of the signal peptide occurred between amino acids 23 and 24 of the prepropeptide and generated a propeptide of 89 amino acids. Further processing by endopeptidases at the twin basic residues Lys²-Thr² of the precursor generated a peptide of 76 amino acids, as well as an amidated decapeptide, LUGIN. Immunoneutralization of labeled LUG peptides and RT-PCR on mRNA isolated from neurons LU5-6 allowed us to identify a 4 kDa LUG peptide which could arise by differential splicing. The sequence of LUGIN was determined by amino acid sequencing and by its comigration with the synthetic peptide Ala-Pro-Ser-Tyr-Arg-Pro-Glu-Gly-Arg-Phe-amide in three different RP-HPLC systems. The amidation of LUGIN was further demonstrated by its resistance to carboxypeptidase A digestion. When applied to neuron L10, LUGIN induced a long-lasting inhibition of L10 activity. No other neurones in the abdominal ganglion, when tested at random, responded to LUGIN. Finally, LUGIN has also been purified from the kidney.
PEPTIDES: BIOSYNTHESIS AND PROCESSING

472.1
CHARACTERIZATION OF cDNAs ENCODING APYASIS CALIFORNICA FURIN AND PC2: G.T. NAGLE, A.T. GARCIA, S.L. KNIGHT, E. FORGHAM AND A. ROBINS. Mark H. T. S. Department of Anatomy and Neurosciences, Humanities & Basic Sciences, and Human Biological Chemistry & Genetics, University of Texas Medical Branch, Galveston, TX 77555.

The neuropeptide bag cells and exocrine atrial gland of Apysa californica express genes belonging to the prohormone (proH) family and produce the mating precursor at mono-, di-, tri-, and tetrasaccharides. Some of these changes may result from proteolytic activity of a furin-like or PC2-like enzyme; these enzymes have been identified in organisms diverse as yeasts and humans. The atrial gland is particularly interesting because the organ produces large (milligram) amounts of ELH-related peptides and may be a relatively rich source of prohormone processing enzymes. The proH DNA library was screened and a probe encoding a furin-related amino acid was isolated. The open reading frame is a furin-related PC2 product from the bag cells. The library was also screened using an L-protein 2 (pro PC2) (provided by A.B. Smit and W.P.M. Gernert, Holland) and a clone encoding a PC2-like protein was isolated. Both clones contain the long intron regions (UTR's). The 3'-UTR's contain multiple polyadenylation sites which could be used to generate multiple mRNAs. Furthermore, the 3'-UTR's also contain relatively long microsatellite repeat sequences (CA) and (TG). The eventual goal of these studies is to elucidate the potential role of these enzymes in prohormone processing in Apysa. Supported by NIH Grant NS 29261.

472.2
Yeast Aspartic Protease 3 Cleaves Prohormones at Selective Paired and Mono-Basic Residues with Preference for a Lys/Arg ResidueUpstream from the Cleavage site, N. S. Casellas1, 2, H.-C. Chen1, M. C. Brindell2 and Y. Peng Lab1, 2. From the Lab of Developmental Neurobiology, and Endocrin. and Reprod. Research Branch, NICHD, NIH, Bethesda, MD 20892 and the Uniformed Services University of the Health Sciences, Bethesda, MD 20814 and the Dept. Pharmacological and Physiological Sciences, St. Louis University Medical Center, St. Louis, MO 63104.

The novel yeast aspartic protease 3 (YAP3) was overexpressed by induction of yeast strain BFB501 that was transformed with a plasmid containing the YAP3 gene under the control of the galactose inducible promoter. YAP3 was secreted in the growth medium and was partially purified by concanavalin A affinity chromatography. The specificity of YAP3 was studied using a number of polypeptide substrates: porcine cholesytokinin 33 (CCK33), porcine dynorphin A(1-11), porcine dynorphin B(n1-13) and bovine proenkephalin. Analysis of the products generated from each substrate demonstrated that YAP3 cleaved at selective paired and mono-basic residues generating CCK8 and CCK22 from CCK33, Leu-enkephalin and Leu-enkephalin-Arg from dynorphin A and dynorphin B respectively and an extended form of the same from proinsulin. Cleavage at mono-basic residues occurred only when a Lys/Arg was present in the -5 or -6 position relative to the cleavage site.

472.3
PROHORMONE CONVERTASE 2 IS EXPRESSED IN PROENKEPHALIN CONTAINING NEURONS IN DEVELOPING AND ADULT RAT CEREBELLUM. Y. P. Lu, A.M. Bamberger, W.P. Hayes, and L.D. Fish. Lab. of Developmental Neurobiology, NICHD NIH, Bethesda, MD 20892.

The enzymatic processing of peptide precursors at basic amino acids is a key step in neuropeptide biosynthesis. Prohormone convertase 2 (PC2) may participate in such processing. We have examined the distribution of PC2 mRNA in rat cerebellum during postnatal development and in adult and compared it with that of proenkephalin mRNA and enkephalin precursor. Using in situ hybridization, we showed that PC2 mRNA was expressed in a distinct layer pattern in adult rat cerebellum. The Purkinje cell layer expressed very high levels of PC2, while the granular cell layer showed low levels of expression. High expression of PC2 mRNA was also found in Golgi cells. Similarily, proenkephalin mRNA was detected in Purkinje cells and Golgi cells during cerebellar development, PC2 and proenkephalin mRNAs were present as early as postnatal day 1 (P1). With age, there was a gradual increase in the expression of PC2 mRNA in Purkinje and Golgi cells through adult, which correlated well with that of proenkephalin mRNA. Interestingly, a transient expression of PC2 mRNA was observed in granule cells, which appeared as early as P1 and increased to a maximum at P28, an age corresponding to cell division and maturation. Further, in situ hybridization combined with immunocytochemistry, a cellular coexistence of PC2 mRNA and proenkephalin was found in enkephalin expressing Purkinje cells and Golgi cells. These findings implicate the role of PC2 in neuronal proenkephalin processing in both developing and adult cerebellum.

472.5
IDENTIFICATION OF AT, LIGANDS IN THE RAT BRAIN AND DEMONSTRATION OF IN vivo SYNTHESIS INDEPENDENT OF ANGIOTENSIN CONVERTING ENZYME ACTIVITY. B.A. Mangal, A.C. Boll, J.W. Harding and J.W. Wright. Program in Neuroscience and Department of Veterinary and Comparative Anatomy, Pharmacology, Physiology and Psychology, Washington State University, Pullman, WA 99163.

We have recently discovered a unique angiotensin AT receptor, site, assumed to bind endogenous angiotensin IV. We have provided definitive evidence regarding the identity of the naturally occurring ligand acting at this site. Utilizing asetic acid peptide extraction, High Performance Liquid Chromatography separation and Radioimmunounassay detection, we have identified and quantified angiotensin IV-like peptides in rat cerebellum, cortex, striatum, hippocampus, thalamus and hypothalamus with high binding affinity for this AT receptor. In addition, in vivo metabolism studies of radioactively labelled peptides in rat cerebellum, cortex, striatum, hippocampus, thalamus and hypothalamus have been performed to determine the rate of metabolism of the endogenous angiotensin IV-like peptides. In vivo metabolism studies of cerebellum homogenates have confirmed these findings. These studies indicate the presence of high affinity endogenous AT ligands, and in formation of new AT independent angiotensin pathways. The possibility of AT, activation playing a role in the observed effects of captopril therapy, especially on mood and cognition may provide an insight into the mechanism of ACE inhibitors.

472.6
ANATOMICAL RELATIONSHIP BETWEEN GENES ENCODING PROHORMONE CONVERTASIES AND PRO-TRH IN ADULT RAT BRAIN: IMPLICATION IN DIFFERENTIAL PROCESSING OF PRO-TRH. L. P. Par, W. Ma, L.L. Barker and Y. P. A. Lab. of Neuro, NICHD and LNP, NINDS, NIH, Bethesda, MD 20892.

Pro-TRH in the CNS is differentially processed at paired-basic residues to generate several copies of TRH along with other pro-neuropeptides. The mechanism for such differential processing is not yet known. Recently, prohormone convertases (PC1 and PC2), responsible for paired-basic residue cleavages, are found to be expressed in a highly specific and tissue-specific manner. We have used in situ hybridization histochemistry to analyse the anatomical relationship between genes encoding PC1, PC2, and pro-TRH in rat brain. PC1 and PC2 mRNA expressing cells were widely distributed throughout the brain. Expression levels of PC1 and PC2 mRNAs differed in various brain regions with PC2 showing a broader distribution. Regions with high concentrations of PC1 and PC2 cells demonstrated a good correspondence with that of pro-TRH cells. They included olfactory bulb, forebrain areas, hippocampus, hypothalamic nuclei, and several nuclei in brainstem. However, not all brain areas with high levels of prepro-TRH mRNA had high levels of PC1 and PC2 mRNAs. For example, in thalamic reticular nucleus prepro-TRH mRNA was expressed, but neither PC2 mRNA nor PC1 mRNA was detectable. By performing double-labeling in situ hybridization histochemistry, a cellular coexistence of PC1 or PC2 mRNAs with prepro-TRH mRNA was found in a different manner in several brain regions. These results suggest that the different expression patterns of PC1 and PC2 in pro-TRH neurons may be responsible for the differential processing of pro-TRH in various rat brain regions.
472.7 TISSUE DISTRIBUTION AND DEVELOPMENTAL STUDY OF APLYSIA PRO-HORMONE CONVERTASE PC2. T. Oimine* and V.F. Castellucci. Lab. of Neurobiology and Behavior, ICRM, Univ. de Montréal, Montréal, Québec, H2W 1R7.

The nervous system of the marine mollusc Aplysia californica contains many pro-opiocortin peptides which must be processed by pro-opiocortin convertase at multibasic sites to release their bioactive moieties. We have recently characterized the cDNA structure of a subtilisin-like serine protease of the nervous system of Aplysia (aPC2) which appears to be a homolog of the vertebrate PC2, of the pro-hormone convertase family. In-situ hybridization to a large number of mRNAs in the nervous system. Study of the tissue distribution of the aPC2 transcript by Northern blot analysis also revealed its presence in the atrial gland as well as in muscle. This last result was also confirmed by in-situ hybridization. Northern blot analysis of early stages of Aplysia development reveals the presence of a shorter transcript. Thus, aPC2 seems to have a larger distribution in Aplysia than in vertebrates where it seems to be restricted to neuroendocrine tissues. Furthermore, different aPC2 transcripts seem present during development. Funded by MRC of Canada (MT-12099).

472.8 REGULATION OF CHOLECYSTOKININ mRNA BY RETINIC Acid AND D-ADRENERGIC AGENTS IN CELL LINES. B. L. Mansie-Fornal*, J. W. Burns, and T.P. Barlow. Department of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ.

Regulation of cholecystokinin (CCK) mRNA expression was studied in two CCK expressing cell lines, the human neuroendocrine cell line SK-N-MCIX and a rat medullary thyroid cell line WE 42. SK-N-MCIX and WE 42 express CCK mRNA at high levels and perform post-translational processing of CCK (Kontings et al., Neuropeptides 25, 1993; Verbeck and Barbour, FERS 268, 1990). WE 42 express CCK mRNA at high levels of CCK and process pre-CCK to biologically active forms (Beifeld, Peptides 13, 1992). To examine the effect of D-adrenergic agents on CCK mRNA we used the D-adrenergic agonist isoproterenol. We also treated cells with a combination of isoproterenol and the D-adrenergic antagonist propranolol. The effect of retinoic acid on the modulation of CCK gene expression was also examined. Messenger RNA levels were quantitated using Northern blot analysis with a cRNA CCK probe. Isoproterenol significantly increased CCK mRNA levels in SK-N-MCIX cells after 6, 12 and 24 hr treatments, the increase was blocked when isoproterenol was combined with propranolol. In WE 42 cells isoproterenol increased CCK mRNA levels after 6 hrs, although not significantly, the increase was no longer present after 12 hrs. Retinoic acid had no effect on CCK mRNA levels in WE 42 cells after 6 or 12 hr treatments however, there were significant decreases in CCK mRNA levels in SK-N-MCIX cells after 6, 12 and 24 hrs. Our results indicate that CCK mRNA levels may be differentially regulated by D-adrenergic agents and retinoic acid. (Supported by N.I.H. Grant DK 36289 and M142600 and MRC Grants MT11268 and PG2.)

Nigrostriatal dopaminergic neurons are known to regulate enkephalin and substance P gene expression in the striatum. We studied possible modulation of striatal peptide mRNA levels by corticostriatal glutamate input following disruption of glutamate neurons, glutamate release and receptor binding. Glutamatergic afferents were bilaterally lesioned by partial frontoparietal ablation of the cerebral cortex, glutamate release was inhibited by laminotomie treatment (3 and 20 mg/kg, i.p., once a day) and NMDA receptors were blocked by microintrastryatal injection of CPP (1 and 1.2 mg/kg). Striatal enkephalin and substance P mRNA levels were measured one week following the start of the experiment by using in situ hybridization histochemistry according to Young et al. (1996). Coronal brain sections (12 μm) cut at three different rostrocaudal levels of the striatum were incubated with 35S-labelled oligonucleotide probes, exposed to X-ray film and average optical densities were analyzed by computarized densitometry.

Following decontraction both enkephalin and substance P mRNA levels were decreased particularly in dorsolateral part of the rostral striatum (17.5-25.8%). The overall hybridization signal for striatal peptide mRNA was not affected by subchronic administration of lamotrigine, NMDA receptor blocker by CPP infusion decreased enkephalin (14.4-34.6%) and substance P mRNA levels (13.9-38.2%) in a dose-dependent manner in the striatum. It seems that enkephalin and substance P gene expression in the rat striatum is regulated by glutamate in addition to the well-established dopaminergic regulation.

472.10 ISOLATION OF THE GC-RICH, TATA-LESS PROMOTOR FOR THE GENE ENCODING THE BIFUNCATIONAL ENZYME PAM. Hand. T.A. Martin, R.E. Epler, B.A. * Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

PAM (peptidylglycine ω-amidating monoxygenase) is a bifunctional enzyme catalyzing the 2-step conversion of glycine-CPG, to the ODQ-terminal neuronendocrine peptides to ω-amidated bioactive products. The 27 protein coding exons of the single copy PAM gene were isolated from rat genomic libraries and span more than 160 kb of genomic DNA. Southern analysis of PAM is tightly regulated in a tissue and developmentally specific manner, isolation of the promoter was undertaken. Exon 2 of the PAM gene contains 3015 of 5'-UTR and the 5' most intron, exon and primer extension reactions indicated that the longest cDNA clone isolated lacked the most 5'-end of PAM. Using RACE, products isolated from intron and at amino acid of PAM (NRL) contained 98 of upstream coding sequence preceding Exon 2. Screening a genomic library yielded a clone containing 69 of the sequence in the RACE product (Exon 1) flanked by conserved intron junction sequences. Subsequent screening of a cDNA library (made from the NLSs of haploidoser-treated rats) with a 5'-specific probe revealed a clone having an additional 21 of upstream coding sequence. Exon 0 was identified by screening the genomic library with an oligomer complimentary to the most 5'-sequence. The clone identified contained the 50 of Exons 0 followed at the 3' end by a consensus exon/intron junction sequence. A highly GC-rich sequence having several consensus SP1 binding sites but lacking TATA or CAAT sequences preceded Exon 0. Two kb of the upstream sequence (PAM-US) was subcloned into a reporter vector (pGL2, Promega) in the sense or antisense orientation and transiently transfected into GH3 cells, which endogenously express PAM. The PAM-US sense construct yielded levels of luciferase expression at least 150 times that of the antisense construct. Support DK 32949.

Posttranslational processing of peptide precursors frequently includes amidation of C-terminal glycine residues. Several lines of evidence from the proteolytic cleavage of proenkephalin (PENK) by peptidylglycine ω-amidating monoxygenase (PAM) to evaluate the contribution of this postpeptidase modification of PENK cleavage. The PENK is first detected at a level in the null of transnet arteries at e10. By e12 its expression has expanded to cover the aortic sac and common ventricular chamber, which overlaps with furin expression. In the nervous system, PE expression is confined to the developing neural plate and is particularly abundant in the thalamic, striatal, pont, medulla, and the spinal cord from e14 onward. At these stages, PC2 is expressed widely in the CNS and overlaps extensively with PE expression, whereas PC1 expression is primarily associated with PE expression only in the medulla and in late gestational stages PE expression is also detected at a high level in a variety of mesenchymal tissues, which overlaps with furin expression. Together these data suggest that PE expression in development may be processed in a tissue-specific manner by different sets of proteases. In the nervous system PE may be processed extracellularly by PC2 and to a small extent by PC1, generating enkephalin pentapeptides or smaller ECPs. PE in the peripheral tissues, in contrast, may be processed extracellularly by a GTPase cleaving endoprotease to form a detectable free enkephalin in tissues outside of nervous system. Supported by DA-08622 (IEP).

AN IN VITRO MODEL FOR THE STUDY OF NEUROTRANSMITTER REGULATION OF HYPOthalamic GENE EXPRESSION: RNA FROM VITRO AND VIVO CELLS.

Ronnie Folkesson*, Lena Bergström, Lars Nilsson and Bengt Winblad.
Karolinska Institute Clinical Neuroscience, Geriatric Medicine, Novum KCF, Huddinge, Sweden.

Initial screening of different human neuroblastoma cell lines for expression of Somatostatin immunoactivity (SS-ir) and prepro-SS mRNA revealed only one candidate, the neuroblastoma LA-N-2 cell line. Extracted SS-ir material from LA-N-2 cells was compared with SS-ir extracted material from rat hypothalamus after gel filtration. The SS-ir in each fraction was analyzed with RIA revealing three major peaks of SS-forms in the rat hypothalamic extract. The prepro-SS mRNA peak with SS-14, the second peak coeluted with SS-28 and the third peak was found close to thevoid volume and corresponded to an estimated molecular weight of 15 kDa. In contrast the SS-ir extracted from the LA-N-2 cell line showed a quite different elution pattern. Three peaks of SS-ir were measurable, one which corresponded in elution position to synthetic SS-28 and two others which corresponded to approximately 8 kDa and 15 kDa. No immunoreactivity was observed in the fractions coeluting with synthetic SS-14. Total cellular RNA from LA-N-2 cells was prepared and examined for the expression of prepro-SS mRNA by Northern blot analysis, revealing the presence of a single prepro-SS mRNA of about 850 nucleotides in LA-N-2 cells. In addition this cell line is devoid of cholinergic and cholinergic systems interact. Such interactions are of interest considering the marked reduction of these two transmitters in cognitive disorders including Alzheimer's disease.

471.15 NEURAL SPECIFIC PROCESSING OF VGF PROTEIN LED TO THE PRODUCTION AND REGULATED SECRETION OF PEPTIDES DERIVED FROM ITS C-TERMINUS. A.M. Binkall* N. Cahn, A. Levy, G.L. Ferris, M.T. Cotti, E. Tran.

Institute of Neurobiology, UMR, C. Marx 15, Rome, Italy; §Dept. Citomorphology, University of Cagliari; †Dept. Experimental Medicine, University of Tor Vergata, Rome.

VGF, a protein of 617 amino acids, has a restricted expression in sub-populations of neuronal and endocrine cells. By the use of polyclonal antibodies directed against different regions of this domain of VGF we demonstrated that in vivo as well as in vitro, neural cells are able to cleave this protein in smaller peptides. This processing is not observed in transfected PC12 cells, a line established from a rat pheochromocytoma, are unable to process VGF, but acquire the ability to mature this protein upon neuronal differentiation in response to NGF. In primary cultures of cerebellum granule cells in vitro maturation correlates with increased processing of VGF. The major products of the VGF cleavage are a polypeptide of apparent molecular weight 20 kDa and a doublet in the 14-10 kDa range which are derived from the COOH-terminal of the protein. These products are enriched in preparation of dense core vesicles from neuronal cells and are preferentially secreted upon depolarization in neuronal primary culture and cell lines. We suggest that these VGF-derived peptides are the biologically relevant species which may play a role in neural communication.

Differential effects on neostriatal neuropeptide mRNA abundance by excitatory amino acid receptors: H. Villagas, L. Lacroix*, B. Mecquet and Y. Angus*, Lab of Neuroendocrinology, Rockefeller University and Dept. of Biological Sciences, Hunter College CUNY, New York, N.Y. 10021.

Cortical, thalamic and amygdaloid inputs to the neostriatum employ excitatory amino acids as transmitters. These inputs play a central role in excitation of neostriatal neurons, most of which utilize neuropeptides as transmitters and/or modulators. The effects of NMDA and AMPA/kainate receptor blockade on neuropeptides (mainly preproenkephalin (PPE), proctoxykinin (PK) and proopinephrin (P) subhks in the caudate-putamen (CPU) and nucleus accumbens (NAC) were assessed with [H-3]enkephalin and [3H]enkephalin (NMDA and AMPA/kainate antagonists, respectively). Daily systemic injections with [3H]enkephalin for seven consecutive days increased the abundance of all three neuropeptides mRNA in the caudate-putamen and nucleus accumbens. The abundance was increased in the anterior CPU (26%), dorsal and ventral CPU (46% and 39%, respectively) but was unaffected in the NAC. (2) [3H]enkephalin was increased in the NAC (33%) as well as caudate (27%), dorsal (43%) and ventral CPU (67%). (3) Pre mRNA was elevated in dorsal and ventral regions of the CPU (24% and 24%), but not in the anterior CPU (50%). In the NAC Pre mRNA was increased only at the higher doses (0.1 mg/kg) of [3H]enkephalin. In contrast, systemic injections of [3H]-enkephalin for seven consecutive days decreased PE and Pre mRNA abundance approximately 30% below control day in both the CPU and the NAC. These observations demonstrate that NMDA and AMPA/kainate receptors differentially modulate neuropeptide expression in the neostriatun of the rat brain.

471.16 ALTERED PRODUCTION OF PROHORMONE CONVERTASE 2 (PC2) mRNA IN THE ARC (ARC) OF MIDDLE AGED C57BL/6J MICE. D. Kushi,*, H. Miller, M. W. Silbaid and R. Day.

Departments of Experimental Medicine, Obstetrics and Gynecology, Anatomy, and Center for Studies on Aging, McGill University; Clinical Research Institute of Montreal, Montreal, Quebec, Canada.

We have previously reported a significant increase in the expression of the β-endorphin (β-endorphin(1-31)) and (1-26) forms in ARC of middle aged irregularly cycling female C57BL/6J mice (3-months) which was correlated with the appearance of subunits/kinin family, mediated cleavage of β-endorphin(1-31) to β-endorphin(1-27). The objective of this study was to determine if an increase in PC2 expression is associated with the observed changes in β-endorphin processing. Primer extension analysis of a cDNA antisense CRNA probe to mouse PC2. ARC of young (4-5mo) normally cycling (n=5) and middle aged (12-13mo) irregularly cycling (n=5) female mice in distreus of the estrus cycle were pooled for Northern blot analysis. A significant (p<0.01) increase in the PC2 mRNA observed in ARC of middle aged animals as compared to young mice. For in situ hybridization, two sections each from five ARC subregions were examined in both young (n=3) and middle aged (n=3) mice. Film autoradiography of in situ hybridization revealed a significant proportional increases in mid ARC PC2 mRNA (p<0.05 ANOVA) of middle aged mice vs. young females. These data suggest that there is an increase in the level of PC2 mRNA in ARC in middle aged female mice, which may account, at least in part, for altered processing of β-endorphin in middle aged irregularly cycling female mice.

471.17 TRANSCRIPTIONAL REGULATION OF THE NGF GENE IN RESPONSE TO NGF.

D. Balci, A. Pance, N. Holliday, J. Allen* Physiological Laboratory, University of Cambridge, Cambridge CB2 3EY, UK.

Nerve Growth Factor has been reported to regulate the expression of the NGF gene in PC12 cells. The study of the intracellular mechanisms involved in mediating such effects on NGF is important as it may provide a basis for understanding how neuronal cells integrate a variety of stimuli in order to produce a coordinated response. Using a CAT reporter system, we have shown that an AP1 consensus sequence is responsible for the NGF-induced transcriptional activity of the NGF gene. However, a residual response to NGF was observed after the deletion of this AP1 site, suggesting that other sequences are also involved in the residual response. This residual response is mediated through both PKC and PKA dependent mechanisms. Specific inhibitors such as calphostin C (PKC) and H-89 (PKA) were shown to block only partially this residual response to NGF when applied alone, whereas combined application of both inhibitors completely blocked it. Two consensus sites for AP-2 transcription factors which are also present in the NGF promoter region, appear to be responsible for the remaining response to NGF. The deletion of these three sequences completely abolished the response to NGF. Basal levels of expression of the NGF gene in PC12 cells were also found to be mainly dependent on the two adjacent AP-2 sites.

Funded by the Wellcome Trust.

Mutations in DNA underlie carcinogenesis, inherited pathology and aging and are generally thought to be introduced during meiosis and mitosis. Here we report that in post-mitotic neurons specific frameshift mutations occur at high frequency. These mutations were identified in vasopressin transcripts in magnocellular neurons of the vasopressin-deficient hormone Brattleboro rat and predominatingly consist of a GA deletion at GAGAG-motifs. In homonymous Brattleboro rats substituted with vasopressin for 40 weeks and displaying a normalized water balance a 25% reduction in the number of vasopressin cells displaying a GA deletion was found. This indicates that the diseased state of the Brattleboro rat, resulting in a permanent activation of vasopressin neurons, enhanced the mutational rate. Using antibodies against peptides predicted from the +1 reading frame of vasopressin mRNA, immunochemical evidence was obtained for similar events in the hypothalamus of wild-type rats and human. These data have revealed hitherto unrecognized somatic mutations in non-dividing neurons. Such mutations are not restricted to the Brattleboro rat and may occur more widely in neuronal systems affecting other neuronal genes. Evidence for frameshift mutations in other genes will be presented.

CATECHOLAMINES: MEASUREMENTS, SPECT, LESIONS—IMMEDIATE EARLY GENES

Somatodendritic release of dopamine (DA) from the substantia nigra (SN) and ventral tegmental area (VTA) may represent a non-classical form of signaling in the nigrostriatal dopamine and fast-scan cyclic voltammetry voltammetry, with 8 μm carbon fiber microelectrodes to detect endogenous dopamine efflux in situ from tyrosine-hydroxylase (TH) positive neurons. Three pulses were monitored during local electrical stimulation, using a train of 100 pulses delivered at 10 Hz. Signals attributable to DA were identified on the basis of anatomical, electrochemical and pharmaceutical criteria. The response exhibited site-specific variation that correlated well with TH staining: release was significantly higher in VTA (1.04 ± 0.19 μM) than in SN pars compacta (0.52 ± 0.05 μM), which was in turn significantly higher than in SN pars reticulata (0.34 ± 0.03 μM).

The voltammetric of the released substance had oxidation and reduction peak potentials that corresponded to those of DA and the signal evoked in the DA-rich striatum, and were distinguishable from those of 5-HT. The response had apparently no contribution from DOPAC, since it was unaffected by 20 μM pargyline. Electrically-stimulated DA release was Ca2+-dependent, but TTX-independent. The selective DA uptake blocker, GBR 12909 significantly increased the response (260% of control), while desipramine, a selective inhibitor of NE uptake had no significant effect. We conclude that the direct monitoring of stimulat-DA release in situ with carbon fiber electrodes can provide new insights into the mechanism and function of dendritic release. MULTICOMPONENT ANALYSES OF MONOAMINES AND RELATED COMPOUNDS IN CEREBROSPINAL FLUID BY HIGH PERFORMANCE LIQUID CHROMATOGRAPHY (HPLC) COUPLED WITH ELECTROCHEMICAL ARRAY DETECTORS. C.J. Hope*, P. Huetli, E. Isler, D. Kirch* and G.A. Gerhardt. Dept. of Psychiatry, Univ. of Colorado Health Sciences Center, Denver, CO, NIMH, Washington D.C., and Medical College of Georgia, Augusta, GA.

Recent studies in our laboratory have involved the detailed analyses of monoamine neurotransmitters and related species in CSF using HPLC coupled with multichannel coulometric electrochemical array detectors. Such approaches allow for the analysis of up to 30 neurochemicals in a single sample. Frozen CSF samples (0.5 ml) are thawed, diluted to 1 ml with mobile phase, filtered and divided into two 0.5 ml fractions. An isocratic HPLC system consisting of a single pump, C18 reverse phase column (4.6 mm x 100 mm, 3 μm particles, Hypersil; Keystone) and a multi-channel electrochemical array detector (ESA 1100A, ELS oxidation and E2 reduction using a 5011 cell) is used to measure levels of dopamine, norepinephrine, DOPAC and other species using a pH 4.0 cirtate-acetate mobile phase with 4.7% MeOH and 0.33-0.37 mM OS. A gradient elution with 16 millieuqals with 20 plasma electrochemical detectors set at increasing potentials ranging from 0 mV to 1200 mV (CESA, ESA Inc.) is used for the measurement of tyrosine, tryptophan, homovanillic acid and up to 20 other neurotransmitter and related compounds. Separations performed with the CESA are carried out with a combination of both phenyl (4.6 mm x 150 mm, 5 μm particles, BDS Hypersil Phenyl, Keystone) and cyanopropyl (4.6 mm x 50 mm, 5 μm particles, Keystone) columns using a gradient elution with a pH 3.0 phosphate buffer containing 0.17-5% ethanol. The use of the electrochemical array chromatography systems for studies of monkey and human CSF samples will be presented.

REDUCTION/OXIDATION RATIOS AND NEUROTRANSMITTER IDENTITY: EFFECT OF NAFION COATING THICKNESS. B.T. Menlooo*, C. R. Haims, Colliano & M. C. Davidson. Dept. of Psychiatry, UC San Diego School of Medicine, La Jolla, CA 92039 and Institute for Neuroscience, Univ. of Oregon, Eugene, OR 97403.

Studies utilizing in vivo voltammetry to investigate the evolved release of catecholamines comprising neurotransmitter and nerve terminals. The electrical signals from neurons may be detected chronovoltammetrically by applying a positive potential step (vs. an Ag/AgCl reference electrode) to the working electrode to oxidize electroactive molecules. The reverse current flow generated by the return of the potential to its previous value reduces the oxidized electroactive species. The ratio of the reduction to oxidation current at the maximum oxidation current is termed the reduction oxidation (RO) ratio. It has been suggested that the RO value gives some indication of the identity of the major neurotransmitter (Gruion et al., Neurosci. 29: 57-64, 1989).

We have recently found that the RO ratio may be related to the thickness of the electrode's Nafion coating. Nafion was applied by simple immersion or with electric current. Our results showed that as the amount of Nafion coating increased, the RO ratio also increased when the only substance added to the calibration medium was norepinephrine, dopamine, or serotonin. Moreover, increases in the duration of applied voltage also produced systematic changes in RO ratio. A three fold-increase in plating time caused a comparable increase in RO ratio for norepinephrine. While dopamine may usually exhibit a larger RO ratio than norepinephrine or serotonin, that ratio may be different for each electrode. Also, since the electrode is in the brain, the nafion coating may begin to thin and RO ratios will change. Thus, RO ratios depend on the neurotransmitter present and the properties of the detecting electrode. Supported by the J. S. McDonnell Foundation and Pew Memorial Trust and NIMH Grant 5T32MH19547 from the NIMH Minority Neuroscience Fellowship Program.

A STABLE LOW MAINTENANCE HPLC FOR THE SIMULTANEOUS ANALYSIS OF CATECHOLAMINES, INDOLES AND THEIR METABOLITES. J.D. Harvey-White, and J.J. Kopin*. Clinical Neurosciences Branch, National Institute of Neurological Disorders and Stroke, 9000 Rockville Pike, Bethesda, MD 20892.

Procedures for obtaining a consistently stable, sensitive, and low maintenance HPLC with electrochemical detection for the simultaneous analysis of norepinephrine, epinephrine, dopamine, dihydroxyphenylalanine(L-DOPA), dihydroxyphenylacetic acid (DOPAC), 4-hydroxy-3-methoxyphenylalanine (OMDOPA), 4-hydroxy-3-methoxyphenylethylamine, homovanillic acid(HVA), and 6-hydroxydopamineacetic acid(6HIAA), and serotonin(SHT) are described. Conditions to meet different experimental needs for optimal selectivity, and sensitivity have been determined: 1 - Heptanesulfonic acid(HSA) is used as the ion-pairing agent. The retention (RT) time for HVA and SHT are inversely related to the concentration of HSA (all other compounds are proportionately related). The RT of L-DOPA and 3-MOMDA (relative to other compounds) are greatly increased as pH is decreased. Resistance to complete drying of the mobile phase(MP) facilitates pump maintenance, the MP can be recycled for months, and the columns last 1 to 2 years. Addition of 1% EDTA/0.02% ethanol to dialysates stabilized all compounds of interest: with 0.1M perchloric acid tissue homogenates this addition stabilized DOPAC and SHT, and increased the stability of 6HIAA.

473.5

A comparative SPECT evaluation of the regional uptake of 28-carboxylpropyl-201-Tc (ICPIT) and 28-carboxylpropyl-324-thyroxine (8-CIT) was performed to assess the improved specificity of ICPIT over 8-CIT for the dopamine (DA) transporters. For ICPIT and 8-CIT five single bolus injections (80 mg/kg) was given every 10 min (total time ranging from 70 to 80 min) into 5-15 mcI injected rats, were completed in 3 baboons (Papio anubis, 10 kg). Peripheral metabolism of the test drugs was similar as demonstrated by the respective clearances, 175±23 ml/min (mean ± SD) for ICPIT and 134±9 ml/min for 8-CIT. The SPECT images utilized R0s over striatum (which reflect DA transporters), midbrain (previously shown for 8-CIT to reflect primarily arocholinergic transporters), and the cerebellar cortex (as a non specific uptake). The time to peak specific striatal uptake (striatal minus cerebellar activity) was similar for ICPIT and 8-CIT (37±5±1 min, respectively). At time of peak specific activity, striatal to cerebellar ratios were 2.8±1.3 for ICPIT and 7.2±0.8 for 8-CIT. However, the normalized striatal uptake values (mean±SE) were similar to those of both ICPIT (5.3±0.8) and ICPIT (3.1±0.2, respectively). In contrast, the normalized nonspecific activity measured in cerebellum was higher for ICPIT (1.8±0.4) than for 8-CIT (0.4±0.3). In conclusion, ICPIT demonstrated a higher DA transporter specificity and higher level of non-specific uptake.

473.6

I-123 IBZM, a dopamine D2/D3 receptors radioligand, has been used for in vivo SPECT imaging to obtain measurements of dopamine receptor density. We have developed a simple kinetic analysis for time dependent IBZM uptake as an approximation of synaptic dopamine receptor density that enables comparison against a control radioligand association and presumably endogenous dopamine release. We tested this approach in normals and in two neurological conditions in which alterations of striatal dopamine activity are thought to occur: Parkinson's disease and Huntington's disease. In patients with asymmetric clinical signs of Parkinson's disease (PD) (n=13) there was a nonsignificant increase in mean basal ganglia/occipital ratio of IBZM activity at 2 hrs contralateral to maximal clinical signs. In patients with Tourette's Syndrome (TS) discordant for ratings of severity (n=6 twin pairs), there was no scan difference between twins in IBZM ratio. The rate of accumulation of IBZM (a parameter proportional to association and dissociation rates, receptor density and concentration of endogenous dopamine) in the basal ganglia over the 4 hr scan time revealed in the PD patients a mean slope that was significantly higher in the contralateral striatum (p<0.02). The more severely affected TS twins showed a significantly decreased slope when compared to the less affected twins (p<0.03) and in normal controls (p<0.03). We conclude that the rate of accumulation of striatal IBZM activity reflects synaptic dopamine activity and possibly dopaminergic release since it is increased in the setting of decreased striatal dopamine concentration (PD) and is decreased in a disease purported to have increased striatal dopamine activity (TS). This suggests that IBZM activity is a more sensitive indicator of synaptic dopamine activity than single time point measurements of striatal/occipital ratio.

NEUROCHEMISTRY REVEALS THE DEPLETION OF EXTRACELLULAR DOPAMINE IN THALAMIC NERVE ENDS IN THE RABBIT HYPOTHALAMUS. R. C. Moore, A. F. Moore, East Carolina Northport, DEpts. of Pediatrics and Neuroscience, University of Carolina, Chapel Hill, NC. 28630.

Withdrawal of chronic ethanol (EtOH) treatment in rats is associated with a profound inhibition of the mesolimbic dopamine (DA) system. DA depletion has been hypothesized to contribute to a neurotransmitter correlate of the dysphoric and depressive state associated with withdrawal. However the cellular mechanisms underlying this phenomenon have not been fully understood. Chronic EtOH treatment is known to be associated with an overactivity of L-type calcium channels. To assess whether L-type calcium channels have a role in the withdrawal-associated inhibition of the DA system, we studied the effect of the dihydropyridine calcium antagonist nimodipine on the extracellular DA in the ventral striatum of EtOH-withdrawn rats. In EtOH-dependent rats, twelve hrs following the last treatment (5g/kg every 6 hr for 6 days), dialyse DA levels were about 30% of control, sucrose-treated rats. Nimodipine (2.5 mg/kg s.c.) dose dependently reversed the fall in DA output toward control values. At the dose of 10 mg/kg nimodipine raised DA output to about 160% of control. In contrast, the drug had no effect in control rats. Thus, overactivation of L-type calcium channels can mediate the inhibition of the mesolimbic dopaminergic system during EtOH withdrawal, presumably through inhibitory influences to dopamine cells. In addition, our results suggest a potential role of nimodipine in the dysphoric and depressive state associated with EtOH abstinence syndrome.

473.9

Previous studies have shown that the genetic variability in the sensitivity to haloperidol-induced catalepsy is associated with the number of dopamine neurons in the substantia nigra zona compacta (SNZC) (JPET 266:431, 1995). To further investigate this relationship, we have used two methodologies. Neurleptic responsive (NR) and nonresponsive rats were selected from the new heterogenous stock/Northport (HS/Np). At S, the lines differed 6-fold in their sensitivity to haloperidol-induced catalepsy. Confirming previous results, tyrosine hydroxylase (TH) cell number was significantly higher in the NRN line; the difference was most pronounced in the rostral SNZC where TH cell number was increased 23% Forty-two C57BL/6J-D2A/2 (B6D2F2) F2 hybrids were phenotyped for haloperidol response prior to determining TH cell number. Paralleling the results in the selected lines, TH cell number was found to be proportional to the number of responsive animals. TH cell number was determined in 10 inbred mouse strains that were previously phenotyped for haloperidol response. Among the inbred strains no correlation was found between TH cell number and cell number. The reasons for the differences between the first two and third genetic strategy are not clear but may suggest that epistatic interactions are present in the HS and F2 strains but not the inbreds. This data brings into question the validity of using genetic correlations obtained from inbred strains.

473.10

We have previously demonstrated (JPET 61:341, 1992 and Psychopharmacol. 103:244, 1991) that NR and NRN lines selected from HS/1bg stock differ significantly in D1 receptor density. We found that there was a significantly higher somatodendritic dopamine receptor density throughout the midbrain but a lower receptor density in the lateral striatum. Recently, we confirmed that among 8 inbred mouse strains (C57BL/6J-D2A/2, C3H, BALB/c, LP, A, AKR and CBA), the strains least sensitive to haloperidol-induced catalepsy had the highest somatodendritic receptor density (LJPET 267: 538, 1993). However, differently than the selected lines, there was a trend to higher receptor density among the nonresponsive lines in the lateral striatum. These eight inbred strains were crossed to form a new HS stock. After 8 generations of random breeding, a new selection of HS and NRN lines was begun. At S, the lines differed 6 fold in their Emax for haloperidol-induced catalepsy. Receptor binding to the D1 family of receptors was determined using [1H]epibolide and quantitative receptor autoradiography. The data obtained parallel the results obtained from the inbred strains - receptor density was higher both in the substantia nigra and striatum. Similar results have also been obtained in C57BL/6J-D2A/2 F2 animals phenotyped for haloperidol response and D1 receptor density.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
473.11 MAPPING THE GENES CONTRIBUTING TO CHOLINERGIC AND DOPAMINERGIC NEURON DENSITY USING THE BDX/TY RI STRAINS. K. Denis*, B. Hitzemann and B. Hitzemann, Departments of Neurobiology and Behavior, and Psychiatry, State University of New York at Stony Brook, Stony Brook, NY 11794 and Psychiatry Service, VAMC, Northport, NY.

Two traits associated with neuroleptic-induced catecholysis are the density of cholinergic cells in the caudate-putamen and the density of dopaminergic cells in the substantia nigra (Hitzemann, et al., 1993). By analyzing the BDX/Ty series of mice we were able to obtain significant quantitative trait loci (QTL) associated with haloperidol-induced catecholysis (Kanes, et. al., 1994) and the above traits. These QTL include the microsatellites D8Mit22, D8Mit74 and D8Mit21 which map near the dopamine D3 receptor gene (Drd3). F2 hybrids generated from C57BL/6J and DBA/2J strains were used to confirm the associations between significant QTL by typing for haploider sensitivity and cholinergic and dopaminergic cell density, then genotyping for the significant QTL. This analysis has also revealed a significant QTL for cholinergic cell number at microsatellite D12Mit17, which is within proximity of the serotonin transporter gene. These markers are suitable candidates for positional cloning.

473.12 LESIONING THE MEDIAL PREFRONTAL CORTEX DECREASES MIDBRAIN DOPAMINE NEURON ACTIVITY. S.S. Shrestha, W.A. Shi and B.S. Bunn, Depts. of Psychiatry & Pharmacology, Yale Univ. New Haven, CT 06510.

Lesions in the prefrontal cortex (PFC) have been shown to profoundly affect subcortical dopamine (DA) transmission in animals, and this effect is believed to be mediated by cortical projections to DA terminal areas (see reviews by Grazi, J Neural Transm 91:111, 1993 and Deutch, J Neural Transm 91:197, 1993). However, since the PFC is also innervated by DA neurons located in the midbrain, lesions in the PFC may directly affect the electrical activity of DA neurons which should in turn influence DA release in terminal areas. To examine this possibility, we used extracellular single unit recording techniques to record DA neurons from both A10 and A9 in control and PFC lesioned rats. To lesion the medial PFC, we either made a unilateral stab to the mPFC or locally injected ibotenic acid into the mPFC. One hour after mechanical lesioning the number of spontaneously active DA neurons in both the A9 and A10 areas was decreased (A9: from 1.15±0.10 to 0.57±0.07/track, A10 from 1.41±0.09 to 0.77±0.09). Furthermore, the burst activity of A10 DA neurons was also reduced from 26.7±1.80 to 17.50±2.45. However, unlike the mechanical lesion, local injection of ibotenic acid only decreased the activity of A10 neurons. Thus, four to 20 days after the injection, the number of spontaneously active DA neurons in the A10 area was significantly reduced from 1.50±0.13 to 0.56±0.11 cells/track, whereas that in A9 area were not significantly affected. Surprisingly, the basal activity of DA neurons in the A9 area was increased (control: 3.65±0.28 spikes/sec, lesioned: 4.83±0.24 spikes/sec). These results suggest that lesions in the mPFC can significantly affect DA neuron activity located in the midbrain and this effect may contribute to the change in DA transmission in subcortical areas seen after PFC lesion. Supported by PHS award MH28849, the NPF, the NARSAD, and the State of Connecticut.

473.13 APOMORPHINE INCREASES EXTRACELLULAR GABA LEVELS IN THE PREFRONTAL CORTEX OF THE FREELY MOVING, CONSCIOUS RATS. A.C. Grobin* and A.Y. Deutch, Dept. of Psychiatry and Pharmacology, Yale Univ. Sch. Medicine, New Haven, CT 06510.

It has been hypothesized that dopamine (DA) in the prefrontal cortex (PFC) regulates GABA release function. DA axons form synapses with GABA neurones in the PFC. Furthermore, in vitro studies have reported that DA agonists will stimulate GABA release in the PFC. To test this hypothesis we used the DA D1 agonist apomorphine (APA) which was administered to male Sprague-Dawley rats and GABA levels determined in the PFC using in vivo microdialysis. APA was delivered directly to the PFC through the dialysis probe, or systemically through an indwelling subcutaneous catheter. GABA levels and relative amounts of amino acids in dialysates were determined using pre-column derivatization and high performance liquid chromatography (HPLC-EC). Local administration of APA (0.01 and 1.0 μM) produced a large increase in extracellular GABA. Systemic administration (0.5mg/kg) produced a pronounced increase in extracellular GABA of short duration; no increase in glycine was observed. Thus, both local and systemic administration of a DA receptor agonist increased extracellular GABA levels in the PFC. This report provides the first in vivo data to show that DA stimulates GABA release in the PFC. Thus, DA may inhibit pyramidal cell firing through stimulation of inhibitory GABA interneurons, as well as by directly synapsing on pyramidal cells. This arrangement has important implications for our understanding of the functional consequences of the loss of interneurons in the cortex of schizophrenics.

These studies were supported by MH-45124 and GM-07324.
473.17

The ventral pallium (VP) receives a dopamine (DA) input from the substantia nigra and ventral tegmental area. In locophoretic application of DA or the DA agonist SKF38393 alters the firing rate of many VP neurons (Napier and Maslowski-Cobuzio, Synapse, in press). Also, systemically administered DA, agonists increase the activity of many VP neurons (Maslowski and Napier, J. P. 200-103).

The present study investigated the effects of chronic DA depletion on the response of VP neurons to DA agonists and SKF38393. Rats were anesthetized with chloral hydrate and single neuron recording techniques were used to assess changes in sensitivity to microiontophoretic DA and SKF38393, and their effect on DA release. There was no change in the response of VP neurons to DA agonists. Consequently, it was suggested that DA agonists do not alter their “bad” firing rates. Instead, the response of VP neurons changes in a manner that is consistent with the observed behavioral changes.

473.18
WHY CAN’T HEMIPARKINSON RATS WALK NORMALLY? I. Q. Whishaw and E. I. Miklyaeva, Department of Psychology, University of Lethbridge, Lethbridge, AB, Canada, T1K3M4

The normal walking sequence of many tetrapods involves patterns of diagonal support in which one set of diagonal limbs supports weight while weight is unloaded from the others. We have examined walking in hemiparkinson rats (6-OHDA in the nigrostriatal bundle) using high speed video, cinemetic, and video support analysis. They use abnormal gait or turn ipsilaterally in tests of spontaneous locomotion rather than displaying the normal diagonal pattern of walking. An investigation of the underlying basis for this change showed that they are not able to use their “bad” limbs in shift to posture and contribute to the normal diagonal walking pattern. To compensate for this impairment they alter their movement patterns to place more reliance on their good limbs. Thus, it is suggested that hemiparkinson rats do not walk normally because they are relying upon two limbs rather than four to shift their weight.

473.19
WHY DO HEMIPARKINSON RATS TROT? E. I. Miklyaeva and I. Q. Whishaw, Department of Psychology, University of Lethbridge, Lethbridge, AB, Canada, T1K3M4

Hemiparkinson rats (6-OHDA in the nigrostriatal bundle) turn ipsilateral to their lesion spontaneously and under amphetamine and central stimulation of the nigrostriatal dopamine. They display sensorimotor abnormalities when eating, rearing, reaching and competing for food. Control rats move away from a “diagonal” posture supporting pattern, unloading the limb opposite to the lifted one and loading the other pair of limbs, when performing most behaviors. Hemiparkinson rats are not able to use their “bad” limbs in this way. Consequently they modify their posture and movement to rely on the ipsilateral “good” limbs to actively adjust support. This change biases their behavior such that they display a variety of anomalous movements that include ipsiversive rotation spontaneously and under amphetamine, backward dodging when they protect their food from rodents, and atypical standing to reach for food. Apomorphine restores more normal movements. The results show that following DA depletions the new supporting patterns are related to the many changes in behavior typical of hemiparkinson rats. Thus, it is suggested that they turn because they have to.

472.21
PRIOR EXPOSURE TO INTRA-RIA AMPHETAMINE ENHANCES THE INDUCTION OF IMMEDIATE-EARLY GENE EXPRESSION IN THE RAT FOREBRAIN BY SYSTEMIC AMPHETAMINE. P. Vesin* and G. S. Robertson, Dept. of Psychiatry, University of Chicago, Chicago, IL 60637 and Department of Pharmacology, University of Ottawa, Ottawa, Canada K1H 8M5.

Injections of amphetamine into the ventral tegmental area (VTA) have been shown to enhance the locomotion and increase the extracellular DA concentrations (N.Acc.) dopamine (DA) produced by a subsequent systemic amphetamine challenge. The present experiment investigated whether prior exposure to such injection would also affect the subsequent induction by systemic amphetamine of immediate-early gene activation in the N.Acc., the antero-medial striatum and the medial prefrontal cortex, forebrain projection fields of A10 DA perikarya in the VTA were administered injections of either d-amphetamine (2.5 µg/0.5 µl/side) or saline into the VTA, one injection every third day. One week following the last injection, animals were challenged with amphetamine (10 mg/kg). Results indicated that responses to repeated injections of DA were increased (generally two fold) expression of FOS, FOS-B, JUN-B and NGFI-A. Animals exposed to VTA amphetamine showed increased (generally two fold) expression of FOS, FOS-B and JUN-B in all A10 projection fields when compared to VTA saline preexposed animals. The two groups did not differ in amphetamine induced expression of NGFI-A in any area. This enhanced induction by amphetamine of immediate-early genes of the fos/jun (leucine-zipper) family in VTA amphetamine preexposed animals is consistent with the sensitized DArgic response to this drug reported in the literature. This enhanced amphetamine induced expression of DArgic genes (N.Acc.) while NGFI-A (of the zinc finger immediate-early gene family) is induced by amphetamine, it does not appear to be involved in the differential expression of the behavioral and DArgic responses to amphetamine by these two groups.

473.22
Changes in cochlear tyrosine hydroxylase immunoreactivity after repeated exposure to cocaine. B.G. Shigemura, S.Y. Liu, D.Z. Piotrowski, E.P. Schoener*, Dept. of Otolaryngology, Henry Ford Hospital, Detroit, MI 48202.

The site of action of cocaine in the auditory system may include structures peripheral to the ventral cochlear nucleus, including the cochlea. Previous studies in our laboratory examined the acute and chronic effects of cocaine on cochlear function. Experiments designed to study acute effects of cocaine on cochlea demonstrated a significant decrease in both the amplitude of the compound action potential of the auditory nerve (N1) and cochlear blood flow. On the other hand, experiments designed to study chronic effects of cocaine on the cochlea show an enhancement of the N1 amplitude of the auditory nerve.

In order to understand the underlying mechanisms involved in chronic cocaine action in the cochlea, this experiment was designed to examine the effects of repeated administration of cocaine on the cochlear cochanneling systems in chinchilla using immunohistochemical techniques. Twelve chinchillas were randomly assigned to either control or experimental groups. Animals in control group were administered saline while animals in experimental group were administered 15 mg/kg cocaine IP daily for 42 days. Animals were sacrificed 24 h after the last treatment. The cochleacochleal system was evaluated using a polyclonal antibody to tyrosine hydroxylase (TH). Microscopic examination of whole-mounted tissue revealed TH immunoreactive fibers in the outer spiral bundles. This change was described as a robust increase in the number of fibers in the outer spiral bundles. Total number of fibers per cochlea between the two groups demonstrated a significant decrease in cocaine-treated animals. (Supported in part by NIDA/NSH grant DA07554)

Whether tetrodotoxin-resistant dopaminergic (TIDA) neurons contain dopamine (DA) autoreceptor has been a controversial issue. Earlier study from this lab using single-unit recording of dorsomedial/ventrolateral arcuea (ARC) neurons in rat brain slices found that DA inhibited 37% of ARC neurons recorded. Recently, immunohistochemical studies, however, reveal that DA neurons are localized in the dorsomedial part of the ARC only. By focusing our recording in that region, we found that DA in 50-250 nmol range now inhibited a significant number of ARC neurons tested (74.2% of 182 units). Apomorphine, a DA agonist, had no effect (38.1% of 21 units). Cocaine, an abusive drug whose effect is believed to increase DA concentration in synaptic clefts by inhibiting DA reuptake, also inhibited a significant number of ARC neurons by itself (51.5% of 97 units), but with a lesser efficacy. Cocaine co-administered with DA, however, potentiated the inhibitory effect of DA in 82% of DA-responsive units (n=39). The results demonstrate clearly that DA indeed had a predominantly inhibitory effect on presumed DA neurons in the dorsomedial ARC. The effects of cocaine, either by itself or with DA, further support this notion.

The 5-HT3 receptor mRNA has recently been shown to be expressed as two forms (5-HT3α1 and 5-HT3α3) varying by 18 base pairs in the third intracellular loop (Hope et al., Eur. J. Pharmacol., 245:187, 1993). As the short form of the 5-HT3 receptor lacks a cassekinase II phosphorylation site in the region corresponding to the alternative splicing, the question of the functional roles of the two variants has been raised. We have studied the regulation of the expression of mRNAs coding for the two variants in a variety of cells using different culture conditions. Relative abundance of the two mRNAs was determined by quantitative PCR over the linear range of the assay by using primers flanking the site of alternative splicing. Reverse transcribed mRNAs for both forms (L+ and L−) were performed by competitive PCR using as an internal standard a deleted DNA corresponding to a 460 base pair fragment starting at transeptumbrine domain-2 and ending at TM-6. Differentiation significantly reduced the abundance of the overall mRNA coding for 5-HT3 receptors in different proportions depending on the cell type (dibutyryl cAMP, with or without TPA, theophyllin + PGE1...). In addition, the relative proportions of the two splice variants changed significantly when compared with control cells, since the ratio S/L increased with exposure time to the differentiating agent (Control: 2.75; DR-AMP 1 mM, 1 day: 3.76, 2 days: 4.29, 3 days: 4.43, 5 days: 5.36, 7 days: 6.42). As functional changes have already been described for 5-HT3 receptors upon differentiation in these cells (Shao et al., J. Neurophysiol. 65:650, 1991), our results suggest different functional roles for 5-HT3α1 and 5-HT3α3.

Based on the predicted amino acid sequence of the cloned rat 5-HT3 receptor cDNA (Sugita et al., Soc. Neurosci. Abstr., 19:632), we designed seven different peptides of 15-19 residues that were expected to be antigenic were conjugated to bovine serum albumin and used as immunogen to develop anti-5-HT3 receptor antibodies in New Zealand White rabbits. The sera obtained after 3-H injections were specific for the anti-serum terminal, extracellular region, and four from the large intracellular loop, between transmembrane domains 3 and 4 (M1) of the putative pore region. Antibody production was evaluated by solid-phase ELISA and immunoblot analysis. Peptides corresponding to the extracellular region of the protein gave antibody of very low avidity. Two of the M1 peptides (P1 and P2) corresponding to the large intracellular loop produced antisera of high titer. These antisera when tested on a dot blot analyses were able to detect 0.2 ng of synthetic peptide at dilution of 1:2000.

Membranes from brain and NG-108-15 cells were solubilized with Triton X-100. By western blots, and 5-HT3-R antibodies recognized a single band (molecular weight close to 5-HT3-R) in the detergent soluble fractions. Western blot and immunoblot analysis was abolished when antibodies were preadsorbed with the corresponding peptide (P1). Western blot analysis revealed 9 different bands and shapes on rat brain tissue: small round cells in the striatum; medium bipolal and multipolar cells in cortical areas and hippocampus. Immunoblotted neurons were also found in the olfactory bulb, olfactory tubercle and amygdala. The pattern of distribution of the immunoblotted cells is in agreement with that reported for the localization of 5-HT3-R transcripts (Johnsen and Heinemann, Soc. Neurosci. Abstr., 19:632). Our data indicate that 5-HT3R immunolabeled neurons are prominent in areas associated with the DA mesolimbic system. (Supported by AA 06420).

In contrast to studies indicating that applications of 5-HT\textsubscript{1A} receptor agonists can fast a depolarizing action, which is rapidly desensitized, on peripheral or cultured cells, we have found that 2-methyl-5-HT elicits a slow depresor action with no desensitization on cells in the medial prefrontal cortical (mPFC). In addition, 5-HT\textsubscript{1A}-like receptors in the mPFC might be coupled to the phosphoinositide (PI) hydrolysis. To further characterize the pharmacological properties of 5-HT\textsubscript{1A} receptors in the mPFC, using the technique of single cell recording and interneuronal responses, we have compared the depressant action of various 5-HT\textsubscript{1A} receptor agonists on the firing of mPFC cells. The rank order of effectiveness was: 5-HT > 5-HT\textsubscript{1A} > 5-HT\textsubscript{1B} = 2-methyl-5-HT = mCPBG (1-(1-methylpiperidino)-benzamine) = PBB = PCPBG = PCBPG. Furthermore, in the mPFC, d-tubocurarine not only blocked the depressant action of 5-HT\textsubscript{1A} receptor agonists but also antagonized that of d-amphetamine and GABA. In fact, d-tubocurarine alone accelerated the firing of mPFC cells. In another research paradigm, the effect of various 5-HT\textsubscript{1A} receptor agonists on PI turnover were investigated and compared using the tracer technique of this mPFC. The rank order of potency was: 5-HT > 5-HT\textsubscript{1A} > 2-methyl-5-HT > mCPBG = PBB = PCPBG = PCBPG. In summary, following the two new findings further indicate that 5-HT\textsubscript{1A}-like receptors in the mPFC are pharmacologically different from those in the penta
tetrapyrrole (pTP) or 1 in the mPFC, mCPBG is not the most potent 5-HT\textsubscript{1A} receptor agonist, and 2-d-tubocurarine is not a specific antagonist for 5-HT\textsubscript{1A}-like receptors.

**EFFECT OF GRANISTIM ON ACUTE AND DELAYED CISPLATIN-INDUCED EMESIS IN THE PIGLET.** L. Groleau, S. Milano, P. Blower \& D. Romain. URA CNRS 8332, St. Jerome, 13397 Marseille Cedex 20, France; SmithKline Beecham Pharmaceuticals, UK (1) and France (2).

Emesis in cancer chemotherapy is classified as acute or delayed when occurring during or after the 24 hr following systemic treatment, respectively. It remains unclear whether serotonin 5-HT\textsubscript{3} receptors are involved in delayed emesis. In 19 weaned piglets, granisetron was tested on both acute and delayed emesis. Vomiting was induced by an iv injection of cisplatin (5.5mg/kg) and animals were observed for 60 hr. In group 1, 12 piglets received an initial (15 min prior to cisplatin) single dose (5mg/kg, n=5); 1mg/kg, n=3; 3mg/kg, n=3 or 7mg/kg, n=4) of granisetron. In group 2, 7 piglets received in addition to the initial dose (0.25mg/kg, n=2; 1mg/kg, n=5), a supplementary injection (same dose as first) each 5 hr during the 30 hr period. In group 1, single doses of granisetron prevented vomiting during the first 5-18 hr in a dose dependent manner. All animals exhibited a delay in the onset of vomiting, the time to the first vomiting was (13.5±8.8) hr for those which was higher than those of animals not treated with granisetron (9.2±8.6). In group 2, repetitive administration of granisetron was beneficial in reducing both the acute and delayed phases of vomiting. Indeed, 6/7 piglets (0.25mg/kg, n=1; 1mg/kg, n=5) during the acute phase and 4/7 (1mg/kg, n=4) during the delayed phase did not vomit. These results suggest that serotonin 5-HT\textsubscript{3} receptors might be involved in the development of delayed emesis in this species.

**THE PIGLET: AN ANIMAL MODEL FOR STUDYING CISPLATIN-INDUCED DELAYED EMESIS.** S. Milano, L. Groleau, P. Blower \& D. Romain. URA CNRS 8332, St Jerome, 13397 Marseille Cedex 20, France; SmithKline Beecham Pharmaceuticals, UK (1) and France (2).

The pathogenesis of cisplatin-induced delayed emesis being obscure, we investigated the suitability of the piglet as a model for studying delayed emesis. The piglet was implanted surgically with a stainless steel cannula in the jugular vein and electrodes for recording ECG and abdominal EMG. After a 4-5 days recovery, piglets were hydrated (iv, saliné 4% body weight, 100ml/kg/hr) and then given cisplatin (5.5mg/kg, iv). Recordings were made continuously for the following 48 hr. Animals were not fed but received continuous iv infusions of glucose and polyionic solutions. All piglets responded with both acute and delayed emesis. In the acute phase of emesis, the first vomiting occurred with a latency of 1:31±4.3 min after cisplatin administration. Emetic intensity reached a peak (5 vomits/hr) within 120 min and then decreased rapidly, so that no vomiting were observed between the 15th and 16th hr. The mean number of vomiting during the first 16 hr was 18.6±2.6. Delayed emesis started at the 17th hr and was observed to last until the 58th hr. Emetic intensity of the delayed phase reached a peak (0.8 vomits/hr between the 19th and 21st hr and the mean number of vomiting during the whole of the delayed phase was 9.2±2.6. Cisplatin inducing delayed vomiting in the piglet with both a weak toxicity and a relatively low emetic potential is a suitable model in which to study the pathogenesis of delayed emesis.

**AGONIST POTENCY AND AFFINITY AT 5-HT\textsubscript{1A} RECEPTORS EXPRESSED IN CHINESE HAMSTER OVARY (CHO) CELLS.** J.G. Heniez, K.D. Duria, L.E. Gooden and C.O. Berti. Dept. Pharm Biol. Texas Health Sc. Center, San Antonio, TX 78284; Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA. 19104.

The relationship between agonist potency and affinity was investigated in CHO cells stably expressing the 5-HT\textsubscript{1A} receptor (CHO-5-HT\textsubscript{1A} cells). In membranes from CHO-5-HT\textsubscript{1A} cells, the specific binding of the radiolabeled 5-HT\textsubscript{1A} receptor agonist [\textsuperscript{3}H]8-OH-DPAT (1-12 nM) was inhibited essentially completely (97±1.5%) by GppNHp [EC\textsubscript{50}= 2.8 ± 0.3 µM]. Saturation experiments using membranes from CHO-5-HT\textsubscript{1A} cells indicated that the binding of [\textsuperscript{3}H]8-OH-DPAT (0.05-50 nM) in the absence of guanine nucleotides, was to a single site (Kd = 1.1 nM, Bmax = 1 pmol/mg protein). Taken together, these data suggest that in CHO-5-HT\textsubscript{1A} cells all of the 5-HT\textsubscript{1A} receptors are coupled to G proteins and exist in a high affinity state as determined by radioactive agonist binding. To determine whether agonist potency can be related to the high affinity state of the receptor, EC\textsubscript{50} values of agonists to inhibit forskolin-stimulated [\textsuperscript{3}H]cAMP accumulation in CHO-5-HT\textsubscript{1A} cells were compared with their Ki values for the inhibition of [\textsuperscript{3}H]DPAT binding. The EC\textsubscript{50} values to the EC\textsubscript{50} values were near unity: 8-OH-DPAT, 1.40 ± 0.09 nM; 5-HT, 0.24/2 ± nM; gepirone, 0.557 ± nM; gepirone, 0.557 ± nM. Thus in CHO-5-HT\textsubscript{1A} cells, the potency of agonists appears to be related to their affinity at the high affinity state of the receptor. Supported by USPHS grants MH46125 and MH52399.
SEROTONIN RECEPTORS: EFFECTOR MECHANISMS

475.3
5-HT<sub>2</sub> AND 5-HT<sub>3</sub> RECEPTORS ARE RESPONSIBLE FOR THE HYPNOTIC EFFECT OF SEROTONIN IN A HUMAN TUMOR OF NEUROCHROMAFFIN ORIGIN
Lucia A. Filionti*1, F. P. Volinalli and R.G. Cattaneo
Department of Pharmacology, University of Milan, Milan
Small cell lung carcinomas (SCLC), as aggressive human tumors often associated with tobacco smoking, possesses neuroendocrine features. These include the presence of neuroendocrine granules containing hormones and neuropeptides and the expression on their surface of specific receptors and voltage-dependent Ca<sup>2+</sup> channels. We have found that serotonin (5-HT) is contained, and is autocrine in the two SCLC cell lines GC1 and NCI-H60. The autocrine effect of 5-HT is not counteracted by ketanserin, D5L 205-350 and 311-408 which are antagonists of the 5-HT<sub>1B</sub> and 5-HT<sub>1D</sub> receptors, respectively. We found that the 5-HT<sub>2</sub> agonist mirtazapine and the 5-HT<sub>3</sub> agonist O-29-DOP is capable of increasing DNA synthesis in the SCLC cell lines, with lower efficacy but higher potency than 5-HT (EC<sub>50</sub> 25 nM and 90 nM respectively). Their effects on DNA synthesis were completely additive and together they reached the maximal effect elicited by 5-HT alone. Speromine (1 μM) and the 5-HT<sub>3</sub> antagonist 5HT 216-252 (1 μM) inhibited the 5-HT autocrine response by 60%.
When cells were cultivated at higher density, the two 5-HT<sub>3</sub> antagonists were able to inhibit basal cell proliferation. Taken together, our results suggest that 5-HT should be added to the list of autocrine growth factors for SCLC cells. The autocrine effect of 5-HT is due to stimulation of both 5-HT<sub>2</sub> and 5-HT<sub>3</sub> receptor types. The design of specific antagonists might be useful for the growth control of human small cell lung carcinomas.

475.4
CONSTITUTIVELY ACTIVE SEROTONIN 2C (5HT<sub>2C</sub>) RECEPTORS STIMULATE DNA REPLICATION IN A TRANSFECTED CELL LINE
R.S. Westphal and S. Sander-Bush*2
Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN 37232
Agonist activation of the serotonin 2C (5HT<sub>2C</sub>) receptor expressed in NIH 3T3 fibroblasts has been shown to result in the development of a transformed phenotype. In light of recent evidence demonstrating 5HT<sub>2C</sub> receptor constitutive activity, the contribution of agonist independent receptor activation to transformation of NIH 3T3 fibroblasts transfected with 5HT<sub>2C</sub> receptor cDNA was examined. [3H]thymidine incorporation was used as a measure of cell growth in serum starved NIH 3T3 fibroblasts transfected with 5HT<sub>2C</sub> receptor cDNA. Three classes of 5HT<sub>2C</sub> receptor ligands were distinguished. In transfected, but not nontransfected, fibroblasts basal levels of [3H]thymidine incorporation were increased by agonists, decreased by inverse agonists and minimally affected by neutral antagonists. The effects of agonists and inverse agonists were blocked by a neutral antagonist. Pharmacological characterization of agonist-mediated increases in [3H]thymidine incorporation was consistent with properties of the 5HT<sub>2C</sub> receptor. In addition, the rank order of potency of inverse agonists to decrease basal [3H]thymidine incorporation was reciprocally modulated by 5HT<sub>2C</sub> receptor agonists and inverse agonists. These data suggest that constitutively active 5HT<sub>2C</sub> receptors stimulate cell division and may contribute to the development of a transformed phenotype (Supported by the National Institute of Mental Health, MH 30407).

475.5
5-HT<sub>2C</sub> RECEPTOR ACTIVATION INCREASES ARACHIDONIC ACID RELEASE: W.P. Clarke*1, K. A. Berg*2 and S. Mayanagi*3
Departments of Pharmacology1 and Anesthesiology, Mount Sinai School of Medicine, CUNY, New York, NY 10012
The 5-HT<sub>2C</sub> (formerly 5-HT<sub>2A</sub>) receptor is a member of the 5-HT receptor family which have been shown to be coupled to phospholipase C (PLC)-mediated phosphatidylinositol (PI) lipid hydrolysis. Recently it has been shown that some PLC-coupled receptors can also activate phospholipase A2 (PLA<sub>2</sub>) to liberate arachidonic acid (AA). We have investigated the effects of 5-HT<sub>2C</sub>-receptor agonists on the PLC-PLA<sub>2</sub>-AA pathway. CHO cells were transfected with human 5-HT<sub>2C</sub> cDNA and a stable line expressing 300,000 protein was selected for study. Cells were incubated for 4 h at 37°C with 0.1 μM of [1<sup>4</sup>C]-AA. After washing, 5-HT<sub>2C</sub>-agonist-induced release of [1<sup>4</sup>C]-AA was measured at various time points (3-50 min). 5-HT (EC<sub>50</sub> 28 nM), DOPA (EC<sub>50</sub> 100 nM) and quipazine (EC<sub>50</sub> 1.2 μM) each increased AA release by 43% and 32%, respectively. The EC<sub>50</sub> values for each of these agonists for PI hydrolysis were similar to those for AA release (26 ± 13 nM and 1.5 μM for 5-HT, DOPA and quipazine, respectively). 5-HT<sub>2C</sub>-mediated AA release desensitized by 60% after 15 minutes treatment with 10μM 5-HT, whereas ATP-mediated AA release was unaffected. 5-HT<sub>2C</sub>-mediated AA release was insensitive to treatment with pertussis toxin. Both 5-HT and medium-induced AA release was reduced (90%) in the absence of extracellular Ca<sup>2+</sup>. Inhibitors of PLC (U-73122 and ET-18-OCH<sub>3</sub>), at concentrations that reduced PI hydrolysis by greater than 90%, had little or no effect on 5-HT<sub>2C</sub>-agonist mediated AA release. However the PLA<sub>2</sub>-inhibitor nap cyancine completely blocked 5-HT<sub>2C</sub>-mediated AA release but did not affect 5-HT-mediated PI hydrolysis. These results suggest that 5-HT<sub>2C</sub>-receptors couple to the PLA-2 AA pathway in CHO cells. (Supported by UPHS grants GM 34825, DA06620, MH48125, HD26437).

475.6
5-HT<sub>1B</sub>/1D receptor function via arachidonic acid metabolism. K. A. Berg1, S. Mayanagi2, and W. P. Clarke1
Departments of Anesthesiology1 and Pharmacology2, Mount Sinai School of Medicine, CUNY, NY 10012
5-HT<sub>1B</sub>/1D receptor-mediated inhibition of forskolin-stimulated Ca<sup>2+</sup> accumulation (FSAC) is inhibited by activation of transfected human 5-HT<sub>2C</sub> but not 5-HT<sub>2A</sub>, receptors in CHO cells (Berg et al., Mol. Pharmacol., in press). We have investigated the role of phospholipase A2 (PLA<sub>2</sub>)-mediated arachidonic acid (AA) metabolism as a mediator of the effect of 5-HT<sub>2C</sub> receptor activation.
In CHO cells stably expressing 5-HT<sub>2C</sub>-receptors (200 fmol/mg protein), 5-HT<sub>2C</sub>-agonists (such as DO1) increase AA release via PLA<sub>2</sub>-dependent mechanisms (see Clarke et al., this meeting). As reported previously, activation of 5-HT<sub>2C</sub>-receptors with DOI (1 μM) abolished 5-carboxamidotryptamine (5-CT, 5-mg/ml)-induced inhibition of FSAC. This effect of DOI was blocked following incubation with the PLA<sub>2</sub> inhibitor napycine (100 μM). The inhibition of FSAC (mean ± SE, n=5) was as follows: 55 ± 5% for 5-CT alone vs. 9 ± 7% for 5-CT + DOI, in the presence of napycine, 58 ± 6% for 5-CT alone vs. 61 ± 8% for 5-CT + DOI. Furthermore, the cyclooxygenase inhibitor indomethacin (2 μM) also blocked the DOI-mediated reduction of 5-CT inhibition of FSAC (73%±3% vs. 68%±4% for 5-CT and 5-CT + DOI respectively, n=5). Activation of PLA<sub>2</sub> by melittin (2.5 μg/ml) as well as activation of naturally expressed ATP-receptors abolished 5-CT-mediated inhibition of FSAC and napycine blocked these effects. These data suggest that PLA<sub>2</sub>-AA release mediates the 5-HT<sub>2C</sub>-receptor regulation of the 5-HT<sub>1B</sub>/1D receptor pathway in CHO cells. (Supported by UPHS grants GM 34825, DA06620, MH48125, HD26437).
PROTEIN KINASE C (PKC) INHIBITORS ENHANCE 5-HT ACTIVATION OF INTERNEURONS IN RAT PERFORM CORTEX MEDIATED BY THE 5-HT5A RECEPTOR. D. L. Mares and G. K. Azghani. Dept. of Psychiatry and Pharmacology, Yale School of Medicine, New Haven, CT 06520-

The excitation of interneurons in rat perform cortex is known to be mediated via stimulation of 5-HT5A receptors. Since activation of the phosphodiesterase (PDE) second messenger by 5-HT acting on 5-HT2A receptors leads to increased intracellular calcium, we explored the role of PKC in the 5-HT5A signal transduction mechanism by testing structurally distinct PKC inhibitors. Experiments were performed on interneurons isolated by the negative selection of layers II and III in periform cortex slices. A specific PKC inhibitor, the benzolothiazidone alkaloid dithienyromethane, increased the excitation of interneurons by 5-HT (100 nM). The isoquinolinesulfonamide kinase inhibitors H7 and HA 1004 (100 nM) were also tested. H7 application robustly enhanced the excitation of interneurons by 5-HT. In contrast, H8 application only weakly enhanced the excitation of interneurons by 5-HT (100 nM) and HA 1004 had no effect. None of these PKC inhibitors altered the excitation of interneurons by NE (100 nM). The rank order potency of these isoquinolinesulfonamides is in agreement with the rank order potency of these compounds for inhibition of PKC, but not for PDE, PKG, or PLC.

Based on these results we propose that: 1) The activation of PKC by 5-HT rapidly desensitizes the 5-HT5A-mediated excitation; 2) PKC inhibitors prevent this rapid desensitization, unmasking the effect of the 5-HT5A receptor response. Thus, activation of PKC, rather than mediating the excitation action of 5-HT at the 5-HT5A receptor, appears to have a negative feedback role.

SEROTONIN RECEPTORS: MOLECULAR BIOLOGY

SITE-DIRECTED MUTAGENESIS OF THE 5-HT3 RECEPTOR: IDENTIFICATION OF RESIDUES INVOLVED IN GATING AND BLOCKING RECEPTOR ACTIVATION. N. J. Stocks, P. V. Vardy, P. Colledge, J. A. Bignall, P. G. Rose, and B. G. Dover. Yale University School of Medicine, New Haven, CT 06510.

Throughout the central and peripheral nervous system multiple 5-HT receptor subtypes are expressed to the superfamily of G protein-coupled receptors.

The molecular processes by which agonists and antagonists bind to 5-HT receptors are currently unknown.

In order to investigate the molecular basis for ligand binding to the 5-HT3 receptor we have constructed a site-directed mutagenesis model for the receptor using the atomic coordinates of the structurally related bacteriorhodopsin as a template. Based on our model and data from other studies we have chosen six residues, proposed to be involved in 5-HT binding, for site-directed mutagenesis studies. First, we investigated the role of two aromatic residues (Phe328 and Phe329) in transmembrane domain IV, that are conserved among all G protein-coupled 5-HT receptors. To investigate the role of these aromatic residues in ligand binding and receptor activation we have substituted these residues for alanine. Additional site-directed mutations were performed for two serine residues in transmembrane domain IV and six serine residues in transmembrane domain V. Both sites in transmembrane domain IV are conserved among all members of the 5-HT receptor family, with the exception of the 5-HT1A receptor in which Ser 187 is replaced by a Gly, and in the recently cloned 5-HT2F receptor in which this residue is replaced by an Ala. The Ser in transmembrane domain V is present in all members of the 5-HT5A-like (5-HT2A, 5-HT2C, 5-HT1B) receptors but not in 5-HT1D-like receptors. In our model, these three Ser residues are in a position that they may interact with 5-HT. Finally, we investigated the role of an acidic residue in transmembrane domain IV, which is conserved only in cationic amine receptors and which is postulated to interact with the positively charged amine group of 5-HT. Mutations and wild-type receptors have stably been transfected into NG108 cells and are currently pharmacologically characterized. Initial experiments indicate that some of the mutations affect differentially agonist binding as compared to antagonist binding.
476.3 AN AROMATIC RESIDUE AT POSITION 340 IS ESSENTIAL FOR ERGOT BUT NOT ERGOPEPTIDE BINDING TO THE 5-HT2A RECEPTOR. MS Choudhary**, A.Ulner, RB Westkaerper, RA Glennon, and BL Roth*. Department of Psychiatry, Case Western Reserve University Medical School, Cleveland, OH.

We have investigated the molecular requirements for drug binding to serotonin2a (5-HT2a) receptors and previously discovered a single, highly conserved, aromatic residue, Phe340, which is essential for ergot binding to the 5-HT2a receptor. To clarify the details of ergot- receptor interactions, an additional 8 mutations were constructed and expressed in COS-7 cells. The effects of these point mutations on the binding of 14 different ergot and ergopeptide derivatives were then determined. Mutations at position 340 in which the aromatic residue was substituted for an aromatic residue (e.g. F340L, F340A) greatly diminished ergot (100-1000 fold) decrease in Kd) but not ergopeptide (<10 fold decrease in Kd) affinities. By contrast, mutations at position 340 in which an aromatic residue was conserved (e.g. F340Y) did not affectably affect or ergopeptide affinities. Mutations at position 339, in general, had either no effect (F339A, F339L) or modest effects (F339V) on ergot and ergopeptide Kd's. The F125 mutations had little effect on ergot and ergopeptide binding. Two molecular models (one in which ergots and ergopeptides bind to different residues, another in which they utilize similar residues) were evaluated using three-dimensional computer-graphic models of 5-HT2A receptor-ligand interactions. The results suggest that an aromatic residue at position 340, but not 339, is essential for ergot but not ergopeptide binding to the 5-HT2A receptor.

476.4 A SMALL REGION IN THE SIXTH AND SEVENTH TRANSMEMBRANE DOMAINS OF THE HUMAN 5-HT1D* AND 5-HT1E* RECEPTORS DETERMINES 5-CARBOXAMIDOTRYPTAMINE AFFINITY. E.M. Parker*, D.A. Shapiro, and R.A. Gilbert. Departments of Psychobiological and Molecular, Chemistry, and Biological Sciences, California Institute of Technology, and Departments of Psychiatry, Case Western Reserve University, Cleveland, OH.

We have shown that the human 5-HT1D* receptor has high affinity for 5-c-arboxamidotryptamine (5-CAT) whereas the 5-HT1E* receptor has low affinity for this compound. In order to ascertain the structural basis for this difference, a series of chimeric 5-HT1D*5-HT1E* receptors was constructed. Using radioligand binding experiments showed that a stretch of 57 amino acids extending from the beginning of the sixth to the middle of the seventh transmembrane domain of these two 5-HT receptors was largely responsible for determining 5-CAT affinity. All the chimeric receptors had high affinity for 5-HT and yohimbine. Supporting the results of this study, the gross three dimensional structure of the chimeric receptors was not altered. A mutant 5-HT1D* receptor in which two residues in the sixth transmembrane domain were changed to the corresponding residues in the 5-HT1E* receptor (E333G334 converted to K333G334) showed markedly lower affinity for 5-CAT than did the wild type 5-HT1D* receptor but retained high affinity for 5-HT and yohimbine. Neither single mutation alone (i.e. E333 converted to K333 or G334 converted to E334) was sufficient to alter 5-CAT affinity. These data suggest that two amino acids in the sixth transmembrane domain largely determine the affinity of the 5-HT1D* and 5-HT1E* receptors for 5-CAT.

Serotonin, a modulatory neurotransmitter, acts on different receptors to elicit a variety of post synaptic responses. In particular, serotonin can elicit short-term and long-term facilitation of the monosynaptic connections between the sensory and motor neurons of the Aplysia gill-withdrawal reflex. The short-term actions of 5-HT likely involve activation of at least two types of 5-HT receptors, one coupled to cAMP and PKA and those coupled to PKC. To analyze this mechanism on the molecular level, we isolated two 5-HT receptor genes from Aplysia, Ap5HT2A and Ap5HT2B and one encoding an octopamine receptor, ApOctR. Both 5-HT receptors contain characteristic seven hydrophobic regions. The amino acid sequence in this putative transmembrane region is homologous to those of other serotonin receptors. The protein homology between the two receptors is 80%. Homology with mammalian 5-HT1A, 5-HT1C, 5-HT2, 5-HT3 receptors Drasaphila 5-HT receptor Drs1, Drs2b, Lynemaus 5-HT receptor Lym1, are 37%, 39%, 41%, 38%, 35% and 32% respectively. When expressed in mammalian cells both Ap5HT2A and Ap5HT2B stimulate phosphoinositol turnover by phospholipase C activation and mobilize intracellular Ca++ . Both are expressed in the Aplysia CNS. To further analyze the role of CAMP we also isolated an octopamine receptor that stimulates adenyl cyclase to increase cAMP over 500-fold in mammalian cultured cells. Since the sensory neurons of Aplysia lack octopamine receptors, transfection of this receptor into the sensory neurons should allow us to study the short- and long-term consequences of the selective activation of the CAMP pathway.

We isolated a mouse brain cDNA library and a human genomic library the genes encoding the 5-HT5A and 5-HT5B serotonin receptors. Amino acid sequence comparisons revealed that the human 5-HT5A receptor is 85% homologous to the mouse 5-HT5A receptor. We only found one human 5-HT5B pseudogene raising the possibility that there is no functional homolog of the HSA receptor. The mouse 5-HT5A receptor was expressed in Cos-7 cells, the mouse 5-HT5A receptor displayed (Kd=0.84 nM) and low affinity (Kd=13 nM) binding sites for the radiolabelled ligands [3H]10B-222 and [3H]10B-223. Both sites were insensitive to GTPyNop suggesting that the 5-HT5A receptor is not coupled to G protons in Cos-7 cells. The pharmacological profile of the 5-HT5A receptor is the profile of a G protein, which was altered on binding PKNop in Cos-7 and NIH 3T3 cells expressing the receptor. We did not detect any change in adenylate cyclase or phospholipase activity in response to serotonin. We are currently analyzing the possible coupling of 5-HT5A receptors to ion channels in a variety of neuronal cell lines. In order to study the function of the 5-HT5A receptor we are using gene targeting techniques to generate transgenic mice lacking this receptor.

The 5-HT6 receptor, one of three known subtypes of mammalian G-coupled serotonergic receptors, has garnered interest for its high affinity for the atypical neuroleptic clozapine. We previously reported the cloning of the rat 5-HT6 receptor and now report the isolation of the corresponding human gene and its chromosomal localization.

The human 5-HT6 receptor is a 440 amino acid polypeptide that is 96% identical to its rat homologue within transmembrane regions. The nucleic acid sequences of the open reading frames from the two species are approximately 84% identical. Comparison of genomic and cDNA sequences reveals that the 5-HT6 gene is approximately 3 kb intron occurs after base 714 and a 190 bp intron occurs after base 873. Using hybridization to a somatic cell hybrid panel, the 5-HT6 receptor gene was localized to 1p35-pter. This localization indicates that the 5-HT6 and the 5-HT1D loci may be closely linked. Such clustering has not been previously found within the serotonin receptor family. We have tentatively identified an 1p35-pter polymorphism within a 5-HT6 coding region, which may be informative in linkage studies examining the role of this receptor in various human diseases.

**SEROTONIN IA RECEPTOR BINDING IN THE ENTORHINAL CORTEX IN SCHIZOPHRENIA AND SUICIDE.** B.C. Ohlman, H. M. Hermann, C.E. Squires, D.J. Saboisa* and J.E. Kleinman.

Clinical Brain Disorders Branch, NIMH, Neuroscience Center at St. Elizabeth's Hospital, 2700 M.L. King Ave S.E., Washington, DC 20032.

Over the years, there has been a growing interest in the role of the entorhinal cortex in various neuropsychiatric disorders, such as Alzheimer's disease and schizophrenia. In this study we examined 5HT1A receptor density in post-mortem entorhinal cortex, using quantitative autoradiography comparing patients with schizophrenia to normal controls and non-schizophrenic neuroleptic-treated psychiatric patients. Blocked sections of fresh frozen brain containing the entorhinal region were obtained and compared. Quantitative autoradiography of 5HT1A receptors was performed using [3H]8-OH-DPAT. Non-specific binding was determined by incubating consecutive sections in the presence of 10μM 8-OH-DPAT. Preliminary analysis of the autoradiograms using computerized image analysis did not reveal any statistically significant differences between patients with schizophrenia and other groups, confirming a prior study of schizophrenics and suicides of this brain region.

**477.3**

The relationship between the expression of 5-HT1A receptors and the level of receptor mRNA was examined in coronal sections of brain from Sprague-Dawley rats. Sections were labelled with [125I]-8-OH-PHAT to visualize 5-HT1A receptors. Adjacent sections were labelled with a 183 base 5S labelled ribogene complementary to rat 5-HT1A. Preliminary experiments demonstrated that [125I]-8-OH-PHAT selectively labels 5-HT1A receptors. In the hippocampus and cortex, the density of receptors decreased significantly between days 3 and 21. After day 21, receptor density increased in CA1, plateaued in CA3 and decreased in cortex. The pattern of mRNA expression paralleled the expression of receptors in each region between days 3 and 21. However, mRNA and receptor expression diverged in all of these regions between days 21 and 60. In contrast, the density of receptors in the thalamus increased between days 3 and 14 and then declined. The density of receptors in the cerebellar cortex declined steadily to almost undetectable levels between days 3 and 60. The pattern of mRNA expression paralleled receptor expression in both of these regions at every age. These results suggest that 5-HT1A receptor expression is directly related to mRNA levels during development. However, it is likely that additional mechanisms regulate receptor expression in the mature brain. (Supported by USPHS MH 43821 and MH-48125)

**477.4**

Corticosterone (CORT) appears to have a role in regulating the 5-HT system. Stress, resulting in increased circulating CORT, acutely facilitates 5-HT turnover. Studies in adult rats have shown that following acute adrenalectomy (ADX) 5-HT1A receptor density is elevated. Cort replacement at the time of ADX maintains the normal levels of receptor density and hippocampal 5-HT1A receptor mRNA expression. In the neonatal rat between post-natal day (pnd) 4-14 CORT levels are normally low and non-circadian. The adrenal is hypersensitive to endogenous and exogenous ACTH. This period is designated as the stress-hyporesponsive period (SHRP). In these experiments we studied the role of CORT on the 5-HT1A receptor during development in order to determine the role of CORT at the 5-HT system. The 5-HT1A receptor density in the rat hippocampus and brain stem was examined at pnd 6 (in the SHRP) and pnd 21 by in vitro binding studies using the selective 5-HT1A agonist [3H]8-OH-DPAT. These studies showed that administration of corticosterone (CORT) reduced 5-HT1A receptor occupancy in the hippocampus and brain stem. In contrast, the 5-HT1A receptor density in the hippocampus and brain stem was examined at pnd 6 (in the SHRP) and pnd 21 by in vitro binding studies using the selective 5-HT1A agonist [3H]8-OH-DPAT. These studies showed that administration of corticosterone (CORT) reduced 5-HT1A receptor occupancy in the hippocampus and brain stem. In contrast, the 5-HT1A receptor density in the hippocampus and brain stem was examined at pnd 6 (in the SHRP) and pnd 21 by in vitro binding studies using the selective 5-HT1A agonist [3H]8-OH-DPAT. These studies showed that administration of corticosterone (CORT) reduced 5-HT1A receptor occupancy in the hippocampus and brain stem.

CHRONIC ESTROGEN TREATMENT OF FEMALE RATS ENHANCES 5-HT1A-MEDIATED ADAPTED AMPLIFICATION IN HIPPOCAMPAL SLICES. Y. Chen*, K.A. Berg and W. P. Clarke. Departments of Pharmacology and Anesthesiology, Mount Sinai School of Medicine, CUNY, New York, NY 10029.

Female sex hormones and 5-HT1A receptor systems have been implicated in the pathophysiology of affective disorders such as anxiety and depression. Recently, we have shown that chronic treatment of ovariectomized (OVX) female rats with estrogens (E) enhances 5-HT1A-mediated electrophysiological responses in rat hippocampal slices. E-treatment also enhances the 5-HT1A receptor binding of adenylate cyclase in hippocampal membranes, but to a much smaller degree. To study effects of E on both responses coupled to the 5-HT1A receptor in hippocampus we have developed a methodology to assess adenylyl cyclase activity in rat hippocampal slices that are maintained under similar conditions as for electrophysiological recordings. O VX female rats received sc implants of either cholesterol (controls) or 10% 17b-estradiol in cholesterol. Treatment of females with 5-days E (1 mg/kg i.p.) resulted in a significant increase in 5-HT1A receptor-binding of 2-3 fold. In contrast, 5-HT1A-mediated inhibition of forskolin-stimulated AMP-activated (F5CA) was not altered after 1 day E treatment in vivo nor after 30 min or 2 hr treatment with 10 nm E in vitro. In preliminary experiments we have begun to test the hypothesis that the effect of E on 5-HT1A-mediated signal transduction may be mediated by inhibition of protein kinase C (PKC), which can desensitize the 5-HT1A receptor system. 5-day E treatment increased maximal PKC activity measured in vitro in membrane and cytosol fractions of hippocampus. Western blot analysis revealed small increases in the quantity of PKC in hippocampal cytosol and membrane fractions and a slight decrease in PKC in hippocampal membranes in response to E treatment. Treatment of hippocampal slices from OVX rats with the PKC inhibitor staurosporine for 90 min did not mimic E's effect on 5-HT1A mediated signal transduction. More work is needed to evaluate a role for PKC as a mediator of the E effect on 5-HT1A-mediated signal transduction. (Supported by HD46347 and MH48415).

CHRONIC TREATMENT WITH 5-HT1A RECEPTOR AGONISTS INCREASES 5-HT1A RECEPTOR BINDING IN HIPPOCAMPAL AND CORPUS CALLOSUM SLICES. J. Adrian, J. Rosay and C. Mangenot. Departments of Pharmacology and Psychiatry, University of Montreal, Montreal, QC H3G 1A4.

To determine the effects of chronic treatment with 5-HT1A receptor agonists on binding of 5-HT1A receptors, homogenates of rat hippocampal and corpus callosum slices were incubated in the presence of [3H]-5-HT1A receptor antagonist and increasing concentrations of unlabelled 5-HT1A agonists. The following agonists were used: 8-OH-DPAT, mCPP, buspirone, clozapine, G177, 8-cyclopentyl-1,3-dipropyladenine, a 5-HT2 receptor agonist. The results showed that only 8-OH-DPAT increased 5-HT1A receptor binding in both hippocampal and corpus callosum slices. At 10 nM, 8-OH-DPAT increased 5-HT1A receptor binding by 20% in hippocampus and by 30% in corpus callosum. In hippocampus, the highest increase was observed with 100 nM 8-OH-DPAT. The parallel increase in the binding of 5-HT1A receptor antagonist, [3H]-5-HT1A receptor agonist and 8-OH-DPAT suggests that the increase in 5-HT1A receptor binding is due to a specific increase in the number of 5-HT1A receptors. The specificity of the increase in 5-HT1A receptor binding was further supported by the lack of effect of other 5-HT2 receptor agonists. These results suggest that chronic treatment with 5-HT1A receptor agonists may increase the number of 5-HT1A receptors in hippocampus and corpus callosum and may contribute to the pathogenesis of schizophrenia.

GRECC, SVAMC, and the Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98108.

The 5-HT1A and 5-HT1B receptors were initially described as presynaptic autoreceptors which regulate the release of serotonin. However, these receptors have also been found to regulate the release of several other neurotransmitters in various regions of the rat brain. In this study we investigated the effects of chemical lesioning of serotonergic systems on the levels of mRNA expression in the presynaptic 5-HT1A and 5-HT2B receptors.

5-HT1A mRNA expression (5,7-DHT) or vehicle was infused sequentially into the fourth and lateral ventricles using standard protocols. Serotonergic neurons were identified using 5,7-DHT autoradiography. The mRNA expression levels did not appear to be altered by the 5,7-DHT lesions. In the stratum and CA1 regions of the hippocampus, 5-HT1A mRNA levels did not appear to be altered. However, there was a greater than two-fold increase in hybridization signal density detected for both receptor mRNAs in the dorsal raphe, a major source of serotonergic projections to the forebrain. The increase in mRNA levels detected in the dorsal raphe may reflect spreading of new axonal processes and increased synthesis of axonal proteins.

These results suggest that these receptors are differentially regulated when expressed in presynaptic vs. postsynaptic neurons, and that the postsynaptic receptor mRNA levels can be relatively insensitive to decreases in endogenous ligand concentration.

5-HT1A AND 5-HT1B SEROTONERGIC RECEPTORS MEDIATE HYPERTHERMIA FOLLOWING LONG-TERM TREATMENT WITH 5-HT2A AND 5-HT2C RECEPTOR ANTAGONISTS IN RATS: Pascal Marcel-Pomietto, Chachiquen S. Aakahl, James Tollever*, and Dennis J. Murphy. Lab of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

We have recently demonstrated that hyperthermia induced by (1) 1-2((5-dimethylamino-4-iodophenyl)-2-aminopropane (DOI) and (2) 5,7-dihydroxytryptamine (5,7-DHT) or vehicle was infused sequentially into the fourth and lateral ventricles using standard protocols. Serotonergic neurons were identified using 5,7-DHT autoradiography. The mRNA expression levels did not appear to be altered by the 5,7-DHT lesions. In the stratum and CA1 regions of the hippocampus, 5-HT1A mRNA levels did not appear to be altered. However, there was a greater than two-fold increase in hybridization signal density detected for both receptor mRNAs in the dorsal raphe, a major source of serotonergic projections to the forebrain. The increase in mRNA levels detected in the dorsal raphe may reflect spreading of new axonal processes and increased synthesis of axonal proteins.

We have recently demonstrated that hyperthermia induced by (1) 1-2((5-dimethylamino-4-iodophenyl)-2-aminopropane (DOI) and (2) 5,7-dihydroxytryptamine (5,7-DHT) or vehicle was infused sequentially into the fourth and lateral ventricles using standard protocols. The increase in mRNA levels detected in the dorsal raphe may reflect spreading of new axonal processes and increased synthesis of axonal proteins.

5-HT1A and 5-HT1B receptors are unique among autoreceptors coupled to guanine nucleotide-binding proteins in that chronic treatment in vivo with agonists as well as antagonists decreases receptor density. The decrease in receptor density is thought to be related to down-regulation of the serotonin receptor, the ability of agonists and antagonists to alter receptor density was examined in three heterologous expression systems transfected NIH 3T3 cells with a cDNA for the transfected Madin-Darby Canine Kidney and transfected AT-20 cells. All three transfected cell lines exhibited pharmacological properties consistent with that predicted for cells expressing the serotonin receptor. However, the three cDNAs cloned from different cell lines and transfected into NIH 3T3 cells had different receptor regulation properties after treatment with drugs acting at the serotonin receptor. In transfected NIH 3T3 cells, neither agonist nor antagonist treatment altered receptor density. Treatment with agonist as well as antagonist led to up-regulation of the serotonin receptor in transfected Madin-Darby Canine Kidney cells. In transfected AT-20 cells, treatment with agonist led to receptor down-regulation, whereas antagonist treatment increased receptor density. Thus, the cellular background in which the serotonin receptor is expressed appears to determine the regulation properties of the receptor.

MOLECULAR MECHANISM OF AGONIST-INDUCED REGULATION OF THE RAT 5-HT2 RECEPTOR. A.C. Chen,* B.D. Ciocanelo, Nancy Ptzinker Lab, Dept. of Psychiatry, Stanford University, Stanford, CA 94305.

The rat serotonin 2 (5-HT2) receptor is expressed in a wide variety of neuronal and non-neuronal tissues. Interestingly, the regulation of the 5-HT2 receptor in response to agonist exposure differs in the various cell types. In primary cultures of rat uterine myocytes, the 5-HT2 receptor is involved in the regulation of collagenase expression; exposure of the cultures to 5-HT2 agonists results in the up-regulation of both the 5-HT2 receptor and collagenase. We present data demonstrating that the agonist-induced regulation of the 5-HT2 receptor is mediated by protein kinase C (PKC) and results in an increase in 5-HT2 mRNA. Furthermore, this up-regulation by agonists (and PMA) is blocked in the presence of PKC inhibitors such as staurosporine and chelerythrine. Experiments addressing whether this regulation is at the transcriptional or post-transcriptional level are currently underway and the results will be presented. In addition, we have recently described the existence of a gene coding for a possible receptor subunit. The cloning and characterization of promoter elements required for expression of the receptor gene in different cell types. Promoter deletion plasmids will be utilized to define the cis-sequences required for affecting the agonist-induced increases in 5-HT2 mRNA levels.

DOWN-REGULATED CORTICAL 5HT2KETANSERIN BINDING IN ANOREXIC MUTANT MICE EXPRESSING SEROTONERGIC HYPERINNervation. E.S. Camp*, N.M. Tim, T.H. Lab and L.H. Sop, Burke Medical Research Institute and Bourne Laboratory, Cornell University Medical College, White Plains, NY 10605, and Neuropsychology Program, Queens College, CUNY, Flushing, NY 11367.

The murine recessive anorexia mutation anorexia (anore) is characterized by pre-weaning weight loss resulting in death at about 21 days. Weight differences can be seen as early as post-natal day (PD) 6, and by PD 16 mutants (anore) can weigh as little as 30% of normal littersmates. Anorex mice display dysfunctions in ingestive and motor behaviors that are consistent with defects in the central serotonergic systems. Previously, it was demonstrated that the anore mutation is associated with profound serotonergic hyperinnervation in frontal cortex and olfactory areas. We now report that in 20-day-old anorex mice, specific 5HT2Ketanserin binding in the frontal cortex is reduced in comparison with normal littersmates. In vitro autoradiographic binding methods and computerized image analysis were employed. Binding parameters were determined using nonlinear regression assuming a single-site model. Differences were assessed using t-tests (mice per group, *p < 0.02).

Kd (nM) Bmax (fmol/mg)
Normal 12 ± 3 145 ± 15.0
Mutant 7 ± 1.5 71 ± 9.3 *

Although Kds were slightly higher than would be predicted, the location of 5HT2Ketanserin binding sites in the frontal cortex strongly suggests that binding is to 5HT2 receptors. There were 51% fewer receptors in the frontal cortex of the mutant mice compared to their normal littermates. Since serotonin hyperinnervation is a key feature of the anore mutation, the reduced receptor number most likely represents down-regulation of post-synaptic 5HT2 receptors in response to high synaptic levels of serotonin.

DIFFERENTIAL REGULATION OF SEROTONIN 5-HT1A AND 5-HT1B RECEPTORS AFTER CHRONIC TREATMENT WITH CLOZAPINE, CHLORPROMAZINE AND SOME NOVEL PUTATIVE ATYPIcal ANTIPSYCHOTIC DRUGS. M. Kuppaamaki, E. P. Päivimäki, E. Syvälahti and J. Hieta*, Dept. of Pharmacology, University of Turku, FIN-20520 Turku, Finland.

Previous studies have suggested that 5-HT1A and 5-HT1B receptors may be important for the atypical effects of clozapine. We have used quantitative autoradiography to study the number of 5-HT1A and 5-HT1B receptor binding sites after chronic treatment (14 days, s.c. injections once a day) with saline (SAL, 1 ml/kg), clozapine (CLOZ, 25 mg/kg), chlorpromazine (CPZ, 15 mg/kg), ORG 5222 (ORG, 0.1 mg/kg), risperidone (RIS, 0.3 mg/kg), and amperozide (AMP, 5 mg/kg). Receptor binding was measured 68h after the last injections.

In the doses used, CLOZ, CPZ, and ORG decreased the frontal cortical 5-HT1A receptor binding of 5HT1Ketanserin and 1H[3H]DOB by 40-60%, AMP also significantly decreased 5-HT1B receptor 5HT1Ketanserin binding by 30%, whereas RIS did not affect 5-HT1B receptor binding. In contrast to 5-HT1A receptors, only CLOZ decreased significantly (by about 50%) the 5-HT1B receptor 5HT1Ketanserin and 1H[3H]DOB binding in the choroid plexus. For comparison, we also determined the number of striatal D2 and D3 receptor binding sites with [3H]spiperone and [3H]spiroperone, respectively. CPZ was the only drug to significantly upregulate D2 receptor binding sites. None of the drugs affected D3 receptor binding to any extent. In conclusion, this study suggests that chronic treatment with CLOZ, CPZ, ORG, RIS and AMP differentially regulate 5-HT1A and 5-HT1B receptors.

477.22
REGULATION OF THE 5-HT6 SEROTONIN RECEPTOR IN STABLY TRANSFECTED 293 CELLS. Steven J. Marx*, Frederick J. Montminy, Jr. and David R. Smith, Molecular Neuropharmacology Section, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892 and Hoffman-LaRoche, AG, Basel, Switzerland.

We investigated the regulatory properties of the cloned rat 5-HT6 serotonin receptor in stably transfected HEK-293 cells. The cell line was characterized using the radioligand [3H]-lysergic acid diethylamide ([3H]-LSD) and exhibited Kd and Bmax values of approximately 5 nM and 1 pmol/mg protein, respectively. Exposure to 5hydroxytryptamine (5-HT) resulted in a dose-dependent stimulation of adenyl cyclase activity in both intact cell and membrane preparations. Stimulation of cAMP accumulation by 5-HT was maximal at 100 μM with an EC50 of 1.5 μM. Pretreatment of the cells with 100 μM 5-HT for 20 hours resulted in a sixty percent decrease in the maximal response for cAMP accumulation with no appreciable change in the EC50. This effect was time-dependent, reaching maximal levels at 8 hours with a half-life of 1 hour. The 5-HT pretreatment appeared to have no effect on the maximum binding capacity of 5-HT-LSD nor the Kd value. Treatment of the cells with various intracellular activators of protein kinases had mixed effects on 5-HT6 receptor function. Exposure to 1 μM phorbol-12-myristate-13-acetate (PMA), an activator of protein kinase C, for 20 hours appeared to have no effect on receptor function or binding capacity. On the other hand, treatment with 1 mM 8-(4-chlorophenylthio)-cAMP (8-CPT-cAMP), an activator of cAMP-dependent kinase protein, resulted in a 55% reduction in the maximal 5-HT cAMP response with no apparent change in potency. In contrast, there was no effect on the Bmax nor the Kd as measured by [3H]-LSD binding. Overall, the data suggest that agonist-induced desensitization of the 5-HT6 serotonin receptor occurs via stimulation of cAMP-dependent protein kinase as measured by a decrease in maximal cAMP accumulation. Furthermore, there does not appear to be a concomitant agonist-induced down-regulation of the 5-HT6 receptor as detected with [3H]-LSD.
**478.1** DISTRIBUTION OF TRYPOTSYLINE HYDROXYLASE IMMUNOREACTIVE AXONS AND CELLS IN RAT MELANOTROPHES AND GLIAL-LIKE CELLS OF THE RAT PITUITARY INTERMEDIATE LOBE. B.M. Chromwell\(^{1}\) and K.A. \(^{2}\) Stricker. \(^{1}\) School of Biological Sciences, University of Missouri-Kansas City, Kansas City, MO; \(^{2}\) Department of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

The majority cell population in rat pituitary intermediate lobe (IL) is the melanotrope, a chromophobic-endothelin- and e-NOS-positive cell. Melanotrope secretion is regulated by tonic inhibition via dopaminergic axon terminals. A smaller population of glial-like cells is present in the IL, and synaptic contacts have been described between these IL axon boutons in amphibian and rat. This study utilizes image analysis methods to evaluate the anatomical relationship of tyrosine hydroxylase (TH) immunoreactive axons to cellular elements in the rat IL. Processes were fixed and VIBATOLN stained at 75 µm. Sections were incubated in anti-TH serum, processed for immunohistochemistry, and embedded in Epon. One micron serial sections were toluidine blue stained. Individual melanotropes associated with TH immunoreactive axons were identified, digitally imaged, and followed through successive sections. This process was repeated with individual glial-like cells associated with immunopositive axons. Melanotropes among other melanotropes exhibited lower numbers of TH immunoreactive boutons than those sharing cell membrane surface with glial-like cells. Morphometric measurement of all membrane surface area in single sections revealed higher densities of immunopositive axons associated with glial-like cell structural than with individual melanotropes. Using Image-1 image analysis software, three-dimensional reconstruction of individual melanotropes and glial-like cells indicate that TH immunoreactive axons were closely apposed with glial-like cell processes and followed these processes over several microns. These observations suggest interactions between dopaminergic axons and glial-like cells of the rat IL.

**478.2** GLUTAMIC ACID DECARBOXYLASE: mRNA IS EXPRESSED IN BOTH EXCITATORY AND INHIBITORY NEURONS IN CULTURED HIPPOCAMPAL NEURONS. M.A. Dichter\(^{3}\), Y. Cao, K.S. Williams, \(^{4}\) J. Eberberg. \(^{3}\) Dept of Neurology, Pharmacology, and Psychiatry, Univ. of Penn. School of Medicine and the Graduate School of Medicine, Philadelphia, PA 19104.

The recently developed procedure of single cell mRNA amplification, when coupled with the whole cell patch clamp technique, can be used to investigate the expression and distribution of mRNAs of a variety of proteins in identified cell types. The goal of the present set of experiments was to develop specific molecular "profiles" of excitatory and inhibitory neurons. It was hypothesized that the mRNA encoding glutamic acid decarboxylase (GAD), the enzyme which catalyzes the conversion of glutamic acid to GABA, would be present in detectable quantities only in neurons which utilize GABA as a neurotransmitter. Experiments were performed in low density hippocampal cultures. The whole cell patch clamp technique was used to record from monosynaptically connected pairs of neurons. The presynaptic neurons were positively identified as either excitatory or inhibitory based on the reversal potential and waveform of the evoked postsynaptic current. Excitatory neurons release neurotransmitter which activates postsynaptic glutamate receptors, whereas inhibitory neurons use GABA as a neurotransmitter. Ten neurons were identified as inhibitory and six neurons were identified as excitatory. Initials of the neuronal types were posttranscriptionally regulated. Supported by AG8990 (JE).

**478.3** COMPARISON OF GLUTAMIC ACID DECARBOXYLASE (GAD) IMMUNOREACTIVITY TO DORSOLATERAL STRIATAL (DL-DN) NEURONAL RESPONSE AND UNRESPONSIVE TO CITOCINIC AGONISTS E.M. Sveriges*\(^{3}\), W.C. McDannel and J.P. Gallaghier. \(^{1}\) Dept. of Pharm. & Toxic., \(^{2}\) Univ. of Texas Med. Prep. School, Houston, TX 77030. 

Using intracellular recording, we have previously reported that nicotine and 1,1'-methyl-4-phenylpyridazine (DMPP) hyperpolarize the majority of DLN neurons by a postsynaptic mechanism (Sveriges et al., 1986). We have now compared the morphology, electrophysiology, and GAD immunoreactivity of DMPP responsive (RES) and unresponsive (UNR) neurons.

Neuron (1,2,3), injected was injected into neurons at the end of recording sessions. After cutting the fixed tissue into 75 µm sections, neurons were visualized using the ABC method (Vector) with DAB as the chromogen. Sections containing stained neurons were processed for the GAD immunohistochemistry using a primary antibody at 1:500 (Hoshino et al., 1989) or 1:2000 (Chemicon) dilution. Vector SG was the secondary chromogen. Of the 36 neurons visualized, 18 were DMPP RES (61%). Neither membrane potential nor input resistance were significantly different between DMPP RES and UNR neurons. Furthermore, no other electrophysiological differences were observed, such as the occurrence of low threshold calcium action potentials. AHPs following single action potentials or slow ADPs following a train of action potentials. DMPP RES cells were either multi- or bipolar whereas the DMPP UNR neurons were all multipolar. While no morphological differences were apparent between multipolar DMPP RES and UNR cells, all of the DMPP UNR cells tested were GAD-negative whereas only 60% (6/10) of the DMPP RES cells were GAD-negative. In summary, DMPP UNR cells appear to be GAD-negative, multipolar neurons. Supported by DHHS 1F31 DA00472 to EMS and The Council for Tobacco Research, USA, Inc. to JPG.

The distribution of MAO-A gene products in the adult rat brain and adrenomedulla (AM) was examined by in situ hybridization and by immunocytochemistry with a polyclonal antiserum. The highest levels of MAO-A mRNA and protein expression were found in the locus ceruleus; moderate levels were detected in the serotonergic dorsal raphe nucleus (DRN), habenula, and the adrenergic neurons of the medulla oblongata; low levels were found in the substantia nigra compacta (SNc), hypothalamus, hippocampus, and the cortex. Northern blot analysis of DRN and regions confirmed this distribution. Compared to young adult rats, aged rats showed a clear increase in MAO-A mRNA in the SNc, DRN, and AM by in situ hybridization. In vitro experiments using the rat PCT cell line revealed no significant upregulation of the MAO-A gene in response to the protein kinase (A) activator, forskolin. This is in contrast to the rapid increase observed in tyrosine hydroxylase (TH) and dopamine β-hydroxylase (DBH) mRNAs. PAF-deficient phenocytomatic cell lines showed normal MAO-A mRNA levels but decreased TH and DBH levels, suggesting that the basal transcription of the MAO-A gene is not dependent on cyclic AMP. Promoter analysis of the MAO-A gene will further delineate the response to interacting elements in this important gene.

**478.5** CLONING OF A NOVEL MONOAMINE OXIDASE (MAO) cDNA FROM TROUT LIVER. K. Chen, H.-F. Wu, G. Grishbny and J.C. Shih. \(^{1}\) Dept. Mol. Pharmacol. and Toxicol., \(^{2}\) Sch. of Pharmacy, Univ. of Southern California, \(^{3}\) 1985 Zonal Avenue, Los Angeles, CA 90033.

A trout liver monoamine oxidase (MAO) cDNA was cloned by screening a cDNA library with a human MAO cDNA probe. The trout MAO cDNA encodes 499 amino acids with a molecular weight of 56.6 kDa. The deduced amino acid sequence between trout MAO and human MAO showed 79% and 71% identity respectively. Trout MAO contains the pentapeptide sequence Ser-Gly-Gly-Cys-Tyr motif in which the cofactor FAD is covalently bound. Transient expression in COS cells expressing all three mammalian MAO oxidizes both serotonin (5-HT) and 4-phenylethylamine (PEA), unlike human MAO or MAOB which oxidizes only 5-HT or PEA, respectively. The Km for 5-HT is 9.3 µM for trout MAO (180.7 µM and human MAO (119.3 µM). The Km for PEA is similar for trout MAO (4.8 µM) and human MAO (4.6 µM). When SHET was used as a substrate, similar to human MAO, the Km for this substrate was 2.7 µM and 6.6 µM for human MAO (2.7 µM and 6.6 µM). When using PEA instead of TS, results indicated that trout MAO displays substrate and inhibitor selectivities that are identical to those of human MAO and therefore represents a novel type of MAO. The structure of trout MAO will provide insights into the substrate and inhibitor selectivity of the MAOs. (Supported by NIMH grants R33 MH59983 (MERIT Award), R01 MH37020 (Research Scientist Award), K05 MH00796 and Welin Professorship).

**478.6** DYNAMICS OF SEROTONIN-DEGRADATIVE PATHWAYS IN THE BRAIN OF SOME FROGS. Naokuni Takeda*, Department of Biotechnology, COSMOS Research Institute, Satte, Saitama, 340-01, Japan.

Butofenate (BUTN) has been found in the brain of Bufo bufo japonicus (Soc. Neurosci.19,1171; Comp.Biochem.Physiol.107C,275,94). The main pathways are as follows: Serotonin - N-methyl serotonin (N-MET) - BUTN and serotonin (N-MET) - di-methyltryptamine (DM). In the brain of Rana japonica, serotonin was degraded to N-MET, but not to BUTN. The pathway to DMT was not found. By the injection of NILAMIDE into the body cavity, amounts of each monoamine were highly increased. Furthermore, N-MET was gradually degraded to BUTN, and the pathways to DMT were also detected. In Bufo, NILAMIDE was directly injected into the brain by microdialysis. The amounts of N-MET, BUTN and DMT were highly increased. The monoamine oxidase inhibitor was shown to evoke the appearance of intrinsic metabolic pathways from Serotonin to BUTN and to DMT.
478.7
LOCALIZATION OF TRANSMITTER RECEPTORS IN THE CHICK BRAIN IN RELATION TO AUDITORY IMPRINTING. B. Schnebel and K. Braun. *Federal Institute for Neurobiology, 39118 Magdeburg, FRG.*

The learning process of auditory imprinting in the domestic chick is associated with a significant, regionally restricted increase in the incorporation of radioactive deoxyglucose in the rostro-medial neostriatum/hypothalamus (MNDA), the lateral septal division (LSP) and the ventral tegmental area (VTA) of 17-day-old embryos. The MNDA is the site of initial imprinting and of the VTA the site of memory consolidation. In situ hybridization experiments revealed that the mRNA of the GABA receptor subunits A, B1, and B2 is present in the same brain regions. The results indicate that the GABAergic system plays a role in the learning process of auditory imprinting.

478.8
NMDA RECEPTOR IMMUNOSTAINING IN MOUSE DORSAL COCHLEAR NUCLEUS AND CEREBELLUM. M. Bilak, S. Bilak, and K. Mostert*. Anatomy Dept., Univ. CT Health Ctr., Farmington 06030.

With mAb to NMDAR1 (Pharmingen) light microscopic labeling (Vestacast) of cell surfaces was the same in 3 ICR adults. In cerebellum Purkinje cell body staining varied from intense to negative; dendritic staining was only on 1/2 shafts. No labeling of 3' dendritic, synaptic, or glial structures was evident in the molecular layer. Golgi II cells were stained with negative results. In the intense labeling was associated with granule cell bodies, dendrites, and rosettes. In dorsal cochlear nucleus staining of fusiiform cell bodies varied; their dendritic shafts were negative. In the molecular layer there was an intense pattern resembling that of the 3' dendrites reflecting the synaptic form of parallel fibers, as seen by synaptophycin immunostaining. Granule cells were negative. There was also staining of cartwheel, core, and giant cell bodies and dendrites. We conclude that a significant component of the NMDA receptors differs in the granule cells, inhibitory interneurons, and projection neurons of cerebellum. Also, in the cochlear nucleus, there may differ reflecting roles for NMDAR1 in the processing carried out in these different circuits. Supported by NIH grants R01DC12716, 132DC00025.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994
COMPARATIVE IMMUNOCHEMISTRY OF GLYT1 AND GLYT2 GLYCINE TRANSPORTERS IN RAT BRAIN.

1. Introduction

GLYT1 and GLYT2 are two glycinergic neurotransmitter transporters that are localized in the central nervous system (CNS). They are involved in the regulation of neuronal excitability, and their expression patterns are substantially different across different brain regions. Understanding the functional significance of these differences is crucial for elucidating the role of glycine in various neurological disorders.

2. Methods

We used immunohistochemical techniques to measure the expression of GLYT1 and GLYT2 in various brain regions. The antibodies used were raised against recombinant protein sequences specific to each transporter. The brains were harvested and cryoprotected, and then sectioned on a cryostat. Immunohistochemical staining was performed using standard protocols, and the images were acquired and analyzed using confocal microscopy.

3. Results

GLYT1 and GLYT2 are expressed throughout the CNS, with notable differences observed between different brain regions. GLYT1 is predominantly expressed in the dorsal horn of the spinal cord, while GLYT2 is more abundant in the cerebral cortex. Furthermore, GLYT2 expression is found in higher densities in specific areas such as the hippocampus and the cerebellum, possibly indicating a role in synaptic plasticity and learning.

4. Discussion

The differential expression patterns of GLYT1 and GLYT2 suggest a functional specialization within the CNS. GLYT1 might play a role in the tonic inhibition of spinal dorsal horn neurons, whereas GLYT2 could be involved in the modulation of neuronal activity in the cerebral cortex. These findings open new avenues for understanding the role of glycine in neurological disorders, such as pain and addiction.

AUTORADIOGRAPHIC DISTRIBUTION OF NICOTINIC RECEPTOR SITES Labeled with [3H]Pyridine in the HUMAN BRAIN: COMPARISON WITH MUSCARinic RECEPTORS. L. LeGates, D. Chen, C. Przyborski, and R. Lescot. Department of Neuroradiology, School of Medicine, University of Massachusetts Medical School, Worcester, MA.

The localization of central nAChRs and nicotinic receptor sites might provide insights into the organization of the cholinergic system in various brain areas. Using in vitro autoradiography, the distribution of nAChR ([3H]Pyridine, 20 nM; [3H]Hepazine, 15 nM) and M3 ([3H]AF-DX 384, 2 nM) binding sites was investigated in postmortem human brains from the frontal, temporal and occipital cortices, the basal ganglia, the thalamus, and the cerebellum.

478.20

A Volskenin lesion of striotonal neurons produces a marked decrease in mRNA expression for the m4 subtype of the muscarinic acetylcholine receptor. *M. Tissot et B.H. Ulley, UVA, Charlottesville, VA 22908 and DVMAC and Vanderbilt Univ., Nashville, TN 37212

By in situ hybridization, 3 subtypes of the muscarinic acetylcholine receptor are expressed in rat striatum, the m1 subtype in the majority of striatal neurons and the m2 subtype, a probable autoreceptor, in cholinergic interneurons which also express the m3 subtype. The m3 subtype is consistently expressed on striatal neurons which express PPE mRNA but only in a subgroup of neurons expressing PPE mRNA.

479.1

By whole cell patch clamp, somatostatin (SRIF) (0.1 μM) significantly decreased glutamate sensitivity to a pertussis toxin-dependent mechanism in neuronal cultures from foetal (E16) mouse hypothalamus after the onset of neuronal maturation (14 days in vitro). At this time, five subtypes of G-protein linked SRIF receptor have been cloned in rodent hypothalamic membranes. We recently reported that SRIF receptor are expressed in the developing hypothalamus. At 14 days in vitro, SST3 mRNA levels were twice higher than those of SST2 and SST4 while SST3 and SST5 mRNAs were not detected. By 125I-SRIF receptor radioautography, a small population of hypothalamic neurons (~10%) was endowed with binding sites that are localised on both cell bodies and axonal processes in the hypothalamus. 

479.3

This study examines the recovery of melatonin receptor expression in visual areas of chick brain following suppression by intracarotid TTX administration. Chick embryos (3 weeks old) were injected with either 6 μg TTX or salinevehicle (C), and were sacrificed at day 7 (time 0) or after 1, 3 and 7 days recovery. Brain sections were labeled with [3H]-iodomelatonin. A high density of binding sites localized in the optic tectum (1 mA). Areas ipsilateral to the TTX-injected eye were used as a control. Reductions in specific [3H]-iodomelatonin binding to TTX (time 0) were observed in the contralateral optic tract, primary optic tectum, n. basal optic root, secondary (n. triangularis) and tertiary (ecostolatum) visual areas (also see ref 3). The eye remained depressed for 2-3 days but was completely recovered following TTX. The extent of recovery correlated with the degree of pupillary reflex suppression. We conclude that expression of ML-1 melatonin receptors in chick brain visual areas is selectively modulated by the visual input. MH-42922.

479.4

We previously reported that a high density of 2-5 ml melatonin receptors in the retinoventricular layers of the chick optic tectum (stratum griseum et fibrosum superficiale, SGFS) and lower levels in the optic nerve (ON). Binding in both regions is decreased by ON transection (Brain Res. 590:252-359, 1992), which suggests transport of melatonin receptors from the ON to the retina to terminals in the SGFS. We have examined the electrophysiological effects of melatonin on retinotectal transmission in a brain slice preparation of the chick tectum. Bath application of 10-20 nM melatonin suppressed tectal field potentials by stimulation of retinal afferents at the level of the ON or stratum opticum. Alterations in the presynaptic components of the field potential isolated in the retinotectal preparation in the ON of a presynaptic site of action for melatonin. We have also found that in vivo intracarotid injections of tetrodotoxin (TTX, 6 μg), which blocks the electrical activity of the retinal ganglion cells, decreases 2-5 ml melatonin binding in the ON and optic tectum to a similar extent as that seen following transection. TTX (in one eye of 3 week-old chicks, every 3 days for 7 days) decreased binding in the contralateral ON (25%), SGFS (20%) and ipsilateral ON (18%) and layers: 58%, inner layers: 38%) and stratum griseum centrale (34%). Binding in these areas recovered to control levels by 3-7 days following cessation of the TTX treatment. This suggests that expression of melatonin receptors in the retinotectal pathway, including presynaptic receptors which modulate visual input, is regulated by the activity in the pathway. (Supported by NS 24560 and EY 06860 to HJG and MH-42922 to MLD.)

DOPAMINE RECEPTORS ARE ELEVATED IN SCHIZOPHRENIA AND ALZHEIMER'S (AD) CASES

The binding of \({}^{3}H\)-7-OH-DA (PIPA; 0.2 nM, or 0.25 nM) to the ligand that binds selectively to D2 dopamine receptors, was analyzed in sections of human brain from AD cases and control subjects. The binding varied from 4 to 8 fmol/100 mg protein in different striatal areas, which is approximately 5-7 times lower than that of D2 receptors. The highest concentration of D2 receptors was observed in the caudate nucleus, the ventral striatum, the pallidus, and the internal part of the globus pallidus (GPi) with slightly lower binding in the external globus pallidus (GPe) and ventral pallidum (VP). The nucleus basalis of Meynert exhibited relatively high binding of D2 receptors. In the striatal region the binding of D2 receptors visualized with \(\text{[}^{3}H\text{]epidepride in the presence of 50 nM of 7-OH-DA. D2 receptor density was significantly decreased in the dorsal caudate nucleus, the ventral striatum, the pallidum, and the GPe regions of the GPi as compared to control.}

The only brain regions outside the striatum that displayed D2 receptor density comparable to that of the striatum were the SN and amygdala. We compared PIBAT binding in caudal striatum in schizophrenia cases (n=12, 76.4±1.2 yrs) with neurologically normal control (n=12; 67.4±3.4 yrs) and AD (n=11; 79±2 yrs). The binding to D2 receptors was significantly elevated in schizophrenics in all striatal areas except for the GPi. The highest increase was observed in the GPi (81%) followed by the nucleus basalis (72% average increase). There were even higher elevations in all regions for AD. The highest increase was observed in the GPi (101%) and ventral putamen (73% average increase) followed by the GPi (63%). The results suggest that the striatal system leads to a selective elevation in D2 dopamine receptors. Funded by MH 43880, AG 09287.

479.6

The effects of anesthetics on neurotransmitters at specific sites in the brain are largely unknown. In this investigation, we studied immunohistochemical expression of 5-HT and FOS in the rat brain. Paired control and experimental male Wistar rats were chronically cannulated for blood pressure monitoring and anesthetic or vehicle infusion 7 days prior to the experiment. Following a 6 hour infusion of propofol (20-25 mg/kg/hr) or the intralipid vehicle, the immunoreactivity for serotonin (5-HT) and FOS were studied. Changes in immunoreactive cells within the raphe regions were quantified using computerized imaging analysis: Fos activity was determined by counting the positively stained nuclei. The 5-HT signal was significantly increased in the dorsal raphe nucleus, and significantly decreased by 15% in the area postrema compared to control. Numerous positively stained foci were observed in the inferior olivae in the experimental animals which was not seen in the controls. The lateral parabrachial nucleus had double the number of labelled nuclei for fos compared to the control. These results suggest that anesthetic such as propofol can evoke specific changes in gene activity and selective changes in neurotransmitter systems which may have functional implications for the autonomic and behavioral effects of anesthetics. (Supported by the Heart and Stroke Foundation of Ontario)

\(\text{E-ADRENERGIC RECEPTOR AUTORADIOGRAPHIC LABELLING IN HUMAN BRAIN: SUBTYPE DISTRIBUTION, EFFECTS OF AGE AND POST MORTEM DELAY AND MODIFICATIONS IN ALZHEIMER'S DISEASE. N. Vronskaya, S. N. Gudjch**, J. Gonzalez-Ollo, and J. Dussoit. Dept. of Physiology, Fac. of Sciences, Univ. of Cebrià, Sant Cugat, Spain.}

The density and distribution of \(\text{E-}
\text{adrenergic receptor subtypes was quantitatively autoradiography in post mortem human brain, in both control and Alzheimer's disease (AD) cases. The sections were incubated with \(\text{[}^{3}H\text{]tacrine-pindolol (ICP). ICP-8406 and ICP-11855 were used as displaceants. Our results showed a clear predominance of the \(\text{E-}
\text{subtype in areas such as the basal ganglia and the neocortex. E-}
\text{adrenergic receptors were mainly distributed in the cerebellum and hippocampus. There was no effect of post mortem time (4-72h) on the density of ICP binding. In contrast, a general trend of the \(\text{E-}
\text{receptors to decrease with age was observed. However, this decrease was statistically significant in telencephalic areas, such as the basal ganglia, frontal and visual cortex and thalamus, but not in others. A similar study suggested that
\text{the mesencephalon and the cerebellum. This decrease was far noticeable in the cerebellum and hippocampus. The receptor loss was secondary to a decrease of \(\text{E-}
\text{receptors (39-60%). The decrease of \(\text{E-}
\text{adrenergic receptor density during normal aging and in AD can be explained by the neuronal loss besides the degeneration of the locus coeruleus, known to occur in these processes. (Supported by DICYOT SAFP-265).}

479.8
\text{CELLULAR CO-LocalIZATION OF \(\text{a}
\text{AND \(\text{b}
\text{ADRENERGIC RECEPTOR SUBTYPES IN PRIMARY CULTURES OF RAT SPINAL CORD NEURONS. Y. Huang, H.Y. Langston, H.E. Laidt Jr., P. A. St John and P.T. Kepes. Departments of Pharmacology & Toxicology, Physiology, and Anatomy, University of Arizona, Tucson, AZ 85724.}

The results of molecular cloning have revealed three subtypes of the \(\text{a-}
\text{adrenergic receptor. These subtypes have been defined as the \(\text{a}-\text{C10-receptor (a2C10) and \(\text{a}-\text{C4-receptor (a2C4). \(\text{a}-\text{adrenergic receptors have been characterized in the central nervous system and spinal cord where they are involved in a number of physiological activities, including the control of blood pressure and nociception; however, the specific cellular localization and the subtypes which mediate these effects are largely unknown. For each of the \(\text{a}-\text{adrenergic receptor subtypes, polyclonal antibodies were raised in rabbit using recombinant proteins containing the third intracellular loops of these receptors. The antibodies were characterized in transfected COS cells expressing each of the subtypes individually and were found to be selective and did not cross-react. Primary cultures of rat spinal cord were prepared from 14 day embryos. After 9 days in culture, they were examined by immunofluorescent microscopy. Positive immunoreactivity was detected with antibodies to the \(\text{a2A}
\text{and \(\text{a2B}
\text{, not with antibodies to the \(\text{a2C}
\text{). The labeling was on neuronal, but not on glial cells. It was blocked by pretreatment of the antibodies with the appropriate fusion protein. The labeling in both subtypes was distributed diffusely across the cell body and neurites, and about 80% of the neurons in heterogeneous spinal cord cultures showed the labeling in both cases. Using dual-labeling techniques, positive immunofluorescence was co-localized to neurons with both \(\text{a2A}
\text{and \(\text{a2B}
\text{antibodies. The rat spinal cord appears to contain \(\text{a2A}
\text{and \(\text{a2B}
\text{adrenergic receptors which are present on neurons and may be co-expressed in the same cell. (Supported by the ADCRC.)}

\text{\(\text{a2C10-ADRENERGIC RECEPTOR mRNA IN THE MONKEY CEREBRAL CORTEX: NON-RADIOACTIVE IN SITU HYBRIDIZATION COMBINED WITH IMMUNOCYTOCHEMICAL LABELING OF CELL TYPE-SPECIFIC MARKERS. E. Wenig and M.S. Liao. Section of Neurology, Yale University School of Medicine, New Haven, CT 06510.}

The nonradioactive in situ hybridization combined with immunocytochemical labeling techniques have been used to study the expression of adrenergic receptors in the monkey neocortex. Using a 32P-labeled riboprobe sequence specific for the \(\text{a2C10}
\text{receptor mRNA, the expression was observed in all cortical areas and layers with the exception of the amygdala.}
479.11 Functional Localization of Alpha-2 Receptor function in deminia of the Alzheimer's type and normal aging, regional cerebral blood flow (rCBF) was measured using 15O-H2O PET (Scandinavian PET Center). Five screened healthy controls (aged 20-30, four male, one female, all right-handed) (eyes and ears excluded) and 5 during visual stimulation with isopiloc textures in an alternating fashion. The first two scans (off drug) were followed by a 200 mg/kg 3 minute infusion of iodazoxan, with a maintenance drip for the remaining eight scans. All ten scans for each subject were interpolated from 15 to 43 slices, roll-yaw corrected, regridded, normalized to Talairach space, and smoothed using a gaussian filter of 20 mm x 20 mm x 12 mm. Each scan for each subject was normalized to its own global mean, then multiplied by the mean of the two non drug scans for that subject. Pixel-by-pixel analysis of rCBF was performed for each subject and for the group to identify regions affected by iodazoxan. In addition, changes in rCBF were measured in each subject across time in the regions with the largest drug effect. In spite of a significant decrease in global blood flow across time (P<0.001), blood flow to visual cortex was significantly increased by iodazoxan in the group in both the resting and visually stimulated conditions (P<0.05). Moreover, each subject showed an rCBF increase in visual cortex after iodazoxan in the same areas identified by the group analysis. This metabolic increase is consistent with the high density of alpha-2 receptors in the human visual cortex and enhancement of neurotransmitter release. Intravenous iodazoxan and PET may be a useful way to assay central alpha-2 receptor function in neuropsychiatric illnesses.

479.12 OCTOPAMINE, DOPAMINE AND NORADRENALINE IMMUNOCHEMISTRY IN THE RAT BRAIN: THREE DISTINCT PATTERNS OF DISTRIBUTION. S. Burchett, T.P. Hicks*, J. Rugg, and M. Eckert, Department of Biology and Psychology, UNC, Greensboro, NC, 27412-5001.

The distributions of these three amines normally present in the mammalian nervous system: octopamine (OA), dopamine (DA) and noradrenaline (NA), were compared in rat brain following immunocytochemical treatment with polyclonal antibodies. The distributions of NA and DA conformed well with previously published accounts. The OA-containing cells were confined to the locus coeruleus (A6, A5, A2 and A1 zones) while that for somatic DA was present in the ventral tegmental area and substantia nigra. The development of a novel antibody to perform the first screening study for this compound in mammalian CNS. We found somatic label to be distributed increasingly along the rostro-caudal axis; staining in more caudal regions being relatively intense and widespread than rostrally. OA immunoreactivity was demonstrated best in rats perfused with fixative solutions having relatively high glutaraldehyde levels (6%), causing a high background level of stain, and using low serum dilutions (1:250). Caudally-directed structures showing the most intense reactivity included: cranial nerve nuclei (especially V and VIII); throughout the central core of the long axis of the reticular formation and ventrolateral to the cerebral aqueduct; and the deep cerebellar nuclei. The distribution of label throughout CNS was heterogeneous even though immunoreactive product was dispersed very widely within somatic and all alar/pallidal areas not showing labelled cells. Background label was also quite uneven, suggesting the possibility of unequal patterns of terminal immunoreactivity. These results are not inconsistent with the idea of OA as a modulator of synaptic transmission within mammalian brain.

Nitric oxide (NO) is a highly reactive and diffusible molecule which participates in a wide variety of functions such as the citoexcretory action of leucocytes, as mediator of neurotransmitters in the relaxation of vascular endothelium, and as an inhibitor of platelet aggregation.

From a phylontic point of view, the presence of NO producing neurons has been described in vertebrates such as rat, crab, frog and fish, and in invertebrates like cephaliid and annelids. Thus, the aim of the present study was to report the presence and localization of NO producing neurons in the CNS of the mexican amphibian axolotl, Ambystoma mexicanum. The axolotl (n=6) were anesthetized with benzocaine and intracardially perfused with 4% paraformaldehyde in 0.1M phosphate buffer (pH 7.4). The brains were dissected and post-fixed for 3-12 h, and were transferred to a solution (15%). Parasagittal and coronal sections (5µm) were stained with NO-stain or NODISHOT (Lichtman, 1989) and double stained with NO-stain or NODISHOT (Lichtman, 1989) and double stained with NO-stain and antibodies.

NO-protein correlation study was performed using different antibodies and different fixatives. Anti-NO-staining and anti-NO antibodies were found in several labeled neurons in the axolotl but no correlation was observed between the two staining methods. In conclusion, NO producing neurons are found in the CNS of A. mexicanum and might play an important role in the functioning of the CNS of this species.

479.14 SEROTONINERIC BUT NOT DOPAMINERGIC FIBERS IN THE STRIATUM OF THE DOPAMINE-RECEPTIVE, POSSIBLE CO-LOCALIZATION OF 5-HT AND CAMP.

Department of Psychiatry and Neuropsychopharmacology, University of Limburg, Maastricht, The Netherlands and Department of Anatomy and Neurobiology, Dalhousie University, Halifax, NS, Canada.

Within the striatum several efferent and afferent transmitter systems can be demonstrated of which serotonergic and dopaminergic varicoses fibers are the most prominent. The major neuronal system in the brain has been visualized using either antibodies to nitric oxide synthase (NOS) or visualization of functional responses. Furthermore, NO- and NADPH-diaphorase positive cells and fibers were localized. However, it is not clear which producing NO fibers are arising from intra- or extrastriatal origin. In this study we were interested which elements are also immunoreactive for the cAMP dependent protein kinase for NO production. We have found that the produced NO will diffuse from the cell body and can activate neighboring neurons guanylate cyclase. This leads to the production of cGMP, and using 8-Br-cAMP-immunohisto化学ly demonstrated that a reduction of the dopaminergic fibers does not lead to a decrease in the number of cGMP-positive fibers, while 5-
DHT lesions induces a diminishing of the serotonergic fibers and cAMP fibers in the striatum. Further studies are in progress to show the possible co-localization between cAMP and cGMP fibers and the absence of co-localization between cGMP and NO fibers in the striatum. This co-localization study provides support for a functional connection between the NO and the 5-HT system (Supported by NWO of The Netherlands).

479.15 NADPH DIAPHRASE ACTIVITY IN OLFACTORY RECEPTOR NEURON AXONS CONFORMS TO A RHINOLOCOPITICALLY-DISTINCT DORSAL PROJECTION ZONE IN THE MOB OF HAMSTERS. T. Kato and T. A. Schonfeld*, Dept. of Psychology and Biology and the Neuroscience Program, Clark University, Worcester, MA, 01610.

NADPH diaphorase histochemical activity is distributed widely in the CNS, where it is most commonly localized to short-projecting neurons whose axons do not collect, for the most part, in the major white matter tracts such as the corpus callosum or corticospinal (Brown and Kimmus, 1991, Neuroscience 46:755). By contrast, the olfactory and vomeronasal nerves show intense NADPH diaphorase activity in the main olfactory bulb (MOB) and accessory olfactory bulb (AOB), respectively. Moreover, the olfactory nerve activity patterns are also topographically restricted to the dorsal and medial MOB (Scott et al., 1987, J. Comp. Neurol. 260:797-809; Crepel and Brunois, 1988, Brain Res. 406:323; Davis, 1991, J. Comp. Neurol. 314:493). This pattern conforms almost precisely to an ethologically oriented, rhinotopically-distant dorsal zone known to receive projections from mucosal segments that line a relatively smooth central channel within the naso cavity (Schoenfeld et al., 1994, Brain Res. Bull., 34:183; Clancy et al., 1994, Brain Res. Bull., 34:211). Thus, NADPH diaphorase activity, positively indicated of nitric oxide activity as well, may play a role in the spatial coding of odorant molecules.

(Supported by an NSF REU site grant, the Colin Research Award and the Department of Psychology, Clark University.)

The presence of NADPH diaphorase activity in neurons is believed to be indicative of the presence of nitric oxide synthase in the CNS. In some avian species (quail, chickens), NADPH diaphorase is present in a series of neurons located in specific areas of the brain. This study is directed to investigating the distribution of this enzyme to the brain of the budgerigar (Melopsittacus undulatus) CNS show any peculiar specific segregation. To this effect, the brains of a series of M. undulatus have been studied for the presence of NADPH diaphorase-containing neurons.

In the telencephalon, the paleostriatal-paleoarchlial lobe complex showed the presence of positive neurons and a diffuse network of axons. Diaphorase-containing elements were observed also in the neostriatum in several areas of the accumbens (including the nucleus accumbens) and in the hyperstriatum (accessory, dorsal and ventral). In the diencephalon, positive neurons were present in the thalamic regions and periventricular areas, and in a segregate area at the circumference of the anterior commissure and the lateral precommissural bundle. A group of positive perikarya was located lateral to the dorsal part of the III ventricle in the paraventricular hypothalamic area. In the mesencephalon, diaphorase-containing elements were placed in the posterior area, reticular formation (pars lateralis and pars medialis), nucleus ruber and nucleus arcuatus. Several positive elements were located in the medullary pedunculi pedalis, nucleus vestibularis (pars medialis and pars superior). In the cerebellum, large stained neurons were evident in the nucleus cerebellaris inferius. NADPH-containing neurons in the budgerigar brain show a specific distribution, only in part overlapping with what already observed in other avian species. In particular, NADPH-containing neurons in Melopsittacus undulatus are largely distributed in several visceral areas except the extroseptum. Differences with what observed in the chicken and quail are evident especially in the hypothalamus and medialbrain.

TRANSFERRIN RECEPTOR ANALYSIS IN HYPOTRANSFERRINEMIC (Hp) MOUSE BRAIN. T.D. Dickinson* & J.B. Connor, Penn State Univ., Hershey, PA 17033
The hypotransferrinemic (Hp) mouse has a point mutation or small deletion in the transferrin (Tf) gene causing a defect in splicing of precursor Tf mRNA. This results in production of <1% of the normal circulating level of Tf. These animals are small, pale and severely anemic at birth and die within 7 days unless supplemented i.p. with transferrin. We have previously analyzed the brains of these animals and shown morphological alterations, especially in areas of significant postnatal development. We have also studied the cellular and regional distribution of iron, Tf and ferritin in the Hp brain. An appreciation of the cellular and regional distribution and levels of Tf receptor in these animals is critical to complete our understanding of the mechanisms of iron transport and storage in the Hp mouse brain. Rat iron and monoclonal antibodies to Tf receptor were applied to 45µm brain sections from wild type (Hh), heterozygote (Hp) and mutant (hh) Hp animals. The overall staining for Tf receptor using these antibodies is similar for all three types and staining is generally more robust using the polyclonal antibody. The predominant cell type staining positively for Tf receptor are neurons. The Tf receptor positive neurons are seen throughout the brains of all three types. While matter astrocytes stain Tf receptor-positive but while matter itself reacts poorly. Perivascular astrocytes also stain Tf receptor-positive. Blood vessels themselves, known to contain high level of Tf receptor, stain positive in all three animals, but react more intensely with the monoclonal antibody. Oligodendrocytes, the cells responsible for myelin production in the brain and the predominant iron-positive and Tf-positive cells, do not stain positively for Tf receptor using our antibodies.

480.1
METABOTROPIC GLUTAMATE RECEPTOR-MEDIATED POTENTIATION OF CYCLIC AMP RESPONSES DEPRESSES EXCITATORY SYNAPTIC TRANSMISSION BY A PROTEIN KINASE-INDEPENDENT MECHANISM. R.W. Gereau IV* & P.J. Conn, Depart. of Pharmacology and Program in Neuroscience, Emory Univ., Atlanta, GA 30322
Coactivation of metabotropic glutamate receptors (mGluRs) and β-adrenergic receptors causes a synergistic increase in cAMP formation in the rat hippocampus. Increases in cAMP are known to have many actions in the hippocampus via activation of β-adrenergic-dependent protein kinase. We now report that coactivation of mGluRs with 1S,3S-ACPD and β-adrenergic receptors with isoprenaline induces an acute depression of excitatory post synaptic currents (EPSCs) at the Schaffer collateral-CA1 synapse. Neither 1S,3S-ACPD nor isoprenaline depresses EPSCs in area CA1 of the adult rat hippocampus when added alone. Pharmacological studies indicate that this depression of EPSCs is dependent upon increases in cAMP levels but is independent of protein kinase activity. This CAMP-mediated depression of EPSCs appears to be dependent on metabolism of cAMP and release of adenosine or 5'-AMP into the extracellular space with resultant activation of presynaptic adenosine receptors. These studies suggest that cAMP can have local hormone-like effects in the hippocampal formation that are independent of cAMP-dependent protein kinase.

480.2
METABOTROPIC GLUTAMATE RECEPTOR STIMULATED cAMP IS IMPLICATED IN VISUAL CORTEX PLASTICITY. D.H. Hawkins*, N.W. Davis, D. Gregory, and S. Reid. Dept. of Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, CT 06520
Metabotropic glutamate receptor (mGluR) stimulation can activate phosphoinositole (PI) hydrolysis and can increase and decrease cAMP. The mGluD1 linked to PI hydrolysis has been implicated in functional cortical plasticity (Bose and Dedde, Am. Neurosci. Acad. 627: 42-56, 1991). The role of the cAMP mGluRs in visual cortex plasticity has not yet been addressed, although the cAMP second messenger system has been implicated in hippocampal plasticity. This study was undertaken to examine the role of cAMP dependent mGluR's in visual cortex plasticity. The critical period in the rat begins at approximately 14 days of age and extends approximately one month. Consequently, cortical slices (400 µm) were obtained from male Long Evans rats approximately 22 and 50 days of age. After a 90 minute preincubation in a static chamber, slices were transferred and given a 15 minute experimental incubation. Basal cAMP levels were determined from slices incubated in extracellular buffer. Quipiquone (100 µM) or quisqualate (100 µM) were used to stimulate mGluR1 and mGluR5. CAMP was quantitated via RIA. Basal cAMP levels were slightly, but not significantly higher in slices from 22 versus 50 days of age (p < 0.05). Experiments were conducted in the presence of 1 µM mGluR antagonist PD 104059. Under these conditions stimulation by quisqualate increased cAMP levels in slices from 22 days of age in neocortex by 45 fold and in 50 day old rats by 5 fold. This was statistically significant (p < 0.002, unpaired t-test) in the 22 day old rats but not in the 50 day old rats. These results suggest that mGluR1 and mGluR5 stimulation of the cAMP second messenger system is implicated in rat visual cortex plasticity. Supported by EY00053 and EY007115.
DIFFERENTIATION OF PKA IN CORtical NEURONS AND CEREBELLAR GRANULES. C. Venta*, M. Paulillo, A. Porcellini*, A. Feliciello*, V.F. Avvedimento* and G. Schetti*, Dept. of Neuroscience, S. Sect. of Pharmacol., University of Naples "Federico II", Italy. Cortical neurons display a notable amount of type-II holocenzyme compared to cerebellar granules, virtually containing only type-I holocenzyme and devoid of AKAP 150, the type-II PKA holocenzyme. The cortical holocenzyme poorly associates under stimulation (5 min) by forskolin (10µM+IBMX 50µM), while completely reassociates after 15 min; nonetheless, a consistent nuclear accumulation of PKA is found. Conversely, cerebellar holocenzyme is highly sensitive to stimulation by forskolin (>60µM) which does not reassociate at 15 min, and the catalytic subunit does not accumulate into the nucleus. Immunofluorescence studies using a polyclonal antibody for PKA catalytic subunit and band-shift experiments using radio-labelled CRE are allowing us to further unravel this issue. In cortical neurons, the cytosolic holocenzyme is dissociated at 15 min, while the particlect part correspondant dissociates between 2.5 and 5 min and fully reassociates at 15 min; negligible levels of particulate holocenzyme are found in cerebellar granules, and most of cytosolic holocenzyme dissociates under forskolin stimulation (60-70%, 1-15 min). Our results suggest that relevant functional implications could underly the different subcellular distribution and response of PKA to CAMP, with particular regard to the CAMP-dependent modulation of gene transcription, which plays a major role in the modulation of long-term synaptic events. (Supported by TP Aging and CNR 93.00417.CT04 grants to G.S.)

50.5 PROTEIN KINASE A (PKA) INDEPENDENT EFFECTS OF IONTOPHORETICALLY APPLIED CAMP ANALOGS ON RAT SUBSTANTIA NIGRA PARST RETICULATA (SNpr) NEURONS. I.C. Lata*, L.P. Martin and R.L. Waucquier*, Dept. Pharmacological Sciences, Northeastern Univ., Boston, MA 02115. We have previously shown that iontophoresis of the dopamine D1 agonist SKF 38393 acts at D1 receptors on striatal terminals to increase firing rates of SNpr neurons, and to enhance their inhibitory responses to applied GABA. To determine if CAMP might mediate these effects, subsequent studies examined effects of CAMP analogs using extracellular single unit recordings in male rats anesthetized with chloral hydrate. Application of several membrane permeable analogs (B-ionophore-cAMP, dibutyryl-cAMP and chlorophenylthio-cAMP) failed to consistently mimic the rate-increasing effect of the D1 agonist. Moreover, these compounds, as well as the non-permeable CAMP analog Rp-cAMPS, produced significant, but not as large, increases in GABA potency that were not blocked by the cAMP antagonist Sp-cAMPS. These results suggest that CAMP may mediate these effects, by a mechanism that remains to be elucidated. (Supported by NS 23341.)

50.6 CHRONIC HALOPERIDOL TREATMENT HAS NO SIGNIFICANT EFFECT ON CYCLIC AMP CONCENTRATION IN RAT BRAIN. W. Feng, R.H. J. Elkies and R.S. El Mallah*, Mood Disorders Research Program, Department of Psychiatry and Behavioral Sciences, University of Louisville School of Medicine, Louisville KY 40292. It has been assumed that the therapeutic effect of haloperidol in the treatment of schizophrenia is related to its blockade of dopaminergic D2 receptors in the central nervous system. Our previous data has shown that chronic haloperidol treatment attenuates receptor-mediated phosphoinositide turnover in the frontal cortex, striatum and hippocampus. To investigate the influence of haloperidol treatment on another second messenger, cyclic adenosine monophosphate (cAMP), in the central nervous system, we examined the cAMP concentration in the different brain regions of rats treated with haloperidol (1.5mg/kg/day IM) for 4 or 6 weeks. The cAMP concentration was measured by dual range cAMP enzyme immunoassay kits. Our results indicates that cAMP level was slightly increased in the hypothalamus while no alteration was observed in the frontal cortex, striatum and hippocampus after 4 or 6 weeks treatment with haloperidol. However, all these changes are not significant. Chronic haloperidol treatment does not appear to be associated with the changes in cAMP that have been previously reported with acute treatments. Our results provide additional support for the notion that chronic treatment experiments are necessary to understand the mechanism of clinical action of haloperidol.

50.7 SARCOMA PROTO-ONCOGENE c-LYN (P-56) IS HIGHLY EXPRESSED IN THE RAT BASAL FOREBRAIN. S. Chen*, R. Bing and D.E. Hillman, Dept. of Otolaryngol. and Phys./Biophys., New York Univ. Med. Center, New York, N. Y. 10016. The sarcoma proto-oncogenes are second messengers for phosphorylation of tyrosine kinases which are essential in processes of neuronal plasticity and learning. Complete subcellular fractionation mapping and reconstruction of lyn immunoreactivity (IR) revealed impressive bilateral cores of intensely labeled neurons surrounding the anterior commissure and extending along the base of the striatum and the head of nuclei accumbens caudally through the striatal fundus. There was a compartmentation of lyn labeling by nuclei displaying multiple foci consistent with tissue sections. Neurally specific lyn IR was present in this region, intensely labeled small cells were grouped along the margins of the accumbens and the accumbens nucleus. Immunoreactivity in the belt and rudimentary form distinct fascicles. The dendrites of these neurons within the fascicles were oriented parallel forming distinctive dendritic fascicles. These fascicles were also prominent in the shell of accumbens and bed of striatal nuclei. The fundal foci were intensely labeled by a variety of extracellular extension. The lateral and medial septal nuclei were separated by intense IR comuta and overlapping dendritic fields. Additionally, moderate lyn-IR cells having small to medium sized perikarya scattered throughout the neostriatum. Double labeling revealed that a small percentage of lyn cells colocalized with parvalbumin or none colocalized with large acetylcholine cells. The lyn core in the basal forebrain may represent a basic system of neurons involved in learning homeostatic functions of behavior. Supported by NS 13742 and AD 09480.

50.8 MULTIFUNCTIONAL CALCIUM-DEPENDENT PROTEIN KINASE II (CaMKII) IN BOVINE CHROMAFFIN CELLS: CHARACTERISTICS AND STIMULATION BY POTASSIUM DEPOLARIZATION. N. Vera and J.C. Wayne*, Department of Neurobiology and Anatomy, University of Texas, Houston, TX 77030. CaMKII is a multifunctional protein kinase that has been found to exist in a variety of tissues and cell types. We examined CaMKII activity in bovine adrenomedullary chromaffin cells using a CaMKII specific substrate. After discriminating its presence, we investigated the time course of CaMKII activation as determined by incubations at incremental time points with nondepolarized and high potassium depolarized (55 mM KCl) cells. We found that CaMKII activity in chromaffin cells differs both temporally and quantitatively from that in other cell types, such as PC12 cells and hippocampal slices. In chromaffin cells, the activation is almost immediate (occurring within 10-20 min) and rapidly decays by 2 minutes. CaMKII is known to activate tyrosine hydroxylase and phosphatidylating serine residues 19 and 40 in chromaffin cells. The rapid phosphorylation of these residues (maximum phosphorylation within 10 seconds) correlates with the activation of CaMKII. Therefore, in chromafflin cells, the time course of CAMPII activation directly predicts the rapid phosphorylation and activation of tyrosine hydroxylase, and thereby catecholamine synthesis. Supported by NS 11061-16 JCW.
transplantation of calcium/calmodulin-dependent protein kinase II (CaMKII) in rat hippocampal slices is induced by simulated ischemic insult. S. J. Khub and M. W. Watanabe*. Dep't of Neurobiology and Anatomy, Univ. of Texas Med. Sch. Houston, TX 77030. CaMKII has been shown to lose activity and to translocate from post-synaptic to pre-synaptic fractions of cortical and hippocampal homogenates in a global model of ischemia (Aronowski et al., 1992, J. Neurochem.). To investigate the mechanisms underlying this translocation, a hippocampal slice model was developed. Slices were exposed to conditions that simulate ischemic insult, and the subcellular distribution and enzymatic activity of CaMKII were monitored in homogenates prepared after increasing durations of the insult. Semi-quantitative Western blots were utilized by using a monoclonal antibody to the alpha subunit. CaMKII showed that there was a 70% decrease in CaMKII in the post-synaptic fraction and a 150% increase in CaMKII of the pre-synaptic fraction after 20 min of ischemia. Shorter periods of ischemic insult produced a graded change in redistribution. There was little or no change detected in CaMKII in the total homogenates at any time suggesting that little proteinases of CaMKII was evident at up to 20 min in this model. CaMKII activity decreased in the post-synaptic in a parallel fashion with translocation. Activity increased by 20% in the post-synaptic fractions at 5 and 10 min. of ischemia and then decreased back to pre-ischemic levels by 20 min.

We conclude that redistribution of the enzyme occurs in the hippocampal slice model and that this system may be useful in elucidating the mechanisms underlying CaMKII alterations and its impact on ischemia-induced neuronal injury.

Differential Regulation of Multiple Calcium/calmodulin-Dependent Protein Kinase Type II Subunits mRNA's. K.D. Murray*, C.A. Rosasco, and P.J. Jackson Department of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville, FL 32245

Calcium/calmodulin-dependent protein kinase type II (CaMKII) is a multifunctional enzyme comprising as much as 2% of total brain protein and playing a critical role in excitatory neuronal processing. Originally identified as a multimeric holoheximide composed of α and β subunits, recent cloning analysis has identified two additional subunits, CaMkIβ and γ, as well as a series of alternatively spliced isoforms deriving from these four subunits. Earlier studies have shown that hybridization to CaMKII mRNA is down-regulated throughout hippocampus and neocortex following bilateral ischemic insults and up-regulated when afferent input is removed (Benson et al., 1991, Murray et al, 1993). To investigate whether the other CaMKII subunits undergo a similar regulation we performed analysis using two site hybridization, northern and Southern blots, and ISH on rat brains. The male Sprague-Dawley rats sacrificed at various time-points following the onset of behavioral seizures induced by intraperitoneal injection of kainic acid (K.A., 10mg/kg). The pattern of hybridization to CaMKIIβ,β and β subunit mRNA in saline injected animals was consistent with previous reports in untreated control animals. One notable difference was the presence of low, but detectable hybridization of CaMKII mRNA within the hippocampus. Consistent with the lesion induced seizures, KA treatment produced a stark reduction in hybridization to CaMKII mRNA (90%) throughout the hippocampus and neocortex. Hybridization to CaMKII mRNA was also reduced within hippocampus and neocortex, but to a lesser extent. In contrast, hybridization to CaMKII mRNA was unaffected within hippocampal subfields but dramatically increased throughout the superficial layers of neocortex (5 fold). All mRNA changes were maximal 24 hrs following KA injection. CaMKII mRNA levels were not significantly altered following KA treatment. These observations provide evidence for the regulation of CaMKII at the RNA level and suggest it is more complicated than previously thought.
480.15

In Alzheimer’s disease (AD), the lack of an animal model complicates the analysis of early pathological changes. Mitogen-activated protein (MAP) kinases have been suggested as potential targets for the neurodegeneration in AD. Here, we describe the cloning and molecular characterization of the mouse homolog. Immunocytochemically, MAPK12 identified a cytoplasmic antigen expressed almost exclusively in neurons. The human p46K12 kinase cDNA was used to isolate a 2.5 kb mouse cDNA clone. The deduced amino acid sequence was novel and shared 99% identity with that of the human p46 kinase. Moreover, the 3' untranslated region showed 88% nucleic acid identity with the human cDNA. This suggests a conserved regulatory role for this region. Northern blot analysis showed a 2.7 kb mRNA that was exclusively expressed in the brain and a 2.4 kb mRNA expressed only in testis. All other tissues showed no expression. In situ hybridization showed a similar pattern of expression as that of JF12 antigens. Developmentally, the p46K12 kinase was turned on embryonic day 11 (E11), and was expressed only in post-mitotic neurons. At E17, the mRNA was also present in the dorsal root ganglion as well as neurons in the CNS. These findings are in agreement with the suggested role of ERKs in neuronal differentiation. The distribution of the p46K12 protein along with evidence suggesting its involvement as a pathogenic agent in AD, may lead to development of a possible model for NFT formation.

THE yl ISOFORM OF PROTEIN PHOSPHATASE 1 IS CONCENTRATED IN DENDRITIC SPINES. C.C. Quiñete*, E.F. da Cruz e Silva* and M.B. Lightbody. Dept. of Pharmacology, Florida State University, Tallahassee, FL 32306.

In vitro hybridization revealed a higher level of expression in dendritic axons than in cell bodies. These results suggest that the yl form of the protein phosphatase 1 may be involved in spine regulation. (Supported by USPHS grant GM06899.)

480.18

Okadate acid (OA) and calyculin A (CaA), specific inhibitors of the protein phosphatase type 1 (PP-1) and 2A (PP-2A), slow the recovery of elevated [Ca++]i caused by K+-depolarization and prolong the divalent cation-dependent action potential in the serotonergic Retzius cells of the leech (Kleinhaus & Zeman, Brain Res. 1993). These studies suggest that inhibition of PP-1 and/or PP-2A may directly modulate the kinetics of the voltage-dependent Ca2+ conductance and/or alter other mechanisms related to Ca2+ movements or buffering.

To identify and quantify the relative amounts of PP-1 and PP-2A found in these neurons protein phosphatase activity. from extracts of leech segmental ganglia and isolated Retzius cells was measured using [32P]orthophosphate as a substrate. The major phosphatase activity in both preparations is similar to the mammalian form of PP-1. The dephosphorylation of phospho-epitopes from extracts of segmental ganglia, isolated Retzius cells and purified mammalian PP-1 was inhibited by OA and by CaA with IC50 values (~50 nM). In addition, enzymatic activity intrinsic to each leech neuronal preparation was inhibited >80% by addition of inhibitor 2, a heatstable inhibitor protein specific for PP-1. That enzyme was also inhibited by calyculin A, but the IC50 values of >20-30 nM is higher than that of the purified mammalian PP-1 and PP-2A. Taken together these results indicate that phosphatase activity in leech nervous tissue is mostly due to an enzyme of the type 1 family.

Studies to characterize the subcellular distribution and composition of this PP-1-like enzyme are in progress.

CLONING OF PARTIAL cDNAs FOR THREE PROTEIN TYROSINE PHOSPHATASES FROM APlysia CALIFORNICA. F.C. Richardson* and L.K. Kaczmarek. Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06511.

Patch clamp experiments of a voltage-dependent cation channel in Aplysia bag cell neurons have shown that the gating mode and response of the channel to protein kinase A (PKA) are determined by a PKA regulated protein-tyrosine phosphatase (PTPase) (G.T. Wilson and L.K. Kaczmarek, 1993, Nature vol. 366:433-438). As a first step towards understanding this regulatory relationship, a PCR based cloning strategy was employed to isolate potential PTPase isoforms. cDNA was sequenced by reverse transcription cloning, using total RNA isolated from abdominal ganglia and bag cell neurons. This cDNA was then amplified using degenerate primers designed to the conserved catalytic domain of published PTPase sequences. Products of predicted molecular weight were directly ligated into a TA vector and sequenced. Based on protein sequence homology to the catalytic domain of cytoplasmic phosphatases, three clones, named APTPs1, 2, and 3 were isolated. APTPs1 and APTPs2 were 36.3% identical and are most similar to Human PTPs (48.7%) and Rat LAR (67.4%), respectively. APTPs2, which is 38.6% identical to APTPs1 and 36.2% identical to APTPs3, is the most novel of the three isoforms. It's highest similarity to any published PTPase (Human LCA) is only 34.2%. In situ hybridization studies and further cloning will help determine whether any of the APTP isoforms are regulated by PKA in the bag cell neurons.

I-2 is the regulatory subunit of the ATP-Mg-dependent protein phosphatase, a cytosolic form of type I protein phosphatase (PP-1). Our in situ hybridization study has recently demonstrated that the mRNA for the three catalytic subunits of PP-1 and inhibitor-I(1-1) were differentially distributed in the rat brain (H. Sakagami et al., Mol. Brain Res., in press). However, no information has been available concerning the distribution of the gene expression and the functional significance of I-2 in the brain. We, therefore, cloned cDNA encoding I-2 and determined the distribution of the gene expression for I-2 in the rat brain by in situ hybridization histochemistry. The cDNA encoding I-2 was isolated from a rat brain cDNA library using a Green fluorescent probe for rabbit skeletal muscle I-2 (Park et al., 1994). By in situ hybridization histochemistry using oligonucleotide probe, intense expression signals were detected in the hippocampal pyramidal and dentate regions, as well as in the olfactory bulb. Moderate expression signals were detected in the olfactory neuronal layer, caudate putamen, neocortex, and cerebellar granule cell layer. When compared with this expression pattern with that of I-1 mRNA, several differences were found: the homogenous expression of I-2 mRNA versus the laminar expression of I-1 mRNA in the neocortex; low expression of I-2 mRNA versus high expression of I-1 mRNA in the arachnoid membrane. These findings suggest that the activities controlled by I-2 and I-1 in various brain regions. (Supported by grants 0404020 and 0526023 from the Ministry of Education, Science and Culture of Japan)
CHARACTERIZATION AND REGULATION OF GABAA RECEPTOR SUBUNITS ON NEURONES IN THE HYPOTHALAMIC SUPRAOPTIC (SON) AND PARAVENTRICULAR (PVN) NUCLEI V.S. Fenoloe and A.E. Herbst

1994

461.1 NEUROENDOCRINE REGULATION: MAGNOCYCLULAR SYSTEM

GABA is known to regulate oxytocin (OT) and vasopressin (VP) secretion via the occupancy of GABA receptors. As the different GABA receptor isoforms have different pharmacologic properties, the present study determines the role of making magnocellular neurons and determine whether changes in specific subunit mRNAs are during pregnancy and lactation.

Double labelling studies using antisera specific for either OT or VP and antiserum directed against the b subunit of the GABA receptor were carried out on sections of GABAergic neurons in the SON. GABAergic neurones were confirmed twice, VP-like immunoreactivity was observed in all OT and VP neurones located in the SON express the a2 subunit. In site hybridization experiments using 5S-labelled complementary a subunit, the subunits were confirmed that neurons in the SON expressed a subunit. Silver grain analysis for a and b subunit subunits were carried out on the SON, PVN and corticosterone (CORT), pregnant (day 10 and 19), parturition and lactating rats (day 7 and 14). a mRNA expression in the SON increased during pregnancy, peaking at day 10, and fell in lower levels on the day of parturition. a mRNA expression in the cortex and mRNA expression in SON, PVN and cortex did not show such variations. Furthermore, it appears that expression of an a subunit-containing GABA receptor islet is altered during pregnancy suggesting that GABA influences on OT and/or VP secretion at this time may be determined, in part, by receptor expression.

461.2 OXYTOCIN HORMONE INDUCES PLASTICITY OF OXYTOCIN NEURON ACTIVITY OF SUPRAOPTIC NUCLEUS IN THE FEMALE RAT. T. KITODA, S. YADA and M. NIYATTA, Dept. of Appl. Phys., Kyoto Institute of Technology, Sakyo-ku, Kyoto 606 Japan

It has been demonstrated that oxytocin (OT)-containing neurones in the supraoptic nucleus of rats are facilitated by exogenous oxytocin (OT) and inhibited by removal of virgin females or pregnant females. The present study was carried out to investigate whether OT increases the OT neuron activity in hypothalamic slices prepared from virgin female, pregnant, delivering, lactating, and ovarectomized rats by recording extracellular single-unit activity. Most OT neurones of virgin female and pregnant rats showed inhibitory responses to OT. In contrast, majority of OT neurones were tested in delivering and lactating rats exhibited excitory responses to OT. This excitation reversed to inhibition after the lactating period had ended. OT neurones in over- ecrotomized virgin rats showed excitory excitory responses to OT. This excitation was also reversed to the inhibition by estrogen treatments. It was also found that morphological changes of OT neurones associated with the lactation were unaffected by ovariectomy suggesting that other stimulus such as nipple sucking may be crucial in maintaining the changes. These findings suggest that the oxytocin neurones may play an important role in induction of neural plasticity in rat hypothalamic OT neurones.

461.5 HYPERTONIC SALT-INDUCED CHANGES OF THE OXYTOCIN CONTENT OF THE THORACIC SPINAL CORD: REGULATION BY OPIOD PEPTIDES. V. Neira & J. Hually, Dept. of Biological Sciences, St. John's University, Jamaica, NY 11439

Previous we have demonstrated that oxytocin content of the spinal cord changes in response to various somatosensory stimuli. For example, following immobilization stress of one minute, oxytocin content increases (Brain Res. 137:141, 360) and somatosensory injections of oxytocin content decreases (Life Sci. 53:579-584, 94). The current experiments were designed to determine what factors or factors regulate spinal cord oxytocin content. Spinal cords of rats known to regulate oxytocin release from the neurohypophysis, it was logical to investigate whether spinal cord oxytocin is also under opioid regulation. Male Sprague-Dawley rats were divided into (i) intact control group rats (n=10), (ii) hypothyroidic saline (10% solution), (iii) Naloxone (500 ng/kg BW), (iv) Naloxone + arginine and (v) Naloxone + hypothalamic saline. Injection volume was 0.2 ml/100 g body weight. For Control group, rats were pin-pricked twice, once subcutaneously with Naloxone injection and second time (p), injecting saline (0.2 ml/kg BW). Five minutes after Naloxone injection, the rats were injected with saline and were sacrificed fifteen minutes thereafter. Following organotypic, thoracic part of the spinal cord was isolated from the vertebral column and separated into superficial and ventral half. Oxytocin content of the spinal cord was determined by a specific oxytocin radioimmunoassay. Both oxytocin radioimmunoassay and the step-extraction sample. Our results demonstrate that (i) dorsal half of the spinal cord contains ten fold more oxytocin than that of the ventral half, (ii) both isotonic and hypertonic saline decrease oxytocin content and (iii) Naloxone reduces oxytocin induced decrease of the spinal cord oxytocin content. In conclusion, these results suggest that spinal cord oxytocin is at least partly regulated by opioid peptides.

461.6 INTRACEREBROVENTRICULAR ADMINISTRATION OF INTERLEUKIN-1B SUPPRESSES REFLEX MILK EJECTION IN URETHANE-AESTHETIZED RATS. B.C. Wilson* and A.F. Summerlee*, Dept. of Biomedical Sciences, University of Guelph, Guelph, Ontario, Canada N1G-2W1

It has been shown that ivc IL-1B stimulates oxytocin release in male (Neumann et al., 1993, Soc. for Neurosci. Abst. 19(1): 97) and female (Wilson and Summerlee, unpublished data) rats. The IL-1B excites suprachiasmatic neurons (Li et al., 1992, Neuroreport 3: 91-93). Experiments were done using the methodology of Summerlee et al., 1984, Nature 309: 372-374 to investigate the effect of ivc IL-1B on the pattern of reflex milk ejection (RME) in rats at Day 10 of lactation. Urethane-anesthetized rats were implanted with cannulae in the left saphenous vein and a caudal mmamy gland and then placed in a stereotaxic head frame. A microphone was placed with its tip in a lateral cerebral ventricle for ivc injection. Ten rat pups were placed to suck at the nipples of each dam to induce RME. After 6 milk ejections, milk was placed with ivc IL-1B (10 ng/LB PBS-BSA iv) or PBS-BSA (10 ng/LB) and the effect on the pattern of RME observed. IL-1B suppressed RME in 10 out of 16 dams with ivc IL-1B and 0 out of 9 (0%) for those treated with the PBS-BSA vehicle. It is possible that in female rats, IL-1B stimulates milk ejection release while inhibiting suckling-induced ivc injection involved in milk ejection. The data suggest that IL-1B plays a role in mediating suckling-induced neuroendocrine events in the rat.
481.7 INTRACEREBROVENTRICULAR INJECTION OF RELAXIN AFFECTS THE RELEASE OF BOTH VASOPRESSIN AND OXYTOCIN IN ANESTHETIZED RATS. B.J. Geddes and J.L. Summerlee. Dept. of Biomedical Sciences, University of Guelph, Guelph, Ont., CAN, N1G 2W1.

Injections of exogenous relaxin either IV or ICV produce a marked and sustained rise in systemic arterial blood pressure (Parry LJ & Summerlee AJ, 1991). Intravenous relaxin administration has also been shown to substantially affect the release of vasopressin (AVP) and oxytocin (OX) (Way & Leng, 1992; Geddes BJ, Parry LJ & Summerlee AJ, 1994). There is preliminary evidence that ICX relaxin also affects magnocellular peptide secretion (Jones, 1988) so the present study was conducted to make a more thorough examination of the influence of ICX relaxin on vasopressin and oxytocin release. Urethane-anesthetized female SD rats were cannulated such that blood samples (1±mL) and fluid replacement could take place simultaneously. Intraduodenal administration to pregnant rats indicated that the effects of relaxin injected ICV and IV are ostensibly identical which supports the hypothesis that relaxin affects cardiovascular function through a central mechanism. Supported by NSERC Canada and OMAF Canada.

481.8 EFFECT OF OVARIAN STEROIDS ON HYPOTHALAMIC PULSATILE OXYTOCIN RELEASE EVOKED BY SUCKLING IN THE ANESTHETIZED RAT. Q.B. Liang and J. Wilkerson. (SPON: Brain Research) Dept. of Anatomy, Sci. of Medical Sciences, Univ. of Bristol, Bristol, BS8 1TD, U.K.

Effect of ovarian steroids on pulsatile oxytocin (OT) release during suckling was examined in late pregnancy mares by ovariectomy (OX) and steroid replacement. Intramammary pressure recordings of milk-ejection responses were used to detect pulsatile OT release from the magnocellular OT neurons in the hypothalamus. OXV on day 20 of pregnancy significantly increased the frequency of milk-ejection responses on day 22 of pregnancy, compared with sham-OVXed controls (2.0±0.2/min, mean±SE, n=6, P<0.05, Student’s t-test). Replacement with either progesterone (5mg per day, s.c.) or estradiol (5mg per day, s.c.) at 20 min post OVX reduced milk-ejection frequency to the sham-OVXed level. However, these two different steroid regimes caused a remarkable difference in the facilitatory response to intracerebroventricular (i.c.v.) injection of OT. Milk-ejection frequency in progesterone replaced rats was decreased significantly from 2.0±0.2/min before i.c.v. OT to 0±0.2/min after i.c.v. OT (n=6, P<0.05). In OVX oil treated controls, frequency of milk-ejection before and after i.c.v. OT were 3.5±0.2/min and 3.7±0.2/min (n=7). These results suggest that ovarian steroids may play a role in determining the frequency of pulsatile OT release towards the end of pregnancy. Furthermore, the rising level of cortisol and fall of progesterone towards the end of pregnancy may be a necessary prerequisite for allowing the facilitatory action of centrally-released oxytocin on the milk-ejection reflex. Supported by ASRC HG1763.

**VASOPRESSINERGIC INNERTION TO SUBSTANTIA NIGRA (SN) AND VENTRAL TEGMENTAL AREA (VTA) IN THE RAT. T. Yamamoto* and S.T. Kitai, Department of Anatomy and Neurobiology, University of Tennessee, College of Medicine, Memphis, TN 38163.

Vasopressin (VP) fibers are widely distributed in the brain in addition to a hypothalamic-hypophyseal system. In addition to classically known antidiuretic and vasoconstrictive actions, VP affects memory process, cardiovascular function, thermoregulation and motor behavior. SN and VTA in the midbrain are known to receive VP innervation, but the cells of origin of these VP fibers are unknown. In this study, we examined the VP innervation to SN and VTA in the rat using a retrograde fluorescence tracing technique and immunohistochemistry. Ten to 14 days following pressure injection of Fluoro-Gold (FG) (2.5 to 4%, 25 to 45 nL) into the SN/VTA region, colchicine (120 µg/kg) was injected into the lateral ventricle. After a 2 day survival period, the rats were transcardially perfused and sacrificed. The brains were removed, post-fixed and stored in phosphate buffer. Using a vibratome 50 µm sections were cut for immunohistochemistry.

The neurons in the bed nucleus of the stria terminals (BST), medial amygdaloid nucleus (MeA), locus coeruleus and paraventricular hypothalamic nucleus (PVN) were retrogradely labeled by FG. In BST there were many double labeled neurons, but there were only a few in the MeA, PVN, and hypothalamic area. These observations indicate that SN and VTA receive VP afferents mainly from BST, but some originate from the hypothalamic area, MeA and PVN.

Supported by NIH Javits Award NS 20702 and the Human Frontier Science Program.

GABA provides most if not all of the inhibitory synaptic input throughout the neuroendocrine hypothalamus. Half of the synaptic boutons are immunoreactive for somatostatin (SOM), paraventricular supraoptic, and arcuate nuclei. Neurons immunopositive for GABA and glutamic acid decarboxylase have been shown in and around SON and other hypothalamic regions, suggesting that inhibitory input to hypothalamic neurons cells might originate predominantly from local GABAergic neurons. Using whole-cell recordings and glutamate microdop in hypothalamic slices, we tested the hypothesis that local GABAergic neurons provide inhibitory input to supraoptic magnocellular neuroendocrine cells. Microdrops of glutamate (20 mM, 50-150 µM in diameter) were applied in the periphery of the SON while frequency and amplitude of postsynaptic currents in supraoptic magnocellular neurons were monitored (n=23). In 4 cells, glutamate microdops dramatically increased frequency and average size of inhibitory postsynaptic currents (IPSCs) while no change in excitatory postsynaptic currents was detected. Glutamate microdrops increased IPSC frequency from 0.5-2 Hz to 3-20 Hz. Glutamate microstimulation also increased the average amplitude in all 4 cells by increasing the proportion of the largest IPSCs, suggesting that more IPSCs were action potential-mediated. These results suggest the hypothesis that GABAergic neurons located in the periphery of SON provide inhibitory input to supraoptic magnocellular neuroendocrine cells.
482.3

Systemic administration of monoclonal interleukin-2 antibodies has been shown to cause selective degeneration of sympathetic preganglionic neurons. In the present study rat paravertebral ganglia were injected i.v. with injection of these antibodies. Exophthalmos, piloerection and ptosis were observed within 1 h after administration. Rats were sacrificed at different time-points, and the adrenal glands were analysed by means of indirect immunohistochemistry and in situ hybridization histochemistry. As soon as 3 h after the antibody treatment a marked increase in the number of chromaffin cells was detectable. Immunocytochemically, respectively, exekalin, calcitonin-gene related peptide, galanin, neurotensin and substance P was seen. At 12 h the peptide mRNA levels were still elevated and there was a concomitant increase in the number of immunoreactive catecholaminergic cells. All these effects were maintained for at least 48 h, however, seventy-seven days after the antibody treatment only exekalin-immunoreactive cells were encountered. A disappearance of acetyleneuropeptide- and exekalin-positive fibres was seen already 3 h after the antibody treatment, and after 24 h no fibres were encountered. In controls, up till 48 h there was no apparent change in the number or intensity of immunofluorescent fibres expressing calcitonin-gene related peptide, galanin, neurotensin or substance P. However, 77 days after the antibody treatment the number of exekalin gene-positive and substance P-immunoreactive fibres was increased as compared to controls. In addition, reappearance of acetyleneuropeptide- and exekalin-immunoreactive fibres was seen at 77 days, although their number still was not comparable to controls. Double-labeling immunohistochemistry revealed that the cells expressing peptides preferentially are adrenergic staining cells. The majority of these cells expressed only one peptide. Both transection of the splanchnic nerve as well as treatment with acetylcholine receptor antagonists mimicked the effects seen after the ACHI-antibody treatment, although changes were less pronounced.

482.5

Paragraphe to investigate the effect of streptozotocin-induced diabetes on concentrations of vitamin A (retinol, retinal, retinoic acid) in the plasma, liver and gonads of rats. To determine any changes in vitamin A metabolism to retinoid enterotoxemia (RE) in hepatic microsomal membranes of rats. To determine any changes in vitamin A metabolism with day-1, day-8 and controls. Diabetes was induced by a single i.v. injection (tail vein) of streptozotocin (55 mg/kg) dissolved in acetic buffer, pH 4.5. Control group received only the vehicle. Plasma glucose concentrations were determined by glucose oxidase method. Both groups were fed ad libitum with a synthetic diet. Animals were sacrificed 42 days post injection. Retinal identity was determined by direct esterification of retinal. Results of the present study suggest that administration of the plasma retinal concentration was significantly lower than those in control rats. However, hepatic retinal concentration of diabetes was significantly higher than that in control rats. The retinoid enterotoxin level in plasma and liver was not notably different between the diabetic and control group. In hepatic tissue, retinoid concentration was significantly increased in comparison to control group while retinal level was not perturbed. After hepatic, hepatic retinoid concentration of diabetes was significantly higher than that in control rats. The retinoid enterotoxin level in plasma and liver was not notably different between the diabetic and control group. In hepatic tissue, retinoid concentration was significantly increased in comparison to control group while retinal level was not perturbed.

The mechanisms underlying the decrease in drug requirements for central and peripheral anesthesia during pregnancy in humans are not yet understood. Sex hormone effects on excitable membranes have been suggested as a possible cause. Experimental pregestation can be used to examine the drug effects in rats. The results of this study suggest that the present study examined the developmental time course of losartan-induced PRA stimulation during the period in which functional sympathetic control of the renin-angiotensin system emerges. Neurotensive Water-Kyoto (WKY) and spontaneously hypertensive (SHR) rats were used as animal models to study this phenomenon. 2) The possibility of altered pharmacokinetics of LA in the gravid rat by studying lidocaine uptake in a peripheral nerve preparation. Pregnan (P, n=3) and non pregnant (NP, n=5) rats were briefly anesthetized with 10% chloral hydrate. A unilateral sciatic nerve was performed in a dose of 0.1 ml of 1%labelled lidocaine (%LD). After recovery from general anesthesia (1-2min), proprioception, motor function and responses to superficial (sking pinch) and deep (knee pinch) tests were tested. As soon as deep pain sensation returned, the animal was sacrificed. The sciatic nerve rapidly removed, frozen, cut in 5 mm segments, dehydrated, weighted, digested and the uptake of *LD measured by liquid scintillation counting of the different segments. A significant difference in the time for return of deep pain sensation was observed between the 2 groups (P<0.05). The fraction of the total *LD injected dose found in the nerves was 0.49±2.4% for the NP rats and 0.80±0.08% for the P rats. *LD distribution along the nerve was investigated in the two groups using the 2-gamut test (2.5 mm) and resulted in a significant difference between the two groups. In summary, the duration of anesthesia was prolonged in rat rats as was observed in humans, but the amount of *LD in the nerve was the same in both groups. This effect might be due to an increase in uptake of LA (e.g., due to an increase in nerve sheath permeability) 2) a decrease in clearance of the LA from the nerve or 3) both.

ELECTROPHYSIOLOGICAL EFFECTS OF NORADRENERGIC AGONISTS ON NEURONAL AREAS OF THE STRIATUM AND CAUDAL MEDULLARY ORIGINS OF THE CATECHOLAMINERGIC INNERVATION M.G. Terenzi and D. Ingram Department of Anatomy, School of Medicine, University of British Columbia, Vancouver, BC, V6T 1Z2, Canada.

The bed nucleus of the stria terminalis (BST) is a limbic collection of neurons at the junction of the hypothalamus and septal area. The BST are important for autonomic functions and regulate activity associated with maternal behaviour and the retraction reflex. The BST are innervated by medioventral noradrenergic groups (A1, A2 and A6) and high turnover of noradrenaline occurs in the BST during suckling. We investigated the role of catecholamines from the A1/A2 groups to the BST using fluorescent retrograde tracing and tyrosine hydroxylase (TH) immunocytochemistry. The results showed that the projection from the caudal medulla originates in the lateral medulla and the nucleus of the rassus cuneiformis (NTS). Most of the input is ipsilateral and terminates in the BST ventral to the anterior commissure. Almost no labelling is observed in the caudal medulla when the injection was in the caudal BST. TH immunocytochemically retrogradely labelled neurons were observed in A1/C2 and A2/C2 and a projection of noradrenergic neurons was observed in the NTS in the midline, dorsalateral to the central canal. Electrophysiological studies showed that the basal firing of neurons in the BST is inhibited by iontophoresis of norepinephrine and by noradrenergic antagonists such as clonidine, neuronal activity increases, and the neuronal activity increases, and the neuronal activity is blocked by phenylthio. These neurons were also inhibited by electrical stimulation of the A2NTS area in vivo. The inhibition resulting from iontophoresis of clonidine and the electrical stimulation of the BST is blocked by iontophoresis of the alpha-2 antagonist yohimbine. The BST receive strong catecholaminergic innervation from the medulla which appears to exert an inhibitory effect via alpha-2 receptors and an excitatory effect via alpha-1 receptors.

INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) PROTECTS GT-7 CELLS FROM OXIDATIVE INJURY. M.A. Sottini*, L. Scapagnini and P.L. Canico Instituto of Pharmacology, University of Catania School of Medicine and "Chair of Pharmacology, University of Pavia School of Dentistry, Italy.

The neuroprotective action of insulin-like growth factor-1 (IGF-1) has been recently demonstrated in models of cerebral and retinal degeneration. Immortalized hypothalamic, gonadotroph-releasing hormone- (GnRH) secreting, GT-7 cells display a marked sensitivity to toxicity induced by reduced glutathione- (GSH) depleting agents that in these cells cause necrotic death. GT-7 cells express IGF-1 receptors whose activation causes a bidirectional modulation of GSH secretion. On these bases we have studied the potential protective effect of IGF-1 in GT-7 cells. Subconfluent GT-7 neurons cultured for two days were exposed to different concentrations (50-500 uM) of buthionine sulfoximine (BSO), which reduces the intracellular levels of GSH, for 24 hours or to dibutyryl cyclic AMP (DBcAMP, 1 mM) which increases the levels of GSH, for 1 to 3 hours. Both treatments produced extensive neuronal death that was more pronounced in DEM-treated cells. Concomitant exposure of GT-7 cells to IGF-1 and the mammalian growth factor resulted in a remarkable reduction of neuronal death as assessed either by trypan blue exclusion or by staining with fluorescein diacetate and propidium iodide. The neuroprotective effect of IGF-1 has been compared to that induced by the potent antioxidant idebenone that, in this model, provided a virtually complete protection of the oxidative stress produced by either BSO or DEM. These results suggest that IGF-1, as already proposed in different cellular systems for various growth factors, may exert its neuroprotective action through antioxidant mechanisms.

Egglaying behavior in mature Aplysia occurs in response to egg-laying hormone (ELH) released from neuroendocrine bag cells; ELH release is triggered by a prolonged pattern of axonal-neuronal firing (afterdischarges). Electrical stimulation of bag cells from immature Aplysia does not trigger afterdischarges. However, prolonged depolarization (lag phase potentials) can be elicited in the presence of the K+ channel blocker TEA (Nick et al., Soc Neurosci, Abst 708, 1993). In the present study, we sought to determine whether stimuli that might cause firing of bag cells that are incapable of showing afterdischarges contain the functional mechanisms required for secretion. Sucrose electrodes were used for both electrical stimulation and extracellular recording from bag-cell preparations (avg body wt=256 g) or immature (avg body wt=10 g) Aplysia. Medium bathing the preparations was collected every 5 min before, during, and after stimulation for a total of 125 min. Samples were frozen at -20 °C until radioimmunoassay for ELH was performed. Immature preparations (n=3) showed -9 plateau potentials (no afterdischarges), while mature preparations (n=3) showed afterdischarges lasting -18 min with ~650 action potentials fired during that period. Both immature and mature bag-cell preparations secreted ELH above baseline, although the total amount (~36 ng/ml vs. -2400 ng/ml) and duration (-25 min vs. 105 min) of secretion was significantly lower from immature preparations. These results indicate that immature bag cells that do not show afterdischarges can nonetheless be stimulated to release ELH, and therefore must contain the necessary cellular machinery for secretion. Supported by NIH HD 28336 (to NSF), NSP-BNS 614681 (to TC) and NIH-N5 18492 (to LLK).

482.11 EFFECTS OF STREPTOZOTOCIN-INDUCED DIABETES ON NADPH-DIPHOSPHATE POSITIVE NEURONES IN THE RAT PANCREAS. S.B. Try*, G. Burnstock*, Department of Anatomy, National University of Singapore, Kent Ridge, Singapore 0511 & Department of Anatomy and Developmental Biology, University College, London, WC1E 6BT, U.K.

In streptozotocin (STZ) rats, NADPH-diphosphatase positive neurones were dispersed in the interlobular septa, near blood vessels and ducts as well as within pancreatic lobules. This neurone activity was localized in the cell cytoplasm but not in the nucleus. Most of the neurones were heavily labelled while others were moderately to lightly and some were negative. Some labelled neurones sent processes that ramified amongst the exocrine acinar cells. Numerous fine varicose NADPH-diphosphatase positive fibre nerves formed networks around the individual islet cells. At 8 weeks post-diabetes, the number of NADPH-diphosphatase positive neurones and nerve fibres was reduced. Labelled neurones that persisted were solitary or in small groups (2-5 cells). They were heavily labelled for NADPH-diphosphatase activity, some appeared rounded and possessed few short and stubby processes. Lumps of langerhans were not easily distinguishable and their associated nerve networks seemed to have disappeared. NADPH-diphosphatase positive macrophages were also found in the interlobular spaces. These results suggest that diabetes has a drastic effect on NADPH-diphosphatase positive neurones and nerve fibres in the rat pancreas.

482.13 DECREASED GLUCOSE, BUT NOT FATTY ACID AVAILABILITY INCREASES FOS-LIKE IMMUNOREACTIVITY IN THE CAUDAL BRAIN STEM OF FEMALE SYRIAN HAMSTERS. B.F. Florey*, Y. Zhu, and J.E. Schneider. Department of Psychology, Lehigh University, Bethlehem, PA 18015

In Syrian hamsters, extrudary cycles are inhibited by food deprivation or treatment with 2-deoxy-d-glucose (2DG), a drug that inhibits glucose metabolism, and methyly-palmitate (MP), a drug that inhibits fatty acid oxidation. For example, hamsters become anorexic when treated with high doses of 2DG alone (1750 mg/kg), or with low doses of 2DG (500 mg/kg) and MP (20 mg/kg, respectively), but not with either drug alone at low doses. Systemic administration of 2DG at high doses (<1750 mg/kg) stimulates expression of the proto-oncogene c-fos in the area postrema and in the nucleus of the solitary tract (NTS). These and other data suggest that the effects of 2DG on extrudary cycles may occur via a gliaocpic signal detected in the APNTS. The present study investigated whether other metabolic changes also affect c-fos expression and general activation in the APNTS. Hamsters received one of the following treatments: (1) 1750 mg/kg (high dose) (2) 750 mg/kg 2DG (low dose) (3) 20 mg/kg of MP (low dose) (4) low doses of both 2DG and MP (5) high dose vehicle alone. c-fos was observed in the APNTS only in groups that were treated with high doses of 2DG. This suggests that glucose deprivation (decreased glucose availability) but not lipoprivation (decreased availability of metabolic fuels necessary for reproduction may be specifically related to glucose availability. MP may have effects on carbohydrate and/or lipid metabolic effects via the APNTS. Supported by research grant BNS9212056 from NSF.

482.10 VARIATIONS OF MEMBRANE CURRENTS DURING SOMATOSTATINE RELEASE AS MEASURED ON IDENTIFIED HELIX NEURONS BY AN IMMUNOMOLECULAR TECHNIQUE. MATH P., DABRON P., CRIST M., BRIDGM & GOLAM. Neuroendrobiology du développement,25030, Besançon, France and Neurobiologipe Moluinaire, C08,13000 Marseille, France.

Helix neurones of the visceral ganglia were studied in-situ using simultaneous current clamp and somatostatin release using a micro-immunoelectrode. The results have shown it exists a somatostatin release in the extracellular spaces. This release was potential-dependent since it appears for mature bag cells (lag phase potentials) but it was present at +20 mV. Nevertheless, the release intensity seemed to voltage-independent but was delayed when membrane potential increase. Calcium channels blockade suppressed the release. Under slow stimulations (10 hz, +20 mV) the release became cyclic during some minutes but higher frequency increased the somatostatin release in a dependent manner. Even-though a recent demonstration of a noticeable regional difference of calcium channels density, it seemed that somatic eosyoxin characteristics were a good fit for synaptic release. This is in good agreement with previous works which have demonstrated that eosyoxin was not only related to calcium channels but also to sodium channels.

There is evidence on the existence of different ovulatory thyrhythmia between the right and left ovary (RO, LO) depending on ovarian innervation; which is very significant in hemivariectomized [Novx] animals. Present study was conducted to analyze if the blockade of ovarian innervation induced by lidocaine-adrenaline (LiA) injection into the ovarian bursa, previous the extravasation of controlateral ovary, affects the ovulatory ability by the in situ ovary, performed at 15.00 h in the day of proestrus of 4-day cyclic rats. The animals were sacrificed on the next expected day of estrus. When LiA was injected to the LO and the LO extraptipated 0/6 rats ovulated, while when the RO was injected and the LO extraptipated 8/8 rats ovulated (p<0.01). When Novx by the LO or RO was performed without LiA injection, 8/8 and 9/9 rats ovulated. 6/6 rats treated at 18.00h with LiA on the LO and the RO extraptipated ovulated next morning.

Present results support the hypothesis that the RO is more dependent on neural information than the right one. Supported by DGAPA grant IN210893 and PIII.

Inflammation produced by complete Freund's adjuvant injection in the rat hindpaw produces plasma extravasation, and histamine and inflammatory mediator, bradykinin (160 nM), perfused through the knee joint. This negative feedback process has been shown to be neurally mediated with capacin (100 mg/kg) to deplete most of their unregulated primary fibers. Injection of the hindpaw also inhibited bradykinin-induced plasma extravasation in the knee joint. Acute surgical interuptions of lumbar sympathetic affereances to the hind limb did not attenuate the depression of bradykinin-induced plasma extravasation produced by c-fos injection. Injection of bradykinin into the hindpaw did not depress negative feedback process is mediated by activation of primary afferent C fibers. Elevation of C-fibers with electrical stimulation (25mA, 3Hz) of the hindpaw also inhibited bradykinin-induced plasma extravasation in the knee joint.

Acute surgical interuptions of lumbar sympathetic affereances to the hind limb did not attenuate the depression of bradykinin-induced plasma extravasation produced by c-fos injection. Injection of bradykinin into the hindpaw did not depress negative feedback process is mediated by activation of primary afferent C fibers. Elevation of C-fibers with electrical stimulation (25mA, 3Hz) of the hindpaw also inhibited bradykinin-induced plasma extravasation in the knee joint.

Our data demonstrate a negative feedback inhibition of an inflammatory process, which is mediated by sympathetic and peripheral afferents. It is mediated by ascending pathways in the spinal cord, and probably the hypothalamic-pituitary-adrenocortical axis. Supported by NIH grant AM32634
AFFERENT PROJECTIONS TO THE ROSTRAL NUCLEUS RAPHE PALLIDUS BY IONTOPHORETIC APPLICATION OF CHOLERA TOXIN B.

In order to investigate its role in thermoregulation, the afferents to the rostral nucleus raphe pallidus (nRNP) were examined by extremely restricted injection sites of cholera toxin b, which seemed necessary, since the nRNP is wrapped both dorsally and laterally by the central nucleus raphe magnus (nNRM).

Substantial bilateral afferents were received from the precentral, the medial infralimbic, and the subpericaleral cortex for the nRNP.

Strong afferents from the periventricular preoptic area, the paraventricular and the dorsal hypothalamic area could be confirmed in this study; additional afferents from the caudal preoptic area and the adjacent bed nucleus, the central amygdala and the perifornical lateral hypothalamic area were shown. Compared with the nNRM, fewer were afferents from the fields of Forel, the midbrain and pontine periaqueductal gray and the deep mesencephalic reticular formation.

Specific afferents for nRNP, but not for nNRM, were found close to the dorsal raphe nucleus in the ventromedial pontine periaqueductal gray and laterally to the third nucleus inside the midbrain reticular formation. Afferents from the nucleus Kolliker-Fuse and the lateral medullary reticular formation were stronger for nRNP than nNRM, afferents from the subarcuate nucleus, the lateral parabrachial area and the caudal pontine reticular formation less intense for nRNP than nNRM. By highly restricted injection sites, substantial afferents could be shown for nRNP from key structures of central nervous thermoregulation.

PREOPTIC PROSTAGLANDIN E2 (PGE2) AND CORE TEMPERATURE (Tc) RESPONSES OF GUINEA PIGS TO LPS i.v., INDOMETHACIN i.m., AND/OR PGE2 i.a. ADMINISTRATION. E. Schin, M. Erykowski, L.J. Unger and C.M. Blintz*. Dept. of Physiology & Biophysics, Univ. of TN, Memphis, TN 38163.

PGE2 has been postulated to be a central mediator of fever. It is generally believed that PGE2 is produced in the preoptic area (POA) because its level increases both in the third ventricle and the POA in response to i.v. pyrogen. However, lately the question has arisen whether PGE2 may in fact be formed outside the brain substance and then diffuse into it across cerebral vessels. If produced outside the brain substance, the blockade of its synthesis should prevent LPS-induced fever, whereas the intracarotid infusion of PGE2 should produce an increase in Tc as well as in preoptic PGE2. To verify this hypothesis, continuous measurements of PGE2 levels in the POA were made (sampling by microdialysis and analysis by RIA). Tc was monitored continuously during the following experiments: 1) Following a 90-min stabilization period, indomethacin (50 or 50 mg/kg) was administered i.m. 30 min before S. enteritidis LPS (2 µg/kg, i.v.); 2) PGE2 (100 or 10 µg/kg) was infused at 2 µl/min into a carotid artery for one hour. LPS-induced a temperature of 1.2°C was consistently associated with an increase in the level of PGE2 in the POA. Indomethacin at 10 mg/kg attenuated the LPS-induced fever and prevented the associated increase in PGE2 for 90 min after fever onset; moreover, PGE2 was significantly reduced by comparison to controls. Indomethacin at 50 mg/kg completely abolished both the fever and the increase in preoptic PGE2. Intracarotid infusion of PGE2 produced a dose-dependent hypothermia without any increase in preoptic PGE2. The blockade of fever and inhibition of the increase in preoptic PGE2 levels further substantiate the presumptive link between preoptic PGE2 and fever. The failure of exogenous PGE2 intracarotid infusion to induce increases in Tc and preoptic PGE2 excludes the possibility that PGE2 formed outside of the brain diffuses into the POA across cerebral vessels and induces fever. (Supported by NIH grant NS 22716.)

BOMBESIN-INDUCED HYPOTHERMIA IN ADRENALONIZED RATS. C. Barten*, D.A. York and G.A. Bray. Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA 70808.

Bombesin (BOM) is a tetrapeptide known to produce hypothermia when administered centrally in rats tested at normal ambient temperatures. Previous studies have demonstrated bombesin-induced hypothermia to require a state of reduced sympathetic nervous system activity. The importance of adrenal activity on this phenomenon is unknown. The present study examines the impact of bombesin injection (100µg/50µl) or vehicle (VEH) into the lateral ventricles on core body temperature of food-deprived (24hr) adrenalectomized (ADX) and sham operated (SADD) rats with peripheral corticosterone (CORT) replacement (0.1 mg/kg, i.p.) or vehicle (VEH). Blood pressure and heart rate were monitored in ADX rats as assessed by serum aldosterone assay at the completion of testing. This produced a significant difference between those rats exposed to the four experimental conditions: VEH/VEH/ADX, VEH/SADD, BOM/VEH/ADX, & BOM/CORT/ADX (p<0.03). Conditions were recorded at time of central injection and 60 min later. Central bombesin injection in all conditions as compared to central vehicle with a significantly greater hypothermia seen in ADX + CORT (+4.1±3.9°C) & VEH + CORT (+10.1±8.5°C) vs ADX (1.9±3.2°C) + VEH (+1.9±3.2°C).

These results demonstrate that adrenalectomy potentiates bombesin-induced hypothermia, and suggests that corticotrophin-releasing hormone and adrenal catecholamines modulate this phenomenon.
Efferent sympathetic nervous activity (SNA) from a small branch of the intercostal nerve, which ended in the intercostal brown adipose tissue (IBAT), and metabolic heat production (MHP) were measured in C57BL/6J male adult and aged mice under urethane/isoflurane anesthesia and was recorded as HR variability, from the recordings in the absence of urethane and isoflurane anesthetics and an IC1 blocker. HR variability was calculated on the basis of arterial pressure variability measured in the urethane- and isoflurane-free state and was expressed as the difference between the mean values of the heart rate standard deviation before and after the application of the specific blocker.

The studies were conducted in two experimental groups, one consisting of adult mice and the other of aged mice. Both groups were divided into two subgroups, one receiving the IC1 blocker alone and the other receiving the IC1 blocker plus the alpha2-adrenoreceptor agonist clonidine. The results obtained from the adult mice were compared with those from the aged mice to determine whether age-related changes in HR variability occurred.

In conclusion, the present study provides new insights into the role of SNA and MHP in regulating HR variability in mice. The findings suggest that age-related changes in HR variability are associated with changes in SNA and MHP, and that these changes may be mediated by alpha2-adrenoreceptor agonists. Further studies are needed to investigate the underlying mechanisms and their potential therapeutic implications.

The activity of preganglionic sympathetic neurons is maintained by an excitatory input from neurons located in the RLVM. Previous studies conducted in tissue slices (Sien et al. Brain Res. 1988; 451:345; and 1991, 556:61) examined the morphology and presence of catecholamine containing RLVM neurons. However, due to functional and anatomical heterogeneity in this medullary region, it is important to examine neurons which can be directly compared as baroreceptive and reticular neurons. This was possible in the present experiments conducted in vivo, in pentothal-anesthetized adult rats (see Lipinski et al., this meeting). Recordings were made with microelectrodes filled with 1% Neurobiotin or 3% Lucifer Yellow. RLVM neurons which responded with IPSPs following stimuli applied to the aortic nerve were intracellularly labeled. Some of these neurons could be excited antidromically following stimulation in T2 segment. Filled somas were found ventromedial to the compact formation of nucleus ambiguous. Dendrites extended up to 800 μm from cell bodies. Some main axon bifurcated in the dorsomedial tegmentum, and a few had axon collaterals which displayed bouton-like varicosities in the ipsilateral RVLM. CV adrenergic cells were revealed by immunofluorescence using antibody to tyrosine hydroxylase. Some injected neurons were shown to be double labeled.

RLVM bulbo spinal neurons were identified by the presence of retrogradely transported green latex microspheres injected under anesthesia in the spinal cord at Ts, 4-7 days prior to sacrifice. Then these cells were labeled intracellularly in fixed 100 μm-thick sections (horizontal or parasagittal) with Neurobiotin that was visualized with an avidin-HRP reaction. Drawings and quantitative analysis of morphological features were done with the Neuronal software. Some of the sections were doubly labeled for tyrosine hydroxylase (TH) and Neurobiotin using fluorescent tags.

In coronal sections, 83 well-filled cells were analyzed. They had 2 to 11 dendrites (mean ± SD, 3.2 ± 1.2) that extended 212 ± 10 μm (up to 690 μm) and branched up to five times. Their perikarya were fusiform (66%), round (16%), triangular (10%) or multipolar (8%) and had a mean cross sectional area of 417 ± 15 μm², corresponding to a roughly computed diameter of 23 μm (range: 14 to 31 μm).

Comparing parasagittal (23 cells injected), horizontal (N=21), and coronal (N=83) sections, we failed to find a predominant orientation in any plane for the extension of the dendritic tree in the whole population of the injected RVLM cells.

Forty five percent of the RVLM neurons examined in the coronal plane (37/83) had sparsely distributed spines and protruberances on their perikaryons and dendrites. In double stained cases, TH-positive cells, which account for 67% of the injected retrogradely labeled RVLM cells, contained both neurons with and without spines. (Grant: HL 26705 to PGG and NS 17143 to GFA).

GABA AND GLUTAMATE INPUTS TO BULBOSPINAL NEURONS IN RAT ROstral VENTROLATERAL MEDULLA. I.J. Llewellyn-Smith*, J.B. Minson, P.M. Plojesky, L.F. Amolda and J.P. Chalmers. Department of Medicine and Centre for Neuroscience, Flinders University, Bedford Park, SA, 5042, AUSTRALIA.

A potent vasopressor area coincides with the C1 group of catecholaminergic neurons in the rat rostral ventrolateral medulla (RLVM). Bulbo spinal RLVM neurons participate in the baroreflex and receive anafferent inhibitory input from the caudal ventrolateral medulla and an afferent excitatory input from the nucleus tractus solitarius. These pathways probably use amino acid neurotransmitters.

To study amino acid inputs in synapses on bulbospinal RLVM neurons, we injected cholera toxin B-gold into the intermedio lateral column. Bulbo spinal neurons were visualized with silver-intensification. Immunoreactivity from neurons containing glutamic acid was detected by post-embedding immunocytochemistry; and GABA or glutamate, by postembedding immunogold. Only the inputs to bulbospinal RLVM neurons forming a light cluster ventral to the nucleus ambiguous complex were examined. The cell bodies and dendrites of these neurons received synapses and contacts from GABA and glutamate nerve fibers. GABA occurred in 43% (23/54) and glutamate in 73% (39/54) of inputs. GABA was TH neuron in 39% (59/150) and glutamate in 54% (74/136) of inputs to non-TH bulbospinal neurons. Studies are underway to determine the origin of the amino acid synapses on bulbospinal RLVM neurons and whether GABA and glutamate are co-localized in any of these inputs.

EFFECTS OF GAAB RECEPTOR AGONIST BACLOFEN ON NEURONS IN ROstral VENTROLATERAL MEDULLA (RLVM): AN "IN VITRO" AND "IN VIVO" ELECTROPHYSIOLOGY STUDY. Y.-W. Lee and P.G. Gugenheim. Department of Pharmacology, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

We studied the effects of baclofen, a GABA receptor agonist, on neurons in the RLVM of the rat. In 17 neurons recorded intracellularly with sharp electrodes, bath application of baclofen (1-3 μM) produced a membrane hyperpolarization of 812 ± 160 mV (baseline 582 ± 160 mV, n=7), 2 a 15% decrease in the membrane input resistance (baseline 138±17MΩ, n=10), 3 a decrease in firing rate (n=14) and 4 a decrease in spontaneous post-synaptic potentials (n=10). Of 83 single units recorded extracellularly in the RLVM in vivo, all but 2 were inhibited by baclofen (1-1.3 μM). The inhibition was concentration dependent (0.1-3.0 μM, max. inh. = 94±8%, n=16), and persisted in low-Ca²⁺/high-Mg²⁺ medium (n=15). The GABAB receptor antagonist CGP35485A (1 μM, n=10) and CGP35485A (1 μM, n=15) or 2-hydroxysaclofen (0.5 mM, n=3), attenuated the inhibitory effect of baclofen (1-3 μM), but not that of GABA or muscimol (GAAB receptor agonist). In vivo, iontophoresis of baclofen (40-120 nA) inhibited most RLVM neurons including 13 out of 16 bulbospinal baroexcitatory cells. This effect was antagonized by iontophoresis of the GABAB antagonist, CGP35485A (60-80 nA, n=6), but not the GABAB antagonist, bicuculline (40 nA, n=5). These results suggest that 1) most RLVM neurons including sympathetically premotor neurons have somatodendritic GAAB receptors, 2) GAAB receptors in the RVLM may play a role in control regulation of cardiovascular function.
484.11 DIFFERENTIAL TIME- AND DOSE-RELATED EFFECTS OF HEMORRHAGE ON TYROSINE HYDROXYLASE (TH) AND NEUROPEPTIDE Y (NPY) mRNA LEVELS IN MEDULLARY CATECHOLAMINERGIC NEURONS. R. W. K. Chua* and P. E. Suschek. The Sak Institute, La Jolla, CA 92037.

Hypotensive hemorrhage induces cellular activation and up-regulation of TH mRNA in medullary catecholaminergic cell groups. To shed light on the significance of the widespread up-regulation of NPY in amine-secreting neurons, quantitative hybridization histochemical methods were used to compare the impact of graded doses of hemorrhage (15, 20 and 25%) on the time course of changes in relative levels of TH and NPY with respect to baseline staining for nucleolar, autonomic and other organ distribution in the brain. The data permitted comparisons between cells that ostensibly were not targeted by the challenge.

The major results can be summarized as follows: (1) Hemorrhage-induced significant up-regulation of TH mRNA in all medullary amine cell groups and NPY transcripts in all but the A2 region. At later time points (2-4 hrs) these changes were predominantly seen in Fox-iir neurons. (2) Neuronal cell groups displayed more robust maximal increases in relative levels of TH mRNA, while the reverse was true of the adrenergic cell groups. (3) Hemorrhage-induced up-regulation of TH and NPY mRNAs in Fox-iir neurons displayed differential time courses, with NPY responses peaking more rapidly, particularly in the C1 and C2 adrenergic cell groups. (4) At early time points (0.5-1.0 hr), a majority cells displaying increased levels of each transcript in the aminergic regions of interest were non-Fox-i. Sampling at early time points, however, may preclude the ability of cells to mount a detectable Fox protein response. These findings indicate that hemorrhage differentially affects relative levels of TH and NPY mRNA in medullary catecholaminergic cell groups that have no prior participation in anesthetic-mediated atropine and/or autonomic control mechanisms. The surprisingly robust NPY mRNA responses in adrenergic cell groups suggest a mechanism by which the peptide content of the projection fields of these cell groups is defended.

Spike-triggered averaging and coherence analysis was used to study the relationship between the discharges of 246 CVLM neurons and the 10-Hz rhythm in renal sympathetic efferent nerve fibers (SN) in urethane-anesthetized cats. The study was repeated after bilateral microinfusions of muscimol at four sites in the CVLM ipsilateral to the renal nerve recording in chemically inactivated neurons in this region. This procedure reversibly eliminated the 10-Hz rhythm in SN. Thus, we propose that CVLM neurons are elements of the network responsible for the 10-Hz rhythm in SN. (Supported by NIH grants HL-33366 and HL-13187.)

We previously demonstrated directional relationships among the 10-Hz rhythmic discharges of the cardiac, renal, and spriophageal sympathetic nerves by using partial coherence analysis in baroreceptor-denervated, urethane-anesthetized cats (Simpson et al., Soc. Neurosci. Abstr. vol 19, Part 1, 1993). Partialization mathematically removes the portion of the coherence of two signals attributable to the sources of a third signal. For example, we found partialization using spriophageal sympathetic nerve discharge data that reduced the coherence of the 10-Hz discharges of the left and right cardiac nerves to a significantly greater extent than did partialization using renal SN. Such results may reflect, among other things, 1) nonuniform coupling of multiple brain stem oscillators, each controlling a different nerve or 2) nonuniform crossstalk among spinal circuits that control different nerves but share inputs from a common source. In the present study, we compared coherence estimates and partial correlation between the left and right cardiac nerves in the presence of vagal parasympathetic nervous system activity in response to artificial means respiratory pattern and low level right renal nerve stimulation in urethane-anesthetized cats. The results indicate that the coherence of these signals is reduced by vagal parasympathetic nervous system activity and is abolished in a stochastic manner. The results suggest that a period of reorganization within the physiological range of rhythmic generating circuitry (Supported by NIH grants HL-28931 and HL-20864.)

We examined sympathetic nerve activity (SNA) and exaggerated sympathetic responses to isometric contraction in the spontaneously hypertensive rat (SHR) suggest that central nervous system dysfunction may contribute to the pathogenesis of hypertension in this model. In the present study, we compared the hypertensive responses of vasopressor neurons in the caudal ventrolateral medulla (CVLM) is diminished in SHR. Prior studies have demonstrated that excitolesions in CVLM in Sprague Dawley rats increase both SNA and mean arterial pressure (MAP). In urethane-anesthetized SHR and Wistar-Kyoto (WKY) rats, we examined the effects of kainic acid lesions in CVLM on spontaneous SNA, resting MAP and the evoked nerve responses to POH stimulation. In all rats, CVLM lesions produced significant increases in both SNA and MAP. Peak post-lesion MAP was no longer significantly different between strains (140 ± 30 mm Hg SHR vs. 129 ± 30 mm Hg WKY). However, the increase in total power (RMS) in SNA after the lesions was significantly smaller in SHR (111 ± 14) than in WKY (203 ± 30; P < 0.01). In both strains, post-lesion evoked responses to POH stimulation were greater than control, although this enhancement of evoked sympathetic responses was smaller in SHR than in WKY. We conclude that CVLM neurons may be less active in SHR, resulting in diminished sympathoexcitation.

A 10-Hz rhythm is ubiquitous in different species and conditions, and has been studied within cardiovascular reflexes in the presence of different targets in urethane-anesthetized or decerebrate cats. This rhythm can coexist with a low frequency component (a cardiac-related rhythm in cats with intact baroreceptor nerves). This rhythm is generated by a partialization of a fundamental oscillation with a period near 2-6 Hz (baroreceptor denervation). Spike-triggered averaging was used to study the relationship between the discharges of individual medullary neuronal groups and SN. Data from these studies show that the generators of the 10-Hz rhythm and low frequency components in SN are comprised of separate pools of brainstem neurons. First, in baroreceptor-denervated cats, medullary sympatetic nerve cell groups with activity correlated to the 10-Hz rhythm did not have activity correlated to the irregular 2-6 Hz oscillations. Second, in baroreceptor-innervated cats, CVLM nerve cell groups with activity correlated to the 10-Hz rhythm did not have discharge correlations 1:1 to the cardiac-related rhythm when both rhythms were prominent in the spectra of SN. Third, for CVLM neuron activity with activity correlated to the 10-Hz rhythm, the relationship between their discharge and SN was eliminated when the predominant pattern in SN was changed to a cardiac-related rhythm by raising arterial pressure. Fourth, lateral tegmental field neuronal activity had activity correlated to the low frequency components but not to the 10-Hz rhythm in SN. Some rostral ventrolateral medullary and raphe neuronal groups had activity correlated to both the 10-Hz rhythm and low frequency components in SN. Thus neurons in these regions receive converging inputs from the two generators. (Supported by NIH grants HL-33366 and HL-13187.)

Simultaneous recordings of cervical SYMP, splancnic and parovascular (PHR) activity along with arterial and directly recorded atrial EKG and end-tidal CO_2 were obtained in Saffan-anesthetized, paralyzed and artificially ventilated (100% O_2) 1-4 days old kittens. Power spectra and coherence estimates between SYMP nerves and between SYMP and PHR discharge were obtained by a FFT routine. PHR discharge defined the inspiratory (I) and expiratory (E) epochs used for gating spectral estimates. Coherence between SYMP nerves was significant at birth in the 3-5 Hz range; the value of coherence was not age-related. In the 5-12 Hz range, coherence revealed age-related maturation attaining significance circa 2 wks. At about 16 days, higher frequencies (>12 Hz) were present in the preganglionic SYMP power spectra. Highest coherence estimates related to low frequencies were significant until about 4 wks. In both power spectra and coherence estimates, these higher frequencies disappeared after 4 wks of age. Coherence between PHR and SYMP was not significant until circa 3 wks. By 1 mo, SYMP activity resembled that observed in adult mammals (Gootman & Cohen, Acta Physiol. Polon. 1973, 24-97). The results suggest that there is a period of reorganization within SYMP rhythm generating circuits. (Supported by NIH grants HD-31641 and HL-28931.)
CARDIOVASCULAR ANATOMY, MEDIUM-SIZED BY VALUES OF...  

We have previously shown by chemical microinjection methods (Brain Research, 548:279-286, 1991) that the rostral depressor area (RDA) of the brain stem in cat contains sympathoinhibitory neurons involved in cardiovascular regulation. We now report on pentobarbital anesthetized cats a study of 55 cells in the RDA whose spontaneous activities, detected extracellularly with a metal micro-electrode, were found to be correlated with tonic activity in 2-6 Hz sympathetic discharge of the inferior cardiac nerve. The method employed was that developed by Barman & Geber (Progress in Brain Research, 81:117-129, 1991), in which the RDA unitary action potentials serve as triggers for averaging 1 sec segments of the sympathetic discharge envelope wave. The activities of 17 cells yielded sympathetic slow wave averages of 2-3 Hz (synchronous with the heart rate), while the activities of 38 cells failed to correlate with the sympathetic discharge. Baroreceptor reflex activity (induced with IV phenylephrine or balloon-inflation in the aorta) revealed that, of these 17 cells, 8 were sympathoexcitatory, 5 were sympathoinhibitory, and 4 that RDA activity was heterogeneous. This indicates that the RDA is a heterogeneous population of cells, with cardiac-related sympathoinhibitory neuronal activity not as predominante as our previous methods suggested.

Sympathetic nerve discharges have both fast sympathetic-specific rhythms (2-6 Hz and 10 Hz) and respiratory rhythm. In 13 micodilator-decarcerated, paralyzed cats, we recorded phrenic and cervical sympathetic (CS) nerve discharges together with discharges of neurons in ventral medullary regions (Cooper et al., 1989). Of 208 recorded units, 26 had distinct and significant CS coherence peaks (range 2.1-17.8 Hz). Of these, 12 had peak coherence values > 0.1 (range 0.11-0.71, mean 0.280±0.23SD). The other 14 units had peak coherence values < 0.1 (range 0.05-0.09, mean 0.070±0.01SD). Most of the neurons (21/26) had a respiratory modulated rhythm (usually tonic I or E modulated) as determined by the eta-square test (Orem & Dicke, J. Neurophysiol. 50:1099-1107, 1983). These results suggest that the combination of fast and slow (respiratory) rhythms seen in CS discharges originate in the medulla. (Supported by N.I.H. Grant HL-73500.)

MEDIUM-SIZED RETINAL GANGLION CELLS PROJECTING TO THE GROUND COLLIUOUS SUPERIOR IN THE RABBIT, R.E. BLANCO AND N. LUSO. Inst. of Neurobiology and Dept. of Anatomy, U.P.R.C.M., San Juan, P.R. 00901.  

In the thirteen-lined ground squirrel (Spermophilus tridecemlineatus), retinal ganglion cells have been classified into 3 groups on the basis of their soma cell diameter: large (>14 μm), medium (10-14 μm) and small cells (6-10 μm; Flores, 1983). Of these, mostly small and medium-sized cells project to the superior colliculus (SC) and mostly large cells project to the dorsal lateral geniculate nucleus (Lugo-Garcia and Klicier, 1988). In order to characterize further the ganglion cells projecting to the SC, a retrograde tracer, cholera toxin subunit B (CTB), was injected into the superficial layers of the SC. After a survival period of 5-7 days, the animal was perfused, the retina dissected and the CTB immunohistochemically detected with a goat anti-CTB antiserum (List Biologicals, 1:2,500). Labeled cells were drawn and measured with a Neurohalla and an ocular. Our results confirm that retinal ganglion cells projecting to the SC are medium and small-sized. Most medium-sized cells had diameters of 10-11 μm. Their dendritic trees were extensively labeled. They differed in soma shape, number of primary dendrites, density of branching, symmetry of branching and pattern of dendritic ramification within the inner plexiform layer. This morphological diversity suggests that medium-sized cells are composed of more than one population. (Supported by ONR grant N00014-89-J-3070 & NIMH Grant MH-48190.)

Spectral analysis of heart rate (HR) and arterial pressure (AP) variables in man as well as in experimental animals displays two major components: a low frequency (LF; 0.04-0.15Hz) and a high frequency respiratory related (HF; 0.25 Hz) rhythm. HF is considered a marker of vagal modulation while LF is considered a behaviorally unmodulated component of HR fluctuation. In a previous study (Montano et al., 1980; 40:21-32, 1992) spectral analysis of cardiac sympathetic effenter discharge, in the range between 0 and 0.5 Hz, showed a predominance of LF oscillation, highly correlated with the LF detectable in HR and AP. This study was undertaken to evaluate whether LF rhythmicity could also be present in the variability of discharge of single medullary neurons involved in cardiovascular regulation. We analyzed, by means of autoregressive analysis algorithms, AP and impulse activity of single units recorded from lateral tegmental field, medullary raphe and rostral ventrolateral medulla in decerebrate and in urethane anesthetized, baroreceptor-denervated cats. The activity of medullary neurons was correlated to higher frequency components (2- to 6 Hz or 0.5 Hz) in sympathetic nerve discharge. Power spectra of single neurons discharge displayed an LF oscillation, highly coherent (between 0.6 and 0.8Hz) with the LF detectable in systolic AP. In conclusion we described for the first time that the impulse activity of single medullary neurons contains an LF rhythmity similar to that detectable in spectral analysis of the cardiovascular variables, thus raising the possibility of an involvement of these nuclei in generating this oscillation.
485.3 NON-SPECIFIC EFFECTS OF ANTIANGIOTENSIN II AND ITS AGONISTS AND ANTAGONISTS IN THE SUPERFICIAL LAYERS OF THE RAT SUPERIOR COLICULARIS. J. C. Mandel, R. L. Mandel, S. C. Mandel, Dept. of Ophthalmology, Physiology and Biophysics, Neurosurgery; Faculty of Medicine, Universidad de Sheffield, Sheffield, UK.

We have reported previously (Mandel et al., ARVO'94) that activation of angiotensin type 1 (Ang I) receptors in the superficial layers of the rat superior colliculus (SC) had a significant effect on evoked potentials (VEP). Some of our initial observations have suggested that the ‘early’ and ‘late’ components of the VEP complex are ‘on’ and ‘off’ responses respectively, and were differentially affected by the peptide. In the attempt to further characterize these effects, we investigated the impact of various concentrations of Ang I and specific agonists and antagonists (DUP 753, CGP 42112A). We also studied the effects of Ang I on separate ‘on’ and ‘off’ response components. Experiments were carried out on unanesthetized adult rats (15-16 weeks). A recording-injecting microelectrode filled with the peptide was implanted in the superficial layers of the SC in order to record VEP. Visual stimulation was provided by either a diffuse flash or a small testing spot (diameter of 500μm) placed in the corresponding field to evince ‘on’ or ‘off’ responses. The substance was injected at various concentrations (from 10-5 M to 10-2 M). Inhibitory effects of Ang I were observed at concentrations greater than 10-6 M and we were able to observe a differential effect on ‘on’ and ‘off’ responses. Increasing concentrations of Ang I gave different effects depending on its concentration. At lower concentrations (10-6 M), there were no significant changes in the amplitude of the evoked potentials. However, at 10-5 M, a concentration known to activate AT receptors predominantly, there was a reduction in the amplitude of the potential (5%) similar to that observed with Ang I. Injection of the AT antagonist DUP 753 together with Ang I yielded no significant changes in the amplitude of the responses. Further, in our original observation, Ang I equally reduced the amplitude of both the ‘on’ and ‘off’ potentials suggesting a non-specific effect for the peptide. These results contribute to earlier findings that Ang I has a suppressive effect on the superficial collicular layers in the adult rat. These responses appear to be mediated by the sole activation of AT receptors and tend to be nonspecific. Supported by MRC of Canada and Ciba-Geigy Ltd.

Previous work from our laboratory suggested that multiple adrenergic receptors were present in the superficial layers of the hamster’s superior colliculus (SC), and that the substantial number of α2 and β2 receptors may be located presynaptically on retinal and/or corticostriate mesotelencephalic terminals. The functions of these receptors were tested by intracellular or whole-cell recording in a perfused SC slice that included only the optical nerve, substantia nigra, and mesencephalic stimulation of retinotectal fibers. Addition of norepinephrine or epinephrine to the bath or application of microperfusion hyperpolarized ~55% and depolarized ~35% of 207 SC neurones tested, respectively, enhanced the membrane potential by ~3 mV. On average the membrane potential hyperpolarized from ~70 ± 1.5 mV to ~74.3 ± 0.9 mV when voltage clamped at ~70. The results indicate that the hyperpolarized neurones had net outward currents of 18 to 35 pA and depolarized cells had inward currents of 26 to 38 pA. The EPSP was reduced from 10.8 ± 3.7 mV to 6.7 ± 3.7 mV by NE, but the decrease was not correlated with any change in membrane potential. To date, tests with more selective ligands have shown that (S)-3-methyl-α-aminonitrone (α2), dobutamine (β1), and isoproterenol (β2 and β3) have effects on SC cells similar to those of NE. In conclusion, our data indicate that the adrenergic neurones, which could be located presynaptically on retinal or corticostriate mesotelencephalic terminals, produce significant effects on the membrane potentials of SC neurones. Supported by NIH NS 9342-90 and NS 32540.

485.5 EFFECTS OF ADRENERGIC AGENTS ON NEURONAL RESPONSES IN THE HAMSTER’S SUPERIOR COLICULARIS. Y. Zhang, R. W. Rhodes, and R. J. Monnery. Dept. of Anatomy, Medical College of Min. Toledo, OH 43699.

Radioimmunoassay binding experiments have demonstrated the presence of multiple adrenergic receptor subtypes in the hamster’s superior colliculus (SC) and the present experiments were undertaken to characterize the pharmacology of adrenergic effects on the visual, optic chiasm (OX), and visual cortical (VCTX) responses of PNs in the hamster. Of 40 neurones tested visually, 90% were suppressed by NE to 39.4 ± 28.4% of control responses and 10% were excited. Similar results were obtained during OX stimulation (N=28 cells). Both α1 agonists (phenolamine) and β agonists (dopamine) had marked effects on SC neurones similar to those of NE. Dobutamine (N=16 cells) had effects that varied, while methoxamine suppressed 4 cells and excited 6. The effects of NE were strongly antagonized by α1 antagonists and β adrenergic antagonists (P  and P2). α2 agonists were ineffective in nearly all neurones. These results indicated that α2 agonists completely blocked NE-evoked excitation, but did not reduce the suppressive effects of this amin. Thus, the suppressive effects of NE upon SC neurones appear to be mediated primarily by α1 and β2 receptors while excitation involves α1 receptors. No α2 adrenergic receptor subtype was specifically associated with either the retinotectal or corticostriatal pathway and experiments carried out to date have not allowed us to determine whether any of the effects of NE are exclusively pre- or post-synaptic. Supported by NIH NS 9208211 and NS 32540.

Neurones in the superficial grey layer (SGS) of the SC are innervated by the retina and visual cortex. SGS has 3 sublayers SGS1, SGS2, Retinal inputs dominate in SGS, SGS3, and SGS4 (from the surface) cortical inputs are prevalent. The NMDA antagonist AP5 reduces visual responses in 60% of SGS neurones indicating that NMDA receptors participate in these responses. Many of these cells are in SGS4. To test whether the contribution of NMDA receptors to visual responses is derived from cortical input to SGS, multibarrelled pipettes were used for single unit extracellular recording and iontophoresis of AP5, NMDA, AMPA and NMDA/AMPA in cats anaesthetised with halothane/N₂O/O₂ and paralysed with gallamine. The effects of NMDA receptor selective applications of AP5 on visual responses were studied before and during inactivation of the visual cortex with topical lignocaine. In 8 neurones where AP5 reduced the response to visual stimulation, the visual response was resistant to the effects of AP5 following cortical inactivation. Since the cortex is considered to influence the directional bias of SGS neurones, the effects of AP5 (n=17) and cortical inactivation (n=16) on directional responses were compared. Neither procedure altered the directional bias of SGS neurones. These data imply that, considerable NMDA receptor mediated input to SGS is mediated via the cortex. However, the cortex may not influence the directional bias of SGS neurones.

485.7 GAMMA-AMINOBUTYRIC ACID (GABA) IS EXPRESSED EARLY IN PREMATURAL DEVELOPMENT IN THE CAT SUPERIOR COLICULARIS. J.P. Henri*, M.T. Simon, F.T. Banfo, and R. R. Mige*. Dept. of Anatomy and Neuroscience Ctr., Louisiana State Univ. Med. Ctr., New Orleans, LA 70112. GABA is expressed prenatally in the superior colliculus (SC) in the cat adult, but the time of expression of GABA in this structure is not known. We therefore studied the expression of GABA-ir neurones in kittens ranging from 2 days to postnatal day 60 using antibody immunocytochemistry. Labeled cell position and density were determined using a neuron tracing system. At E24, GABA-immunoreactive neurones were observed in the SC and were concentrated deep within the superficial layers of SC than deeper. Some cells in the deeper layers were also present on the superolateral surface of the SC, reminiscent of cells in the process of migration. The number of GABA-ir cells increased roughly eight fold from E30-E46, and the adult pattern of cell distribution was clearly evident during this period. There was a two-fold decrease in GABA-ir cell number between E46 and P60. Cells also increased in maturity during this period. Based upon labeling of adjacent sections with antibody to vimentin, a glial fibrillary acidic protein (GFAP), we believe that most of the GABA labeling is in neurons and not glia throughout this developmental period. In summary, GABA is expressed very early in prematurnal development in the SC, which is consistent with the endogenous binding protein calcium in this structure. GABA is expressed in some cells before they migrate into SC and clearly precedes the formation of the adult pattern of GABA neurones. The increase in number of GABA-ir cells may be due to loss of expression of the neurotransmitter or to cell death. Supported by NIH EY02973.

Parvalbumin (PV) is found in neurones in some neurones in the cat superior colliculus (SC) are projection neurones that form a dense sublamina tier in the deep superficial grey and upper laminar regions of the SC. Calbindin (CB) neurones are multiform neurones that form a sublamina tier with the PV neurones in the superficial grey and upper laminar regions of the SC. We have examined kittens aged E24 to P60 to determine when these tiers develop. Sections were immunocytochemically treated with monoclonal antibodies directed against PV and CB. Labelled neurones were then scattered throughout the SC as well as within the subventricular zone. By E28-30, GABA-ir cells and neurones were more densely concentrated within the superficial layers of SC than deeper. Some cells in the deeper layers were also present on the superolateral surface of the SC, reminiscent of cells in the process of migration. The number of GABA-ir cells increased roughly eight fold from E30-E46, and the adult pattern of cell distribution was clearly evident during this period. There was a two-fold decrease in GABA-ir cell number between E46 and P60. Cells also increased in maturity during this period. Based upon labeling of adjacent sections with antibody to vimentin, a glial fibrillary acidic protein (GFAP), we believe that most of the GABA labeling is in neurons and not glia throughout this developmental period. In summary, GABA is expressed very early in prematurnal development in the SC, which is consistent with the endogenous binding protein calcium in this structure. GABA is expressed in some cells before they migrate into SC and clearly precedes the formation of the adult pattern of GABA neurones. The increase in number of GABA-ir cells may be due to loss of expression of the neurotransmitter or to cell death. Supported by NIH EY02973.
CALCUT BINDING PROTEIN CALBINDIN D-28K IN THE PRETENTIC
AND ACCESSORY OPTIC SYSTEM OF THE RABBIT. B. Nune Cordero,
J.J. van der Want, G. Butler and R.B. Mize. SPON: European Neuroscience
Association111. Dept. of Morphology, The Netherlands Ophthalmic Res. Inst.,
1100AC Amsterdam and Dept. of Anatomy and Neurosurgery Civ.,
Los Angeles State University Med. Ctr., New Orleans, LA 70112.

The calcium-binding protein calbindin-D-28K (CIB) is a highly selective marker
of specific cell types in the CNS. In the cat pretectum (PT), CB cells form four
cell clusters, two of which lie partially within the nucleus of the optic tract (NOT).
CB cells are mostly large projection neurons that precisely overlap the retinal input
to PT and cross nuclear borders. In this study, we determined whether these same
cell clusters are present in the rabbit, a lateral-eyed species with a well developed PT.
CB cells through the NOT and accessory optic system (AOS) nuclei of three
rabbits were incubated with an antibody directed against CB and visualized using
silver-gold enhanced DAB. A few neurons in the retinal NOT were CB positive,
while the caudal NOT was devoid of CB neurons. Unlike the cat, separate dense
clusters of neurons were not observed in the PT of rabbit. However, clusters of
CB neurons were observed in the caudal portion of the dorsal terminal nucleus
(DTN) and in the transition area of the DTN and interstitial nucleus of the superior
fasciculus posterior fibers (mSTP). However, the medial terminal nucleus (MTN)
was completely free of CB neurons. In contrast to cat, the clusters of CB neurons
in the AOS fell within the established borders of these nuclei. In addition, there
was no precise overlap between CB cells and retinal afferents in the rabbit PT and
AOS. CB appears to label different cell classes in the two species. Supported by
NIH EY02973.

CROSS-MODAL INHIBITION IN MULTISENSORY NEURONS IS
BASED ON UNIMODAL RECEPTIVE FIELD ORGANIZATION. D.C.
& Anatomy, Bowman Gray School of Medicine/Wake Forest University,
Winston-Salem, NC 27157

A fundamental principle of multisensory integration is that spatially
 coincident stimuli from different modalities enhance one another’s
effectiveness, whereas spatially disparate stimuli may depress one’s
effectiveness. The present experiments in cat superior colliculus (SC)
were designed to examine the basis for this cross-modal inhibition,
and to determine whether the excitatory-inhibitory organization of
multisensory RFs is significantly different from that of unimodal RFs. A
total of 114 (55 unimodal; 59 multisensory) neurons were examined.
Surprisingly, each multisensory RF was organized in fundamentally the
same manner as its unimodal counterpart. However, the incidence of
inhibitory regions borders differed across modalities. The majority (81%)
of auditory RFs had inhibitory regions, but far fewer visual (22%) and
somatosensory (15%) RFs did. In many multisensory neurons RF inhibitory
borders were not modality-specific (e.g., auditory stimuli would suppress
visual excitation); in others, inhibitory regions were modality-specific
and this was most common for visual inputs (e.g., visual inhibits only
visual). These data indicate that while cross-modal inhibition in SC is
due to the presence of nonspecific inhibitory regions, inhibitory regions
themselves do not guarantee such effects. In these cases the inhibitory
effect is on the input rather than on the target multisensory SC neuron.
Supported by NIH grant NS2543.

SIMULTANEOUS RECORDINGS OF MULTI-SINGLE NEURAL ENSEMBLES IN THE SUBCORTICAL VISUAL SYSTEM REVEAL PRESENTATION OF OSCILLATORY WAVES. Rowshanak Hashemiyoon1 and John K. Chapin. Department of Physiology & Biophysics, Hahnemann University, Philadelphia, PA 19104

We have spontaneous oscillations (10-40Hz) that are ubiquitous in the subcortical retino-geniculo-striate visual system. These oscillations are broadcast from the retina to synchronize unit activity across multiple visual pathways. These are simultaneously recorded upon recording of multi-single units in the visual midbrain, thalamus and optic tract. Further, we investigate the spatiotemporal structure of these oscillations, electrode arrays consisting of 16-microelectrodes (18 0.5 mm) were chronically implanted across the stratum griseum superficiale (SGS) of the superior colliculus. Under anesthetized and awake conditions spatiotemporal synchronous discharge rhythms recorded from these electrodes exhibited variable phase angles of up to 15ms, indicating propagation of activity waves across the SGS. A small (14") flashing light (1s ON, 1s OFF) in the contralateral visual field suppressed the oscillatory activity of the SGS. LIGHT-OFF produced a phase resetting oscillatory rebound, without latency differences by up to 15ms, suggesting propagation of waves away from the LIGHT-OFF point. Other studies investigated the effect of non-photopic, non-patterned stimulus. Whereas non-pat-
tempered flashing circles of light produced simple LIGHT-OFF suppression, addition of a dark bar to the middle of the circle produced a more complex response, consisting of an additional oscillatory peak during the LIGHT-OFF period. In conclusion, the propagating spatiotemporal pattern of these oscillations may not only integrate sensory processing across the subcortical visual system, but might also carry a distributed code for visual sensory information. Supported by NS25722 to JKC.

GABAa MEDIATED DISINHIBITION OF THE SUPERIOR COLICULUS RESTORES VISUAL ORIENTING BEHAVIOR IN RABBITS IN THE PREVIOUSLY HEMIANOPTIC VISUAL FIELD OF THE CORTICALLY BLIND CAT. V. Ciaramarco1, J.S. Durmer, W.E. Todd and A.C. Rosenquist
Dept. of Neuroscience, Univ. of Penn, Phila., PA 19104

Following unilateral removal of all known visual cortical areas, a cat is rendered hemianopic in the contralateral visual field as measured by visual perimetry and other behavioral tests. It has been shown that visual orientation behavior can be restored to the previously blind hemifield by transection of the commissure between the two colliculi, or by destruction of the contralateral substantia nigra. (Sprague, I.M., Science 151:1544-1547, 1966; Wallace, S. F. et al., J. Comp. Neurol. 296:222-252, 1990) It was hypothesized that the mechanism mediating recovery is disinhibition of the SC ipsilateral to a cortical lesion.

We directly tested this hypothesis by reversibly disinhibiting the SC ipsilateral to a cortical lesion with bicuculline, a GABAa antagonist. In accordance with the model, disinhibition of the SC ipsilateral to the cortical lesion restored visual orienting responses in the hemianopic visual field for a period of several hours. Control injections of saline had no effect on visual orienting behavior. Conversely, inhibition of the SC with muscimol, a GABAa agonist in a normal animal renders the animal unable to detect and orient to visual stimuli in the hemisphere contralateral to the SC.

(Supported by EY02654, 2 T32 EY07035 and 2 P01 EY01583.)
485.15 RECOVERY OF VISUAL ORIENTING IN THE HEMIANOPIC CAT AFTER SMALL SUBSTANTIAGeba LIGATION IS NOT ABOLISHED BY SUBSEQUENT ENLARGEMENT OF THE INITIAL LESION

A.C. Rogenski* and T.C. Ciarimboto.
Dept. of Neuroscience, Univ. of Penn., Phila., PA 19104

Unilateral, 90% of all known visual cortical areas in the cat renders the animal hemianopic in the contralateral visual field as measured by visual perimetry and other behavioral tests. Visual orientation behavior is retained in the lesioned eye by an activation of the unlesioned sensory system as a result of increased visual input to the unlesioned visual cortex. Performance of the visual perimetry tests were normal in both eyes. After unilateralling the unlesioned eye, normal visual orientation behavior was retained, but pretend to normal visual orientation behavior is not abolished by subsequent enlargement of the initial lesion.

Supported by EY02654 and 2 T32 EY07015.

485.16 IOTIOTIC ACID LESIONS OF THE PEDUNCULOPONTINE NUCLEUS RESTORE VISUAL ORIENTING RESPONSES IN THE PREVIOUSLY HEMIANOPIC VISUAL FIELD OF THE CORRECTLY BLIND CAT

Dept. of Neuroscience, Univ. of Pennsylvania, Phila., PA 19104

The unilateral removal of normal visual cortical areas in a cat results in an enduring hemianopia as measured by visual perimetry and other behavioral tests. This unilateralling the properly visual cortex with ibotenic acid destruction of a critical zone in the substantia nigra pars reticulata (SNpR) contralateral to the cortical lesion (Wallace, S.F. et al., J. Comp. Neurol. 296:222-259, 1990). Paradoxically, large lesions to the SNpR which include but extend beyond this critical zone fail to restore visual orienting behavior.

In an attempt to understand this paradoxical finding, we made unilateral visual cortical lesions followed by ibotenic acid lesions of the contralateral SNpR critical zone in 5 cats. All cats recovered visual orienting behavior in the hemianopic field. In these recovered animals, the original SNpR critical zone lesion was subsequently enlarged with ibotenic acid an average of 3.4 weeks after the initial lesion. None of the 5 animals showed a loss of recovery. This finding argues strongly for the role of plasticity in nigrostriatal circuitry and visual orienting behavior. The time between a critical zone lesion and an enlargement of this lesion appears to be sufficient for compensatory mechanisms to maintain recovery.

Dept. of Anatomy and Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112

Most afferents to the cat superior colliculus (SC) are present at birth, including those from the substantia nigra. It is not known when these reach the SC during prenatal development. We have therefore studied the development of innervation of the SC by SN fibers in fetal tissue using the cytochrome d oxygen Dil. Dil crystals were placed within the SN in blocks of brain perfused at ages E46, 46, 51, 57, 57, and 59 days post-conception. These blocks were stored in fixative in an oven at 37°C for 4-5 days, then sectioned and examined with an epifluorescent microscope. Labeled fibers were traced with a neuron tracing system. No Dil fibers were present in the superior colliculus at birth, although they were present in the oculomotor nucleus. By E46, Dil fibers were present in the deep layers of the caudal SC, but were not present in the superficial layers. The fibers were thin and had few varicosities. Myelinated fibers were seen on or near the optic tract. Few fibers were found in the rostral SC. The labeled fibers were confined primarily to the unilateral SN. By E51, the number of labeled fibers in the SC had increased. By E57, large labeled fibers were seen on the intermediate gray layer (IL) of the caudal SC. The fibers at this age were thicker and some had numerous varicosities. Fiber density increased at E57 and P1, but no fibers were found above the IL at even P1. Thus, a sharp border between the superficial and deep layers is maintained at this age. No obvious fiber patches were observed at any age. The patch-like organization of SN fibers seen in the adult must therefore develop postnatally. SN fibers reach the SC about 2 weeks after retinal afferents have innervated SC, and by SC lamination is complete. Supported by NIH EY-02973.

485.18 EVIDENCE THAT AREA 17 CORTICAL SYNAPSES IN THE CAT SUPERIOR COLICULARIS ARE GLUTAMATERGIC. G.D. Butler, R.H. Whitworth* and R.B. Mize.
Dept. of Anatomy and the Neuroscience Center, Louisiana State Univ. Med. Ctr., New Orleans, LA 70112

We have previously shown that antibodies to the excitatory amino acid neurotransmitter, glutamate, label at least two types of synaptic terminals in the cat superior colliculus (SC). One type contains large round synaptic vesicles and appears to stain the nigrostriatal synapses. The second type contains smaller round vesicles and dark mitochondria (RSD). The origin of the latter type is unknown. To determine if RSD arise from synaptic vesicles, we made unilateral aspiration lesions of area 17 in three cats and waited 5, 14, and 28 days before sacrifice. We then examined the distribution of glutamate in the SC of these cats using electron microscopy post-embedding immunocytochemistry and colloidal gold-conjugated antibodies. On the side contralateral to the lesion, both RT and RSD axon terminals were labeled by anti-gluatamate, as in the normal SC. Some conventional dendrites and myelinated axons were also labeled. On the lesioned side, morphologically normal RSD terminals were infrequently observed. However, synaptic terminals in the initial stages of electron dense degeneration that had a dark ground and irregularly shaped swollen vesicles were labeled by anti-glutamate. Axon terminals and myelinated axons undergoing neurofilamentous hypertrophic degeneration also were often labeled. By contrast, terminals in advanced stages of degeneration were not synaptically active and contained little or no glutamate. These results confirm that both major sets of afferents to the cat SC contain glutamate; RT terminals from the retina and RSD terminals from visual cortex. It is possible, however, that not all terminals from these sources contain glutamate because a few RT and RSD terminals were not labeled by the antibody. Supported by NIH EY-02973.

SOCIETY FOR NEUROSCIENCE ABSTRACTS, VOLUME 20, 1994

486.1 CANNABINOID AGONISTS ATTENUATE DOPAMINE-MEDIATED ROTATION IN RATS WITH UNILATERAL 6-HYDROXYPAMINOQUINOLINE LESIONS. L.A. Anderson*, J. Anderson, J.R. Walters and T.N. Chase, ETH, NINDS, NIH, Bethesda, MD, 20892, USA

The presence of cannabinoid receptor (CB-1) and D2 dopamine receptor antagonists and/or cannabinoids in the substantia nigra, caudate nucleus, and striatum, suggests that cannabinoids mediate effects on the striatum and striatal pallidum. This study was designed to examine this hypothesis. Basal ganglia (striatum, caudate nucleus, and putamen) were lesioned with 6-OHDA or monoamine oxidase-B (MAO-B) and subsequent rotation of these animals was measured. Bilaterally lesioned rats were administered D1- and D2-selective cannabinoid agonists or antagonists in the striatum and glutamatergic systems. Rats were allowed to habituate to the rotarod for 2 days before the baseline rotation was measured. Animals were sacrificed at 2, 5, 10, 15, 20, and 25 mg/kg i.p. with the cannabinoid receptor agonists. 15 mg/kg i.p. was the lowest dose that produced a reduction in the baseline rotation. The administration of 15 mg/kg i.p. reduced the baseline rotation by 50% and 25 mg/kg i.p. reduced the baseline rotation by 75%. The administration of 30 mg/kg i.p. reduced the baseline rotation by 90% and 40 mg/kg i.p. reduced the baseline rotation by 100%. This study demonstrates that cannabinoids can attenuate the baseline rotation of 6-OHDA lesioned rats and that the cannabinoids used in this study are effective in reducing the baseline rotation of 6-OHDA lesioned rats.

486.2 EFFECT OF SUBSTANCE P (NK1) RECEPTOR BLOCKADE ON CATALYSIS INDUCED BY DOPAMINE AGONISTS. Jeff Anderson* and Thomas N. Chase, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892

Systemic administration of D1 or D2 receptor antagonists induces catalepsy, a behavior defined as the long-term maintenance of an abnormal posture. Catalepsy is often considered an animal model of neuroleptic-induced parkinsonism. Subsequent to a retinal output pathway lesion, the lateral geniculate body is affected in striatal lesions. Bilaterally lesioned rats were treated with the non-peptide NK1 antagonist CP 99,994 (0.5, 2.5, or 10 mg/kg i.c.v.) or saline 15 min after administration of either the D1 agonist SCH 23390 (0.5 mg/kg i.c.v.) or the D2 agonist raclopride (2.5 mg/kg i.p.). Catalepsy was evaluated by the vertical grid test every 20 min for 160 min. CP 99,994 (2.5 and 10 mg/kg) decreased the catalepsy produced by raclopride by 46% and 78%, respectively. In contrast, CP 99,994 did not diminish the catalepsy induced by SCH 23390. These findings suggest that blockade of NK1 receptors reduces catalepsy produced by D2 but not D1 antagonists and that NK1 antagonists may be important in modulating behavioral responses mediated by D2 receptors. In addition, NK1 antagonists may have therapeutic potential in alleviating motor side effects associated with neuroleptic treatment.
Concurrent stimulation of D1 and D2 receptors by systemically administered dopamine agonists inhibits the activity of substantia nigra pars reticulata (SNr) neurons in rats with 6-hydroxydopamine (6-OHDA)-induced nigrostriatal cell loss. In order to investigate possible sites of action, the D2 agonist SKF 38393 was locally administered into the striatum (0.15 nmol) or the substantia nigra (9-17 nmol) of gallamine-paralyzed rats with unilateral 6-OHDA lesions (6-9 wk post-lesion) while the activity of individual SNr neurons was recorded extracellularly. Rats were tested for apomorphine (0.05 mg/kg, s.c.)-induced contralateral rotation 1-2 wk prior to study. An infusion of SKF 38393 in the striatum (n=7) or in the substantia nigra (n=7) produced no significant changes in the firing rate of SNr neurons. The D2 agonist quinpirole (0.3 mg/kg, i.v.) increased firing of SNr neurons (mean±SE: control 0.02±0.06; quinpirole 0.03±0.02; n=7). However, quinpirole administered after stratal infusion of SKF 38393 (n=7) or after nigral infusion of vehicle (n=6) produced no net change in the firing rate of SNr neurons. These findings suggest that the response to intravenous quinpirole depends on whether D2 receptors are stimulated by SKF 38393 in either the striatum or the substantia nigra. However, the stimulation of only D2 receptors by SKF 38393 at either striatal or nigral sites is not sufficient to alter the activity of SNr neurons. Explanations include the possibility that D2 receptors at another site or at a combination of sites including striatum and substantia nigra are required to produce changes in the activity of SNr neurons.

The mitochrondrial toxin 3-nitropropionic acid induced oral movements in rats. O.A. Andersen* and H.A. Jørgensen†. Deps. of Physiology and Psychiatry. Univ. of Bergen, N-5009 Bergen, Norway.

Tardive dyskinesia (TD) is a serious side effect of long-term neuroleptic treatment. The mechanism of TD development is still unknown. It has been proposed that TD may be a result of neuroleptic-induced excitotoxic neuronal damage in the striatum. To investigate the excitotoxic effects of 3-nitropropionic acid (3-NP), an inhibitor of energy metabolism which has been shown to induce striatal lesions due to glutamate receptor stimulation (in situ excitotoxicity), was studied in a rat model of TD. Three groups of rats (female Sprague-Dawley rats, n = 14-15/group) were treated continuously for 1 month with 3 doses of 3-NP (4, 8 and 12 mg/kg/day) administered SC with osmotic minipumps. Empty plastic tubes were inoperated SC to control rats. The behavior was videotaped regularly and vacuous chewing movements (VCM), a putative sign of TD, were monitored for 6 months, as well as the total behavior, were recorded.

3-NP induced a dose-dependent increase in VCM in the period from 2 to 4 weeks. The effects were somewhat different among rats; while the highest dose of 3-NP had significantly more VCM than controls and the rats receiving the lowest dose were at control level, 3-NP also dose-dependently decreased the general motor activity.

The effect of 3-NP on VCM suggests that striatal glutamate receptor stimulation may underlie the development of VCM in rats and maybe TD in humans.

Dopamine receptor agonists and forskolin. Similarly potentiate responses evoked by excitatory amino acid receptor agonists in rat neostriatal neurons. M. Day, C. Cobelli, N.A. Buchwald, and M.S. Levinger. National Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

Our laboratory has studied the physiological interactions between dopamine (DA) and excitatory amino acids (EAA) in the neostriatum. We have shown that DA potentiates the evoked responses elicited by N-methyl-D-aspartate (NMDA) receptors but attenuates responses mediated by glutamate or activation of non-NMDA receptors. The present experiment was designed to examine the possibility that DA's ability to activate receptors on NMDA receptors involves alterations in the adenyl cyclase transduction cascade. Intracellular recordings were made from neostriatal neurons in brain slices using standard techniques. Similar to previous findings, iophotonic or bath application of the DA D1 receptor agonist SKF 38393 potentiated NMDA-evoked responses by increasing the maximum amplitude, half amplitude duration and number of action potentials evoked. SKF 38393 also enhanced glutamate-evoked responses, but to a lesser degree. Receptor antagonists were used to evaluate the specificity of the agonists' actions. Bath application of forskolin, an activator of the adenyl cyclase which increases cAMP, mimicked the effects of D1 DA receptor activation and enhanced responses evoked by iophotonic application of NMDA. Forskolin also enhanced DA responses and the existence of such potentiation is consistent with a model in which DA, acting through activation of D1 receptors, enhances cAMP-evoked responses through a cAMP-dependent mechanism. Supported by USPHS HD 00958.

AP-1 DNA binding activity in striatum: dopaminergic regulation. K.-X. Huang* and J.R. Walters. ETR, NINDS, NIH, Bethesda, MD 20892.

Stimulation of dopamine (DA) receptors in the basal ganglia affects expression of c-fos, while interruption of c-fos expression in the striatum with antisense DNA reduces behavioral response to DA agonists1,2. Since Fox and Jun proteins influence cellular function by forming AP-1 which binds to DNA sites regulating gene transcription, detection of DA receptor activation by stimulation on striatal AP-1 DNA binding activity were examined using a gel shift assay. Nuclear protein extract (10 μg), prepared from homogenized striatum, was incubated with the striatal DNA containing 42 bp of sequence AP-1 or CREB consensus sequence. In normal rat striatum there was a high level of AP-1 binding. i.p. administration of (+) SKF 38393 (5 mg/kg, n=9) or quinpirole (0.25 mg/kg, n=8) significantly affected AP-1 binding 2 hr later, while did not a combination of these drugs (n=7). In striata of rats treated with reserpine (10 mg/kg, s.c.) for 4-7 hr, AP-1 binding was increased by 90% (n=8, p<0.01). AP-1 binding was also increased by 80% (n=7, p<0.01) 12 weeks after 6-OHDA-induced lesion of the nigrostriatal pathway and by 45% (n=5, p<0.05) 8-9 months later. In 6-OHDA-lesioned rats, a combination of (+) SKF 38393 (10 mg/kg) and quinpirole (0.25 mg/kg) further increased AP-1 binding by 76% (n=6, p<0.01). Striatal CREB DNA binding activity was not significantly affected in reserpine or lesioned rats. Thus, changes in Fox synthesis could be involved in DA agonist behavioral effects.2,12 are not reflected in total striatal AP-1 binding 2 hr after agonist treatment in normal rats, but are evident in 6-OHDA-lesioned rats. The observation that striatal AP-1 DNA binding activity is enhanced by DA depletion as well as by DA receptor stimulation after DA cell destruction suggests that different underlying mechanisms are involved. Regulation of neostriatal neurons by cAMP-dependent mechanisms. C.S. Coletti and M.S. Levine. Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

The purpose of the present study was to examine the possibility that cAMP-dependent regulation of synaptic transmission occurs in the neostriatum. Intracellular recordings were obtained from neostriatal neurons in slices using standard techniques. Depolarizing and synaptic potentials (DPSs) were elicited by local electrical stimulation. Bath application of forskolin (FKK), an activator of adenylyl cyclase, enhanced DPS amplitude (155±8% (mean±se) of control) and duration (122±6% of control). This potentiation of DPS was due to an increase in the frequency of invasion of the GABA receptor antagonist bicuculline, and was not seen with the inactive FKK analog 1,3-didehydroforskolin. Rp-Camps, an inhibitor of cAMPT-dependent protein kinase (PKA) was applied in additional experiments. Rp-Camp (100μM) significantly attenuated FKK's enhancement of DPS amplitude. Moreover, the PKA activator Sp-Camps (100μM, 10 min) also enhanced DPS amplitude. These results suggest that FKK is acting through a PKA-dependent mechanism to enhance DPS amplitude. Interestingly, in some neurons, treatment with Rp-Camps clearly depressed the evoked response. This inhibition was also seen when the intracellularly-activated inhibitor PKI was applied via the recording electrode. In contrast, bath application of the phosphatase inhibitor, okadaic acid (10μM), increased DPS amplitude. These results indicate that, at least under these experimental conditions, activation of PKA and phosphatase activity regulates DPS amplitude. Taken together, these results suggest a role for the adenylyl cyclase cascade in the regulation of synaptic transmission in the neostriatum. Supported by USPHS HD 00958.
DIZOCILPINE MALEATE DIFFERENTIALLY INFLUENCE THE POSTSYNAPTIC EFFECTS OF NIGROSTRIAL DOPAMINE DEAFFERENTATION AMONG SUBPOPULATIONS OF STRIATAL NEURONS.

P. Sain* M.D. Hajii, A. Nicoullon and L. Kerkerian-Le Geoff, Cellular and Functional Neurobiology Laboratory, CNRS, 13402 Marseille cx 20 (France).

It was previously reported that following dopamine (DA) D2 receptor blockade or DA-depletion, neurtensin (NT) immunoreactivity (IR) is elicited in two distinct subpopulations of rat striatal neurons. Colocalized Fos-IR, interpreted as an indicator of enhanced neuronal activity, was observed in one of these subpopulations following D2 blockade (Neurosci. 57: 649-60, 1993). In this study, the degree of colocalization of Fos- and NT-IR in striatal neurons in response to acute midbrain 6-hydroxydopamine (6-OHDA) lesions was studied. It was observed that a subpopulation of smaller neurons exhibited light NT-IR and frequent colocalization with Fos-IR was predominant following reperfusion administration, mainly in the dorsolateral quadrant of the striatum. Another subpopulation of larger, intensely NT-immunoreactive neurons that was rarely colocalized with Fos-IR was observed following all the drug treatments, but was present almost to the exclusion of the smaller cell type three days following 6-OHDA lesions, mainly in the dorsomedial and ventrolateral portions of the striatum. The present data are consistent with two subpopulations of striatal neurons that accumulate NT following DA depletion. The possibility is considered that one subpopulation accumulates NT in response to coordinate increases in neuronal activity and NT synthesis, and the other as a result of decreased release. Support: NIH NS-23805, T32 NS-07254, and the United Parkinson Foundation.

BASAL GANGLIA AND THALAMUS IX

486.10

The accumulation of gamma-aminobutyric acid (GABA) in the mouse thalamus was measured after inhibition of GABA-transaminase (GABA-T) by means of systemic administration of the irreversible inhibitors gamma-acyclenic GABA (GAG, 200 mg/kg ip.) or gabaculine (150 mg/kg). After treatment with reserpine and alfa-methyltyrosine, the accumulation of GABA in both thalamus and cerebellum was decreased to 73% of controls. Likewise, when gabaculine was administered locally in the thalamus, the GABA turnover in thalamus was decreased to 75% of controls. The GABA turnover following an i.p. injection of apomorphine (0.5-1.5 mg/kg) was decreased to 82% or 67% of control, after systemic GAB or gabaculine, respectively.

Results of ongoing microdialysis studies will be reported. The data are discussed in relation to the proposed existence of positive and negative cortico-striato-thalamo-cortical feedback loops.

NEUROTENSIN AND FOS IMMUNOREACTIVITIES IDENTIFY TWO SUBPOPULATIONS OF STRIATAL NEURONS FOLLOWING ACUTE 6-HYDROXYDOPAMINE LESIONS AND REPERFUSION ADMINISTRATION. Judith S. Brog* and D. Z. Zahm, Dept. of Anat. and Neurobiol., St. Louis University School of Medicine, St. Louis, MO 63104

It was previously reported that following dopamine (DA) D2 receptor blockade or DA-depletion, neurtensin (NT) immunoreactivity (IR) is elicited in at least two distinct subpopulations of rat striatal neurons. Colocalized Fos-IR, interpreted as an indicator of enhanced neuronal activity, was found in only one of these subpopulations following D2 blockade (Neurosci. 57: 649-60, 1993). In this study, the degree of colocalization of Fos- and NT-IR in striatal neurons in response to acute midbrain 6-hydroxydopamine (6-OHDA) lesions and reperfusion administration was studied. It was observed that a subpopulation of smaller neurons exhibiting light NT-IR and frequent colocalization with Fos-IR was predominant after reperfusion administration, mainly in the dorsolateral quadrant of the striatum. Another subpopulation of larger, intensely NT-immunoreactive neurons that was rarely colocalized with Fos-IR was observed following all the drug treatments, but was present almost to the exclusion of the smaller cell type three days following 6-OHDA lesions, mainly in the dorsomedial and ventrolateral portions of the striatum. The present data are consistent with two subpopulations of striatal neurons that accumulate NT following DA depletion. The possibility is considered that one subpopulation accumulates NT in response to coordinate increases in neuronal activity and NT synthesis, and the other as a result of decreased release. DIFFERENTIAL MODULATION OF DOPAMINE D1 AND D2-RECEPTOR BINDING IN RATS TREATED WITH A CLASSICAL NEUROLEPTIC, L. Liminga*, M. Curini, A.E. Johnson, L. Kilgarr, L. Hillers, A. Hjort, L.M. Gunie, and F.-W. Wiesel, Psychiatry Department, Ullrerker Hospital, Uppsala University, S-75117 Uppsala, Sweden.

Classical neuroleptics are often employed in the treatment of schizophrenia. These compounds are known to act on the dopaminergic system primarily by blocking dopamine (DA) D2-receptors. In the following experiments, we evaluated the consequences of exposure to the classical neuroleptic, fluphenazine decanoate (FLU), on DA D1- and D2-receptor binding in several regions of the basal ganglia. Adult female Sprague-Dawley rats were treated either chronically or acutely with FLU (30mg/kg) or vehicle. Animals were killed by decapitation and brain sections through the striatum (STR), entopeduncular n. (EP), subthalamic n. (STh) and substantia nigra (SN) were collected and processed for receptor autoradiography. D1-receptors were labelled with [3H]-SKF38398 in the presence or absence of unlabelled SKF38390 and D2-receptors were labelled with [3H]-NACQ298, a Eticlopride. Analysis of autoradiograms showed that in vivo exposure to FLU significantly decreased specific [3H]-NACQ298 binding up to 70% relative to controls in all brain regions measured probably by competing with [125I]-NACQ298 in vitro. With regard to D1-receptors however, FLU treatment decreased [3H]-SKF38398 binding in the dorsal STR (35%), but increased binding in EP (38%) and was without effect in the SN. In vitro competition assays performed on sections from untreated rats showed that FLU is a potent competitor of binding at both receptor subtypes with an affinity of about 10M for D1-receptors in the dorsal STR and EP and 2.5M for D2-receptors in the dorsal STR and SBs. These results suggest that although FLU is an effective competitor of both D1 and D2 compounds in vitro, it acts primarily as a D2 antagonist in vitro. These data suggest that for ligands with high affinity for both D1 and D2 receptors in vitro, these compounds may act primarily at D2 binding sites in vivo. Supported by grant #8318 from the Swedish MRC.

ELECTROPHYSIOLOGICAL EFFECTS OF A CANNABINOID ON NEURONS IN THE SUBSTANTIA NIGRA PARS RETICULATA. A.S. Miller* and J.M. Schrier, Schrier Research Laboratory, Department of Psychology, Brown University, Providence, RI 02912.

Binding studies have demonstrated that cannabinoid receptors are densely distributed in the outflow nuclei of the basal ganglia and are especially abundant in the substantia nigra pars reticulata (SNR). Cannabinoid receptors in the SNR have been localized on the striatonigral terminals. Single unit electrophysiology was used to explore the role of cannabinoid receptors by depleting the SNR. Intravenous or intraperitoneal injection of WIN 55,212-2 in anesthetized rats produced a significant but modest increase in the basal firing rate of SNR neurons. A second set of experiments was performed in order to assess whether this increase represented a disinhibition of SNR activity. Striatal stimulation produced a brief inhibition of neural activity in the SNR. WIN 55,212-2 (up to 1 mg/kg iv.) dose-dependently reversed the inhibition of cell firing in the SNR which was produced by striatal stimulation. These results suggest that cannabinoid receptors on the striatonigral terminals may regulate movement by disinhibiting the activity of SNR neurons, perhaps by inhibiting the release of GABA into the SNR.

PRE- AND POSTSYNAPTIC MEASURES OF SHORT-TERM SYNAPTIC PLASTICITY AT THE CORTICOSTRIATAL SYNAPSE OF THE AGED RAT. X. Ou* and J. P. Walsh, Andrus Gerontology Center & USC Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-0191.

The corticostriatal synapse of the aged rat expresses a decrease in paired-pulse facilitation, without an associated change in short-term synaptic depression (Ou and Walsh, 1994). It is not known, however, whether age affects the kinetics of recovery from synaptic depression. Synaptic depression was induced at the corticostriatal synapse by delivering 15 stimuli (ISI of 50 ms) to the corpus callosum in an in vitro brain slice. Recovery from the depression was monitored by a test stimulus occurring 0.2 to 5 seconds after conditioning. Our data indicate that there is a significant difference between the two-age groups in the kinetics of recovery from synaptic depression with aged cells showing slower recovery from depression than young cells.

We next examined the effect of age on the contribution of NMDA receptor activation to the synaptic response. Paired synaptic responses (ISI of 60 msec) were evoked before and after addition of the NMDA receptor antagonist APV (30 μM) in Mg2+-free ACSF. Subtraction of synaptic responses evoked under these two conditions indicates that neurons from aged rats expressed a decrease in the NMDA component of the synaptic response. All slices were treated with 20 μM bicuculline to block GABA_A receptor mediated inhibition.

Research was supported by a grant from the NIA (5 P01 AG0979).
486.15 EFFECTS OF 5-HT1A and D1 RECEPTOR ANTAGONISTS ON THE INDUCTION OF STRIATAL JUN B AND FOS-LIKE IMMUNOREACTIVITY BY DEXEFENFLURAMINE. A.M. Gardner*, R. Morralia², and A.M. Graybiel².

The indirect serotonergic agonist fenfluramine (20 mg/kg, i.p.) induces Fos-like immunoreactivity (FLI) in the caudoputamen (CPu) and the caudal striatum (SMA) of the rat. In order to examine the role of different striatal subregions and other brain regions, we administered 5-HT1A and D1 receptor antagonists (Richard et al., Brain Res., 594 (1992) 131-137). However, fenfluramine is a racemate in which the d-isomer (d-fen) acts on the serotonergic system by increasing the (extracellular levels of serotonin (5-HT) as a result of vesicular storage (Saramago and Garattini, In Nutrition and The Brain, Vol.5, Raven Press, New York, 1990), whereas the l-isomer increases the turnover of dopamine (DA) in rat CPu (Invernizzi et al., Eur.J.Pharmacol., 129 (1986) 9-15). Here, the induction of rat CPu and d-fen protein was studied in rats 2 hrs after administration of d-fen (0.5, 10, and 40 mg/kg, i.p.) and induced a dose-dependent increase in both Fos-like and Jun B-like immunoreactivity (FLI, Jun B-LI) in the CPu, and in other brain regions included the central amygdaloid nucleus and layer 4 of the somatosensory cortex. The CPu induction of FLI was dose-dependently and, as caudal levels, in localized dorsal and ventral zones. The induction of F-LI and Jun B-LI by d-fen (40 mg/kg) was attenuated in CPu, but not in the cortex, by treatment with low doses (0.2 and 0.3 mg/kg, i.p.) of the D1 receptor antagonist SCH 23390. Furthermore, the induction of F-LI and Jun B-LI by d-fen (40 mg/kg) was attenuated in cortices, but not in CPu, by prior administration of a drug known as the most effective 5-HT1A receptor antagonist, methiothepin. The latter drug was administered at a dose (10 mg/kg) that has been shown to block d-fen effects on brain 5-HT metabolites (Gardner et al., Brain Res., 581(1992)67-74). Our results suggest that an indirect 5-HT agonist d-fen may stimulate FLI and Jun B-LI in the rat striatum at least in part indirectly through striatal DA release, leading to an activation of potent D1 receptor receptors.

486.16 FOS-LIKE IMMUNOREACTIVITY IN BASAL GANGLIA OUTPUTS FOLLOWING ADMINISTRATION OF DOPAMINE AGONISTS. David Witterhake* Dept. Psych., Univ. Illinois at Chicago, Chicago, IL 60609.

The pars reticulata of the substantia nigra (SNpr) and the entopeduncular nucleus (EPN) tonically inhibit cells in a number of structures including the lateral habenula, the pedunculopontine region and certain thalamic nuclei. Many workers have theorized that stimulation of dopamine receptors leads to inhibition of cells in the SNpr and the EPN which, in turn, results in a disinhibition of neurons in the systems listed above. Since many neurons respond to excitation by expressing the immediate early gene c-fos, we attempted to evaluate this model of basal ganglia organization by using immunocytochemistry to examine the distribution of Fos like immunoreactivity following systemic injections of either amphetamine (5 or 10 mg/kg of amphetamine acid (2.5 or 5 mg/kg) or apomorphine (4 mg/kg). Following all of these treatments, many labeled neurons were observed in the lateral portion of the lateral habenula, in the ventromedial thalamic nucleus and the rostral pole of the ventrolateral thalamic nucleus and in the pedunculopontine region. In subjects with unilateral 6-OHDA lesions of the ascending dopaminergic pathways, injections of amphetamine resulted in labeling of all of these structures on the intact, but not the denervated side. Simultaneous processing of tissue for NADPH-diaphorase revealed that staining in the midbrain tegmentum was concentrated in the so called "midbrain extrapyramidal area" just medial to the cholinergic cells of the pedunculopontine nucleus proper.

486.17 STIMULATION OF ADRENALINE A2 RECEPTORS BY CGS 21680 INDUCES C-FOS EXPRESSION IN THE STRIATUM OF DOPAMINE DENERVATED RATS. Morelli M.*, A. Pinna, G. Di Chiara Dept. of Toxicology Univ. of Cagliari (Italy).

The induction of the early-gene c-fos after the adenosine A2a receptor agonist CGS 21680, was studied in the striatum of normal rats or after a unilateral 6-hydroxydopamine (6-OHDA) lesion of the dopaminergic nigrostriatal neurons. CGS 21680 (5 mg/kg) induced c-fos expression in the 6-OHDA lesioned striatum while in normal rats CGS 21680 failed to induce c-fos expression even at doses of 10-20 mg/kg. The dopamine D1 agonist quinpirole reversed CGS 21680-induced c-fos expression, while blockade of muscarinic receptors by scopolamine partially prevented c-fos expression in the dorsolateral part of the striatum. The results are consistent with the coexistence of A2a and D1 receptors on striatal neurons and with their opposite influence on adenylyl cyclase. However the data also suggest that stimulation of cholinergic transmission by CGS 21680, might play a role in the induction of c-fos expression.

487.1 VESTIBULOCOCCULAR REFLEX PHYSIOLOGY

GABAergic pathways originating from the medial and descending vestibular nuclei (DVN, MVN) as well as the nucleus prepositus hypoglossi convey vestibular information to various division of the inferior olive. Previously we have demonstrated a topographic representation of both the vertical semicircular canals and utricular otoliths in one of the subdivisions of the inferior olive, the b-division. In the present experiment we have characterized the inputs, projections, as well as the encoding characteristics of neurons in another subdivision, the dorsal medial cell column (DMCC). We have recorded extracellularly from dopaminergic neurons in the substantia nigra of anesthetized rabbits placed in a three axis rate table, permitting static and sinusoidal vestibular stimulation, as well as the determination of a vestibular null point. All neurons were driven by static or sinusoidal rotations about the longitudinal axis. These neurons responded in phase with contralateral side-down head position during sinusoidal stimulation. Measured null points did not correspond to the orientation of pairs of vertical semicircular canals. These neurons appeared to be driven primarily from the utricular otoliths. These vestibularly responsive neurons were located in the dorsal half of the DMCC. An immunohistochemical stain for glutamic acid decarboxylase demonstrates that the DMCC, as well as the b-division is innervated by GABAergic fibers originating from the substantia nigra. The combination of high pass (2-4 µ, 30%) into both the nucleus-uvula and floculus demonstrates that the dorsal half of the DMCC projects to the nucleus, whereas the ventral half projects to the floculus. In sum, the DMCC accounts for some of the otolithic input to nucleus-uvula and may contribute to the topographic modulation of postural control about the longitudinal axis.

487.2 NEURAL RESPONSES TO VESTIBULAR PARADIGMS IN THE MACAQUE NODULUS. A.F. Rosenberger* and C.A. Studer, Dept. of Otolaryngology, Univ. of Pittsburgh, Pittsburgh PA 15213.

The goal of this study is to investigate the involvement of the nodulus in vestibular processing by characterizing (i) inputs and output signals, and (ii) responses to different vertical axis rotation (OVAR). Both granular layer units (GLUs) and peduncle cells (PCs) were recorded from the cerebellar cortex of an awake, trained, head-fixed monkey during passive vestibular stimulation in both horizontal and vertical planes, and during eye movements. Most neurons were sensitive to vestibular stimulation. Of these neurons that were tested in three orthogonal planes, the vast majority were sensitive to movement in a vertical plane whereas few neurons responded exclusively to yaw rotation. GLUs that responded to vertical motion were sensitive to head velocity (indicating canal or dynamic otolith input) or to static tilt (indicating otolith input). Most responsive PCs were sensitive to some combination of vertical head velocity and tilt, which in some cases, depended on the particular stimulus paradigm. Rotation of the subject resulted in convergent signals originating from multiple types of vestibular afferents. PCs were recorded during OVAR, which presumably involves velocity storage. Some PCs responded only to a modulated firing rate related to instantaneous direction of tilt, or both. The peak firing rate of units that had a modulated response component corresponded to different tilt directions. Some PCs responded to yaw rotation, with a constant rate in firing rate, a modulated firing rate related to instantaneous direction of tilt, or both. The peak firing rate of units that had a modulated response component corresponded to different tilt directions. Some PCs responded only to a modulated firing rate related to instantaneous direction of tilt, or both. The peak firing rate of units that had a modulated response component corresponded to different tilt directions. Some PCs responded only to a modulated firing rate related to instantaneous direction of tilt, or both.

FUNCTIONAL INDEPENDENCE OF NODULAR AND UVULAR MICROVASCULAR COMPONENTS AND THEIR ROLE IN VESTIBULAR STORAGE. R. Cohen, S. Warnek, T. Raphan, H. Reisin. Mt Sinai School of Medicine and Brooklyn College of UNY.

Tilting the gravitostrial acceleration (GIA) vector during yaw-axis vestibular or optokinetic nystagmus reorients the compensatory eye velocity vector toward the spatial vertical (axis reorientation). Two processes are associated with the time constant (damping) and generation of vertical and/or torsional components in the eye velocity vector (cross-coupling). Axis reorientation was studied in rhesus monkeys following decerebration lesions that spared the superior vestibular nuclei. Tilt-induced velocity storage, reducing the horizontal time constant from 1.9±2.1s to 0.4±0.2s, without affecting the VOR gain. This abolished eye velocity reorientation, showing that the reorganization is not due to the ability to control the velocity of the rotation. Pre- and post-transected animals showed no difference in the time constant of eye velocity storage. The GIA vector was tilted in two paradigms: OKAN with static head tilt, centrifugation and dynamic head reorientation during postural changes. The superior vestibular nuclei were not affected by medial sectioning, showing that the ability to control the eye velocity vector is intact. This study is supported by grants from the Whitaker foundation and the Beckman Institute.

We investigated the effects of aminglycoseide-induced hair cell loss on the spontaneous activity and responses of anterior semicircular canal afferents in chicks. Aminoglycosides are known to selectively damage hair cells and have been proposed as a useful tool to study the role of the inner ear in the maintenance of balance. Previous studies using aminglycoseide have shown that the spontaneous activity and responses to mechanical stimulation of hair cells in the anterior semicircular canal are reduced by 60-70% and 30-40%, respectively. In this study, we investigated the effects of aminglycoseide-induced hair cell loss on the spontaneous activity and responses of anterior canal afferents in chicks. We found that the spontaneous activity and responses to mechanical stimulation of hair cells in the anterior semicircular canal are reduced by 60-70% and 30-40%, respectively. These results suggest that aminglycoseide-induced hair cell loss reduces the spontaneous activity and responses of anterior canal afferents in chicks.

SIGNAL CONVERGENCE AND DYNAMICS RECORDED FROM VESTIBULAR-OCULOMOTOR NEURONS IN THE ALERT CAT.  
S. J. Barette1 & D. E. Bialek1 1Dept. of Neurobiology, University of Chicago, IL 60611  

VESTIBULAR-oculomotor neurons contribute to the dynamics and spatial organization of compensatory eye movements produced by the vestibulo-ocular reflex (VOR). We have recorded the responses of 9 vestibular nucleus neurons in alert cats to investigate canal convergence, eye position sensitivity, response dynamics, and otohelic output. Neurons were classified according to latencies and specific responses to labyrinth electrical stimulation and antidromic responses to oculomotor nucleus stimulation.

Extensive spatial testing (14+ runs, 20 neurons), including several sinusoidal rotations about axes near near visual fixation, confirmed canal convergence on oculomotor-projecting neurons. Six of 9 neurons receiving primarily anterior canal input and 2 of 9 posterior canal neurons showed horizontal canal convergence (±20°). Maximum activation direction vectors of anterior canal neurons (AC) varied more widely than those of posterior canal neurons (PC). Vertical and horizontal eye position sensitivity of 28 vestibular neurons (16 oculomotor-projecting) varied from 0 to 31 spikes/sec/° and generally corresponded to vertical and/or horizontal vestibular sensitivity, with some striking exceptions. During sinusoidal rotations at low frequencies, subtraction of the eye position component from the total neuronal response advanced the response phase.

Responses of 26 neurons to sinusoidal rotations were nearly in phase with velocity (90° ± 18° s⁻¹ at 0.5 Hz) with advanced phases at high (129° ± 10° at 4 Hz) and low (horizontal canal, 104° ± 21°; PC, 114° ± 19°; AC, 78° ± 16° at 0.05 Hz) frequency extremes. Comparison of responses to horizontal and vertical axis pitch rotations at 0.05 Hz revealed modest phase changes for some neurons (13° to 27°) while others had large phase shifts (+91° to +98°) indicating otohelic output. CONNECTIONS BETWEEN THE SACCULAR NERVE AND NECK EXTENSOR AND FLEXOR MOTONEURONS IN THE DECEMBRERATE CAT.  
H. Sato1, M. Imagawa1, M. Sasaki1, H. Begam1 and Y. Uchino1 1Dept. of Physiol., Tokyo Medical College, Tokyo 160; 2Dept. of Anat., Niigara Medical School, Tokyo 113  

The saccular (SC) receptors in the otolith organs are sensitive to vertical linear acceleration of the head. We studied the sacculo-neck connectivities by means of intracellular recording from the extensor and flexor motoneurons in C1/C2-sacral segments. Bipolar tungsten electrodes (inter-electrode distance, 0.8 mm) were fixed in place on the SC nerve; the other branches of the vestibular nerve were transected. Dorsal root (DR) and external longitudinal capitis (LC, flexor) motoneurons in C2-C3 were identified antidromically. Stimulation of the SC nerve evoked excitatory postsynaptic potentials (EPSPs) in bilateral DR motoneurons. The latencies of EPSPs ranged from 2.1 to 3.6 ms (2.5 ± 0.4 ms; mean ± SD, n=18) ipsilaterally and from 2.7 to 4.0 ms (3.1 ± 0.4 ms; mean ± SD, n=13) contralaterally. The results demonstrate the presence of reciprocal connections from SC to extensor and flexor muscles which may play an important role in the body under resting condition and during vertical linear acceleration.

LINEAR AND ANGULAR MOTION MAPPED INTO THE VESTIBULAR NUCLEUS.  
J. E. Hally1, B. Boyd and G. McCullom 1R.S. Dow Neurological Sciences Institute, Portland, OR 97209 and Oregon Health Sciences Univ., Portland, OR 97201  

Cells in the vestibular nuclei discharge in relation to motion factors including angular head velocity, linear head velocity or acceleration, the position and/or velocity of the eyes in orbit during ocular tracking and gaze hold, and events associated with eye movement. Each responding cell discharge either is in relation to a single factor or to a certain combination of two or more factors. The number of possible combinations of converging factors grows exponentially with the number of factors considered. The ensemble response across the vestibular nuclei during head and/or eye movement reflects the multitude of combinations of convergence.

We have developed a formal framework that identifies patterns of convergence within the vestibular nuclei and relates these patterns to ensemble response during movement. Each movement of the head maps formally to a certain status of the sensors, one relevant set of sensors being the hairs of the semicircular canals and otolith organs. Deflection of the semicircular hairs evokes a range of primary afferent responses, reflected in the afferent's sensitivity to velocity and/or acceleration. Convergence within the vestibular nuclei determines the ensemble response of secondary vestibular neurons. In the framework, we relate the identified patterns of convergence with the full map from head movement to discharge within the nuclei, thus identifying patterns available to the nervous system for responses such as the vestibulococular reflex, the vestibulocollidal reflex, and self-motion perception.

PVP CELLS RECORDED DURING VERTICAL VISUAL-VESTIBULAR INTERACTION, IN THE ALERT SQUIRREL MONKEY LD Dimangencio, Y Zhuang and S.M. Hightower 2Dept. of Otolaryngology and Program in Neuroscience, Washington Univ. Sch. of Med., St. Louis, MO 63110  

Extra cellular records were taken from the region of the medial (MVN) and ventral-lateral (VLVN) vestibular nuclei in the alert squirrel monkey. Responses were recorded during (i) visual following (of a full-field optokinetic drum), (ii) VOR in the dark, (iii) VOR in the light, and (iv) VOR suppression. Two types of neurons were identified, namely those that had up-eye position and down head velocity sensitivity, and those that had down eye position and up head velocity sensitivity. Both types paused for saccades and are thus classified as classic position-vestibular pause (PVP) neurons, previously reported. We conclude that some MVN & VLVN PVP cells receive input from the anterior canal (AC) and others from the posterior canal (PC). Therefore it appears that there are two components of the 3 neurons from the AC to the 3rd nucleus: 1. via the superior vestibular nucleus that conveys head and eye velocity information and a second via the MVN & VLVN conveying PVP type of information to the 3rd nucleus. The extent of flocculus control of each of these two pathways is under investigation.

VESTIBULAR INPUTS TO THE DORSAL Y GROUP NUCLEI, IN THE SQUIRREL MONKEY. P.M. Blazquez, A.M. Pertaslis and S.M. Hightower 1Dept. of Otolaryngology, Washington University, St. Louis, MO 63110  

Dorsal Y group (Y) neurons in the squirrel monkey carry visual following and vestibular signals, and the nucleus has been implicated in adaptation of the vertical VOR (Pertaslis et al 1993). Y neurons are monosynaptically inhibited by the flocculus; pharmacological inactivation of flocculus removes the visual following signal but spares a head velocity signal to Y cells. To examine the origin of this signal, we studied responses of Y cells to electrical stimulation of the labyrinths in alert squirrel monkeys.

Stimulating electrodes were implanted in the labyrinth bilaterally in two animals. Y cells were recorded extracellularly in the alert animal and identified by their characteristic response patterns during visual following and visual-vestibular interaction paradigms, as previously described (Pertaslis et al 1993). The responses of cells to electrical pulse stimulation of the labyrinths examined. Peristimulus time histograms revealed that the vast majority of Y cells were activated at diatonic latencies following stimulation of either (both) labyrinths.

Taken together with previous evidence, our results suggest that the Y group, an immediate pontomesencephalic center, is a site of interaction between vestibular signals from both labyrinths and flocculus output signals. The interneuron between the primary afferent and the Y group probably lies in the vestibular nucleus. Preliminary anatomical data indicate that the Y group receives a projection from the superior vestibular nucleus.

A COMPARISON OF THE RESPONSES OF RAT AFFERENT VESTIBULAR NEURONS AND VESTIBULAR NUCLEI NERVE CELLS EVOKED BY SINEWAVE POLARIZATION OF THE LABYRINTH. O.-J. Grüsser* and J. Kleins, Department of Physiology, Freie Universitat, 14195 Berlin, Germany  

Sine wave galvanic stimulation (0.1-100 Hz, 2-200 uA amplitude) was applied in pentobarbital-anesthetized pigmented Norwegian rats. The responses of Ggl. Scopae nerve cells were uniform and independent of their peripheral inputs (semi-circular canals, horizontal canals). Within the vestibular nuclei complex (VNC) there was differentiation: (a) Negative ipsilateral labyrinth polarization led to an activation of units driven by one or two SC inputs or by SC- and O-inputs. (b) Some VNC neurons were activated by contralateral negative labyrinth polarization. (c) Some neurons responded with a slow delayed activation to ipsilateral, some to contralateral negative polarization.

The neurons of category (a) exhibited similar response characteristics as Ggl. Scopae neurons tuned up to a frequency range between 60 and 100 Hz. Owing to the lower spontaneous discharge rates of VNC neurons, however, non-linear response components that consisted of a "silencing" during the positive phase of ipsilateral labyrinth polarization tended to emerge at lower stimulus frequencies. The lowest thresholds at 1-2 Hz galvanization did not differ significantly from those of the afferent fibers (<5 uA). The convergence of many fairly uniformly responding fibers appears to determine the response characteristics of this subgroup of VNC cells. Sine wave galvanic stimulation of the labyrinth is a powerful tool to synchronize vestibular input (Supported in part by a BMFT-grant).

488.1 OFFSET OF HUMAN SMOOTH PURSUIT: EFFECTS OF TARGET VELOCITY, POSITION, AND PRESENCE. P. Pole and H. J. Wyatt. SUNY College of Optometry, New York, NY 10010.

We have been studying the offset response of the pursuit system as part of an effort to develop some of the system's dynamic features. Methods: Subjects observed a target moving horizontally at 15 deg/sec. When pursuit velocity became steady, the target either: (1) suddenly disappeared; (2) jumped to a different target velocity and feedback becoming 0 (target stabilized at the focus); or (3) stepped to a retinal position 3 deg ahead of the focus with target velocity of 0 and feedback of either 0 (target stabilized 3 deg from focus), -0.2, -0.4, or -1 (target fixed in space). Results: When the target disappeared, the eye decelerated rapidly (time constant T = 0.1s), but with the target stabilized at the focus, deceleration was slower (T = 0.6s). With the target stabilized 3 deg ahead of the focus, the eye continued at moderate velocity, a response to target position (since target retinal velocity was zero). As feedback increased from 0 to -1.0, eye deceleration systematically increased. Modelling and Conclusions: All of the experimental results can be simulated by a model with target velocity and position inputs, and an internal positive feedback loop. A key feature of the model is that the positive feedback loop is enabled by the presence of a visual target. Thus, long-time-constant offset reflects the action of the positive feedback loop, whereas short-time-constant offset is a result of a loss of positive feedback following target disappearance. The model also suggests that the systematic change in deceleration with increasing feedback depends on the effects of a pursuit position mechanism — the same mechanism that drives the eye when the target is stabilized 3 deg ahead of the focus.
